Object

1 The object of this program was to determine the effect of arctic temperature on the following:

(a) Automotive ignition equipment
(b) A gasoline engine equipped with a fuel injection system
(c) A gasoline engine equipped with a carburetor

Resume

2 This project was a study of the performance of an automotive ignition system and a gasoline engine operating within an arctic, winter temperature range. The test program was divided into three sections designed to demonstrate the effect of low ambient temperature on (1) a battery ignition system, (2) a single-cylinder, Otto-cycle engine operated with a fuel injector in the intake manifold and (3) the same engine equipped with a float-type carburetor.

3 Eight commercially available spark plugs were subjected to four tests each to determine their relative performance at various operating conditions. The plugs were mounted in a bomb-type chamber and connected to a conventional ignition system for the first tests. With a primary voltage of four, nitrogen pressure was applied to the bomb until the spark plugs began to misfire. The plugs and coil were cooled through a temperature range of -65 to 30 °F. The procedure was similar in the second series of tests but the primary voltage was six and the temperature range was 100 to 500 °F. The coil temperature was not controlled but the ignition system was operated for approximately thirty minutes before each test to allow its temperature to become constant.

4 The third set of tests was included to show the primary voltage required for ignition in an engine of normal compression ratio. The nitrogen pressure was 100 psi and the primary voltage was increased until the plugs fired consistently. The temperature of the plugs ranged from -65 to 30 °F. The coil operated at normal temperature.

5 The results of these tests are shown on Data Sheet Nos. 1 to 8, Pages 71 to 78 and Curve Nos. 4 to 6, Pages 47 to 49. The spark plugs tested are listed in Table I, Page 24. Sketch No. 1, Page 33, and Photo Nos. 1 and 2, Pages 29 and 30, show details of the bomb and the arrangement of the testing equipment.

6 The fourth series of tests were conducted to determine the ability of the spark plugs, when cooled to about -65 °F, to ignite a combustible charge. The bomb was attached to a special head and mounted on a single-cylinder engine. While the engine was turned at cranking speed, it was supplied with a combustible mixture of fuel and air and a primary voltage of four. Each plug ignited the charge within a period of one minute's cranking. Although these tests seemed to offer some agreement with the third tests (starting requirement) they were considered inconclusive. Even though the plug was cold, the charge was probably much warmer since it was not refrigerated.

7 The effect of low ambient temperature on the combustion process of a gasoline engine was investigated by operating a Merz, single-cylinder, Otto-cycle engine in an arctic test cell. The refrigeration was supplied by a 15 ton, freon-brine system. Power was absorbed by an electric dynamometer located outside the test cell.

8 For the first group of engine tests, arctic grade fuel MIL - G - 3056, type C, was injected into the intake manifold toward the inlet valve with the engine operating at optimum conditions of speed, spark advance and mixture strength. (See Data Sheet Nos. 19 through 25, Pages 79 through 85 , and Curve Nos. 7 through 9, Pages 50 through 52) Data was recorded at several combustion air temperatures. The program was expanded to include four engine speeds, four throttle settings and eight ambient air temperatures. The running schedule is presented in Table II, Page 25. A drawing of the intake manifold (No 20681) is included on Page 40 . The results are shown by Data Sheet Nos. 26 to 39, Pages 86 through 99, and Curve Nos. 10 to 14, Pages 53 to 57 .

9 The above test program was repeated while using an automotive type carburetor. The results of these tests are shown by Data Sheet Nos. 39 to 84, Pages 99 to 104 , and Curve Nos. 15 to 25, Page 58 to 68 . The difference in performance with the two fuel systems is shown by Curve Nos. 26 and 27, Pages 69 and 70 . Included in Curve No. 26 is a motoring friction test to show the power required to drive the fuel injection system. (See Data Sheet Nos. 85 to 88, Pages 145 to 148)

10 The engine and test cell are shown in Photo Nos. 3 and 4, Pages 31 and 32 . Sketch Nos. 2 to 11, Pages 34 to 43 , show the details of the engine installation. The calibration of the

instruments is presented in Curve Nos. 1 to 3, Pages 44 to 46. The results of the engine inspection are presented in Table III, Page 28.

Conclusions and Recommendations

11 The performance of the ignition coil improved as its temperature was reduced. Although no tests were included to explain this phenomenon, it is assumed to be the result of the windings contracting with respect to each other and to the iron core. Additional research should be conducted to determine the basis for this oddity.

12 It is reasonable to believe, because of this peculiar function of the coil, that high performance engines operating in a hot climate would receive the lowest ignition voltage. Thus the mounting position of the coil should be chosen with great care until this problem has been eliminated. The coil should not be placed where it would be affected by either an engine-heating device or by the engine itself.

13 Spark plugs of higher heat range, especially those with smaller electrodes, have better performance characteristics. Although the tests were limited and the instrumentation was barely adequate, this trend is quite evident. Investigations to determine the optimum size, shape and material for electrodes would probably result in a substantial increase in performance. Perhaps plugs with platinum wire electrodes would be more appropriate for low temperature operation.

14 The performance of the spark plugs was better at higher temperatures during the tests in which the plugs were heated and the coil temperature remained constant. This would seem to be the result of expansion of the center electrode or distortion of the ground electrode. If the curve is extrapolated to the arctic winter temperature range it seems unlikely that any of the plugs would ignite the charge in the cylinder of a moderately high compression ratio engine. Plugs with the ground electrode beside the center electrode, instead of beneath it, may have more desirable temperature characteristics.

15 The performance of resistor-type plugs is inferior to that of the regular type. The main advantage of resistor plugs is in the reduction of radio interference, however, this method of shielding also reduces performance of an ignition system. Development of methods to reduce radio noise without impairing operation of the ignition equipment would overcome another serious impediment to engine research.

16 During all of the engine tests the power output increased as the combustion air temperature was reduced. This shows that, from the combustion standpoint, manifold heating devices are detrimental to engine performance. Since it is known that automotive type engines lose power as the manifold temperature is reduced, it must be assumed that this loss results entirely from improper distribution of the fuel.

17 Operating an automotive type engine with individual carburetors would eliminate the losses resulting from poor distribution of fuel. The loss in volumetric efficiency caused by a manifold heating device would also be reduced. Starting should be facilitated by this change because distribution during the choking process, and before the hot spot is heated, is bound to be very poor. The complications of this arrangement would be partially off-set by excluding the manifold heating device, which, to be efficient, must in itself be complex.

18 There is no advantage in the use of injection systems on automotive engines, except to improve distribution of fuel. Installation and maintenance costs are extremely high. The combustion process is impaired and the volumetric efficiency is reduced. These facts are substantiated by curve numbers 26 and 27. The power output was 30 percent less with fuel injection and the intake manifold was cooled as much as 40 degrees by fuel vaporization.

19 The metering characteristics of some carburetors are seriously changed by low temperatures. This results from contraction of the various parts. This would be one more reason for poor performance of engines in arctic regions.

20 Even though these engine tests provide many of the answers concerning the operation of gasoline engines in cold climates, the program that was originally planned should be completed. That is, the investigation should be extended to include multi-cylinder engines. A program of this kind would show the losses of a conventional installation. Also, practical methods for improving performance could be developed.

21 The two-stage, freon-brine refrigeration system is very satisfactory for low temperature research work. It is comparatively inexpensive and combines adequate capacity with minimum maintenance costs. The control system is very effective. Large changes in capacity are provided with very minute changes in temperature.

22 Separating the engine compartment from the remainder of the test cell is a very effective way of conducting work of

this type. Since all instruments and testing apparatus operate at normal temperature, many of the problems associated with low temperature testing are eliminated. Refrigeration demands are reduced to a minimum because the wall areas are small and, essentially, only the heat developed by the engine need be considered.

Description of Apparatus

23 IGNITION TESTS: The ignition tests were conducted in a special bench set-up consisting of a spark plug test bomb, electric motor-driven distributor, ignition coil, storage battery, battery charger, heating and cooling systems, a nitrogen tank and appropriate electrical equipment. The arrangement of this equipment is shown in Photo No. 2, Page 30. The electrical equipment was connected as shown in Sketch No. 1, Page 33. The construction of the bomb is shown in Photo No. 1, Page 29.

24 The spark plug test bomb consisted of an inner pocket into which a plug was screwed, plus an annular chamber through which a cooled, or a heated, liquid could be circulated. The entire assembly was insulated with crumpled aluminum and encased in a thin sheet-metal shell. The pressure in the spark plug pocket could be increased by admitting compressed nitrogen. A sensitive needle valve was provided to ensure accurate control of the pressure.

25 The automotive distributor was mounted on a steel base and connected directly to the shaft of an electric motor. Five of the six lobes on the breaker point cam were removed to reduce the number of ignition impulses to a frequency typical of a multi-cylinder engine, operating at idling speed. The centrifugal spark advance mechanism was rendered inoperative by wiring the fly-weights in one position. The points, condenser and other parts were standard.

26 The ignition coil was standard except for a thermo-couple attached about half way up on the cylindrical portion of its case. Also, the case was wrapped tightly with copper tubing through which coolant could be circulated for temperature control.

27 A six volt, automotive battery supplied the current for the ignition system. This unit was kept fully charged by a motor-generator set with adjustable output. The voltage was adjusted with a rheostat between the distributor and battery.

28 The energy supplied to the ignition system was read on a conventional direct-current voltmeter and ammeter. The maximum instantaneous values of primary and secondary voltage were determined by measuring the trace on a cathode-ray oscillograph. The oscillograph was connected directly to the leads of the coil for the primary voltage trace. The secondary voltage trace was obtained from a calibrated pick-up surrounding the high-tension lead. In this case the oscilloscope was calibrated from a similar pick-up mounted on a special calibration unit having a known output. The calibration unit consisted of an automotive ignition coil, fed by 400 cycle alternating current at approximately 130 volts. The output of this unit was determined with a vacuum tube volt-meter capable of indicating voltages up to 10,000 RMS. For the primary voltage the scope was calibrated on the 110 volt, 60 cycle alternating current supply. All of this equipment was connected to the scope as required by a special switch box.

29 The spark plug bomb and ignition coil were cooled to arctic temperatures by pumping chilled gasoline to these units. The gasoline was cooled in a tank by spraying it over crushed, dry ice. An aircraft fuel pump and an electric motor provided circulation. This entire apparatus was insulated to minimize heat transfer and condensation.

30 The low temperature starting tests were conducted on a battery charging unit consisting of a single-cylinder engine directly coupled to a direct current, compound wound generator. The cylinder head was replaced with a steel plate on which the spark plug bomb was mounted. The volume of the bomb and special head provided a compression ratio equal to that of the original engine.

31 Temperature was indicated by iron-constantan thermocouples connected to potentiometers that were calibrated in degrees Fahrenheit. Since the arctic temperatures are lower than the calibrated range of these instruments, their values were determined by connecting the thermocouples in reverse polarity. Assuming the potentiometer reading as negative and adding twice the room temperature gave the correct temperature.

32 ENGINE TESTS: The tests to demonstrate the effect of arctic temperature on the combustion process of a gasoline engine were conducted on a special, single-cylinder engine connected to a cradle-type dynamometer. (See Photo No. 3, Page 31) The engine was mounted in an insulated box, which also housed refrigeration coils and circulating blowers. (See Photo No. 4,

Page 32, and Sketch No. 2, Page 34) Refrigeration was supplied by a plant having a rated capacity of 15 tons at -65 °F. (See Sketch No. 7, Page 39)

33 The research engine was developed primarily for detonation testing of extremely high quality fuels. The construction is very heavy, considering that the displaced volume is only 17.6 cubic inches. The liquid cooled, combustion chamber is of the hemispheric type, both valves being sodium cooled. Several cams were available for this engine and a pair providing valve timing typical of current automotive engines was selected. Cooling was provided by circulating arctic grade antifreeze, solution C, through an automotive radiator inside the insulated box: circulation being accomplished with a centrifugal pump, driven from the crankshaft. (See Sketch No. 4, Page 36) The coolant temperature was controlled by an automotive thermostat mounted in the coolant outlet on the cylinder head.

34 The lubrication system of the engine is of the wet-sump type. An oil pump in the cam compartment provided circulation. The temperature may be increased with an electric heater attached to the crankcase.

35 Fuel was supplied to the engine by two separate systems: fuel injection and carburetion. (See Sketch No. 6, Page 38) A special intake manifold was fabricated to support a carburetor and a fuel injection nozzle. (See Sketch No. 8, Page 40) The injection pump was driven at half crank-shaft speed from an accessory drive on the rear of the engine. Fuel was supplied by admitting compressed nitrogen to the storage barrel. The flow was indicated by a Fischer and Porter Flow-rator. Fuel could be supplied at will to either system by valves located on the control panel.

36 The flow of fuel through the carburetor was regulated by turning the adjustable, main jet, needle valve with a hydraulic control. All other flow circuits in the carburetor were plugged off. This special system was required because of the very high vapor pressure of the arctic grade fuel.

37 The delivery of the injection pump was adjusted by moving the control rack with a remote hydraulic control. A special surge pot, consisting of two chambers separated by a diaphragm, was connected to the pump inlet. (See Sketch No. 11, Page 43) The fuel flowed through the lower chamber and the

nitrogen pressure from the barrel was applied to the upper chamber. Since the diaphragm had a large area with respect to the fuel inlet, the pressure surges were essentially removed.

38 The combustion air was drawn from inside the insulated box. (See Sketch No. 5, Page 37) After flowing through a measuring orifice and a surge chamber, the temperature could be increased by an electric heater, mounted on the carburetor inlet. (See Sketches No. 9 and 10, Pages 41 and 42) The airflow was indicated by a slant gage mounted on the control bench. The throttle position was adjusted with a hydraulic control, also mounted on the control bench.

39 Ignition was provided by a conventional automotive system. The distributor used in the spark plug tests was driven from the rear of the injection pump. This unit was rotated with a hydraulic control to vary the spark advance. The spark advance was indicated by a Strobotac-Strobolux system triggered by a pick-up on the high-tension ignition wire and flashing on the graduated fly-wheel.

40 The General Electric, 5 horse-power dynamometer was connected to the engine by a short truck-type drive shaft equipped with Spicer universal joints. The dynamometer control switches and resistors were mounted in a panel beside the control bench. Engine speed was indicated by the Strobotac, used also for indicating spark advance. The dynamometer was originally equipped with a balancing beam for indicating torque. Since a remote indicator is necessary in this test cell, a Shaevitz transformer and spring were attached to the beam. When alternating current was supplied to the transformer, the output read on a vacuum tube voltmeter, gave a linear indication of beam position and consequently dynamometer torque. (See Sketch No. 3, Page 35)

41 The insulated box was assembled in six sections. The top, bottom and ends were bolted together while the two sides were removeable. The side nearest to the control bench was mounted on castors to enable the box to be opened with ease and provide access to the engine. This side also contained an insulated observation window. All joints between the various sections were sealed with strips of sponge rubber. The sides were held securely in place by refrigerator-door type locks. Each panel was built up of seven layers of aluminum foil separated by wooden strips 3/4 inches thick. Each assembly was encased in 1/4 inch marine plywood.

42 The engine was mounted in the box on a machined steel plate supported by an angle iron frame. The refrigeration coils were mounted vertically behind the engine and formed a partition across the box except for a space of approximately 1 foot at the top. Four centrifugal fans, belt driven by an external five horse-power, direct current motor, were mounted on a false ceiling connecting with the upper surface of the coils. Thus cooling air was forced downward over the engine, drawn through the coils and returned to the blowers by flowing upward between the coils and the rear panel of the box.

43 The two stage refrigeration system is of the freon-brine type, using Freon 22 as the refrigerant. (See Sketch No. 7, Page 39) The gas is compressed in a rotary compressor, driven by a 60 horse-power motor. Further compression takes place in a twelve cylinder, reciprocating unit, powered by a 75 horse-power motor. Lubricating oil is separated from the gas as it flows toward the condenser. The flow of liquid freon is controlled by float switches in a vertical receiver beneath the condenser. The switches operate solenoid valves ahead of hand regulated expansion valves. The liquid freon is sub-cooled in a direct expansion liquid cooler and an oil still.

44 Both expansion valves discharge into a pump receiver of about 300 gallons capacity, located in the attic space above the test cell. After the receiver is cold it, and a stand pipe twelve inches in diameter extending from the receiver to the floor of the test cell, are filled with liquid refrigerant. This liquid is forced through the coils and back to the receiver by a centrifugal pump. The temperature in the box is controlled by heating the freon brine with hot gas taken from the discharge of the reciprocating compressor. An electronic air-operated controller, connected to a thermocouple in the box regulates the flow of hot gas by operating a diaphragm type valve.

45 The temperature at fourteen points on the engine and associated systems were read by iron-constantan thermocouples connected to a precision-type electronic potentiometer. Pressures were read on U-tube manometers or bourdon tube-type gages.

46 The specifications of the equipment and instruments are given under "List of Apparatus and Equipment".

Description of Tests

47 IGNITION: For the first group of ignition tests, chilled gasoline was circulated through the spark plug bomb and

the copper tubing surrounding the coil until these units were cooled to about -65 °F. With the primary voltage maintained at 4, the nitrogen pressure was increased until the plug misfired occasionally. After recording all data, the plug and coil were allowed to warm up approximately 15° and the data was again recorded. This process was continued until a temperature of 30° was obtained. This particular primary voltage was selected because it seems typical of the battery voltage available while cranking an engine in an arctic region.

48 Eight different spark plugs were tested in the manner described above. They represented the hottest and coldest types recommended for use in commercial engines by three separate manufacturers. Both regular and resistor plugs by one manufacturer were included. The electrode gaps were carefully set at .025 inch with the exception of the resistor plugs. These were set at .040 inch, according to the manufacturer's recommendation. The manufacturers, model numbers, gaps and electrode diameters are listed in Table I, Page 24.

49 Each plug was again tested in the above temperature range at a constant bomb pressure of 100 psi. In this case the primary voltage was increased until the plug fired steadily. The coil was not cooled but the ignition system was operated for at least thirty minutes to allow its temperature to become steady. These tests were included to show the minimum battery voltage required to start an engine of normal compression ratio.

50 Constant primary voltage tests, similar to those described in paragraph 47 were made while heating the plugs through a temperature range of about 100 to 500 °F. The primary voltage was 6 because the cranking load would be less in warm weather. The coil temperature was not controlled but was allowed to become steady prior to starting each test.

51 In the last series of ignition tests, the bomb was attached to a special cylinder head and mounted on the battery charger engine. The four volt battery potential was applied to the ignition coil through breaker points at the end of the crankshaft. With the spark plug cooled to approximately -70 °F, the engine was cranked using the generator as a motor. After cranking for several minutes with a rich mixture, the charge would be ignited. The engine seemed to fire about every fourth revolution and would not develop enough power to maintain constant speed. Although all eight plugs were tested in this

manner, the difference in performance was negligible. These tests were considered inconclusive because the combustion chamber shape was very poor. With the volume of the bomb and the pipe leading to it constituting the major portion of the combustion chamber, the scavenging of the chamber was very limited.

52 The object of the engine test program being to determine the effect of inlet charge temperature on power output, variable carburetor air temperature tests were made according to the schedule presented in Table II, Page 25. The speeds are 100, 80, 60 and 40 percent of the speed that provides maximum torque. This speed was found to be 2000 RPM by a full throttle constant mixture ratio test. (See Curve No. 7, Page 50)

53 All test runs were made with .08 fuel/air ratio, the mixture that gave maximum power. This was determined by a constant speed, variable mixture ratio test. (See Curve No. 8, Page 51)

54 The spark advance was set at 30 °BTDC for all of the fuel injection runs and for the higher speed carburetion runs. The setting was reduced to 20° at 1200 RPM and 10° at 800 RPM because the detonation became serious. The 30° spark advance gave maximum power as shown by Curve No. 9, Page 52 .

55 A piston providing a compression ratio of 6.78:1 was used during the entire program. A limited number of pistons for different ratios were on hand but this seemed to be optimum for this engine-fuel combination. The optimum compression ratio is considered to be the highest that may be utilized without encountering serious detonation. This theory is based on the fact that the efficiency of an Otto-cycle engine increases as the compression ratio increases, according to the relation

$$E = 1 - \frac{1}{r^{(n-1)}} \quad .$$

56 With the engine operating at 2000 RPM, using the fuel injection system, .08 fuel/air ratio and 30° spark advance, and with an ambient temperature of 80 °F, a complete record of all data was made. The carburetor air was then heated approximately 25° and a second record of data was obtained. This process was continued until the carburetor air temperature, on the last setting, was at least 100 °F hotter than the ambient temperature.

57 Similar test runs were made at the reduced speeds stated and ambient temperatures according to the schedule. Some

of the ambient temperature ranges and most of the part throttle runs were omitted in an effort to find the condition where manifold heat became beneficial to combustion. Since manifold heat never increased the power output, even when the ambient temperature was -65 °F, it seemed unnecessary to make the tests at the intermediate conditions. It also appeared reasonable that part throttle heat requirements would be less than full throttle requirements, thus the part throttle runs could be safely omitted. This reasoning was substantiated by a part-throttle test at the lowest ambient temperature. (See Curve No. 14, Page 57)

58 The tests of engine performance with carburetion were made in the manner described above, however, tests were completed employing all ambient temperatures specified. At -65 °F, runs were made at all four throttle settings.

59 It was noted during the above program that the engine developed more power when operated with carburetion than with fuel injection. A motoring test was made at 2000 RPM, while varying the ambient temperature, to determine the amount of power required to drive the injection system. During this test the fuel air ratio was controlled at .08. The nozzle was allowed to discharge into a separate container to prevent disturbing the lubrication of the cylinder.

60 The cylinder and connecting rod were removed for inspection at the end of the test program. The condition of each major part is listed in Table 3, Page 28 .

Discussion

61 IGNITION TESTS: The primary purpose of this program was to collect factual information concerning the operation of gasoline engines at extremely low temperatures. These data were to be used as a guide for planning future research programs, once the specific problems were isolated. A great amount of work has been done on ignition systems but in very few, if any, of these projects was the effect of low temperature the primary interest. In fact, a relatively small amount of investigation has been conducted on engines operating in low ambient temperatures. Test cells with adequate space and sufficient cooling for arctic research are comparatively few. Thus, the demand for such a unit far surpasses the supply. This situation prevents the primary function of basic research in so far as contracts of this type are usually extended as the problems occur.

62 The importance of the effect of temperature on an ignition system became evident almost as soon as the tests were started. It was impossible to obtain reproducible data on a spark plug mounted in the test bomb without carefully controlling the temperature of the ignition coil. As shown by Reading Nos. 33, 42, 60, 61 and 62 on the A C - 86 plug (See Log Sheet No. 2, Page 73) the performance of the ignition system is affected nearly as much by the coil temperature as by the spark plug temperature. Three conclusions may be stated after analyzing these data:

(a) Raising the coil temperature reduces the limiting pressure whether the plug is hot or cold
(b) Lowering the plug temperature decreases the limiting spark plug pressure
(c) The loss in limiting pressure due to cold plug conditions may be nearly offset by lowering the coil temperature to that of the plug

63 As a result of these findings, the remaining tests were conducted with either the coil being cooled along with the plug or only after the coil had been in operation long enough for its temperature to become constant.

64 The performance of five of the spark plugs, as indicated by the constant voltage, variable pressure tests, was nearly equal over the low temperature range. The Auto-lite B - 9 and the Champion C - 8 were well above average and the Auto-lite Resistor plug BR - 8 was below average. This trend was evident during the high temperature tests although the difference in performance is less outstanding. A further indication of the higher efficiency of the C - 8 and B - 9 plugs is given by the constant pressure tests. These two plugs required the lowest primary voltage and amperage. The resistor type plugs required a high voltage, probably higher than the battery would supply while cranking an engine in cold weather.

65 The spark plugs for the higher temperature range seem to give improved performance. This results largely from the diameter of the center electrode. These electrodes varied from .085 to .125 inch. The plugs having higher performance had the smallest electrodes. This effect is especially noticeable in the Champion plugs. The C - 6 has .125 inch electrode and about average performance. The C - 8 has .097 diameter and high performance.

66 During the first spark plug test (constant primary voltage, variable nitrogen pressure, arctic temperature range) the average nitrogen pressure increased from about 100 psi at 60° to about 170 psi at -60 °F. The trend was reversed on the high temperature test. This results from cooling the ignition coil in the first test but allowing it to operate at constant temperature in the latter test. This shows the importance of coil temperature. The requirement at the spark plug is increasing as the temperature is reduced, but cooling the coil more than compensates for it. Further evidence of this trend is shown by the constant pressure test. The coil must be supplied with increasing voltage as the temperature is reduced.

67 ENGINE TESTS: Adding heat to the combustion air reduced the power output during all of the test runs. This, of course, indicates that manifold heat is not necessary for good combustion in an otto-cycle engine. Since it is a well known fact that automotive type engines do lose power as mixture temperature is lowered, it must be assumed that this phenomenon is the result of poor distribution of fuel and air in the intake manifold.

68 The observed horsepower of the engine was as much as 30 percent higher when the fuel was admitted through the carburetor. This is shown when the full throttle points at 2000 RPM are plotted against ambient temperature. (See Curve No. 26, Page 69) This is not the result of the power required to drive the injection pump. As the friction horse-power curves show, only about .1 horse-power is required by this system. The loss seems to be the result of inadequate mixing of the fuel and air, although the nozzle pressure was set at 1750 psi and the injection process started when the inlet valve was wide open.

69 The engine was much less efficient when operated with fuel injection. This is shown by the indicated specific air and fuel consumption curves. Part of this may be attributed to reduced volumetric efficiency since the manifold temperature is not reduced by vaporization of the fuel. With carburetion the manifold was cooled as much as 40° below the ambient temperature. (See Curve No. 27, Page 70)

70 Further evidence of the non-homogenous mixture in the cylinder is the fact that detonation was less severe with fuel injection. The last portion of charge to burn was either so rich or so lean that detonation was suppressed.

71 The observed indicated horse-power was corrected to standard temperature and pressure according to the expression agreed upon by the Society of Automotive Engineers:

$$HP_c = HP_o \frac{2992}{P_a} \sqrt{\frac{T_a}{520}}$$

These curves are also presented on Curve No. 26, Page 69. The corrected horse-power rises as the ambient temperature is reduced until it reaches a maximum at about -40 °F. At lower temperatures the correct horse-power becomes less. The rise in power seems to be the result of the friction in the intake manifold. The decrease results from overcooling the combustion chamber and cylinder wall. The coolant leaving the cylinder head was held at essentially the same temperature by the thermostat, but it entered the water jacket at ambient temperature.

72 During the engine tests, several difficulties arose while the ambient temperature was being lowered. Little difficulty was experienced during the running of the fuel-injection tests. The hydraulic controls were the only source of trouble and when Univis P - 38 hydraulic oil was obtained, this difficulty was eliminated. However, thermal contraction of carburetor parts caused serious difficulties. The carburetor was supplied with a main jet needle valve of steel and a supporting insert of brass. As the insert was screwed into position, the die-cast carburetor body was stretched slightly. Cooling of the carburetor relieved the stress in the insert, and since the needle valve was supported by the insert, the effective opening changed greatly.

73 After the test runs were completed the engine was dis-assembled for inspection. Carbon deposits on the piston and combustion chamber wall were medium to heavy. None of the parts were worn excessively but the cylinder wall, connecting rod and exhaust valve seat were pitted.

LIST OF APPARATUS AND INSTRUMENTS

74 Spark Plug Test Bomb

Reference: Photo No. 1, Page 29

75 Distributor and Driving Motor

Distributor: Manufacturer - Autolite Electric Co.
Model - IGS-4103-A, 8C277268
Modifications:
(a) Removed five cam lobes
(b) Removed vacuum spark advance mechanism
(c) Locked fly-weights of centrifugal spark advance mechanism

Driving Motor: Manufacturer - Montgomery Ward
Speed - 1725 RPM
Horse-power rating - 1/4
Voltage - 110 AC
Model No. - DPA6004

76 Ignition Coil

Manufacturer - Autolite Electric Co.
Model No. - IG-6V3U

77 Battery

Manufacturer - Sears, Roebuck and Co.
Model - 46
Voltage - 6.3

78 Battery Charger

Motor: Manufacturer - Baldor Electric Co.
Horse-Power - 1
Voltage - 110-220

Generators: Manufacturer - Autolite Electric Co.
Model No. - GCJ4802-A-U
Quantity - 2

Voltage Control: Variable Resistor - 25 ohm
Excitation - 28 volt DC, Laboratory System

79 Cooling Equipment

Tank: Special - Laboratory
Size - 10-1/2" x 11" x 17"

Pump: Manufacturer - Pesco
Model No. - 2P27G

Driving Motor: Manufacturer - Montgomery Ward
Model No. - DP 6005 - 9820
Speed - 1750
Voltage - 110-220
Horse-Power - 1/3

Cooling Medium:
Type - Gasoline

Refrigerant :
Type - Dry Ice

80 Heating System

Heater: Manufacturer - Hevi Duty Electric Co.
Type - M-2012
Capacity - 1400 watts
Voltage - 115-230

Medium: Type - Glycerine

81 Nitrogen

Supplier - Air Reduction Co.
Type - W P

82 Direct Current Ammeter

Manufacturer - Weidenhoff, Inc.
Range - 0-10, 0-50, 0-200, 0-1000

83 Direct Current Voltmeter

Manufacturer - Weidenhoff, Inc.
Range - 0-10, 0-20, 0-50

84 Oscillograph

Manufacturer - Allen B. Dumont Labs.
Type - 204-13
Serial Number - 5382

85 Alternating Current Voltmeter

Manufacturer - R C A
Model No. - WV - 73A
Range - .01-.025-1.-2.5-10-25-100-250-1000

86 Temperature Indicator (Coil)

Manufacturer - Lewis Engineering
Model No. - 14P0
Serial No. - 175
Range - -20 to +500 °F, 400 to 1800 °F
Thermocouple - IC

87 Temperature Indicator (Spark Plug Gasket)

Manufacturer - Leeds & Northrup
Serial No. - 486961
Range - 0 to 450 °F, 400 to 800 °F
Thermocouple - IC

88 High Voltage Calibrator

Reference: Drawing No. 20650, Page 33

Coil: Manufacturer - Autolite Electric Co.
Model No. - IG-6V3U

Resistor: Manufacturer - Unknown
Type - Nichrome Wire
Rating - 1000 W

Output: 6700 VRMS when supplied with 131 V 400 cps

Calibration Meter: Manufacturer - Ballentine
Model No. - 300
Serial No. - 5994 with 100:1 multiplier No. 993
Range - 0 to 10,000 volts

Pickup: 20 turns, 1/8" brass rod, 5/16 ID

89 Switch Box

Reference: Drawing No. 20650, Page 33

90 Primary Voltage Resistor

Manufacturer - Ohmite

91 Pressure Gage

Manufacturer - National Cylinder Gas
Model No. - None
Range - 0 to 400 psi

92 Spark Plugs Tested

Auto-Lite: Manufacturer - Autolite Electric
Models - B5, B9, BR4, BR8

A. C.: Manufacturer - A. C. Spark Plug Div. (General Motors)
Models - 83, 86

Champion: Manufacturer - Champion Spark Plug Co.
Models - No. 6 commercial, No. 8 commercial

Gap Settings: See Table I, Page 24

93 Engine for Ignition Tests

"Tiny Tim": Manufacturer - Continental Motors
Bore - 1.75"
Stroke - 1.75"
Number of Cylinders - 1
Valve Arrangement - L
Compression Ratio - 4
Special Cylinder Head - See Drawing No. 5202, Page 29
Cooling-Air

94 Engine for Combustion Research

Manufacturer - Merz
Serial No. - 11
Number of Cylinders - 1
Bore - 2.625"
Stroke - 3.250"
Valve Arrangement - Overhead
Cooling - Liquid
See Photo No. 3, Page 31

95 Fuel System for Merz Engine

Injection System: Manufacturer - Bosch

Pump: Manufacturer - Bosch
Model - APEIB70P30073
Serial No. - 138104

Nozzle: Manufacturer - Bosch
Model - AKB8078

Transfer Pump: Manufacturer - Bosch
Model - AFPK22N

Carburetor: Manufacturer - Zenith
Model - 10355

Fuel: Specification - MIL-G 3056
Type - C
Vapor Pressure - 12-14 psi

Supply: Barrel - See Sketch No. 6, Page 33
Source of Pressure - Nitrogen

Flow-Rator: Manufacturer - Fischer & Porter
Serial No. - J11-2997
Calibration Curve - See Curve No. 2, Page 45

Surge Chamber: See Drawing No. 20737, Page 43

Controls: Manufacturer - Sperry Products
Model - EIEI-A
Hydraulic Fluid - Univis P-38, Std. Oil

96 Cooling System

Radiator: Manufacturer - Plymouth

Pump: Manufacturer - Crosley

Thermostat: Manufacturer - Crosley

Coolant: Arctic Grade Anti-Freeze, Solution C

Layout: See Sketch No. 4, Page 35

97 Combustion Air System

Layout: See Sketch No. 5, Page 37

Orifice: See Sketch No. 9, Page 41

Surge Drum: Dimensions - 16" x 24"

Heater: See Sketch No. 10, Page 42

Manifold: See Sketch No. 8, Page 40

Slant Gage: Manufacturer - Ellison
Model - Inclined, Vertical Draft Gage

Orifice Calibration: See Curve No. 1, Page 44

98 Insulated Test Cell

Reference: See Sketch No. 2, Page 34

99 Circulating Fans

Government Surplus
Size - 12" dia

Motor: Manufacturer - Louis Allis
Type - 5 HP D.C., 1750 RPM

100 Refrigeration System

Layout: See Sketch No. 7, Page 39

Main Compressor: Manufacturer - York Corporation
Model - F3129-5DE
Series - VW
Motor - Allis Chalmers - 75 HP,
9-5128-1118-620E-1-1

Rotary Compressor: Manufacturer - Allis Chalmers
Alterations - by York Corporation
Serial No. - 1788
Motor - Allis Chalmers - 60 HP,
9-5128-1069-620D-1-3

Oil Separator: Manufacturer - Acme Industries, Inc.
Serial No. - 51-3-369

Condenser: Manufacturer - Acme Industries, Inc.
Model No. - 51-3-6158

Control Receiver: Manufacturer - Richard M. Armstrong
Serial No. - 2030

Float Switches: Manufacturer - Alco Valve Co.
Type - J 5 R

Expansion Valves: Manufacturer - Alco Valve Co.
(1) Type M 330, 3/4"
(2) Type M 620, 1/2"

Oil Still: Special - Laboratory
Size - 1-1/2" x 2-1/2", 20' long

Pump Receiver: Manufacturer - Richard M. Armstrong
Serial No. - 2029

Stand Pipe: Special - Laboratory
Size - 12" x 12'

Circulating Pump: Manufacturer - Buffalo Pumps, Inc.
Model - 4-CS
Motor - Westinghouse, 5 HP, 3PH, 5105

Coils: Manufacturer - Bush Manufacturing
(1) C 36.8.8-24 Q, Right Hand
(2) C 36.8.8-24 Q, Left Hand
Arrangement - Parallel

Liquid Cooler: Manufacturer - York Corporation
Serial No. - 27457

Expansion Valve: Manufacturer - Sporlan Valve Co.
Type - MVC

Oil Receiver: Manufacturer - York Corporation
Serial No. - 20303

Oil Reservoir: Manufacturer - Richard M. Armstrong
Serial No. - 2031

Control Valve: Manufacturer - Hammel Dahl Co.
Serial No. - 515703
Figure No.-3834S
Size - 1/2"

Automatic Temperature Controller:
Manufacturer - Minneapolis Honeywell
Model - 152P13P-63-11
Serial No. - 319065
Calibration - -100 to +120 °F (IC)

101 Temperature Indicator

Manufacturer: Minneapolis Honeywell
Model No. - 156X63P48
Serial No. - 666354
Calibration - -100 to +1600 °F (IC)

102 Dynamometer

Manufacturer - General Electric Co.
Model - TLC - 6
Serial No. - 1540296
Capacity - 5 HP Motoring

103 Engine Coupling

Manufacturer - Spicer Company
Universal Joints - Sleeve Yoke 4-3-98X,
Journal & Bearing 5-15X,
Slip Joint w/Flange Yoke
1501-14X

104 Speed and Spark Advance Indicator

Strobotac: Manufacturer - General Radio Co.
Model - 631-B
Serial No. - 5163

Strobolux: Manufacturer - General Radio Co.
Model - 648-A
Serial No. - 567

105 Torque Indicator

Special - Laboratory
Type - See Sketch No. 3, Page 35

Pickup: Manufacturer - Schaevitz Engineering Co.
Type No. - 18-L
Serial No. - 102

Indicator: (Vacuum Tube Voltmeter)
Manufacturer - RCA
Model - WV-73A
Calibration - See Curve No. 3, Page 46

Champion Spark Plug Co.	8 C	.025	.097

TABLE II

GROUP A — Determine Operating Conditions

Conditions: Arctic Fuel, fuel injection, 20 °SA, ambient temperature, wide open throttle

(1) Purpose: Find maximum torque speed
Procedure: Set 1200 RPM and .080 fuel air ratio: Repeat at 1400, 1600, 1800, 2000 and 2400 RPM

(2) Purpose: Find best power fuel air ratio
Procedure: Set maximum torque speed and .06 F/A: Repeat at .065, .070, .075, .080, .085 and .090 F/A

(3) Purpose: Find optimum spark advance
Procedure: Set maximum torque speed, best power mixture and 0° spark advance: Repeat at 5, 10, 15, 20, 25, 30, 35, 40 °BTDC

GROUP B — Select Optimum Compression Ratio

Conditions: Arctic Fuel, fuel injection, maximum torque speed (2000 RPM), optimum spark advance (30°), compression ratio 6.78:1

(1) Purpose: Find detonation limit
Procedure: Vary fuel air ratio .05 to .10 at full throttle: Load down to 300 RPM at .08 F/A

(2) Purpose: Find detonation limit with 7.23:1 compression ratio
Procedure: Repeat part B-1, avoid excessive detonation

GROUP C-1 — Determine Optimum Heat Supplied to Manifold

Conditions: Arctic Fuel, fuel injection, .08 F/A 30° SA, 6.78:1 compression ratio

Purpose: Find best power air temperature
Procedure: Set speed, F/A, spark advance, room air temperature: Record power: Increase carburetor air temperature in 4 steps of approximately 25 °F each

RUN NO.	RPM	THROTTLE SETTING
1	2000	4/4
2	2000	3/4 *
3	2000	2/4 *
4	2000	1/4 *
5	1600	4/4
6	1600	3/4 *
7	1600	2/4 *
8	1600	1/4 *
9	1200	4/4
10	1200	3/4 *
11	1200	2/4 *
12	1200	1/4 *
13	800	4/4
14	800	3/4 *
15	800	2/4 *
16	800	1/4 *

GROUP C-2 Repeat C-1 with ambient temperature of 32 °F (made 1, 5, 9, 13)

GROUP C-3 Repeat C-1 with ambient temperature of 0 °F (made 1, 5,9,13)

GROUP C-4 Repeat C-1 with ambient temperature of -15 °F (made 1, 5, 9, 13)

GROUP C-5 Repeat C-1 with ambient temperature of -30 °F (made 1, 5, 9, 13)

GROUP C-6 Repeat C-1 with ambient temperature of -45 °F (made 1, 5, 9, 13)

GROUP C-7 Repeat C-1 with ambient temperature of -55 °F (made 1, 5, 9, 13)

GROUP C-8 Repeat C-1 with ambient temperature of -65 °F (made 1, 2, 5, 9, 13)

GROUP D-1 Repeat C-1 using carburetor (made 1, 5, 9, 13, 15) **

GROUP D-2 Repeat C-2 using carburetor (made 1, 5, 9, 13)

GROUP D-3 Repeat C-3 using carburetor (made 1, 5, 9, 13)

GROUP D-4 Repeat C-4 using carburetor (made 1, 5, 9, 13)

*These runs omitted when adding heat at full throttle did not increase power output

**Reduced SA to 20° at 1200 and 10° at 800 because of detonation

GROUP D-5 Repeat C-5 using carburetor (made 1, 5, 9, 13)

GROUP D-6 Repeat C-6 using carburetor (made 1, 5, 9, 13)

GROUP D-7 Repeat C-7 using carburetor (made 1, 5, 9, 13)

GROUP D-8 Repeat C-8 using carburetor (made all 16 runs)

GROUP E Friction

Conditions: Constant speed, full throttle, varying ambient temperature

Purpose: Motoring friction with and without fuel injection

Procedure: Set 2000 RPM, full throttle, .08 F/A with injector removed and manifold plugged: Repeat at zero F/A: Repeat both settings at 20, 0, -15, -30, -45, -55 and -65 °Room Temperature

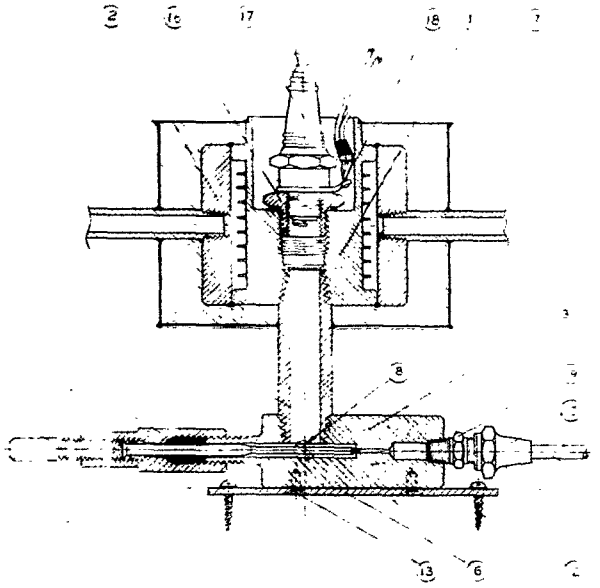
TABLE III

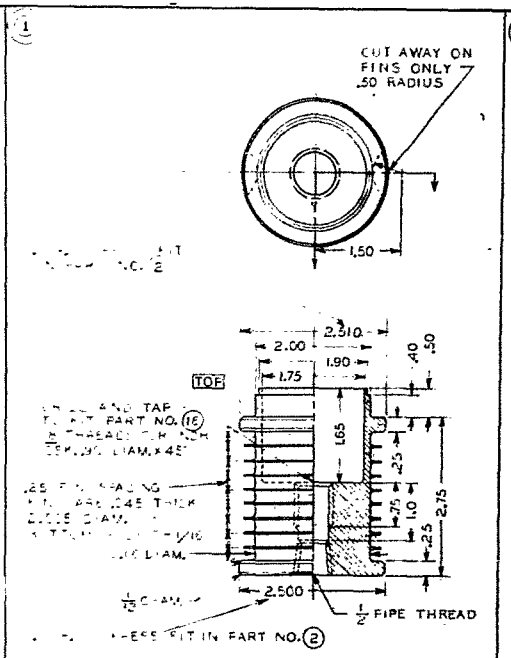
INSPECTION RECORD OF MERZ ENGINE

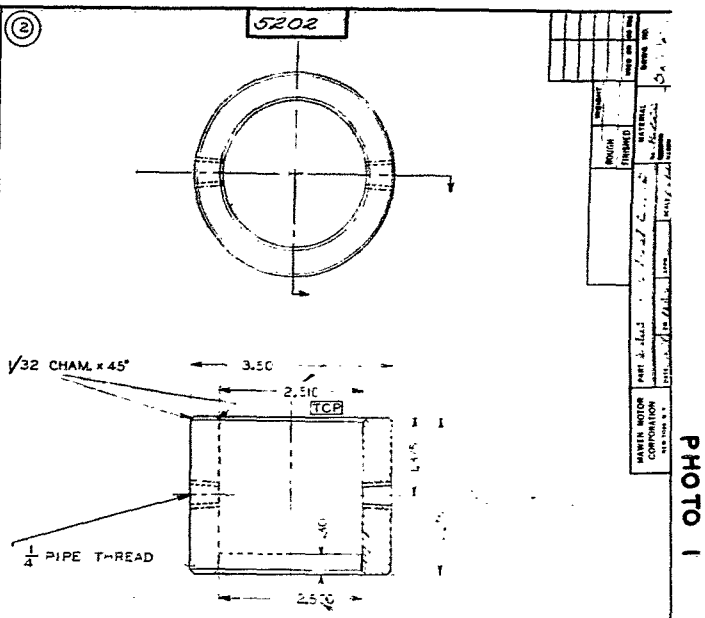
Date: 19 December 1952
Inspected by: V. C. Currens
Compression ratio: 6.78:1

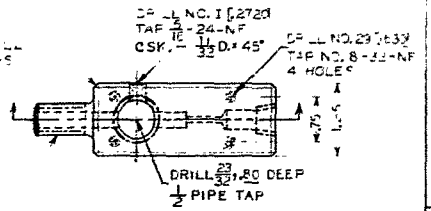
PART			CONDITION	
Rocker Arm Shafts			Good	
Rocker Arm Needle Bearings			Good	
Piston Pin			Good	
Piston Bores			Good	
Connecting Rod (small end)			Good*	
Connecting Rod (large end)			Good*	
Cylinder Bore:	Top		Good	
	Center		Pitted Slightly	
	Bottom		Ground	
Combustion Chamber			Good	
Intake Valve Seat			Good	
Exhaust Valve Seat			Good	
Piston:	General		Good	
	Crown		Good	
	Top Land		Good	
	2nd Land		Good	
	3rd Land		Good	
	4th Land		Good	
	5th Land		Good	
	6th Land		Good	
	Skirt		Good	
	Inside		Good	
Valve Gear & Valves		Intake: Good		Exhaust: Good
	Guide	Good		Good
	Push rod	Good		Good
	Rocker	Good		Good
	Spring (inner)	Good		Good
	Spring (outer)	Good		Good
	Washer (Upper)	Good		Good
	Washer (Lower)	Good		Good
	Thrust	Good		Good
	Adjusting Screw	Good		Good
	Valve Stem	Good		Good
	Valve Head	Good		Poor*

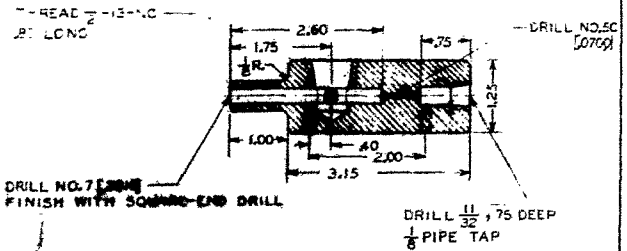
*Cylinder and piston assembly condition "Good" with the exception of exhaust valve which showed considerable pitting on face. Also the connecting rod showed signs of rusting and pitting on the I section. Carbon deposits were medium to heavy and no parts showed excessive wear. The piston rings were all free and in good condition.

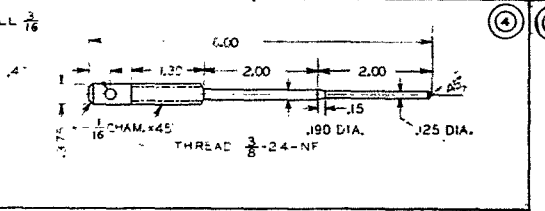


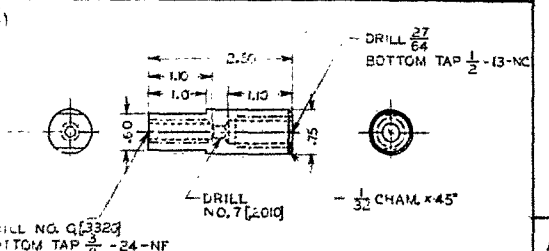


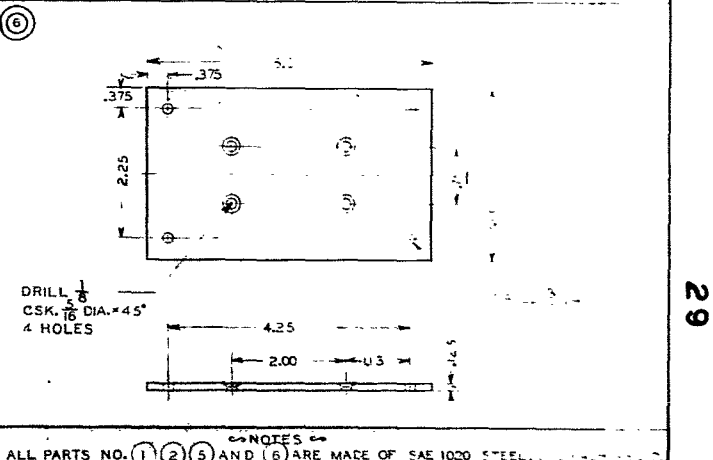












NOTES

ALL PARTS NO. (1) (2) (5) AND (6) ARE MADE OF SAE 1020 STEEL,

PART NO. (3) IS MADE OF BRASS OR BRONZE

PART NO. 4 IS MADE OF DRILL ROD
