66286

ABSTRACTPHASE I.

The leakage current of Foil Type Mylar Capacitors at 150° C. Life Test conditions, is considerably higher than was anticipated by the use of Dielectric Resistance vs. Temperature curves, previously obtained. This abnormally high current drain overloaded the power supplies which were installed for these tests. This high current also precluded the use of the automatic timing and clearing mechanism. By using heavy-duty voltage supplies and substituting manual control for automatic relay circuits, we were able to Life Test the six groups of capacitors reported on, in this document. The results with such a small total of test units is, of course, not conclusive, but the indications substantiate our past theory that our present Mylar C does not effectively operate at temperatures as high as 150° C.

PHASE II.

The greatest problem with Metallized Mylar C Capacitors to date was the high number of opens that occurred during Life Tests. All work done with such units during this quarter was devoted to solving this difficulty. The ensuing

54AA 66286

ABSTRACT (continued)

data in this report reveals that our efforts have not corrected the situation one hundred percent, but the comparative few opens that now occur are sufficient to make our test data significant.

PART I.

PURPOSE

- A. Develop Film Dielectric Capacitors, high temperature, utilizing DuPont "Mylar" film (V-200) or equivalent, as a capacitor dielectric, in order to achieve higher temperature operation and greater reliability of fixed paper capacitors, in accordance with Bureau of Ships Contract Specification SHIPS F-400, dated 15 September, 1951, as follows:
- B. Phase I.
 1. Evaluate a V-200 film or equivalent in accordance with paragraph 3.2.1 of referenced Bureau of Ships Contract Specification SHIPS F-499.

B. Phase I (continued)

2. Furnish fifty (50) each of various capacitors as described in paragraph 3.2.1 of referenced Bureau of Ships Contract Specification SHIPS F-499.
3. Submit reports as specified therein.

C. Phase II

1. Evaluate a V-200 or equivalent with metallized electrodes in accordance with paragraph 3.2.2. of referenced Bureau of Ships Contract Specification SHIPS F-499.
2. Furnish fifty (50) each of various capacitors as described in paragraph 3.2.1 of referenced Bureau of Ships Contract Specification SHIPS F-499.
3. Furnish one (1) set of Type D Class IV Manufacturing Drawings in accordance with Bureau of Ships Specification 16D19 (RE), dated 15 January 1946, and Amendment No. 2, dated 1 May 1948.
4. Submit Reports as specified herein.

- 0 - 0 - 0 - 0 - 0 - 0 -

GENERAL FACTUAL DATA PHASE I

Life Tests were conducted at 125° C. and at stresses of 200, 300, 400, 500, 600 and 700 volts per mil. The 500 volts per mil stress produced a failure of 8% failures in 72 hours; the 600 volts per mil stress, 56% loss in 72 hours. Accordingly, the 30% point presumably will occur within these two values.

It was observed during this quarter that as a result of using manual controls on our Life Tests, thereby extending the exposure time to high temperature without voltage, that the failures occurring late in the Life Test (close to the 72-hour minimum) were more difficult to examine than those of shorter duration. In most cases, the outside half or two-thirds of the section would readily unwind, but the inner portion had become very brittle. In many instances, the Mylar would shatter into tiny fragments as the unit was being unwound.

The actual points of failure differ in physical appearance, also. All previous failures have caused ruptures in the Mylar, both inwardly and outwardly from the exact breakdown. The number of layers on either side of the failure, vary between 3 and 12. All failures that were found in the embrittled Mylar C never penetrated more than two layers.

A gradual decrease in leakage current occurred during Life Test

GENERAL FACTUAL DATA Phase I (continued)

indicating an effective increase in insulation resistance. This phenomenon seemed to occur to an equal degree without the application of voltage. This may indicate the possible requirement of long-term ageing to develop required characteristics.

PHASE II

During the last period, experiments were conducted to evaluate two methods of reducing opens during Life Test on Metallized Mylar Capacitors. The first method was to increase the margin of the capacitor and to melt down the excessive margin during the spraying operation. The hot copper spray melts back a sufficient amount of Mylar so that the use of the wider margin does not result in a larger capacitor.

This method has proven to be generally successful as indicated in the attached data.

The second method has been to fold the edge of the Mylar during the winding operation, thereby presenting a metal surface to the copper spray rather than the edge of a Mylar film. This method resulted in an excessive number of voltage breakdowns during the application of initial voltage tests.

The remaining capacitors went through Life Test satisfactorily without opens.

GENERAL FACTUAL DATA Phase II (continued)

The unusual amount of voltage breakdowns during initial voltage tests were traced to a cracking of the Mylar during the folding operation.

As this operation is difficult and did not produce a good yield, it was abandoned in favor of the first-mentioned method.

DETAIL FACTUAL DATA

PHASE I

All tests made in Phase I during the last quarter were conducted at 150° C. The capacitors used at this time were of similar design to those used previously -- namely 1 Mfd. constructed with two layers of .0005" Mylar C film between foils. The test units were constructed with Mylar C taken from the same lots that were used for the test units made previously. The gauge from roll to roll and within each roll varied between limits of .00048" and .0006".

A. Seventy-five units were divided into three groups of twenty-five each:

1. Tested at 200 VDC, all units passed tests prior to Life Test. Twenty-five units were placed on Life Test, and all twenty-five completed 72 hours. (See Part III, P.1)
2. Tested at 300 VDC, all units passed tests prior to Life Test. Twenty-five units were placed on Life Test and all twenty-five completed 72 hours. (See

DETAIL FACTUAL DATA - Phase I (continued)

Part III, P. 2.)

3. Tested at 400 VDC, all units passed tests prior to Life Test. Twenty-five units were placed on test, and twenty-three completed 72 hours. Both failures were caused by Mylar faults. (See Part III, P. 3.)

B. Seventy-five units were divided into three groups of twenty-five each.

1. Tested at 500 VDC, all units passed tests prior to Life Test. Twenty-five units were placed on test and twenty-three completed 72 hours. Both failures were caused by Mylar faults. One unit opened during the test. (See Part III, P. 4.)
2. Tested at 600 VDC, all units passed tests prior to Life Test. Twenty-five units were placed on Life Test, and eleven completed 76 hours. There were thirteen Mylar failures, 1 mechanical failure and 1 unit opened during the test. (See Part III, P. 5.)
3. Tested at 700 VDC, all units passed tests prior to Life Test. Twenty-five units were placed on Life Test, and sixteen completed 72 hours. All nine failures were caused by Mylar faults. (See Part III, P. 6.)

DETAIL FACTUAL DATA

PHASE II

All tests performed this quarter were at 125° C. and the test unit was the .25 Mfd. Capacitor, constructed with a single layer of .0005" Metallized Mylar C. The material used was slit and margined by the TOBE DEUTSCHMANN CORP. from 2" rolls, slit to 1" rolls with 3/32" margins.

A. Seventy-five units were divided into three groups of twenty-five each:

1. Tested at 600 VDC, all units passed tests prior to Life Test. Twenty-five units were placed on Life Test, and fifteen completed 250 hours.

There were ten failures caused by Mylar faults. Two units opened during the test. (See Part III, P. 7.)
2. Tested at 700 VDC, two units failed during pre-breakdown voltage test. Both were caused by Mylar faults. The remaining twenty-three were placed on Life Test, and six completed 250 hours.

There were seventeen failures caused by Mylar faults. Two units opened during the test. (See Part III, P. 10).
3. Tested at 800 VDC, five units failed tests prior to Life Test. One unit opened during the initial voltage test, and four units failed during the pre-breakdown voltage test. The remaining twenty units were placed on Life Test, and eight completed 250 hours.

DETAIL FACTUAL DATA - Phase II (continued)

There were twelve failures caused by Mylar faults.

(See Part III, P. 13)

B. Seventy-five units were divided into three groups of twenty-five each:

1. Tested at 400 VDC, two units failed tests prior to Life Test. One unit opened and the other failed the initial voltage test. The remaining twenty-three units were placed on Life Test, and all twenty-three completed 251 hours. (See Part III, P. 16).
2. Tested at 500 VDC, one unit failed the initial voltage test. The remaining twenty-four units were placed on Life Test, and twenty-two completed 251 hours. Both failures were caused by Mylar faults. (See Part III, P. 19)
3. Tested at 600 VDC, one unit failed during the pre-breakdown voltage test. The remaining twenty-four units were placed on Life Test and sixteen completed 258 hours. Eight units failed because of Mylar faults. (See Part III, P. 22)

C. Sixty units were divided into three groups of twenty each:

1. Tested at 400 VDC, nine units failed tests prior to Life test. Eight units failed the initial voltage test and one failed during the pre-breakdown voltage test. The remaining eleven units were placed on Life Test, and all eleven completed 251 hours. (See Part III, P. 25)

DETAIL FACTUAL DATA -- Phase II (continued)

C. (continued)

2. Tested at 500 VDC, six units failed the initial voltage test prior to Life Test. The remaining fourteen units were placed on Life Test and all fourteen completed 251 hours. (See Part III, P. 28.)
3. Tested at 600 VDC, one unit failed during pre-breakdown voltage test. The remaining nineteen units were placed on Life Test, and sixteen completed 251 hours. The three failures were caused by Mylar faults. Three units opened during the test. (See Part III, P. 31)

CONCLUSIONS

PHASE I

The number of units tested at 150° C. is too small to yield conclusive results. Indications are that a 1 Mfd. Capacitor with two layers of .5 Mil Mylar C between foils will operate at this temperature for 1000 hours at 300 volts per mil, and 8000 hours at 200 volts per mil.

Capacitors operated at these rather low stresses are extremely bulky and their application probably will be limited by their size.

Obviously, this Mylar C does not yet provide an answer for miniaturization at this temperature.

---0-0-0---

PHASE II

By reviewing the Tables found on pages 11, 12, 13 and 14, it is very evident that by changing our design to a slightly greater protective margin, we have practically eliminated the problem of opens occurring during Life Test. Before the change was made, the column headed "Number Opened" was heavy, and the column headed "Number Failed" was light. Now the

CONCLUSIONS (continued)

PHASE II

situation is completely reversed, which is what it should be since it is the purpose of this project to evaluate the units of Mylar C as a dielectric.

- 0 -

PART II.

PART II.

PROGRAM FOR
NEXT INTERVAL

PHASE I.

We have received from E. I. duPont de Nemours & Co., Inc. a very small trial lot of the new Mylar C which has been wound into capacitors and are now starting Life Test. Upon the performance of these units rests the decision whether additional work be done with plain Mylar C or whether this phase of the project be postponed until the manufacturer of the film can provide us with better and more consistent material.

PHASE II.

Now that the problem of "opens" occurring during Life Test has been corrected, it is our intention to review the entire Life Test program conducted with .25 Mfd. units constructed with a single .5 Mil of Metallized Mylar C. All tests, whether they be at 85° C. or 125° C. that resulted in excessive opens, will be run again with new units of similar construction, but with 3/32" margins.

Twenty-five .25 Mfd.
single half-Mil Metallized
Mylar C units.

The units (24) were wired to a Life Test rack after the initial tests were concluded, and the total capacitance measured at room temperature. Then they were heated in an oven to 125° C. for one-half hour. The capacitance was then measured at 125° C. Next, the units were exposed to 800 v.d.c. pre-breakdown test for one-half hour. During this period, there were 661 temporary breakdowns. Units #22, #20, #16, #23 failed after 64, 106, 415, and 661 temporary breakdowns respectively. The capacitance was then once again measured before the Life Test commenced.

Metallized Mylar C
Units

The units (24) were wired to a Life Test rack after the initial tests were concluded, and the total capacitance measured at room temperature. Then they were heated in an oven to 125° C. for one-half hour. After this, the capacitance was measured at 125° C. Next, the units were exposed to 500 V.D.C. pre-breakdown test for one-half hour. During this period, there were 57 temporary breakdowns. The capacitance was again measured before the Life Test commenced.
