2.0 SUMMARY

This report presents the calculated distributions of normal force coefficient, chordwise force coefficient, and torsion moment coefficient about the 25% chord line of an autorotating rotor at zero degrees collective pitch and at high tip-speed ratios ($\mu = 0.5$ to $\mu = 2.0$). These load distributions are a continuation of the determination of the aerodynamic characteristics of a rotor at high tip-speed ratios presented in Reference 1.

This analysis is for a rotor having rectangular, untwisted blades and no tip drag. The effects of reversed flow, blade stall, and tip loss are included. The rotor has the following physical characteristics:

Number of blades, $b = 3$

Blade mass coefficient, $\gamma = \frac{\rho a c R^4}{I_b} = 5.0$

Solidity ratio, $\sigma = \frac{b c}{\pi R} = .05$

As shown in Reference 1, the coefficients may be considered directly proportional to the solidity ratio and, hence, are applicable to a wide range of rotor solidity ratios.

The coefficients plotted in this report are based on the calculations of Reference 1 and represent the forces or moments on three blades. Therefore, to find the coefficient for one blade, the ordinates of all curves must be divided by three.

3.0 DISCUSSION

3.1 Normal Force (Thrust) Distribution - For Reference 1 the spanwise thrust distributions for twelve azimuth stations were calculated for each of several values of advance ratio, μ ; collective pitch, β ; and control plane angle of attack, α . The thrust found in this manner is normal to the control plane, but in the present case where the collective pitch is zero degrees with respect to the control plane, the thrust is also normal to the chord-plane of the blade.

The present analysis is for the autorotating rotor with no tip drag included. None of the points calculated for Reference 1 coincides exactly with the autorotation points so an interpolation is made to obtain the autorotation values. The spanwise normal force coefficients are plotted in Figures 2 through 7 for μ values from 0.5 to 2.0. The loading around the azimuth is shown in Figures 8 through 13. An harmonic analysis is made of the azimuthal thrust distribution and the mean and first five harmonics are plotted in Figure 14.

3.2 Chordwise (In-Plane) Force Distribution - The chordwise force was not determined as such in Reference 1 but is easily derived from the torque calculations by dividing the section radius out of the torque coefficient distributions. The force found thus is in the control plane and for this special case where the col-

MODEL _____

lective pitch is zero, it is also in the chord-plane. Interpolations to autorotation conditions are made from the calculated values of Reference 1 simultaneously with converting from torque to in-plane force. The spanwise distributions of the chordwise force coefficient are plotted in Figures 15 through 20; the loading around the azimuth is shown in Figures 21 through 26. An harmonic analysis is made of the azimuthal chordwise force distribution and the mean and first five harmonics are plotted in Figure 27.

3.3 Torsion Moment Distribution - The torsion moment coefficients are found by multiplying the normal force coefficients found in Section 3.1 by the chordwise distance from the quarter-chord point to the center of pressure. The center of pressure location at section angles of attack from 0° to 110° is given in Figure 1 which is taken directly from Reference 2. The section angles of attack of the rotor are interpolated from Reference 1. The spanwise distributions of the torsion coefficient are plotted in Figures 28 through 33 and the loading around the azimuth are given in Figures 34 through 32.

The torsion coefficients found above are in the rotating rotor system. They are converted into appropriate vertical components and components about the longitudinal and lateral axes in the non-rotating system to which the helicopter rotor controls are

attached. The mean, maximum and minimum values of these components as well as the mean, maximum and minimum values of the torsion coefficients of one blade are given in Figure 40.

1.0 EQUATIONS

The normal force coefficient, chordwise force coefficient, and torsional moment coefficient are defined, respectively, in the following manner:

$$C_T = \frac{T}{\rho \pi R^2 (\Omega R)^2} \quad (1)$$

$$C_P = \frac{P}{\rho \pi R^2 (\Omega R)^2} \quad (2)$$

$$C_T = \frac{\tau}{\rho c \pi R^2 (\Omega R)^2} \quad (3)$$

Where:

- T = normal force
- P = chordwise force
- τ = torsion about the quarter-chord line of the blade
- R = rotor radius
- c = blade chord
- Ω = rotational speed of the rotor

The conversion of the blade torsion from the rotating to the non-rotating coordinate system is:

Component about longitudinal axis:

$$C_T' = \frac{1}{3} [C_T \sin \psi + C_{T_{(\psi+120^\circ)}} \sin(\psi+120^\circ) + C_{T_{(\psi+240^\circ)}} \sin(\psi+240^\circ)] \quad (4)$$

Component about lateral axis:

$$C_T'' = \frac{1}{3} [C_T \cos \psi + C_{T_{(\psi+120^\circ)}} \cos(\psi+120^\circ) + C_{T_{(\psi+240^\circ)}} \cos(\psi+240^\circ)] \quad (5)$$

The vertical component is the sum of functions (4) and (5).
