SOME ASPECTS OF NON-EQUILIBRIUM FLOWS

SUMMARY

In this paper some of the general features of non-equilibrium flow are discussed. In particular, vibrational relaxation is discussed in detail. This case is somewhat simpler than dissociation and ionization but it illustrates some of the main new features of non-equilibrium flow. Those aspects of two-dimensional and axisymmetric flow behind shock waves are examined analytically which yield significant information without requiring numerical solution of the governing equations.

The thermodynamics of a vibrational relaxing gas is discussed. The conditions for simulating flows are noted. Crocco's theorem and the characteristic equations are derived. Then a simple method of obtaining the initial gradients of the flow variables behind a shock is shown. These gradients are used in discussing two particular flows. An exact solution for flow over a cusped body is obtained. Flow over a wedge near the tip and far from the tip is considered. It is found that far from the tip a boundary layer type phenomenon occurs.

## 1. INTRODUCTION

There have been many recent publications considering the flow of a gas not in thermodynamic equilibrium. No complete bibliography will be given here, but several papers pertinent to the present work will be mentioned.

Probably the first work on this subject, for the case where there are shock waves in the flow, is that of Bethe and Teller<sup>1</sup>. A qualitative discussion of flow over a wedge was given by Ivey and Cline<sup>2</sup> in which the departure from thermodynamic equilibrium was due to vibrational relaxation of a diatomic gas. (Some quantitative results will be given here for this case.) An approximation to the hypersonic flow over a sphere, where the departure from equilibrium is due to dissociation, was considered by Freeman<sup>3</sup>. Flows with small disturbances were considered by Moore and Gibson<sup>4</sup>, and in particular, the flow over a thin wedge.

In a pure diatomic gas at reasonable temperatures, three processes can cause departure from equilibrium: vibrational excitation, dissociation, and ionization. If the relaxation times for these processes are sufficiently different, they may be treated separately. The magnitude of the effects on the flow variables due to the three processes is quite different. The gross effects are directly related to the energy necessary to excite the new degrees of freedom.

In this paper vibrational relaxation only is considered. This is somewhat simpler to handle than dissociation and ionization, but should illustrate some of the main features of non-equilibrium flow. Because the smallest non-equilibrium effects result from vibrational excitation, some of the results obtained here differ little from the results of calculations based on equilibrium flow; or differences are significant only in a negligibly small region of flow. It is hoped that the methods used here can be applied, with almost equal ease, to other non-equilibrium processes.

Only certain aspects of two-dimensional and axisymmetric flows are examined in this paper; these will not involve numerical solution of the differential equations. After a discussion of the appropriate thermodynamics of a vibrational relaxing diatomic gas, the governing equations are transformed to yield the generalization of Crocco's theorem which relates the entropy change to the vorticity. Next a derivation and discussion of the characteristic equations are given. Using the appropriate shock transition relations and the equations of motion, the streamwise gradients of the flow variables are obtained employing natural coordinates (as indicated by Sternberg<sup>5</sup> for equilibrium flows.) These prove to be quite useful in discussing two particular flows; namely, two dimensional flow over (i) a cusped body which supports a straight shock wave, and (ii) a wedge.

For (i) an exact solution is obtained that requires only two quadratures. For (ii) the flow is examined near the tip and far from the tip. At the tip the shock curvature and the wedge pressure gradient can be obtained rather simply using the gradient functions. Far from the tip the flow must be divided into two regions. To a first approximation a large region of the flow is the equilibrium wedge flow, but there is a small region near the shock wave where relaxation is important. Mathematically this small region exhibits a boundary layer type phenomenon. An indication is given of a means of obtaining the next approximation.

## 2. THERMODYNAMICS

Basically the difference in the descriptions of equilibrium and non-equilibrium flows results from differences in the thermodynamic behavior of the gas, the dynamic aspects being the same. A clear explanation of an appropriate model of a non-equilibrium system (and the necessary assumptions) was given by Wood and Kirkwood<sup>6</sup>. The same model will be used here.

For the case of a gas subject to vibrational relaxation the degrees of freedom are divided into two classes: the active (translation and rotation), for which the subscript a will be used, and the internal or inert (vibration), for which the subscript i will be used. It is assumed that local thermodynamic equilibrium exists within the classes but not between them. The rate at which equilibrium is approached is governed by a rate equation which can be specified in terms of the state variables of each class. There are other assumptions, to be mentioned later, which are convenient to make. The model presented<sup>6</sup> is intermediate between a macroscopic and a microscopic description.

From the assumption that the Gibbs relation holds for the "a" class, it follows that the entropy change of the "a" class is

$$dS_a = c_{p_a} \frac{dT_a}{T_a} - R \frac{dp}{p},$$

where the perfect gas law is assumed

$$p = \rho R T_a \tag{2.1}$$

It is assumed that the "i" class is specified by its temperature,  $T_i$ , so that the entropy change is

$$dS_i = dE_i/T_i$$

The total entropy change is then

$$\begin{aligned} dS &= dS_a + dS_i \\ &= c_{p_a} \frac{dT_a}{T_a} - R \frac{dp}{p} + dE_i/T_i \end{aligned} \tag{2.2}$$

The rate equation assumed is the linear form

$$dE_i/dt = [E_i(T_a) - E_i] / \tau \quad (2.3)$$

where  $\tau$  is the relaxation time and  $E_i(T_a)$  is the value of  $E_i$  if equilibrium existed at the temperature  $T_a$ . For a flow the derivative in (2.3) is the substantial derivative.

The linear form of the rate equation presupposes that the departure from equilibrium is not too great. It is exact if the vibrators are quantized harmonic oscillators.<sup>1</sup> The functional relation  $E_i(T_a)$ , for various gases, can be obtained from tables of the properties of gases.<sup>7</sup> With the assumption of harmonic oscillators,  $E_i(T_a)$  can be calculated from

$$E_i(T_a) = R \Theta_v / \left[ \exp. (\Theta_v/T_a) - 1 \right] ; \quad (2.4)$$

where  $\Theta_v$  is the characteristic vibrational temperature. This form will be used when some specific flows are calculated. It is convenient, though not necessary, to carry along both variables  $E_i$  and  $T_i$ . The functional dependence  $E_i(T_i)$ , for the case of harmonic oscillators, has the same form as  $E_i(T_a)$  in (2.4).

For future reference the following well known relations are recorded. For equilibrium flow  $T_a = T_i$  and

$$c_p - c_v = R$$

where

$$c_p = c_{p_a} + c_i$$

$$c_v = c_{v_a} + c_i$$

$$c_i = d E_i / d T_a.$$

Also

$$c_{p_a} - c_{v_a} = R.$$

### 3. EQUATIONS OF MOTION

In this section the equations of motion of a pure diatomic gas subject to vibrational relaxation will be discussed. The equation of state (2.1) is assumed. By a minor modification the results can be extended to the case of a mixture of diatomic gases where only one constituent relaxes. It is necessary to know the effect of the other constituents on this one. This case would arise, in practice, if the relaxation time of one constituent is much shorter than that of the others. This would be the case for air since the relaxation time of oxygen is about one-fifteenth that of nitrogen. This extension, however, will not be included here.

The equations will be written in natural coordinates  $(s, n)$ , where  $s$  and  $n$  are distances along the streamlines and their orthogonal trajectories, respectively. The form of the equations of conservation of momentum, mass, and energy do not change because of relaxation; they are

$$\rho q \frac{\partial q}{\partial s} = - \frac{\partial p}{\partial s} \quad (3.1)$$

$$\rho q^2 \frac{\partial \theta}{\partial s} = - \frac{\partial p}{\partial n} \quad (3.2)$$

$$\frac{1}{\rho} \frac{\partial \rho}{\partial s} + \frac{1}{q} \frac{\partial q}{\partial s} + \frac{\partial \theta}{\partial n} + \frac{\epsilon \sin \theta}{y} = 0 \quad (3.3)$$

$$h + (q^2/2) = h_t \quad (3.4)$$

where  $q$  is velocity,  $\theta$  is the velocity direction,  $\epsilon = 0$  or  $1$  for two-dimensional or axisymmetric flow, respectively;  $y$  is the coordinate perpendicular to the axis of symmetry;  $h = c_{v_a} T_a + E_1 + p/\rho$  is the enthalpy; and  $h_t$  is the stagnation enthalpy (constant along streamlines). These four equations, together with the equation of state (2.1) and the rate equation, give a complete description of the flow. In natural coordinates the rate equation (2.3) is

$$q \frac{\partial E_1}{\partial s} = \left[ E_1(T_a) - E_1 \right] / \tau \quad (3.5)$$

The relaxation time,  $\tau$ , is a function of pressure and temperature. In the following it is assumed to be constant. This would be a poor assumption if there are large changes in pressure and temperature; however, in the regions of flow considered changes of appreciable magnitude in these quantities do not occur.

For the above six equations, the conditions for similar flows over geometrically similar bodies are easily deduced. In addition to the requirements of fixed Mach number and ratio of specific heats,  $\tau U/\ell$  must also be fixed for similar flows. Here  $U$  and  $\ell$  are representative velocity and length, respectively. This type of dimensionless ratio was used by Freeman<sup>3</sup>. Experimentally the appearance of the new length scale  $\tau U$  makes simulation more difficult. Analytically it means that the simple "similarity solutions" (wedge flow and Prandtl-Meyer expansion) no longer exist.

A useful relation for equilibrium flows is Crocco's theorem.<sup>9</sup> It relates the entropy gradient to the vorticity. For a relaxing gas this relation can be derived as follows. The expression for the entropy change (2.2) can also be written

$$T_a dS = dh - dp/\rho - \left[ 1 - (T_a/T_1) \right] dE_1$$

Using (3.4) to eliminate  $h$ ,

$$T_a dS = dh_t - q dq - dp/\rho - \left[ 1 - (T_a/T_1) \right] dE_1$$

From this the directional derivatives of  $S$  in the  $s$  and  $n$  directions are evaluated. After elimination of the pressure by use of the momentum equations (3.1) and (3.2), these derivatives are expressible as

$$T_a \partial S / \partial s = - \left[ 1 - (T_a/T_1) \right] \partial E_1 / \partial s \quad (3.6)$$

$$T_a \partial S / \partial n = q\zeta - \left[ 1 - (T_a/T_1) \right] \partial E_1 / \partial n + dh_t / \partial n \quad (3.7)$$

where  $\zeta$  is the vorticity,

$$\zeta = q \partial \theta / \partial s - \partial q / \partial n$$

Note that  $\partial h_t / \partial s = 0$ , but  $\partial h_t / \partial n = 0$  only for isoenergetic flows. If the flow is in equilibrium,  $T_a = T_i$ , (3.6) gives the result of constant entropy along streamlines, and (3.7) reduces to the usual form of Crocco's theorem. For three-dimensional unsteady flow the vector form of Crocco's theorem is

$$\partial \vec{q} / \partial t - \vec{q} \times \vec{\omega} = T_a \vec{\nabla} S - \vec{\nabla} h_t + \left[ 1 - (T_a / T_i) \right] \vec{\nabla} E_i$$

where  $\vec{\omega}$  is the vorticity vector and  $\vec{\nabla}$  is the gradient operator. An equivalent result, but in different thermodynamic variables, was given by Broer.<sup>10</sup>

It is convenient to eliminate  $p$  and  $\rho$  from the equations of motion and introduce  $S$ . The resulting equations for isoenergetic flow are

$$(M_a^2 - 1) \frac{\partial q}{\partial s} - q \frac{\partial \theta}{\partial n} = \frac{\epsilon q \sin \theta}{y} + \left( \frac{q}{c_{p_a} T_a} \right) \frac{\partial E_i}{\partial s} \quad (3.8)$$

$$q^2 \frac{\partial \theta}{\partial s} - q \frac{\partial q}{\partial n} = T_a \frac{\partial S}{\partial n} + \left[ 1 - (T_a / T_i) \right] \frac{\partial E_i}{\partial n} \quad (3.9)$$

$$T_a \frac{\partial S}{\partial s} + \left[ 1 - (T_a / T_i) \right] \frac{\partial E_i}{\partial s} = 0 \quad (3.10)$$

$$q \frac{\partial E_i}{\partial s} = \left[ E_i(T_a) - E_i \right] / \tau \quad (3.11)$$

$$c_{p_a} T_a + E_i + (q^2 / 2) = h_t \quad (3.12)$$

where

$$M_a^2 = q^2 c_{v_a} / (c_{p_a} R T_a).$$

Thus only the "frozen" Mach number enters. Note that (3.9) and (3.10) are simply (3.6) and (3.7) while (3.8) comes from (2.1), (3.1), (3.3), and the expression for  $\partial S / \partial s$ . The unknowns are  $q$ ,  $\theta$ ,  $T_a$ ,  $E_i$ , and  $S$ .

It is easily verified by the standard technique that the above partial differential equations are hyperbolic if  $M_a > 1$ . Solving the determinant equation for the four characteristic directions, one obtains the streamline

direction counted twice and the Mach lines based on  $M_a$ ; that is, the Mach angle is  $\mu = \sin^{-1} (1/M_a)$ . The equations of motion in characteristic form are (3.10), (3.11), and the following two equations:

$$\begin{aligned} \cot \mu D_{\pm} q + q D_{\pm} \theta &= \frac{\epsilon q \sin \theta \sin \mu}{y} + \frac{\sin \mu [E_i(T_a) - E_i]}{\tau c_{p_a} T_a} \\ &- \cot \mu \left\{ T_a D_{\pm} S + [1 - (T_a/T_i)] D_{\pm} E_i \right\} / q \end{aligned} \quad (3.13)$$

where the operators  $D_{\pm}$  are defined by

$$\sec \mu D_{\pm} = \partial/\partial s \pm \tan \mu \partial/\partial n;$$

that is,  $D_{\pm}$  indicates differentiation along the Mach lines inclined at  $\pm \mu$  to the streamline. The appearance of the "frozen" Mach lines has been noted by other authors.<sup>6,10</sup> A numerical calculation, using the characteristic form, for flow over a wedge is in progress and will be reported in another paper.

#### 4. GRADIENTS BEHIND A SHOCK WAVE

A general method for computing the flow variable gradients behind a shock wave in a two-dimensional flow was developed by Thomas<sup>11</sup> for a gas not subject to relaxation effects. A simpler method, using natural coordinates, was indicated by Sternberg.<sup>5</sup> For two-dimensional flow the gradients are particularly useful; e.g., the slope of the streamlines at shock polar points in the hodograph plane can be obtained from them (the so-called "hedge-hog" introduced by Busemann). It is found that the gradients are proportional to the shock wave curvature.

For axisymmetric flow the same gradients can be computed, but they are linear combinations of the two curvatures:  $K_w$  in the meridional and  $1/y$  in the azimuthal planes. This fact limits the usefulness of the gradients for this case. Extensive tabulations have been made recently<sup>12</sup> of the coefficients of  $K_w$  and  $1/y$ ; with these the gradients can be computed easily. (The two-dimensional result is obtained by setting the coefficient of  $1/y$  equal to zero.)

For a uniform flow which is in equilibrium in front of a shock wave but not behind it, the gradients will depend on the relaxation time. Behind the shock the flow variables are computed from the shock relations for constant specific heats; i.e., the frozen relations.<sup>9</sup>  $E_1$  does not change across a shock.<sup>1</sup> To obtain expressions for the gradients, the equations of motion are combined with the shock relations; the normal derivatives are expressed in terms of derivatives along the shock wave and along the streamline. Referring to Figure 1,

$$\partial/\partial\sigma = \cos \lambda \partial/\partial s + \sin \lambda \partial/\partial n$$

where  $\sigma$  is distance along the shock wave,  $\beta$  is the shock angle, and  $\lambda = \beta - \theta$ . Since

$$\partial/\partial\sigma = \partial\beta/\partial\sigma (\partial/\partial\beta) = K_w \partial/\partial\beta$$

the normal derivative can be written

$$\partial/\partial n = \left[ K_w \partial/\partial\beta - \cos \lambda \partial/\partial s \right] / \sin \lambda \quad (4.1)$$

The normal derivatives in (3.8) and (3.9) are eliminated by use of (4.1);  $\partial E_1/\partial \beta = 0$ , and  $\partial q/\partial \beta$ ,  $\partial \theta/\partial \beta$ , etc. can be computed from the shock relations. The following two equations then result:

$$(M_a^2 - 1) \partial q/q \partial s + \cot \lambda \partial \theta/\partial s = (\epsilon/\gamma) \sin \theta + f_1 + (K_w k_2/\sin \lambda) \quad (4.2)$$

$$\cot \lambda \partial q/\partial s + q \partial \theta/\partial s = K_w (f_2 + g k_1)/(q \sin \lambda) \quad (4.3)$$

where

$$k_1 = \partial q/\partial \beta, \quad k_2 = \partial \theta/\partial \beta$$

$$f_1 = (\partial E_1/\partial s)/c_{p_a} T_a = \left[ E_1(T_a) - E_1(T_\infty) \right] / (c_{p_a} T_a \tau q)$$

$$f_2 = T_a \partial S/\partial \beta$$

and all quantities are evaluated immediately behind the shock wave.

Solving (4.2) and (4.3) for  $\partial \theta/\partial s$  and  $\partial q/\partial s$ , one obtains

$$\partial \theta/\partial s = F_1 K_w + (\epsilon/\gamma) F_2 + (f_1 \cot \lambda)/D \quad (4.4)$$

$$(1/q_\infty) \partial q/\partial s = F_3 K_w + (\epsilon/\gamma) F_4 - q f_1/(q_\infty D) \quad (4.5)$$

where

$$F_1 = \left[ (1 - M_a^2)(k_1 + f_2 q^{-1}) + q k_2 \cot \lambda \right] / (q D \sin \lambda)$$

$$F_2 = (\sin \theta \cot \lambda)/D$$

$$F_3 = \left[ (k_1 + f_2 q^{-1}) \cot \lambda - q k_2 \right] / (q_\infty D \sin \lambda)$$

$$F_4 = - (q \sin \theta) / (q_\infty D)$$

$$D = 1 - M_a^2 + \cot^2 \lambda$$

The  $F_i$  are functions of  $M_\infty$ ,  $\beta$ , and  $\gamma$ , and have been tabulated<sup>12</sup> for  $\gamma = 1.4$ ,  $1.1 \leq M_\infty \leq 10$ , and  $\sin^{-1}(1/M_\infty) < \beta \leq \pi/2$ .

By use of (3.1), (3.3), and (3.4) the gradients of  $p$ ,  $\rho$ , and  $T_a$  can be obtained. Since  $f_1$  and  $D$  are positive, the effect of relaxation is to increase the streamline curvature  $\partial\theta/\partial s$  and decrease the velocity gradient for given  $K_w$  and  $y$ . For reasonably strong shocks at ordinary  $T_\infty$ ,  $E_1(T_\infty)$  can be neglected compared to  $E_1(T_a)$ .

Even for two dimensional flows it is seen that the gradients will not be simply proportional to  $K_w$ ; this will limit their usefulness. Some application will be made of these gradients in the next two chapters.

## 5. AN EXACT SOLUTION

As mentioned previously, the solution for flow over a wedge is no longer simple when the gas behind the shock is relaxing; the flow behind the shock is not uniform and the shock is not straight. This flow will be considered in the next section. Here it will be shown that an exact solution can be obtained for two-dimensional flow over a cusped body (the curvature becoming zero asymptotically) which supports a straight shock wave.

From (4.4), with  $\epsilon = 0$ , it can be seen that if the shock is locally straight,  $K_w = 0$ , the curvature of the streamline at the shock can be easily calculated. Letting  $K_s = \partial\theta/\partial s$ , a convenient non-dimensional measure of streamline curvature is the following quantity:

$$K_s \tau q_\infty / e_1 = (R q_\infty \cot \lambda) / c_{p_a} q D \quad (5.1)$$

where

$$e_1 = \left[ E_1(T_a) - E_1(T_\infty) \right] / RT_a \quad (5.2)$$

A plot of the expression in (5.1) is shown in Figure 2 for a range of values of  $M_\infty$  and  $\beta$ . For the case of pure  $N_2$  with  $T_\infty = 300^\circ K$ ,  $\beta = 60^\circ$ ,  $M_\infty = 6$ , where (2.4) was used with  $\theta_v = 3336^\circ K$ , it is found that  $\theta = 41.1$  and  $K_s = 5.5 \text{ ft}^{-1}$ . The value of  $\tau$  was taken from Reference 8.

Since (5.1) has no physical length scale in it, the shock wave could be straight over any finite distance and  $K_s$  would be the same everywhere. Considering the manner in which a numerical solution of the characteristic equations would proceed, starting from a straight shock, one can see that all the flow variables depend only on the distance along the normal to the shock. A "shock oriented" coordinate system  $\xi, \eta$  is introduced, as shown in Figure 3, and a solution with flow variables independent of  $\eta$  is sought. The streamlines will be parallel curves with initial curvature given by  $K_s$  in (5.1) and initial slope calculated from the frozen shock relations. If the streamlines are physically meaningful, any one of them can be chosen as the body. Reflecting this curve through the free stream

direction gives a pointed cusped body which supports a straight shock wave. Anticipating a result from the next chapter, the curvature of the body should approach zero and the angle of the body should approach the equilibrium wedge angle appropriate to the given shock angle. These expectations are verified by the solution obtained below.

Equations (3.8) to (3.12) are transformed to the  $(\xi, \eta)$  system by

$$\partial/\partial s = \sin(\beta - \theta) \partial/\partial \xi + \cos(\beta - \theta) \partial/\partial \eta$$

$$\partial/\partial n = -\cos(\beta - \theta) \partial/\partial \xi + \sin(\beta - \theta) \partial/\partial \eta$$

Setting all  $\eta$  derivatives equal to zero and letting

$$\psi = \beta - \theta,$$

one obtains the following equations:

$$(M_a^2 - 1) \sin \psi \frac{\partial q}{\partial \xi} + q \cos \psi \frac{\partial \theta}{\partial \xi} = \frac{q \sin \psi}{c_{p_a} T_a} \frac{\partial E_1}{\partial \xi} \quad (5.3)$$

$$q \sin \psi \frac{\partial \theta}{\partial \xi} + \cos \psi \frac{\partial q}{\partial \xi} = 0 \quad (5.4)$$

$$T_a \frac{\partial S}{\partial \xi} + \left[ 1 - (T_a/T_1) \right] \frac{\partial E_1}{\partial \xi} = 0 \quad (5.5)$$

$$q \sin \psi \frac{\partial E_1}{\partial \xi} = \left[ E_1 (T_a) - E_1 \right] / \tau \quad (5.6)$$

$$c_{p_a} T_a + E_1 + (q^2/2) = h_t \quad (5.7)$$

On elimination of  $\xi$ , (5.4) can be written

$$dq/q = -\tan \psi d\theta$$

Integrating,

$$q \cos \psi = q_f \cos(\beta - \theta_f), \quad (5.8)$$

where the subscript  $f$  denotes values computed from the frozen shock relations.

Combining (5.3) with the differentiated form of (5.7) and eliminating  $\xi$ , a first order ordinary differential equation is obtained. The result of integrating this is

$$T_a = \left[ T_{a_f} + (q_f^2/R) \sin^2 (\beta - \theta_f) \right] \cot (\beta - \theta_f) \tan \psi - (q_f^2/R) \cos^2 (\beta - \theta_f) \tan^2 \psi \quad (5.9)$$

where again the frozen shock relations have been applied.  $E_i$  is obtained from (5.7), with the aid of (5.8) and (5.9).

$$E_i = h_t + \left[ (c_{p_a}/R) \tan^2 \psi - (1/2) \sec^2 \psi \right] q_f^2 \cos^2 (\beta - \theta_f) - c_{p_a} \left[ T_{a_f} + (q_f^2/R) \sin^2 (\beta - \theta_f) \right] \cot (\beta - \theta_f) \tan \psi \quad (5.10)$$

With all the variables expressed in terms of  $\theta$ , (5.6) can now be used to obtain  $\theta$  as a function of  $\xi$ . Thus

$$\xi = q_f \tau \cos (\beta - \theta_f) \int_{\theta_f}^{\theta} F(\theta) d\theta$$

$$F(\theta) = \tan \psi (dE_i/d\theta) / \left[ (E_i(T_a) - E_i) \right]$$

The equation of the body is, in parametric form (parameter  $\theta_b$ ),

$$\xi_b = q_f \tau \cos (\beta - \theta_f) \int_{\theta_f}^{\theta_b} F(\theta) d\theta$$

$$\eta_b = q_f \tau \cos (\beta - \theta_f) \int_{\theta_f}^{\theta_b} \left[ F(\theta) / \tan \psi \right] d\theta$$

The above integrations are carried out until  $E_i(T_a)$  is equal to  $E_i$ ; that is, equilibrium is attained. In principle,  $\xi_b$  and  $\eta_b$  become infinite for

this condition; actually, the curvature of the body approaches zero rather quickly and the gas is, for all practical purposes, in equilibrium at finite  $\xi_b$  and  $\eta_b$ .

A representative result (obtained by numerical integration) of the above formulas is shown in Figure 4 for  $N_2$  at  $M_\infty = 8$ ,  $\beta = 65^\circ$ ,  $T_\infty = 300^\circ K$ . Equation (2.4) was used to obtain  $E_1(T_a)$ , with  $\theta_v = 33.6^\circ$ . The angle of the body changes about three degrees from  $\theta_f = 43.6^\circ$  to  $\theta_e = 46.7^\circ$ , the latter being the wedge angle that corresponds to a shock angle of  $65^\circ$  when the equilibrium shock relations are used. For the latter relations see, e.g., Reference 13. The largest change in angle occurs when  $\theta_f$  and  $M_\infty$  are close to the conditions for shock detachment in frozen flow.

Thus an exact calculation (with two quadratures) of the flow with a straight shock wave is possible. These results can be used to check approximate methods of computing flows. In the next chapter this exact solution will be used to investigate a portion of the flow far from the tip of a wedge.

It is desirable to define some measure of the distance over which relaxation effects are important. As in defining the thickness of a viscous boundary layer, there is some arbitrariness in any definition of a relaxation distance. Following Moore and Gibson<sup>4</sup>, one such definition would be

$$\int_0^\infty \left[ 1 - (E_1/E_{1eq.}) \right] d\xi,$$

where  $E_{1eq.}$  is the final equilibrium value of  $E_1$ . If  $E_{1eq.}$  is replaced by  $E_1(T_a)$ , the value of the integral would not be changed much, but the integration would be easier. Calling this relaxation distance  $\xi_r$ ,

$$\begin{aligned}
\xi_r &= \int_0^{\infty} \left[ 1 - E_1/E_1(T_a) \right] d\xi \\
&= q_f \tau \cos(\beta - \theta_f) \int_{\theta_f}^{\theta_e} \left[ (dE_1/d\theta) \tan \psi / E_1(T_a) d\theta \right] \\
&\hspace{25em} (5.12)
\end{aligned}$$

where  $\theta_e$  is the equilibrium wedge angle. For the particular example cited above

$$\xi_r = .136 q_{\infty} \tau = .300 q_f \tau$$

No reason was given for the particular definition of a relaxation distance in Reference 4; it is analogous to the definition of displacement thickness of a viscous boundary layer. In the next chapter a different method of obtaining a distance is given which results in a coefficient of  $\tau q_{\infty}$  thirty per cent higher than the one given for  $\xi_r$ .

## 6. FLOW OVER A WEDGE

Several years ago Ivey and Cline<sup>2</sup> discussed the two-dimensional flow over a wedge. This was mainly a qualitative discussion. However, it was pointed out that at the tip the shock wave should have the angle appropriate to the frozen shock relations, and far from the tip the (smaller) angle appropriate to the equilibrium shock relations<sup>13</sup>. Also the shock curve is concave downward. Here some further quantitative results for this flow are shown.

It seems most natural to use polar coordinates  $(r, \phi)$  with the origin at the tip and  $\phi$  measured from the free stream direction. Transforming Equations (3.8) to (3.12), with  $\epsilon = 0$ , to polar coordinates gives

$$\begin{aligned} (M_a^2 - 1)(r \cos \alpha \frac{\partial q}{\partial r} + \sin \alpha \frac{\partial q}{\partial \phi}) + q(r \sin \alpha \frac{\partial \theta}{\partial r} - \cos \alpha \frac{\partial \theta}{\partial \phi}) \\ = (q/c_{p_a} T_a)(r \cos \alpha \frac{\partial E_1}{\partial r} + \sin \alpha \frac{\partial E_1}{\partial \phi}) \end{aligned} \quad (6.1)$$

$$\begin{aligned} q^2(r \cos \alpha \frac{\partial \theta}{\partial r} + \sin \alpha \frac{\partial \theta}{\partial \phi}) + q(r \sin \alpha \frac{\partial q}{\partial r} - \cos \alpha \frac{\partial q}{\partial \phi}) \\ = -T_a (r \sin \alpha \frac{\partial S}{\partial r} - \cos \alpha \frac{\partial S}{\partial \phi}) \\ - \left[ 1 - (T_a/T_1) \right] (r \sin \alpha \frac{\partial E_1}{\partial r} - \cos \alpha \frac{\partial S}{\partial \phi}) \end{aligned} \quad (6.2)$$

$$\begin{aligned} T_a (r \cos \alpha \frac{\partial S}{\partial r} + \sin \alpha \frac{\partial S}{\partial \phi}) = \\ - \left[ 1 - (T_a/T_1) \right] (r \cos \alpha \frac{\partial E_1}{\partial r} + \sin \alpha \frac{\partial E_1}{\partial \phi}) \end{aligned} \quad (6.3)$$

$$q(r \cos \alpha \frac{\partial E_1}{\partial r} + \sin \alpha \frac{\partial E_1}{\partial \phi}) = (r/\tau) \left[ E_1(T_a) - E_1 \right] \quad (6.4)$$

$$c_{p_a} T_a + E_1 + (q^2/2) = h_t \quad (6.5)$$

where  $\alpha = \theta - \phi$

To consider the flow near the tip a dimensionless variable,  $r/\tau q_\infty$ , is introduced. Until the appropriate boundary conditions for wedge flow are introduced, the following discussion applies to any two-dimensional

flow (e.g., the modifications to Prandtl-Meyer flow over a corner). Assume that all the flow variables can be expanded in a power series in  $r/r_{q_{\infty}}$ ; then it can be shown that, to within  $O(r/r_{q_{\infty}})$  terms, the flow is frozen. The form of these series would be

$$f(r, \phi) = f_0(\phi) + (r/r_{q_{\infty}}) f_1(\phi) + \dots$$

The zeroth order terms satisfy

$$(M_{a_0}^2 - 1) \sin \alpha_0 \partial q_0 / \partial \phi - q_0 \cos \alpha_0 \partial \theta_0 / \partial \phi = 0 \quad (6.6)$$

$$\cos \alpha_0 \partial q_0 / \partial \phi - q_0 \sin \alpha_0 \partial \theta_0 / \partial \phi = 0 \quad (6.7)$$

$$\partial S_0 / \partial \phi = 0 \quad (6.8)$$

$$\partial E_{1_0} / \partial \phi = 0 \quad (6.9)$$

Equations (6.6) and (6.7) present two possibilities; either

$$M_{a_0}^2 \sin^2 \alpha_0 = 1,$$

which is appropriate for corner flow, or

$$\partial q_0 / \partial \phi = \partial \theta_0 / \partial \phi = 0,$$

which, after applying the wedge boundary conditions, gives frozen flow over a wedge. To within an error  $O(r/r_{q_{\infty}})$ , the shock wave is straight.

The next step would be the solution of the differential equations for  $q_1$ ,  $\theta_1$ , etc. Although this is feasible, it will not be done because the most interesting information can be more easily obtained from the gradient functions of Chapter 4. Since, for the wedge,  $\partial \theta / \partial s = 0$ , the curvature of the shock at the tip is, from (4.4),

$$K_w = - (f_1 \cot \lambda) / DF_1$$

The frozen values of the variables are used in the right hand side. In non-dimensional form

$$K_w \tau q_\infty / e_i = - (R q_\infty \cot \lambda) / c_{p_a} q D F_1 \quad (6.10)$$

A plot of the expression in (6.10) is shown in Figure 5 for a range of  $M_\infty$  and  $\beta$ . For the case of pure  $N_2$  with  $T_\infty = 300^\circ K$ ,  $\beta = 60^\circ$ ,  $M_\infty = 6$ ,  $p_\infty = 1$  atm.,

$$\Theta = 41.1^\circ, \quad K_w = 4.1 \text{ ft}^{-1}$$

where (2.4) was used with  $\Theta_v = 3336^\circ K$ ; the value of  $\tau$  was taken from Reference 8, and  $F_1$  from Reference 12. For the same conditions, except  $M_\infty = 10$ ,  $K_w$  is  $220 \text{ ft}^{-1}$ , which means that the curvature would not be detectable in any ordinary scale of experiment.

With  $K_w$  known, the initial velocity gradient along the wedge can be computed from (4.5), and then the pressure gradient from (3.1). A convenient non-dimensional form for the pressure coefficient is

$$(\partial C_p / \partial s)(\tau q_\infty / e_i) = 2(\rho q / \rho_\infty q_\infty) \left[ (R / c_{p_a} D) - (F_3 K_w \tau q_\infty / e_i) \right] \quad (6.11)$$

where

$$C_p = 2(p - p_\infty) / \rho_\infty q_\infty^2$$

A plot of the expression in (6.11) is shown in Figure 6. For the above example ( $M_\infty = 6$ )  $\partial C_p / \partial s = 16.0 \text{ ft}^{-1}$

Thus the shock curvature and the rate of change of the flow variables on the wedge at its tip can be obtained rather easily; if the details of the flow are desired, the series expansion method should be used. Unfortunately, the same method, i.e. employing the gradient functions, cannot be used to investigate cone flow. The use of natural coordinates at the tip of a cone is impossible because of the nature of the singularity there. The series expansion method could be used, but the differential equations for the first order terms would be much more difficult to solve than those of the wedge case.

To consider the flow far from the tip, a series expansion procedure is again adopted, but now  $\tau q_\infty/r$  is the variable. The assumption that the flow variables are analytic in this variable will be seen to be not uniformly valid. The difference between this case and the previous one can be seen by examining (6.4). When  $r/\tau q_\infty$  approaches zero, the right hand side vanishes and nothing unusual happens. When  $\tau q_\infty/r$  approaches zero, the left hand side vanishes and the result is that  $E_1(T_a) = E_1$ ; that is, the flow is in equilibrium. Since derivatives have been lost, a boundary layer type phenomenon (singular perturbation) must be expected. The order of the system (6.1) to (6.4) is reduced from four to three by this limiting process. Also the result that the flow is in equilibrium is inconsistent with the boundary condition  $E_1 = E_{1_\infty}$  at the shock.

If the flow variables are expanded in a series of the form

$$f(r, \phi) = f^{(0)}(\phi) + (\tau q_\infty/r) f^{(1)}(\phi) + \dots$$

the zeroth order terms for  $q$  and  $\theta$  will satisfy equations of the same form as (6.6) and (6.7) except with zero superscripts instead of subscripts and  $M_a$  replaced by the equilibrium Mach number. Thus, to within an error  $O(\tau q_\infty/r)$ , the flow is equilibrium wedge flow. The shock is straight and the flow is uniform and parallel to the wedge.

It is helpful to keep in mind here the procedure for obtaining the viscous flow over a body: (i) the non-viscous flow is computed ignoring one boundary condition (i.e., tangential velocity equals zero), (ii) the structure of the apparent discontinuity (vortex sheet) at the body is investigated using the boundary layer approximation, (iii) the non-viscous flow over the body plus displacement thickness is computed, etc. For the present problem steps analogous to (i) and (ii) will be taken. Note that here part of the problem is to determine the boundary; that is, the shock wave.

In Figure 7(a) a streamline and the fictitious "equilibrium shock", predicted by the first term of the series expansion, are shown in dashed lines. The transition across the shock is governed by the equilibrium shock relations. The angle of the equilibrium shock is fixed by  $M_{\infty}$  and the wedge angle. Extended, it must go through the tip in order to satisfy the conservation of mass. The actual shock (solid line) must be displaced upstream of the equilibrium shock, but its curvature must vanish to within an error  $O(\tau q_{\infty}/r)$ . To this approximation the non-equilibrium flow behind a straight shock describes the flow near the shock but far from the tip (Figure 7(b)). This flow is obtained from the exact solution of Chapter 5. Thus the "boundary layer", or rapid transition region, is determinable. Compared to the equilibrium region between the shock and the body this transition region is negligibly small. It and the shock merge into the equilibrium shock.

The question remains: how to join the two regions; or rather, how far is the shock displaced from the equilibrium shock? This is answered by again invoking the conservation of mass. A transition region streamline must asymptotically approach the equilibrium streamline that originates at the same point of the free stream flow (see Figure 7(b)). The displacement of the shock from the equilibrium shock is denoted by  $\ell$ . From the condition defining  $\ell$  it is easily shown that

$$\ell = b \tan \beta_e / \left[ \tan \beta_e - \tan (\beta_e - \theta_e) \right] \quad (6.12)$$

where  $\beta_e$  is the equilibrium shock angle,  $\theta_e$  is the wedge angle, and  $b$  is the distance (measured perpendicular to the shock) between the shock and the asymptote to the transition streamline (see Figure 7(b) or 3). There is no convenient expression for  $b$ , but it is easily determined graphically when equations (5.11) are plotted. For the conditions of the example of an exact solution given in Chapter 5, viz.,  $\beta_e = 65^\circ$ ,  $\theta_e = 46.7^\circ$ ,  $M_{\infty} = 8$ , in  $N_2$ , (6.12) gives

$$\ell = .177 \tau q_{\infty} = .0008 \text{ ft.}$$

whereas  $\xi_r = .136 q_\infty \tau$ . In Figure 7(c) the two regions are shown according to this approximation; i.e., to within an error  $O(\tau q_\infty / r)$ . The equilibrium shock is shown extended to the tip. The next approximation, with an error  $O(\tau q_\infty / r)^2$ , would show the downstream edge of the transition region to be curved.

This next approximation has not yet been worked out. The following is an outline of how this might be done. By developing gradient functions for equilibrium flow, the curvature of the equilibrium shock wave could be obtained. Then let the actual shock have this same curvature. For this curved shock, a shock oriented coordinate system could be used to attempt to get the next approximation to the transition region.

#### ACKNOWLEDGMENT

The author wishes to thank Dr. J. Sternberg and Mr. G. D. Kahl for their helpful discussions of this work.
