SUMMARY

The two dimensional problem of the interaction of a plane weak shock wave with a cylindrical obstacle of arbitrary cross section is considered. An integral equation for the surface values of the potential is formulated and solved approximately for the case of a square box with completely rigid boundaries.

INTRODUCTION

This report is concerned with the two dimensional problem of the determination of the pressure and velocity fields resulting from the interaction of a plane weak shock wave with a cylindrical obstacle of arbitrary cross section. Such problems have been previously considered and analytical solutions for a number of simple special geometries have been found by various techniques.

The method of images has been employed to construct a solution for an infinite plane obstacle (1). Separation of variables has been used for such simple geometries as the circular cylinder (2). The problem of an infinite wedge has been solved by conformal mapping with the use of geometrical acoustics to determine the proper region of solution (3). This latter problem has also been solved for the more general case of curved wave fronts by the use of the appropriate Green's functions (4). Configurations involving sharp corners are characterized by the fact that these corners act as centers of diffraction leading to different solutions in different regions of space-time. This feature allows the construction of the solution for a box from that for an infinite wedge but the procedure is impractical for more than two corners.

Apart from such simple geometries the general problem does not appear amenable to analytical solution. The use of numerical methods based on finite differences to solve the differential equations is impractical, even with large scale computers, because of the three dimensional (two space, one time) character of the problem and the presence of discontinuities in the field.

A significant simplification can be made, however, if the problem is reformulated in terms of values of the pressure on the surface of the obstacle alone. The spatial dimensions of the problem are reduced from two

to one and this remaining space dimension, if the obstacle is finite, is limited in extent. This formulation is particularly suitable for physical problems which require only a solution on the surface of the obstacle. If the solution in the field is also desired it can be constructed in a straight forward manner from the surface values.

The procedure developed here formulates an integral equation for the the pressure at an arbitrary field point in terms of the initial wave and an integral of time retarded values of the pressure and its derivatives over the surface of the obstacle. An integral equation on surface values alone is obtained by allowing the field point to approach the surface of the obstacle; values throughout the field may be obtained by direct integration over the surface values.

The effect of the discontinuity in the pressure and the velocity at the wave front on the surface can be separated from the remaining surface effects and integrated directly. The remaining integrations are approximated by assuming the surface pressure to have an average value over specified steps in space and time. The integrations are then replaced by summations which, because of the time-retarded effect lead to successive algebraic non-simultaneous equations on the unknown surface values. The fact that these equations are not simultaneous is vital because it permits the use of a large number of mesh points without prohibitive computations.

The pressure distribution on the surface of a rigid square box under a symmetric plane pulse loading is found by desk computations for time steps up to one transit time. The portions of the solution corresponding to the infinite wedge give excellent agreement with the known analytical solutions (3).

1. Initial - Boundary - Value Problem Formulation.

The pressure field that results from the interaction of a plane acoustic shock with a two-dimensional obstacle of arbitrary shape, rigid* and fixed in an acoustic medium is to be determined. For the purpose of analysis it is more convenient to consider a finite cylindrical obstacle of arbitrary length and of constant cross section rather than a two dimensional obstacle. The field corresponding to this three dimensional problem is identical in every plane section normal to the axis of the cylinder, i.e. independent of distance along the axis of the cylinder, for times less than the propagation time from the ends of the cylinder to the nearest section considered. Over these time intervals the three dimensional field provides the desired two dimensional solution. This is a consequence of the hyperbolic character of the wave equation which governs the field.

In this three dimensional field, let a cartesian coordinate system x', y', z' be introduced with the z' axis taken parallel to the generators of the cylinder. The cross section $z' = \text{constant}$ is bounded by an arbitrary piece-wise smooth curve $x'(s), y'(s)$ where the parameter s is arc length along the boundary of the cross section [fig. 1]. At $t = 0$ the obstacle is subjected to a plane acoustic shock; the line of contact between the shock and the obstacle is taken as the z' axis. The incident shock represents a step in pressure whose magnitude is used to normalize the pressures which are given as differences from the pressure in the undisturbed state ahead of the shock. Consequently, the states ahead and behind the shock at $t = 0$, correspond respectively to $p = 0$ and $p = 1$ thus defining the initial state.

*The method developed in this report is applicable to the more general case of a non-rigid obstacle; see forthcoming reports.

The interaction field may be described in terms of a continuous velocity potential $\varphi(x, y, z, t)$ which satisfies the wave equation and is related to the pressure through $p = + \rho_0 \partial \varphi / \partial t$. In terms of φ the incident shock is defined by

$$\varphi_0(\text{WAVE}) \equiv \varphi_0 \varphi_w = \begin{cases} t - x \cos \beta - y \sin \beta & ; t \geq x \cos \beta + y \sin \beta \\ 0 & ; t \leq x \cos \beta + y \sin \beta \end{cases}$$

where $x = x'/c$, $y = y'/c$, $z = z'/c$

c being the speed of sound and β is the angle between the x axis and the normal to the incident shock front. This together with the rigid surface condition $\frac{\partial \varphi}{\partial n} = 0$, n is the normal to the obstacle surface, establishes the following initial-boundary value problem for φ .

$$\left. \begin{array}{l} \text{D.E.} \quad \square^2 \varphi = \varphi_{xx} + \varphi_{yy} + \varphi_{zz} - \varphi_{tt} = 0 \\ \text{I.C.} \quad \varphi_0 \varphi(x, y, z, 0) = \begin{cases} t - x \cos \beta - y \sin \beta & ; 0 \geq x \cos \beta + y \sin \beta \\ 0 & ; 0 \leq x \cos \beta + y \sin \beta \end{cases} \\ \quad \varphi_0 \frac{\partial \varphi(x, y, z, 0)}{\partial t} = \begin{cases} 1 & ; 0 \geq x \cos \beta + y \sin \beta \\ 0 & ; 0 \leq x \cos \beta + y \sin \beta \end{cases} \\ \text{B.C.} \quad \frac{\partial \varphi}{\partial n}(x, y, z, t) = 0 \quad ; \quad x = x(s), y = y(s) \end{array} \right\} (1.1)$$

Although equations (1.1) specify the problem completely, the form is not suitable for analysis when dealing with arbitrary shapes. Instead an equivalent formulation in terms of an integral equation can be developed which is more amenable to further treatment.

2. Integral Equation Formulation.

The integral equation can be developed by treating the problem as a characteristic-boundary-value problem in 4-dimensional space-time (x, y, z, t) to which Green's identity may be applied, rather than as an initial-boundary-value problem. Consider the surface formed by the intersection of the characteristic hyper-plane representing the incident front and the cylindrical hyper-surface representing the obstacle, in space-time. The union of the influence domains of all the points of the surface of intersection is a domain in 4-space exterior to which the "secondary" (disturbance) potential defined by $\phi_s = \phi - \phi_v$ must vanish. The boundary of this region consists of reflection and diffraction characteristics. For ϕ to be a continuous solution for all (x, y, z, t) , ϕ_s must also vanish on this boundary.

In addition to the characteristic surface, say $\psi(x_0, y_0, z_0, t_0)$, corresponding to the secondary potential, there exists at any point (x, y, z, t) , a characteristic half-cone Γ :

$$t - t_0 = [(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2]^{1/2} = R$$

These characteristic surface, together with the obstacle surface form a closed region V in 4-space whose projection in physical space is exterior to the obstacle.

For the wave operator $\square^2 \equiv \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} - \frac{\partial^2}{\partial t^2}$

Green's identity takes the form

$$\iiint_V (u \square^2 v - v \square^2 u) dx dy dz dt = \iint_S (v \frac{\partial u}{\partial \nu} - u \frac{\partial v}{\partial \nu}) dS$$

where $\frac{\partial}{\partial \nu}$ represents conormal differentiation. If now v is identified with ϕ_s , u taken as the progressive wave solution $u = 1 - \frac{t-t_0}{R}$, and V, S correspond to the above mentioned region and bounding surface, the identity reduces to

$$\iiint_{S'} (\phi_s \frac{\partial u}{\partial \nu} - u \frac{\partial \phi_s}{\partial \nu}) dS' + \iiint_{C_\epsilon} (\phi_s \frac{\partial u}{\partial \nu} - u \frac{\partial \phi_s}{\partial \nu}) dC = 0 \quad (2.1)$$

C_ϵ corresponds to a hyper-cylinder of radius ϵ cut out of the region V to account for the singularity in u at $r = 0$; S' denotes the surface of the obstacle plus the surface of the secondary disturbance in 4-space. For the chosen function u , the integrals over C_ϵ can be reduced to

$$4\pi \int_0^t \phi_s(x, y, z, t_0) (t-t_0) dt_0$$

In addition, on that portion of S' corresponding to the secondary front,

$\phi_s = 0$ and consequently $\frac{\partial \phi_s}{\partial \nu} = 0$ since the front is characteristic.

On the obstacle surface $\frac{\partial \phi_s}{\partial \nu} = - \frac{\partial \phi_s}{\partial n}$. Hence, eq. (2.1) simplifies to

$$\int_0^t \phi_s(x, y, z, t_0) (t-t_0) dt_0 = \frac{1}{4\pi} \iint_{S'} (\phi_s \frac{\partial u}{\partial n_0} - u \frac{\partial \phi_s}{\partial n_0}) dS'$$

Differentiating both sides twice with respect to t , yields

$$\phi_s(x, y, z, t) = \frac{1}{4\pi} \frac{\partial^2}{\partial t^2} \iint_{S'_0(x, y, z, t)} dS'_0 \int_0^{t-R} (u \frac{\partial \phi_s}{\partial n_0} - \phi_s \frac{\partial u}{\partial n_0}) dt_0$$

Here the 4-space surface integration has been separated into a surface integration S_0 over the physical surface of the obstacle with limits determined by the intersection of the cone Γ and the secondary front on the surface of the obstacle in 4-space and a time integration whose upper limit is the cone Γ .

The time differentiation may be carried through the S_0 integration since the integrand vanishes along the curves of the intersection; u vanishes along Γ , while ψ_s vanishes along the secondary front. Hence ¹

$$\psi_s(x, y, z, t) = \frac{1}{4\pi} \iint_{S_0(x, y, z, t)} \left[\frac{1}{R} \frac{\partial \psi_s}{\partial n_0} + \frac{1}{R^2} \psi_s \frac{\partial R}{\partial n_0} + \frac{1}{R} \frac{\partial \psi_s}{\partial t_0} \frac{\partial R}{\partial n_0} \right] dS_0 \quad (2.2)$$

Since the solution function ψ_s is uniquely determined by the specification of $\partial \psi_s / \partial n_0$ alone, as given by eq. (1.1), it follows that eq.

(2.2) represents an integral equation for ψ_s .¹

A significant simplifications can be achieved by establishing that

$$\iint_{S_0} \left[\frac{1}{R} \frac{\partial \psi_w}{\partial n_0} + \frac{1}{R^2} \psi_w \frac{\partial R}{\partial n_0} + \frac{1}{R} \frac{\partial \psi_w}{\partial t_0} \frac{\partial R}{\partial n_0} \right] dS_0 = 0 \quad (2.3)$$

for then eq. (2.2) can be written in terms of the total potential ψ :^{2,3}

$$\psi(x, y, z, t) = \psi_w + \frac{1}{4\pi} \iint_{S_0} \left[\frac{1}{R} \frac{\partial \psi}{\partial n_0} + \frac{1}{R^2} \psi \frac{\partial R}{\partial n_0} + \frac{1}{R} \frac{\partial \psi}{\partial t_0} \frac{\partial R}{\partial n_0} \right] dS_0 \quad (2.4)$$

1. This can be considered a generalization of the classical Kirchoff's formula, the latter dealing with a physical space of fixed extent, i.e. S_0 independent of time.
2. An attempt to derive this eq. for ψ directly, would involve consideration of integrals over the characteristic secondary front.
3. An alternate heuristic derivation of this equation by means of Dirac delta functions is given in Appendix I.

E₁. (2.3) may be verified by extending the definition of ϕ or ϕ_s into a space time region whose projection in physical space is interior to the obstacle, by means of a saltus problem. Consider the region $\bar{V}$ in 4-space bounded by the three characteristic surfaces corresponding to the secondary front, the cone T and the incident wave front. This region contains an interior boundary, namely the surface of the obstacle. For $\bar{V}$ considered as a single region it is possible to define a solution ϕ which is discontinuous but whose normal derivative is continuous across the obstacle surface.

This solution is identical to ϕ in V as defined by eq. (2.2) while it vanishes in the region $\bar{V}-V$. That the latter is the correct extension follows from the condition $\phi = 0$ on the incident front and $\frac{\partial \phi}{\partial n} = 0$ on the obstacle-surface. This in turn implies $\phi_s = -\phi_v$ in $\bar{V}-V$. Consequently Green's identity may be applied to this region with $N = \phi_s$ and $u = 1 - \frac{t-t_0}{R}$. Since the field point x, y, z, t is exterior to $\bar{V}-V$, eq. (2.3) follows.

Returning to eq. (2.4), let it be differentiated with respect to t and multiplied by ρ_0 with $\partial \phi / \partial n_0$ set equal to zero:

$$\rho(x, y, z, t) = 1 + \frac{1}{4\pi} \frac{\partial}{\partial t} \int_{\Sigma} ds \int_{z_0-z}^{z_u-z} dz_0 \left\{ \left[\frac{1}{R^2} (\rho_0 \phi) + \frac{1}{R} \rho \right] \frac{\partial R}{\partial m_0} \right\}_{t_0=t-R} \quad (2.5)$$

where

$$z_{0u}-z, z_{0l}-z = \pm \left[\{ t - (x_0(s) \cos \theta + y_0(s) \sin \theta) \}^2 - \{ x - x_0(s) \}^2 - \{ y - y_0(s) \}^2 \right]^{1/2}$$

and s_{0u}, s_{0l} are the roots of $(z_{0u}-z)^2 = (z_{0l}-z)^2 = 0$

The differentiation may be carried out to yield

$$p(x, y, t) = 1 + \frac{1}{4\pi} \int_{s_0}^{s_{ou}} ds_0 \int_0^{z_{ou}-z} \left[\frac{1}{R^2} p + \frac{1}{R} \frac{\partial p}{\partial z_0} \right] \frac{\partial R}{\partial m_0} dz_0 \quad (2.6)$$

$$+ \frac{1}{4\pi} \int_{s_0}^{s_{ou}} ds_0 \left\{ \left[\frac{\partial z_{ou}}{\partial t} \right] \left[\frac{1}{R^2} (p_0 \varphi) + \frac{1}{R} p \right] \right\}_{z_0=t-R}^{z_0=z_{ou}-z}$$

Here $R^2 = (x-x_0(s))^2 + (y-y_0(s))^2 + z_0^2$, so that p is independent of z . Unlike the situation encountered in obtaining eq. (2.3), the integrands of eq. (2.5) do not vanish at $z_0 = z_{ou} - z$. This gives rise to the last term in eq. (2.6) which involves values of φ and p immediately behind the wave front ($z_0 = z_{ou} - z$) and may be interpreted as the effect on a field point of the discontinuity in the incident pressure field; it can be evaluated readily for a given $x(s)$, $y(s)$ since $\varphi(z_{ou}-z) = 0$ and $p(z_{ou}-z)$ is known.

Eq. (2.6) can be interpreted as an integral equation for the pressure. Consider its behavior as the field point (x, y) approaches the surface of the obstacle. The integrands become infinite at the point $R = 0$. By considering the behavior of the integrals in the vicinity of this point, it is readily established (appendix) that these improper integrals converge in the ordinary sense. In fact, the contribution to the double integral from the immediate vicinity of this point approaches the limit value $1/2 p(x(s), y(s), t)$. The remaining portion from the double integral is finite and in the special case of the surface point located directly behind the wave front, this contribution vanishes. In this case the single integral also vanishes. This is in accord with the well-known results that for the interaction between a plane wave and an arbitrary obstacle, the pressure immediately behind the reflected wave front on the surface of the obstacle, is just twice the pressure behind the incident wave.

Eq. (2.6) may then be written

$$p(s,t) = 2 + \frac{1}{\pi} \lim_{\substack{s_0 \rightarrow [R=0] \\ s_0 \in \partial R=0}} \left\{ \iint_{s_0 - s_{00}} dS_0 \left[\frac{1}{R^2} p + \frac{1}{R} \frac{\partial p}{\partial s_0} \right]_{t_0=t-R} \frac{\partial R}{\partial s_0} + \int ds_0 \left[\frac{\partial z_{00}}{\partial t} \right] \left[\frac{p}{R} \frac{\partial R}{\partial s_0} \right]_{t_0=t-R} \right\} \quad (2.7)$$

The procedure employed in solving eq. (2.7) for $p(s,t)$ involves the approximation of the double integration as follows. Let $p(s,t)$ be assumed to have a constant mean value over fixed intervals in s and t . Associated with these intervals are specific regions in s_0 and z_0 in which p is constant. In addition let $\frac{\partial p}{\partial t_0}$ be replaced by a backward difference in time. Then the double integral can be approximated by a double summation of time retarded values of p , whose coefficients are integrals of $\frac{1}{R} \frac{\partial R}{\partial s_0}$ and $\frac{1}{R^2} \frac{\partial R}{\partial s_0}$ over the associated regions in s_0 and z_0 . These latter integrals can be evaluated for a given obstacle shape. With this approximation, eq. (2.7) can be applied to successive intervals in s, t to yield a set of successive algebraic equations for the mean values of p . The details of this method are illustrated in section 3 where a box-shaped obstacle is considered.

Computations have indicated that, since the major contribution to p is made by the terms in eq. (2.7) which can be evaluated exactly, the values of $p(s,t)$ obtained in this manner are relatively insensitive to the magnitude of the fixed intervals (provided $\frac{\Delta t}{\Delta s} < 1$). It is anticipated that this will be the case in general.

3. Solution for the Case of a Box-Shaped Obstacle

The specific configuration for which eq. (2.7) has been solved is a square box whose boundaries are defined by $S_1: x = 0$, $S_2: y = 0$, $S_3: y = a$, $S_4: x = a$. The direction of motion of the incident wave is chosen for

convenience of symmetry, to be such that the normal to the front coincides with a diagonal of the square, i.e. $\beta = \pi/4$ (fig. 2). In this case eq.

(2.7) takes the form

$$p^i(s, t) = 2 + 2 \sum_{j=1}^4 i B_j^i + \frac{1}{\pi} \sum_{j=1}^4 \int_{s_{01}}^{s_{0u}} dS_0 \int_0^{t_{0u}-t} dz_0 \left[\frac{p_j^i}{R_j} + \frac{1}{R_j} \frac{\partial p_j^i}{\partial t_0} \right] \left(\frac{\partial R_j}{\partial t_0} \right)$$

with
$$i B_j^i = \frac{(p_{0u}^j)^2}{2\pi} \int_{s_{01}}^{s_{0u}} dS_0 \left[\frac{\partial z_{0u}}{\partial t} \frac{1}{R_j} \frac{\partial R_j}{\partial t_0} \right]_{z_{0u}-z_0=0}$$

The symbol i refers to the surface S_i containing the point s , at which the pressure is p^i . S_i is not included in the integrations since the expressions containing $\lim_{R \rightarrow 0}$ vanish for a surface of constant curvature (appendix II). In the expression for $i B_j^i$, the term p_j^i is equal to the constant two for $j = 1, 2$ and is equal to zero for $j = 3, 4$ (see appendix II). The regions of integration in s_0, z_0 on each surface are determined by the ellipses:

$$S_{1,2}: \quad t - s_0/\sqrt{2} = R(s_0, z_0, x, y)$$

$$S_{3,4}: \quad t - a/\sqrt{2} - s_0/\sqrt{2} = R(s_0, z_0, x, y)$$

with the restrictions that for $s_{0u} > a$, s_{0u} is set equal to a and for $s_{01} < 0$, s_{01} is set equal to zero.

The double integral is approximated by assuming $p^j(s, t)$ to have the constant value $p_k^j(t - \ell + 1)$ over the space-time interval $(k-1)/2 < s_0 < k/2$, $t - \ell < t_0 < t - \ell + 1$. The time derivative $\frac{\partial p}{\partial t_0}$ is approximated by a backwards difference in time, $p_k^j(t - \ell + 1) - p_k^j(t - \ell)$. For points s_0 swept over by the incident front within the time interval being considered, the derivative is replaced by $p_k^j(t_0) - 2$ for $j = 1, 2$ or $p_k^j(t_0) - 0$ for $j = 3, 4$. The integration may then be replaced by a double summation over k and ℓ in which the coefficients of $p_k^j(t_0)$ are known integrals.

It is also convenient to modify slightly the regions of integration in s_0, z_0 in order to reduce the number of coefficients of p_k^j that need to be computed. For this purpose, the regions of integration are approximated by:

$$t = R(z_0, s_0, x, y) \text{ on } S_i \quad i = 1, 2, 3, 4$$

with the previous restrictions on s_{0u} , s_{0l} still valid and p_k^j being defined as zero in the region exterior to the ellipses $t - s_0/\sqrt{2} = R$, $t - a/\sqrt{2} = R$, i.e. ahead of the wave front. The coefficients obtained in this manner are in fact the same for any orientation of the incident front relative to the box.

It then follows that the approximate system to be solved is given by:

$$p_m^i(t) \equiv p^i\left(\frac{2m-1}{2}\sqrt{2}, t\right) = 2 + 2 \sum_{\substack{j=1 \\ j \neq i}}^2 B^j + \sum_{\substack{j=1 \\ j \neq i}}^4 \sum_{l=1}^t \sum_{k=1}^P \left\{ p_k^j(t-l+1) q_{kl}^j(m) + \left[p_k^j(t-l+1) \right]' \mathcal{L}_{kl}^j(m) \right\} \quad (2.7)$$

$$q_{kl}^j(m) = \frac{1}{\pi} \int_{(k-1)\sqrt{2}}^{k\sqrt{2}} d s_{0j} \int_{\sqrt{(l-1)^2 - (x-x_0)^2 - (y-y_0)^2}}^{\sqrt{l^2 - (x-x_0)^2 - (y-y_0)^2}} d z_0 \left\{ \frac{1}{R_j^2} \frac{\partial R_j}{\partial m_{0j}} \right\}_{s = \frac{2m-1}{2}\sqrt{2}}$$

$$\mathcal{L}_{kl}^j(m) = \frac{1}{\pi} \int_{(k-1)\sqrt{2}}^{k\sqrt{2}} d s_{0j} \int_{\sqrt{(l-1)^2 - (x-x_0)^2 - (y-y_0)^2}}^{\sqrt{l^2 - (x-x_0)^2 - (y-y_0)^2}} d z_0 \left\{ \frac{1}{R_j^2} \frac{\partial R_j}{\partial m_{0j}} \right\}_{s = \frac{2m-1}{2}\sqrt{2}}$$

$$\left[p_k^i(t-l+1) \right]' = \begin{cases} p_k^i(t-l+1) - p_k^i(t-l) & \text{if wave has not passed} \\ & \text{over point } k \text{ between } t-l \text{ and } t-l+1; \text{ otherwise} \end{cases}$$

$$\begin{aligned} p_k^j(t-l+1) &= 2 & \text{on } j=1, 2 \\ p_k^j(t-l+1) &= 0 & \text{on } j=3, 4 \end{aligned}$$

where P is the number of space intervals per side.

At each time step t and space point* m on S_1 eq. (2.7) relates $p_m^1(t)$ to values of p corresponding to earlier times. Hence as previously indicated the system of equations obtained are successive rather than simultaneous. Only at the corners do two adjacent space points have an opportunity to interact within a single time interval. Consequently, at each corner, at each time step there occur two simultaneous equations. The numerical results obtained for the choice of eight space steps on each side of the box and sixteen time steps corresponding to one transit time are listed in tables I and II and figs. (3,4).

4. Discussion of Results.

In the case of the box, the solution in certain regions of space-time may be identified with known solutions obtained by geometric acoustics [3]. For example, for $t < a/\sqrt{2}$ the solution along $S_{1,2}$ coincides with the solution for an infinite wedge of vertex angle $\pi/2$ formed by $S_{1,2}$. Consequently the results for $S_{1,2}$ for the first eight time steps may be compared with the analytic solution given in [3]. Since in this case the solution depends only upon $\frac{x}{t}, \frac{y}{t}$, a comparison of values at all time steps may be made simultaneously and the convergence of the values for increasing time may be examined. The results for the eighth time step are plotted along with the exact solution in fig. (3) and the agreement is excellent; the greatest error is less than 3%.

A further estimate of the accuracy of the numerical solution may be gained by a comparison with the rigid box solution given in ref. [5]. Again the agreement is excellent.

*The field point is taken in the center of the space interval at $\frac{2n-1}{2} / \sqrt{2}$

Examination of fig. (4) indicate that the steady state solution of $\rho = 1$ everywhere appears to be approached rapidly even within the interval of one transit time.

Second Diffraction at Upper Corner

First Diffraction at Upper Corner

Appendix I

Introduce the fundamental solution to the three dimensional wave equation

$$g(\vec{r}, t; \vec{r}_0, t_0) = \frac{\delta[(t-t_0)-R]}{R}$$

which satisfies

$$\nabla^2 g - \frac{\partial^2 g}{\partial t^2} = -4\pi \delta(t-t_0) \delta(\vec{r}-\vec{r}_0)$$

where $R = |\vec{r} - \vec{r}_0|$, $\vec{r} = (x, y, z)$ a field point, $\vec{r}_0 = (x_0, y_0, z_0)$ a source point and δ is the Dirac delta function in one, three or four dimensions as required.

The secondary "disturbance" potential $\phi_s = \phi - \phi_w$ also satisfies the wave equation

$$\nabla^2 \phi_s - \frac{\partial^2 \phi_s}{\partial t^2} = 0$$

with initial conditions: $\phi_s = \frac{\partial \phi_s}{\partial t} = 0$ at $t = 0$

Consequently the following equation is true

$$\iiint_{V_0^{(4)}} dV_0^{(4)} \left\{ g \nabla^2 \phi_s - \phi_s \nabla^2 g - g \frac{\partial^2 \phi_s}{\partial t^2} + \phi_s \frac{\partial^2 g}{\partial t^2} \right\} = \begin{cases} 4\pi \phi_s \\ 0 \end{cases}$$

where $V_0^{(4)}$ is a four dimensional volume in space time and the right hand side is $4\pi \phi_s$ if the point $\vec{r} = \vec{r}_0$, $t = t_0$ is included in $V_0^{(4)}$ and 0 if it is not.

Two different regions of integration are employed. They are both bounded by the initial time plane $t_0 = 0$, the incident wave plane $t = R$, the obstacle surface extended into space time and a surface which will include the characteristic cone $(t-t_0)-R = 0$ in the volume of integration. Due to the singular behavior of the integrand, all contributions come from the surface $(t-t_0)-R = 0$ within the region of integration. One region of integration is taken exterior to and the other interior to the obstacle surface.

Consider first, for either region $v^{(4)}$, the term $t_0 = t + \epsilon$

$$\begin{aligned} & \iiint dV_0^{(4)} \left\{ \phi_s \frac{\partial^2 \phi}{\partial t_0^2} - g \frac{\partial^2 \phi_s}{\partial t_0^2} \right\} = \iiint dV_0^{(4)} \int_{t_0=0}^{t_0=t+\epsilon} dt_0 \left\{ \phi_s \frac{\partial^2 \phi}{\partial t_0^2} - g \frac{\partial^2 \phi_s}{\partial t_0^2} \right\} \\ & = \iiint dV_0^{(4)} \left[\phi_s \frac{\partial^2 \phi}{\partial t_0^2} - g \frac{\partial^2 \phi_s}{\partial t_0^2} \right]_{t_0=0}^{t_0=t+\epsilon} = 0 \end{aligned}$$

since g and $\frac{\partial \phi}{\partial t_0}$ vanish for every value of $t < t_0$ and ϕ_s and $\frac{\partial \phi_s}{\partial t_0}$ are both 0 at $t_0 = 0$.

The remainder of the integral is

$$\begin{aligned} & \iiint dV_0^{(4)} \left\{ g \nabla_0^2 \phi_s - \phi_s \nabla_0^2 g \right\} \\ & = \int_{t_0=0}^{t_0=t+\epsilon} dt_0 \iiint dV_0^{(4)} \left\{ g \nabla_0^2 \phi_s - \phi_s \nabla_0^2 g \right\} \\ & = \int_{t_0=0}^{t_0=t+\epsilon} dt_0 \iint dS_0 \left[g \frac{\partial \phi_s}{\partial n_0} - \phi_s \frac{\partial g}{\partial n_0} \right] \end{aligned}$$

by Green's Theorem where S_0 is the surface bounding the physical space volume of integration $v_0^{(3)}$ and n_0 is the outward normal to S_0 .

Adding the two integrals corresponding to these two regions of integration will give an equation on $\phi_s(\bar{r}, t)$ in terms of a discontinuity in ϕ_s across the obstacle surface since the normal, n_0 , is opposite in sign in the two integrations.

$$4\pi \phi_s = \int_{t_0=0}^{t_0=t+\epsilon} dt_0 \iint_{S_0} dS_0 \left\{ g \frac{\partial [\phi_s]}{\partial n_0} - [\phi_s] \frac{\partial g}{\partial n_0} \right\}$$

where $[]$ represents the discontinuity value and $+n_0$ is taken toward the interior of the obstacle in physical space.

Since ϕ_w is continuous, the discontinuity in ϕ_s must be identical to the discontinuity in ϕ . As seen in the text, the interior value of ϕ is zero and the discontinuity in ϕ is therefore just the value immediately exterior to the obstacle surface.

$$4\pi (\phi - \phi_w) = \int_{t_0=0}^{t_0=t+\epsilon} dt_0 \iint_{S_0} dS_0 \left\{ g \frac{\partial \phi}{\partial n_0} - \phi \frac{\partial g}{\partial n_0} \right\}$$

Because of the behavior of g , the time integration can be taken thru the surface integration and carried out giving Eq. (2.4).

$$\phi = \phi_w + \frac{1}{4\pi} \iint_{S_0} dS_0 \left[\frac{1}{R} \frac{\partial \phi}{\partial m_0} + \left(\frac{1}{R^2} \phi + \frac{1}{R} \frac{\partial \phi}{\partial t_0} \right) \frac{\partial R}{\partial m_0} \right]_{t_0=t}$$

Appendix II-a

The immediate neighborhood of a point on any curved surface may be considered plane as an approximation which becomes exact as the neighborhood shrinks to the point. To find the pressure field at a point immediately behind the wave front on an obstacle surface, it is therefore sufficient to consider the interaction of the wave front with an infinite plane obstacle. The result obtained will of course be equally useful in the specific example of the square box for the two planes which compose the "front" of the box. The integral equation is still valid but now is applied only to S_1

$$\phi(\bar{r}, t) = \phi_w(\bar{r}, t) + \frac{1}{4\pi} \iint_{S_0} d\bar{r}_0 d\gamma_0 \left\{ \frac{\phi^2}{R^2} + \frac{1}{R} \right\} \left(\frac{\partial R}{\partial m_0} \right)_{t_0=t-R}$$

As $\bar{r}$ approaches a point on S_1 , x approaches zero. However, $\frac{\partial R}{\partial m_0} = -\frac{x}{R}$ must also approach zero except at the indeterminate point $R = 0$, i.e. the location of the field point on the surface. To avoid this indeterminacy the point $R = 0$ is removed from the integration by distorting the surface in the neighborhood of $R = 0$ from a plane to a semisphere of radius ρ about $R = 0$. Over this surface $\frac{\partial R}{\partial m_0} = 1$. The integration is then in two parts; the semisphere and the remainder of the plane surface. The latter integration is zero since $\frac{\partial R}{\partial m_0}$ is zero and the former integration is

$$\lim_{p \rightarrow R \rightarrow 0} \iiint_{\text{Semi-Sphere}} \left[\frac{\phi^2}{R^2} + \frac{p^2}{R} \right] (1) R^2 d\Omega = 2\pi \phi^2(\bar{r}, t)$$

since in the limit, the terms $\phi^2(\bar{r}, t_0)$ and $p^2(\bar{r}, t_0)$ can be removed from the integration and evaluated at $t_0 = t, R = 0$.

$$\begin{aligned} \therefore \phi^2(\bar{r}, t) &= \frac{1}{\rho_0} [t - x \cos \beta - y \sin \beta]_{x=0} + \frac{1}{2} \phi^2(\bar{r}, t) \\ \phi^2(\bar{r}, t) &= 2(t - y \sin \beta) / \rho_0 \\ p^2(\bar{r}, t) &= 2 \end{aligned}$$

Appendix II-b

Behind the wave front on each of the rear surfaces of the square box exists a region in space time which is not influenced by any of the corners of the box. The integrations required to determine the pressure in these regions from Eq. (2.7) are then taken only over the neighboring front surface with values for p on that surface corresponding to the infinite plane solution. For example, consider a point on surface 1 = 3

$$p^3(\bar{r}, t) = 2 + 2 {}_3B^1 + \frac{2}{\pi} \iint_{S_1(x_0=0)} dz_0 d\gamma_0 \left\{ \frac{1}{R^2} \frac{\partial R}{\partial x_0} \right\}$$

with integration limits given by

$$t - y_0/\sqrt{2} = \sqrt{(a-y_0)^2 + (x-x_0)^2 + z_0^2} \Big|_{x_0=0}$$

The term ${}_1B^1$ is left in integral form for convenience.

$${}_2{}_3B^1 = -\frac{2x}{\pi} \int_{y_{0L}}^{y_{0H}} dy_0 \left[\frac{1}{(t - y_0/\sqrt{2}) \sqrt{(t - y_0/\sqrt{2})^2 - (a-y_0)^2 - x^2}} \right]$$

where the limits of integration are the roots of

$$(t - y_0/\sqrt{2})^2 - (a - y_0)^2 - x^2 = 0$$

This follows from the fact that y_{ou} must be greater than zero while y_{ol} must be less than a in order that the ends of the front surface (i.e. corners) will not play any role in the integration.

The double integral is reduced to a single integral.

$$\begin{aligned} & \lim_{x_0 \rightarrow 0} \frac{2}{\pi} \int_{y_{ol}}^{y_{ou}} dy_0 \int_0^{z_{ou} = \sqrt{(t - y_0/\sqrt{2})^2 - (a - y_0)^2 - x^2}} dz_0 \left\{ \frac{1}{[z_0^2 + (x - x_0)^2 + (a - y_0)^2]} \frac{(x - x_0)}{\sqrt{z_0^2 + (x - x_0)^2 + (a - y_0)^2}} \right\} \\ &= -\frac{2x}{\pi} \int_{y_{ol}}^{y_{ou}} dy_0 \left\{ \frac{\sqrt{(t - y_0/\sqrt{2})^2 - (a - y_0)^2 - x^2}}{(x^2 + (a - y_0)^2) (t - y_0/\sqrt{2})} \right\} \end{aligned}$$

Combining this integral with the term $2_3 B'$ gives

$$\begin{aligned} & -\frac{2x}{\pi} \int_{y_{ol}}^{y_{ou}} dy_0 \left\{ \frac{(t - y_0/\sqrt{2})}{(x^2 + (a - y_0)^2) \sqrt{(t - y_0/\sqrt{2})^2 - (a - y_0)^2 - x^2}} \right\} \\ &= -2 \end{aligned}$$

$$\therefore p^3 = 2 - 2 = 0$$

The region in which this solution will be valid on the rear surface S_3 is $t < x < t/\sqrt{2}$ from $t < x$ corresponding to $a - y_0 > 0$ and $x < t/\sqrt{2}$ limiting points to those behind the wave front.

-23-
Appendix III

The expressions for the ${}_i B^j$ obtained by integration are given below together with the conditions under which each expression is valid. These conditions are obtained from the limits in the integral expressions for the ${}_i B^j$ and may be interpreted in terms of geometric acoustic theory as representing the diffraction effects produced by the corners of the box.

$${}_i B^j = \frac{1}{\pi} \int_{s_{o1}}^{s_{o2}} ds_o \left[\frac{\partial z_{o1}}{\partial t} \right] \left[\frac{1}{R_j} \frac{\partial R_j}{\partial m_o} \right]_{z_o = z_{o1} - z} \quad ; \quad j = 1, 2$$

$$\begin{aligned} {}_1 B^2 &= 0 ; \\ {}_1 B^2 &= \frac{-y_m}{\pi \sqrt{t^2 + \frac{1}{2} y_m^2}} \left\{ \frac{\pi}{2} - \sin^{-1} \left[\frac{y_m^2}{\sqrt{2} t \sqrt{t^2 - \frac{1}{2} y_m^2}} \right] \right\} ; \quad \boxed{t^2 \leq y_m^2} \\ &\quad \boxed{\left(t - \frac{a}{\sqrt{2}}\right)^2 \leq a^2 + y_m^2} \\ {}_1 B^2 &= \frac{-y_m}{\pi \sqrt{t^2 + \frac{1}{2} y_m^2}} \left\{ \sin^{-1} \left[\frac{at + y_m^2/\sqrt{2}}{(t - a/\sqrt{2}) \sqrt{t^2 - \frac{1}{2} y_m^2}} \right] - \sin^{-1} \left[\frac{y_m^2}{\sqrt{2} t \sqrt{t^2 - \frac{1}{2} y_m^2}} \right] \right\} ; \\ &\quad \boxed{\left(t - \frac{a}{\sqrt{2}}\right)^2 > a^2 + y_m^2} \end{aligned}$$

$$\begin{aligned} {}_3 B^1 &= 0 ; \quad \boxed{\left(t - \frac{a}{\sqrt{2}}\right)^2 < \frac{1}{2} \chi_m^2} \\ {}_3 B^1 &= {}_3 B_u - {}_3 B_L ; \quad \boxed{\left(t - \frac{a}{\sqrt{2}}\right)^2 \geq \frac{1}{2} \chi_m^2} \\ {}_3 B_u &= \frac{-\chi_m}{\pi \sqrt{\left(t - \frac{a}{\sqrt{2}}\right)^2 + \frac{1}{2} \chi_m^2}} \left\{ \frac{\pi}{2} \right\} ; \quad \boxed{\left(t - \frac{a}{\sqrt{2}}\right)^2 \leq \chi_m^2} \\ {}_3 B_u &= \frac{-\chi_m}{\pi \sqrt{\left(t - \frac{a}{\sqrt{2}}\right)^2 + \frac{1}{2} \chi_m^2}} \left\{ \sin^{-1} \frac{\chi_m^2/\sqrt{2}}{(t - a/\sqrt{2}) \sqrt{\left(t - \frac{a}{\sqrt{2}}\right)^2 - \frac{1}{2} \chi_m^2}} \right\} ; \quad \boxed{\left(t - \frac{a}{\sqrt{2}}\right)^2 > \chi_m^2} \\ {}_3 B_L &= \frac{-\chi_m}{\pi \sqrt{\left(t - \frac{a}{\sqrt{2}}\right)^2 + \frac{1}{2} \chi_m^2}} \left\{ -\frac{\pi}{2} \right\} ; \quad \boxed{t^2 < \chi_m^2 + a^2} \\ {}_3 B_L &= \frac{-\chi_m}{\pi \sqrt{\left(t - \frac{a}{\sqrt{2}}\right)^2 + \frac{1}{2} \chi_m^2}} \left\{ \sin^{-1} \left[\frac{\left(t - \frac{a}{\sqrt{2}}\right)^2 + \frac{1}{2} \chi_m^2 - t(t - a/\sqrt{2})}{\left(t/\sqrt{2}\right) \sqrt{\left(t - \frac{a}{\sqrt{2}}\right)^2 - \frac{1}{2} \chi_m^2}} \right] \right\} ; \quad \boxed{t^2 > \chi_m^2 + a^2} \end{aligned}$$

$${}_3B^2 = 0;$$

$${}_3B^2 = {}_3B_u^2 - {}_3B_L^2;$$

$${}_3B_u^2 = \frac{-a}{\pi \sqrt{(t - \frac{x_m}{\sqrt{1-\epsilon^2}})^2 + \frac{1}{2}a^2}} \left\{ \frac{\pi}{2} \right\};$$

$${}_3B_u^2 = \frac{-a}{\pi \sqrt{(t - \frac{x_m}{\sqrt{1-\epsilon^2}})^2 + \frac{1}{2}a^2}} \left\{ \sin^{-1} \left[\frac{(t - \frac{x_m}{\sqrt{1-\epsilon^2}})^2 + \frac{1}{2}a^2 - (t - \frac{x_m}{\sqrt{1-\epsilon^2}})(t - \frac{a}{\sqrt{1-\epsilon^2}})}{\frac{1}{2}(t - \frac{a}{\sqrt{1-\epsilon^2}}) \sqrt{(t - \frac{x_m}{\sqrt{1-\epsilon^2}})^2 - \frac{1}{2}a^2}} \right] \right\};$$

$${}_3B_L^2 = \frac{-a}{\pi \sqrt{(t - \frac{x_m}{\sqrt{1-\epsilon^2}})^2 + \frac{1}{2}a^2}} \left\{ -\frac{\pi}{2} \right\};$$

$${}_3B_L^2 = \frac{-a}{\pi \sqrt{(t - \frac{x_m}{\sqrt{1-\epsilon^2}})^2 + \frac{1}{2}a^2}} \left\{ \sin^{-1} \left[\frac{(t - \frac{x_m}{\sqrt{1-\epsilon^2}})^2 + \frac{1}{2}a^2 - t(t - \frac{x_m}{\sqrt{1-\epsilon^2}})}{\frac{1}{2}t \sqrt{(t - \frac{x_m}{\sqrt{1-\epsilon^2}})^2 - \frac{1}{2}a^2}} \right] \right\};$$

$$(t - \frac{x_m}{\sqrt{1-\epsilon^2}})^2 < \frac{1}{2}a^2$$

$$(t - \frac{x_m}{\sqrt{1-\epsilon^2}})^2 \geq \frac{1}{2}a^2$$

$$(t - \frac{a}{\sqrt{1-\epsilon^2}})^2 < (a - x_m)^2 + a^2$$

$$(t - \frac{a}{\sqrt{1-\epsilon^2}})^2 \geq (a - x_m)^2 + a^2$$

$$t^2 \leq x_m^2 + a^2$$

$$t^2 \geq x_m^2 + a^2$$

The coefficients ${}_i q_{ne}^j(m)$ and ${}_i R_{ne}^j(m)$ must satisfy the following symmetry conditions.

$$\begin{aligned} {}_1q_{ne}^2(Y_m) &= {}_1q_{ne}^2(Y_m) \\ {}_1q_{ne}^3(Y_m) &= {}_1q_{ne}^3(a - Y_m) \\ {}_1q_{ne}^4(Y_m) &= {}_1q_{ne}^4(Y_m) \end{aligned}$$

$$\begin{aligned} {}_5q_{ne}^1(X_m) &= {}_1q_{(p+1-k)l}^2(Y_m) \\ {}_3q_{ne}^2(X_m) &= {}_1q_{ne}^4(Y_m) \\ {}_3q_{ne}^4(X_m) &= {}_1q_{(p+1-k)l}^2(a - Y_m) \end{aligned}$$

$$\begin{aligned} {}_2q_{ne}^1(X_m) &= {}_1q_{ne}^2(Y_m) \\ {}_2q_{ne}^3(X_m) &= {}_1q_{ne}^4(Y_m) \\ {}_2q_{ne}^4(X_m) &= {}_1q_{ne}^2(a - Y_m) \end{aligned}$$

$$\begin{aligned} {}_4q_{ne}^1(Y_m) &= {}_1q_{ne}^4(Y_m) \\ {}_4q_{ne}^2(Y_m) &= {}_1q_{(p+1-k)l}^2(Y_m) \\ {}_4q_{ne}^3(Y_m) &= {}_1q_{(p+1-k)l}^2(a - Y_m) \end{aligned}$$

and a similar set for $\dot{R}_{ke}(m)$ where X_m or $Y_m = \frac{2m-1}{2}\sqrt{2}$ and p is the number of steps in space per side.

Therefore only four sets of coefficients need be computed for each value of m . The integral expressions for the coefficients are simplified by using a constant average value in place of R_j over each region of integration. As R_j can never be zero on any of the surfaces of integration and is practically constant over all separate regions of integration except those near the corners this approximation is quite good. Values near the corners must be obtained without this approximation.

$$q_{ke}^2(m) \approx \frac{-Y_m}{\pi \bar{R}^3} \left\{ [Q_{ke}^2 - Q_{k(k-1)}^2] - [Q_{(k-1)k}^2 - Q_{(k-1)(k-1)}^2] \right\}$$

$$q_{ke}^4(m) \approx \frac{-a}{\pi \bar{R}^3} \left\{ [Q_{ke}^4 - Q_{k(k-1)}^4] - [Q_{(k-1)k}^4 - Q_{(k-1)(k-1)}^4] \right\}$$

$$R_{ke}^2(m) \approx \bar{R} \cdot q_{ke}^2(m)$$

$$R_{ke}^4(m) \approx \bar{R} \cdot q_{ke}^4(m)$$

$$\bar{R} \approx l - \frac{1}{2}$$

$$Q_{ke}^2(m) = \frac{1}{2} \left[\sqrt{2} k \sqrt{l^2 - Y_m^2 - 2k^2} + (l^2 - Y_m^2) \sin^{-1} \frac{\sqrt{2} k}{\sqrt{l^2 - Y_m^2}} \right];$$

$$= \frac{1}{2} (l^2 - Y_m^2) \left(\frac{\pi}{2} \right); \quad \boxed{l^2 - Y_m^2 - 2k^2 > 0}$$

$$= 0; \quad \boxed{l^2 - Y_m^2 - 2k^2 < 0, l^2 - Y_m^2 - 2(k-1)^2 > 0}$$

$$= 0; \quad \boxed{l^2 - Y_m^2 - 2(k-1)^2 < 0}$$

$$Q_{ke}^4(m) = \frac{1}{2} \left[(\sqrt{2} k - Y_m) \sqrt{l^2 - a^2 - (\sqrt{2} k - Y_m)^2} + (l^2 - a^2) \sin^{-1} \frac{(\sqrt{2} k - Y_m)}{\sqrt{l^2 - a^2}} \right]$$

$$+ Y_m \sqrt{l^2 - a^2 - Y_m^2} + (l^2 - a^2) \sin^{-1} \frac{Y_m}{\sqrt{l^2 - a^2}} \Big]; \quad \boxed{l^2 - a^2 - 2k^2 > 0}$$

$$= \frac{1}{2} (l^2 - a^2) \left(\frac{\pi}{2} \right); \quad \boxed{l^2 - a^2 - 2k^2 < 0, l^2 - a^2 - 2(k-1)^2 > 0}$$

$$= 0; \quad \boxed{l^2 - a^2 - 2(k-1)^2 < 0}$$

Appendix IV

It is of interest to note that the pressure at the corner of an infinite rigid wedge of arbitrary angle α may be found exactly from the integral equation

$$\phi = \phi_w + \frac{1}{4\pi} \iint_{S_0} dS_0 \left\{ \frac{1}{R^2} \phi + \frac{1}{R} p \right\} \left(\frac{\partial R}{\partial m_0} \right)_{t_0=t-R}$$

Since $\frac{\partial R}{\partial m_0}$ is zero on both surfaces for a field point at the corner $\bar{r} = a$ the only contribution comes from the point $R = 0$ as in appendix IIa although only a portion $\frac{\alpha}{2\pi}$ of the semi-sphere is required to exclude the corner point from the surface of integration in this case.

$$\phi]_{\bar{r}=0} = \phi_w]_{\bar{r}=0} + \frac{1}{4\pi} \left[\frac{\alpha}{2\pi} 4\pi \phi \right]_{\bar{r}=0}$$

$$\phi]_{\bar{r}=0} = \frac{2\pi}{2\pi - \alpha} \phi_w]_{\bar{r}=0}$$

$$p]_{\bar{r}=0} = \frac{2\pi}{2\pi - \alpha}$$

which is an agreement with the known infinite rigid wedge solution.

$$p]_{\bar{r}=0} = \frac{4}{3} \quad \text{for } \alpha = \pi/2$$
