INTRODUCTION

This report is submitted in partial fulfillment of paragraph 10 of Amendment 6 to Office of Naval Research Contract NOnr 2360(00), "Inflatoplanes".

The Stress Analysis for GA-460 Model Inflatoplane is divided into six sections. These sections are listed below.

Section 1	General
Section 2	Load Analysis
Section 3	Wing Analysis
Section 4	Fuselage Analysis
Section 5	Engine Mount Analysis
Section 6	Summary of Landing Gear, Cockpit, and Empennage Analyses

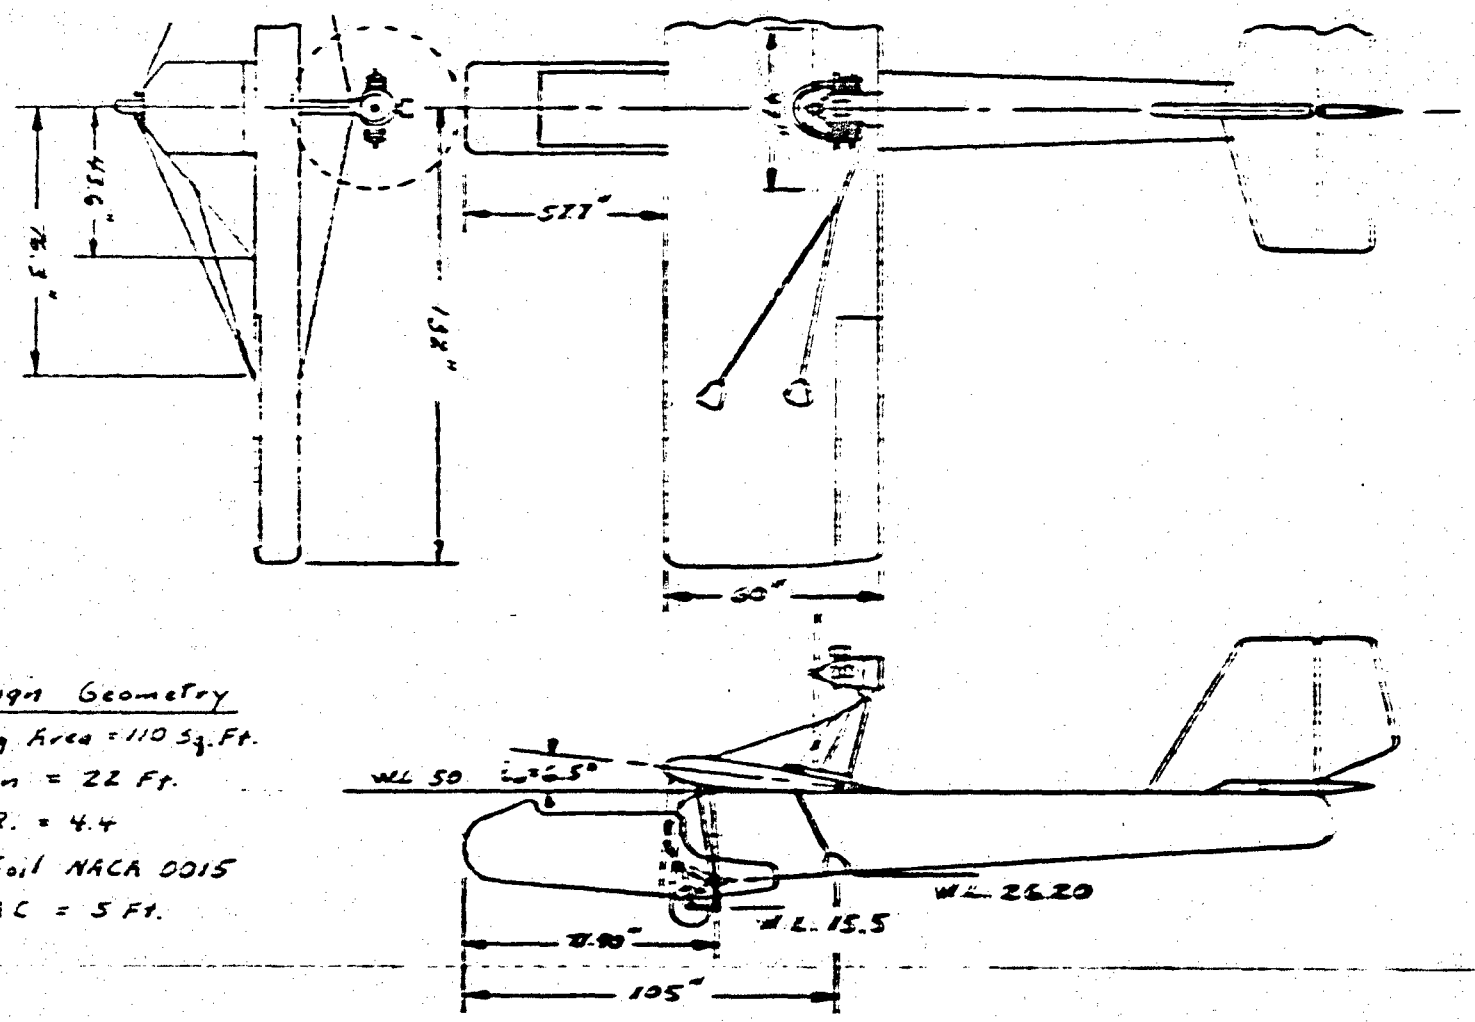
DISCUSSION

The Inflatoplane is a high wing monoplane with a Nelson H63A engine mounted on a pedestal above the wing and fuselage near the trailing edge of the wing. Each wing panel is restrained by two guy cables on the upper surface and three on the lower surface. The two upper cables are anchored to the engine pylon. The forward outboard and inboard cables are tied to the landing gear, while the aft outboard cable is attached to the bottom of fuselage at fuselage station 105.00. A single-seat cockpit is located forward of the conical shaped fuselage. A single wheel landing gear is mounted on the front hemispherical end of the fuselage; this together with the wing tip skids and a tail skid make up the landing gear system. Conventional tail surfaces are restrained by guy cables attached to the fuselage. A general layout with pertinent geometric data is shown in Figure 1.

The GA-460 Inflatoplane was static tested at Goodyear Aircraft to determine the buckling strength of the wing. An ultimate load factor of 5.6 was obtained.

A wind tunnel test was conducted in the NACA Langley full-scale wind tunnel to corroborate the static test results. This investigation resulted in ultimate load factors up to 5.13, reference 5.

An endurance load test was conducted at Goodyear Aircraft to determine the time effect under limit load on the Inflatoplane fabric. The Inflatoplane was inverted and a 2.5g limit load was applied to the wing and fuselage using shot bags. The test was run for 336 hours without appreciable creep.



Design Geometry

Wing Area = 110 Sq. Ft.

Span = 22 Ft.

MODEL

Design Criteria

The Design Criteria covers the design conditions, factors of safety, and allowable stresses for the inflatoplane.

Design Conditions

The Design Conditions were selected using reference (9) as the specification. The maneuvering design conditions are in accordance with paragraph 3.4.2 of reference (9) for the VW classification (Special Search) except that the maximum limit load factor is 2.5 instead of 3.0. Two gross weights are investigated, namely, 550 lbs with most forward c.g. and 404 lbs with the most aft c.g. Maximum flight limit speed is 74.5 knots. Under gusting conditions the limit speed is 44 to 47 knots, based on maneuvering load factor of -1.0. The critical loads are summarized on page 2.00.030.

Ground handling loads are not critical. The landing conditions are based upon a sinking speed of 5 ft/sec. The critical landing conditions are level landing, tail down landing, and side load specified in reference (7).

Factors of Safety

The limit loads are multiplied by the following factors to obtain the structural design loads.

Metal Structure	Yield	1.15
Metal Structure	Ultimate	1.50
Fabric Structure	Wrinkling*	1.00
Fabric Structure	Ultimate	1.75

* No principal stress shall be less than zero at limit load.

Allowable Strength

For the metal structures, the requirements of paragraphs 3.2.1.2 through 3.2.1.8 of reference (9) are used.

The following reduction factors shall be applied to the Quick Break Strength of the fabric structures:

Inflation Only	4
Limit Load	3
Ultimate Load	1.5

The reduction factor for inflation and limit load are based on past experience and account for the fact that fabric under load for a period of time has a reduction in strength.

The reduction factor for ultimate load was chosen arbitrarily.

LOADS

SECTION 2

The critical flight loads shown in Table III, Summary of Critical Flight Loading Conditions were developed using Table I (Summary of Airloads), Figure 6 ($V-n_s$ Diagram M.F.C.O. 350 lbs), and Figure 7 ($V-n_s$ Diagram M.A.C.O. 404 lbs) of reference (4). The letters refer to points on the $V-n_s$ diagram and subscripts to the different conditions applicable to the particular point. The loading conditions specified produced critical design loads for all the primary structure.

The weight distribution, C.G. locations, and moment of inertia calculations are found on pages 2.01.010 through 2.01.090.

Each part of the Loads Section has its own discussion and sketches.

Discussion

Weight and Balance Section

This section of this report presents the weight and balance data and the moments of inertia of the aircraft.

There are two parts. The first is the Group Weight Statement (AN-9103-D) and the second portion incorporates the moments of inertia.

In the Group Weight Statement the weight of the pilot is assumed to be 200 lbs. For the most forward C.G. condition, 240 lbs. was chosen as the pilot's weight and for the most aft C.G. condition, 160 lbs. was used as the weight of the pilot. It is quite obvious that for an aircraft of such low empty weight, the C.G. is affected considerably by the weight of the pilot.

The horizontal datum (from which the X distances are measured) is the nose of the aircraft (Station 0). The vertical datum (from which the Z distances are measured) is the ground line. The lateral datum (from which the Y distances are measured) is the Centerline of the aircraft.

WING LOADS

The wing is of Airmat construction and is a single-piece structural unit forward of the aileron hinge line. External support for the wing is provided by brace cables connected between the upper wing surface and engine mount pylon. The lower wing surface brace cables are connected to the landing gear and fuselage. The wing is attached to the fuselage by fabric straps at the rear cockpit bulkhead and through the engine mount attachment cables at the trailing edge of the wing.

The sign convention used for the wing load calculations is shown on page 2.02.020.

The shears, moments, and torques for the critical wing symmetrical conditions A_2 and C_2 are found on page 2.02.170 through 2.02.210. Unsymmetrical conditions were investigated and found not to be critical.
No torque results from the chordwise force.

BOOK 1 of 1
REPORT NO. 597-3

WING LOADS

Calculation Of Shears, Moments And Torques From The Airloads

Using The Spanwise Lift Distribution Curve (C_{ℓ_e} = Semi-Span) And The Spanwise Drag Distribution Curve (C_{d_e}/N_2 = Semi-Span) of Reference (4) The Normal Force Coefficient (C_N) And The Chord Force Coefficient (C_C) Are Calculated In Table V. Using The Equations Listed Below:

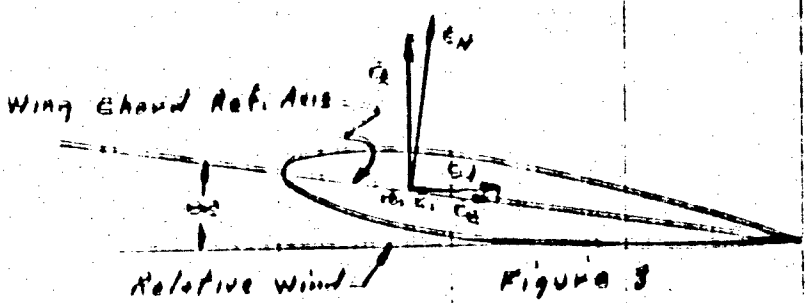

Figure 3

$$C_N = C_\ell \cos\alpha + C_d \sin\alpha$$
$$C_C = C_d \cos\alpha - C_\ell \sin\alpha$$

Where: C_ℓ = Section Lift Coefficient
C_d = Section Drag Coefficient

The General Equation For Airfoil Lift Coefficient Is

$$C_L = \frac{L}{qS}$$

Where: L = Total Lift of The Airfoil - Lbs.
S = Airfoil Area - Ft^2
$q = \rho/2 V^2$ Dynamic Pressure - Lbs/Ft^2
ρ = .002378 Slugs / Ft^3
V = Velocity In Ft/sec.

WING LOADS

Calculation of Shear, Moments, and Torques from the Airloads

The chordwise lift coefficient over the elementary area

$$dL = q\,dS$$

Where $dS = c\,d\eta - c\,\Delta b$

c = Airfoil chord

Δb = An Elementary Spanwise Distance

Then

$$dL = C_L\, c\, q\, \Delta b$$

Similarly

$$dD = C_{Dp}\, c\, q\, \Delta b$$

Resolving These into Normal and Chordwise Force Distribution Curves, dN and dc, And Using A Semi-graphical Method of Integration The Shears And Moments were Calculated. These Calculations Are Shown in Tables VI, VII, VIII, & IX.

The Torques About The Reference Axis Was Computed By Transferring Normal Force From the Quarter-Chord to the Reference Axis. The Calculation For The Torques Appears in Tables VI & VII.

WING LOADS

Calculation of Shears, Moments and Torques from the Inertia Loads

The condition solution for $n_z = 2.5$ was obtained using the wing unit solution, $n_z = 1$, shears and moments and the appropriate load factor. Since the angle of wing incidence is small, resolution of inertia loads in the chordwise direction is small and is conservatively neglected. The centroid of the inertia load was assumed to be located at reference axis. Therefore, no torque results from inertia loads.

WING LOADS

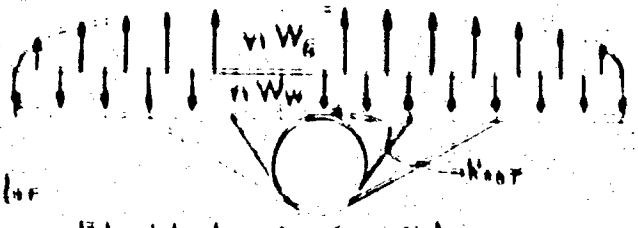
Calculation of Shears, Moments, and Torques Upon The Outer Wing Panels

The cable loads under conditions of flight are determined from values measured under static test conditions. The figure below shows that the wing inertia load when compared to the airload is:

(a) opposite in direction but multiplied by n in flight
(b) in same direction and constant in a static test.

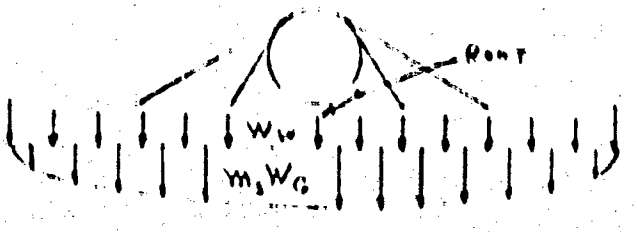


n=Flight Load Factor

(a) Flight Load Condition

W_G= Gross Wt.
= 500 LB
W_W= Wing Wt.
= 50 LB

m_s=Static Test Load Factor



(b) Static Test Load Condition
Aircraft is Inverted

4	63,545	4100	820	500

WING LOADS

Cable loads under flight conditions are determined from Figure 6 in which the load factors n and M_y are plotted vs. net root moment. On the same figure the static test cable loads are plotted vs static test net root moments. By assuming that the cable loads under flight conditions are dependent upon the net root moment it is possible to read flight cable loads from flight load factors n. The table below gives the cable loads corrected to flight load factors n.

Table XIII

Flight Load Factor n	Cable Loads, Lb		
	CD Inboard	AD Fwd Outbd.	BE Aft Outbd.
1	120	140	60

FUSELAGE LOADS

The most important loads are those due to pitching and yawing accelerations and airloads on the horizontal and vertical surfaces. A cable from the engine mount supports the tail when down loads act.

Figure 17 shows the geometry of the fuselage. All the inertia loads are reduced to concentrated forces at points which are numbered 0 to 11. The point 0 is just beneath the cables that fasten the engine mount to the fuselage while point 11 is at the center of the aft spherical end cap. Forces on the horizontal and vertical tail are resolved at point 11 as forces and couples.

The calculations that follow give the rotational inertia loads for pitching about the most forward and aft centroids. The coordinates used for the centroids are early values and do not agree with the final values, however the effect is negligible.

COORDINATES OF CENTROID

		x	z
Early Values	Most Fwd	68.26	47.30
	Most Aft	70.10	47.50
Final Values	Most Fwd	71.76	44.08
	Most Aft	77.58	47.93

MANEUVER LOADS

CRITICAL CONDITIONS

From the summary of airloads the most critical conditions are A2, A4, A6, and A7; B6 and B7; C7; E2; F2, F4, F6, F7, and F11 + horizontal tail load of F13. Conditions 3 and 5 are not critical because engine thrust loads up the tail cable.

As the unit solutions are labeled (a) through (f) then these solutions may be combined according to the equations

V or M = -aθ + nb + P/100 c For conditions 2, 4, 6, and 7

V or M = -aθ + nb - P/100 d For conditions 3, 5, and 7

The combined condition is given by the vector sum of pitching and yawing sheers and moments and the superposition of the torque.

$$[V \text{ or } M]_{pitch} = nb - \frac{P}{100} d + \frac{P_{yaw}}{100} e$$

$$[V \text{ or } M]_{yaw} = -a\theta + \frac{P_{yaw}}{100} f$$

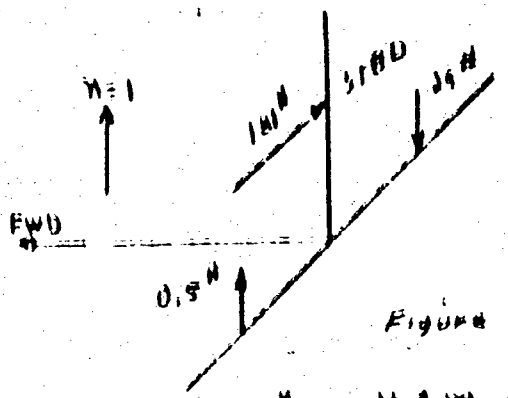
PAGE 209.220
MODEL G-11/12
SER. 706
REPORT 317-3

FUSELAGE FRAME

CHANGED CONDITION III, USING CONDITION III FOR VERTICAL FAIL LOAD



$$\text{New V\&M} = nb = \frac{P_{UP}}{100} d + \frac{P_{SIDE}}{100} e$$

$$= b = \frac{(39+5^{\#})}{100} d + 1.81e$$

$$\text{Figure 39} \qquad = b = .395d + 1.81e$$

$$\text{Yaw V\&M} = -a\ddot{\psi} + \frac{P_{SIDE}}{100} f$$

$$= -a\ddot{\psi} + 1.81f$$

ACTUALLY THE VALUES 'a' ARE FOR $\ddot{\theta}$ AND NOT $\ddot{\psi}$ BUT THE ERROR MADE IN USING 'a' IS INSIGNIFICANT

Y MAY BE CALCULATED FROM THE YAWING MOMENT OF THE 1811# SIDE LOAD AND THE YAWING MOMENT OF INERTIA BOTH ABOUT AN AXIS OF YAW THROUGH THE CENTROID OF THE AIRCRAFT. THE PRINCIPAL AXES OF PITCH AND YAW ARE INCLINED AT ABOUT 20° WITH THE GEOMETRIC AXES SO THAT A YAWING MOMENT ABOUT THE GEOMETRICAL AXIS ACTUALLY CAUSES THE AIRCRAFT TO PITCH AND YAW BOTH ABOUT THE PRINCIPAL AXES.

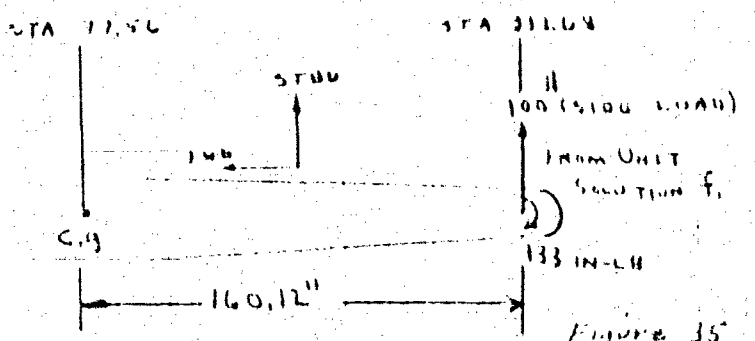


Figure 15

$$M_{YAW} = \left(100\,\frac{160.12}{12} - \frac{133}{12}\right)\frac{1811}{100}$$

$$= 2390 \text{ FT-LB}$$

$$\ddot{\psi} = \frac{M_{YAW}}{I_{YAW}} = \frac{2390}{300.8} = 8 \text{ rad/sec}^2$$

Critical Engine Mount Loads

216-63 (3-5)

EMPENNAGE LOADS

The critical loading condition alone is presented as the stress analysis is a summary one. This load is 101 lb acting on the vertical tail. The distribution, using a 100 lb unit load, is that shown on page 2.05.070.

The hinge line reactions and geometry for the rudder and vertical stabilizer are given on pages 2.05.020 and 2.05.030. As the rudder attachment is statically determinate, the calculations are given on page 2.05.020. The support of the vertical stabilizer is statically indeterminate as is apparent from the equations below. (See page 2.05.030).

$$P_x = P_x - A_x - 32.2 + R_x = 0$$
$$P_y = -P_y - A_y - 7.45 + R_y = 0$$
$$P_z = P_z + A_z - 100 + R_z = 0$$

$$M_x = 24.1\ P_z + 30.6\ A_z - 32.2 \times 19.5 - 64.8 \times 10.22 = 0$$
$$M_y = 29\ P_z + R_z\ X_{Rz} - 64.8 \times 11.16 = 0$$
$$M_z = -24.1 P_x + 29 P_y + 30.6 A_x + 32.2 \times 22 - R_y\ X_{Ry} = 0$$

With direction cosines of page 2.05.030,

$.264P - .102A + R_x = 32.2$
$-.690P - .612A + R_y = 7.45$
$.675P + .782A + R_z = 100$
$16.23P + 23.7A = 1070$
$19.37P + X_{Rz} = 723$
$13.64P + 3.12A - X_{Ry} = -708.4$

These are plotted on Pg. 2.05.040

Solution when $X_{Rz} = X_{Ry}$

$P = .0308A = 2.92$ lb
$A = 76.7$ lb
$R_x = 32.3$ lb
$R_y = 55.9$ lb
$R_z = 38.5$ lb
$X_{Ry} = X_{Rz} = 17.6$ In.
$P_z = 1.97$ lb $\quad A_y = 47.0$ lb
$P_y = 2.01$ lb $\quad A_z = 60.0$ lb

The shear and moment diagrams are on page 2.05.050.

EMPENNAGE LOADS

TORQUE AT THE CRITICAL SECTION IS CALCULATED BELOW.

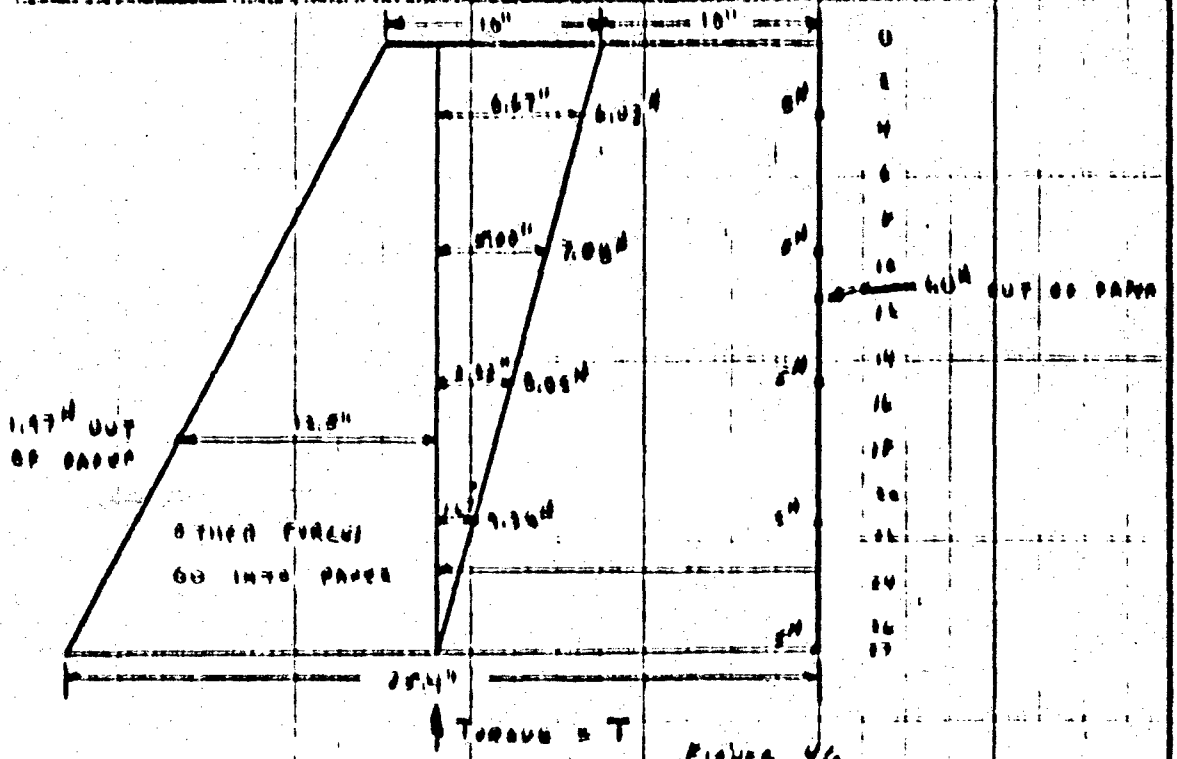

Figure 4G

$T = 40 \times 13.5 - 1.97 \times 13.5 - 6.67 \times 6.03 - 7.00 \times 7.00 - 8.33 \times 8.05 - 1.67 \times 9.33 = 17.78$ in

$= 477$ IN-LB

CORRECTION FOR INERTIA OF VERTICAL TAIL

The vertical tail weighs 5.4 lb and its centroid is at WL 73.5, STA 230.5 (per 2.01.020). The inertia load due to yawing acceleration is:

$$P = \frac{W}{g} \times \dot{\beta} = \frac{5.4}{32.2}(13.18)(4) = 10.9 \text{ lb}$$

where $Y = (230.5 - 73.5) \div 12 = 13.1'$ (see pg. 2.03.220)

$\dot{\beta} = 4$ rad/sec^2

Thus the actual tail load of 161 lb may be reduced by 10.9 lb to 161 lb.

216-83 (3-5)

Cockpit Loads

The cockpit loads are:

(1) Pullout $n_z = 2.5$

(2) Pushover $n_z = 1.0$

(3) Yaw $n_z = 1$, $n_y = .675$

(4) Roll $n_z = 1$, $M_{roll} = 730$ in-lb, $M_{yaw} = 1537$ in-lb.

(5) Level Landing, inclined reactions

$$n_z = \frac{1347}{550} - \frac{1}{3} + 1 = 3.12$$

$$n_x = -\frac{371}{550} = -.675$$

(6) Tail Down Landing $n_z = 3.12$

(7) Ground Load $n_z = 1.33$, $n_y = .83$

Conditions (1) - (4) are flight conditions and are partially derived from Table III, page 2.00.030.

Conditions (5) - (7) are derived from CAM -03, Art. 3.243 to 3.249.

The most critical loads are (1), (5), and (6).

218-83 (3-56)M

Landing Gear Loads

The CAM 3, reference 7, was used as a guide in the determination of landing loads for this aircraft. Article 3.24) of reference 7 gives a minimum descending velocity of 7 ft/sec. However, preliminary investigation showed that such a minimum could not be achieved without an elaborate and heavy landing gear. It was found that the kinetic energy of a 5 ft/sec descending velocity could be absorbed by a single wheel attached to a piston deflecting into the fuselage. The load and energy vs. deflection characteristics of the piston-fuselage system are given in figures 48 and 49, while figures 50 and 51 are for the tire. See reference 8 for the piston-fuselage deflection characteristics.

The conditions examined with the limit loads are given below. One flight condition is included as the lower wing brace cables are attached to the landing gear.

TABLE XXIII

Condition	Limit Loads, Lb.

Section 3

WING ANALYSIS

The wing is of Airmat construction and supports the external loads by virtue of tensile inflation stress. If one of the principal stresses at a point on the wing cross-section becomes zero due to the applied compressive stresses a wrinkle starts to form there. As more load is applied the wrinkle will enlarge to a point where collapse will occur. The pressure in the wing should be large enough to prevent a wrinkle from forming under limit loads and collapse at ultimate loads. For this analysis the ultimate load is 1.75 times limit load.

While the minimum principal stress at the point where a wrinkle first forms is zero, both principal stresses at a point on the opposite surface of the wing are tensile stresses. The allowable strength value on the tension side is the quick break value derived from a cylinder burst test divided by a creep rupture factor of 3. The factor of 3 accounts for the fact that fabric under load for a period of time has a reduction in strength.

The allowable hoop tension strength value on the compression side is the quick break value derived from the cylinder burst test times 0.65 divided by 3. The factor of 0.65 accounts for the fact that the fabric in a cylinder burst test is loaded at a 2-1 stress ratio, while on the compression side of the wing is loaded in only one direction and consequently gets little or no help from the bias plies. The factor is based on a comparison of cylinder burst tests and strip tensile tests.

Since the negative margins shown in Tables XXXII and XXXIII, pages J.01.220 and J.01.230 respectively, cover only a small percentage of the periphery of the wing cross-section shown on page J.01.040, these negative margins are not serious. This is further proved in the wind tunnel test, which gave an ultimate margin of safety of +0.17, reference page J.01.240.

Calculation of bending stress

Method of Analysis

For a cross-section in bending, the general equation for stresses due to bending may be determined from the following expression:

$$f_b = (C_1 I_A - C_2 H_X) z + (C_1 H_X - C_3 H_A) x$$

Where

$$C_1 = \frac{I_{XA}}{I_X I_A - I_{XA}^2}$$

$$C_2 = \frac{I_A}{I_X I_A - I_{XA}^2}$$

$$C_3 = \frac{I_X}{I_X I_A - I_{XA}^2}$$

I_X = Moment of inertia of cross-section about x-x axis
I_A = Moment of inertia of cross-section about z-z axis
H_X = Bending moment about x-x axis, positive when it causes compression above x-x axis
H_A = Bending moment about z-z axis, positive when it causes compression to right of z-z axis

x and z are the ordinates of the elements of the cross-section, x is positive above the x-x axis and z is positive to the right of the z-z axis.

WING ANALYSIS

Calculation of Shear Stress

The shear flow at any point on the cross-section is given by:

$$q = (\theta_1 V_x - \theta_2 V_z)(Q_x - Q_{x_0}) + (\theta_1 V_z - \theta_3 V_x)(Q_z - Q_{z_0}) + q_m M_y$$

where

V_x, V_z = components of shearing force along the x-x and z-z Axes, respectively

Q_x = $\sum A_z$, the summation of the product of the element of area and its coordinate from the x-x axis through the centroid of the section

Q_x = $\sum A_x$ $\qquad Q_{x_0} = \dfrac{\sum q_x \, a}{\sum \Delta a}$ $\qquad Q_{z_0} = \dfrac{\sum q_z \, a}{\sum \Delta a}$

Δa = twice the area enclosed by lines joining the ends of an element of skin with the centroid of the entire cross section

q_m = $1/\sum \Delta a$ = shear flow for a unit torque

M_y = torsional moment about the longitudinal axis through centroid of section, positive if clockwise.

Convention of signs for positive direction of the coordinate axes and the shearing forces and moments applied to the cross section are shown below:

Calculation of Shear Stress — WING ANALYSIS

Condition A_2 Symmetrical Maneuver

Wing Sta. 0.00 (Wing Root)

$$q = (C_1 V_x - C_2 V_z)(Q_x - Q_{x_0}) + (C_1 V_z - C_3 V_x)(Q_z - Q_{z_0}) + g_m M_y$$

$C_1 = 0$ $V_x = 33$ lbs. Ref. Pg. 2.02.190

$C_2 = 160.456 \times 10^{-6}$ $V_z = 179$ lbs. Ref. Pg. 2.02.170

$C_3 = 44.761 \times 10^{-6}$ $M_y = 2070$ in-Lbs. Ref. Pg. 2.02.210

$g_m = 1470 \times 10^{-6}$ $g_m M_y = 3.05$

$$(C_1 V_x - C_2 V_z) = -(160.456 \times 10^{-6})(179)$$

$$= -0.136$$

$$(C_1 V_z - C_3 V_x) = -(44.761 \times 10^{-6})(33)$$

$$= -0.00148$$

$\therefore$

$$q = 3.05 - 0.136 (Q_x - Q_{x_0}) - 0.00148 (Q_z - Q_{z_0})$$

WING ANALYSIS

Calculation of Axial Stress

The axial stress (f_a) is simply the axial load (P_y) divided by the perimeter of the wing cross-section (Total of column ①, page 3.01.010).

The axial load (P_y) is taken as the same for conditions A_2 and G_2.

Conditions A_2 and G_2, Wing Sta. 0.00

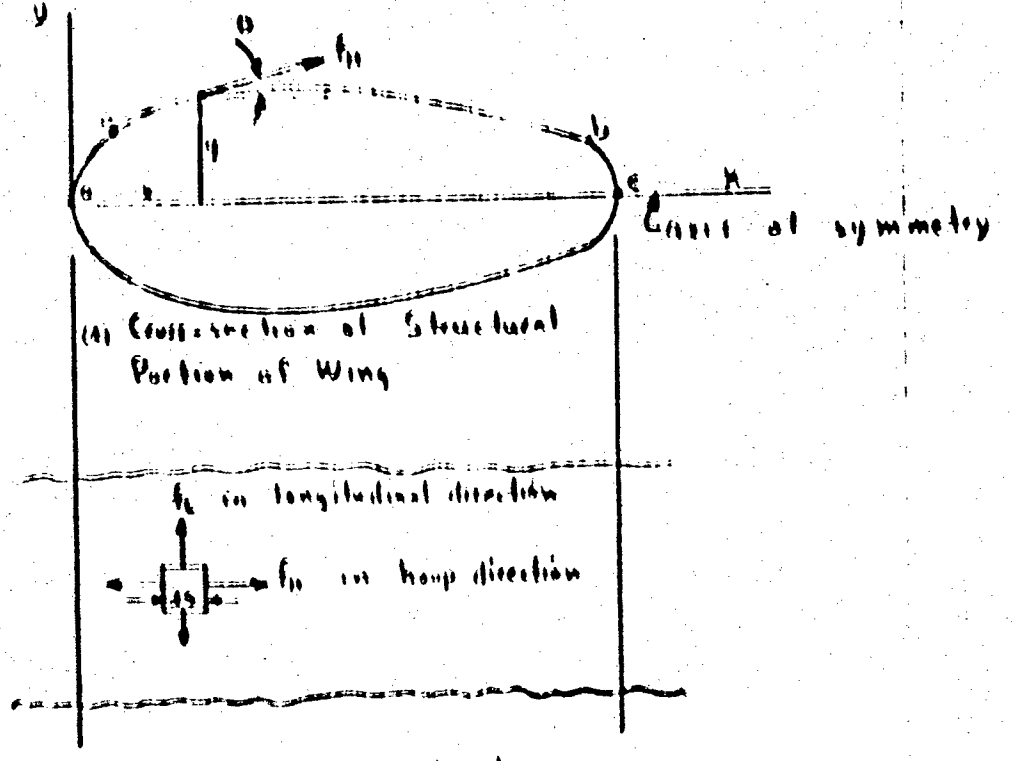
$P_y = -771$ lbs Ref. P_y, 2.02.170

Perimeter = 101.48 in.

$$\therefore f_a = -\frac{771}{101.48} = -7.56 \text{ lbs./in.}$$

Inflation Stresses in an Airmat Wing (See Ref. 3)

WING ANALYSIS



(a) Cross-section of Structural Portion of Wing

(b) Sketch Showing Orientation of Membrane Stresses

Figure 53 Longitudinal and Hoop Inflation Stresses

From summation of forces in x-direction on part of an elemental chordwise strip

$f_H = \frac{-py}{\cos\theta}$ = hoop tension, lb/in, y and θ are in (a) and

p = internal pressure, psi From summation of forces in the longitudinal direction:

$-pA = \int_0^c f_L \, ds$, lb. in which A = enclosed area above x-axis (only half needed because of symmetry),

f_L longitudinal shear, lb/in and dS is an element of arc. The longitudinal unit strain ϵ_L is assumed to be constant (i.e. independent of y) and is given by

$$\epsilon_L = \frac{1}{E}\left[f_L - \mu f_m\right]$$ in which E = elastic modulus of the fabric, lb/in and μ = Poisson's Ratio

From the above three equations and $dx = ds \cos\theta$

$$f_L = \frac{pA}{\delta_E}, \quad \frac{\mu p y}{\cos\theta} = \frac{\mu}{\delta_E}\int_0^{y_E} \frac{y\,dx}{\cos^2\theta}$$

The integral is evaluated in three parts

$$I = \int_0^{y_E} \frac{y\,dx}{\cos^2\theta} = {}_aI_a + {}_aI_b + {}_bI_E$$

${}_aI_a$ and ${}_bI_E$ are for circular arcs $\overline{0a}$ and $\overline{bE}$ while ${}_aI_b$ is evaluated numerically, using NACA 0015 airfoil coordinates, in the table below the arc $\overline{ab}$ is divided into 10 parts referred to as 'points' and $\mu = 0.2$ is assumed

Table XXX

Point	y	θ	$\frac{1}{\cos\theta}$	$\frac{1}{\cos^2\theta}$	$\frac{\Delta x}{2}$	$\frac{\Delta I}{2}$
	in	Deg			in	in
1	2.52	29.1	1.0788	2.08	2.14	2.250
2	3.11	11.8	1.0118	3.82	1.11	1.060
3	4.18	9.3	1.0077	4.10	1.30	1.566
4	4.50	0	1.0000	4.50	1.50	2.106
5	4.41	0.8	1.0001	4.41	1.41	2.068
6	4.25	3.0	1.0014	4.25	1.25	2.556
7	3.96	4.7	1.0034	3.97	3.78	3.502
8	3.58	5.2	1.0041	3.61	5.59	1.9247
9	3.01	6.5	1.0065	3.12	1.09	3.824
10	2.49	6.8	1.0071	2.51	2.51	3.108

The collation stresses are plotted vs chord positions on the next page. The resultant of f_L does not pass through the centroid of 'A' and hence gives a small chordwise moment that is neglected.

Limit Margin of Safety for Wrinkling — WING ANALYSIS

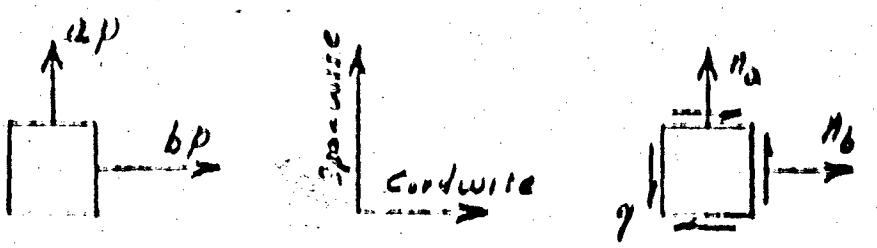
The limit margin of safety for the wing is based on the pressure required to prevent wrinkling of the wing, i.e.

$$M.S. = \frac{P_{inflation}}{P_{req'd}} - 1$$

For Inflation = 7.0 psi,

$$M.S. = \frac{7.0}{P_{req'd}} - 1$$

Determination of $P_{req'd}$



Inflation Stresses — Applied Stresses

where:

$$a = \frac{f_L}{P} \qquad b = \frac{f_N}{P}$$

$$n_a = f_a + f_b$$

$$n_b = 0$$

Wrinkling occurs when one of the principal stresses is zero. It may then be seen from a Mohr's stress circle that the shear stress required to cause wrinkling may be expressed as,

PREPARED BY _____
CHECKED BY _____
DATE _____
REVISED _____

GOODYEAR
AIRCRAFT

DATE _____
SHEET _____
BY _____
SHT NO _____

WING AVAILABLE

$$\gamma = \sqrt{n_x n_y}$$

where: $n_x = ap + n_a$

$n_y = bp + n_b$

then,

$$\gamma^2 = (ap + n_a)(bp + n_b)$$

$$abp^2 + (bn_a + an_b)p + n_a n_b - \gamma^2 = 0$$

$$p^2 + \left(\frac{n_a}{a} + \frac{n_b}{b}\right)p + \frac{n_a n_b}{ab} - \frac{\gamma^2}{ab} = 0$$

therefore, the pressure required to produce

maneuvering is given by,

$$p = -\frac{1}{2}\left(\frac{n_a}{a} + \frac{n_b}{b}\right) \pm \frac{1}{2}\left[\left(\frac{n_a}{a} + \frac{n_b}{b}\right)^2 + 4\left(\frac{\gamma^2}{ab} - \frac{n_a n_b}{ab}\right)\right]^{\frac{1}{2}}$$

since, $n_b = 0$,

$$p_{req'd} = -\frac{n_a}{2a} \pm \frac{1}{2}\left[\left(\frac{n_a}{a}\right)^2 + \frac{4\gamma^2}{ab}\right]^{\frac{1}{2}}$$

Maximum Stress : Combined Loading

$N_x = a_p + N_a = a_p + f_a + f_b$

$N_y = b_p + N_b = b_p + 0 = b_p$

Maximum Tensile Stress

$$f_{max} = \frac{N_x + N_y}{2} \pm \sqrt{\left(\frac{N_x - N_y}{2}\right)^2 + y^2}$$

$$M.S. = \frac{\text{Allowable Limit Strength}}{f_{max}} - 1$$

Inflation Stress

$f_{inflation} = b_p$

$$M.S. = \frac{\text{Allowable Inflation Strength}}{b_p} - 1$$

Tensile Stress Check

Condition C_2 Element 20 Critical

$$f_{max} = \frac{29.91 + 26.50}{2} \pm \sqrt{\left(\frac{29.91 - 26.50}{2}\right)^2 + 11.29^2} = 39.60 \text{ \#/in.}$$

$$M.S._{Limit} = \frac{174 \div 3}{39.60} - 1 = +0.46$$

Ref. Pg. 1.00.080 For 174 \#/in Allowable

Inflation Stress Check

Element 26 Critical

$b_p = 4.50 \times 7 = 31.50$ \#/in.

$$M.S._{Inflation} = \frac{174 \div 4}{31.50} - 1 = +0.39$$

Static Test And Wind Tunnel M.S. Comparison

Ref. Pg. 1.00.050 For g's.

Static Test M.S.

$$M.S._{Ult.} = \frac{5.60}{2.5 \times 1.75} - 1 = +0.28$$

Wind Tunnel M.S.

$$M.S._{Ult} = \frac{5.13}{2.5 \times 1.75} - 1 = +0.17$$

218-63 (3-59)M

FLUTTER ANALYSIS

Section 4

BUCKLING ANALYSIS

The fuselage is an inflated conical envelope with nearly hemispherical ends. It supports external loads by virtue of tensile inflation stresses. If one of the principal stresses at a point in the fuselage becomes zero due to applied compression stresses, a wrinkle starts to form there. As more load is applied the wrinkle will enlarge to a point where collapse will occur. The pressure in the fuselage should be large enough to prevent a wrinkle from forming under limit loads and collapse at ultimate loads. For this analysis the ultimate load is 1.75 times limit load.

While the minimum principal stress at the point where a wrinkle first forms is zero, both principal stresses at a diametrically opposite point are tensile stresses. The material properties should be such that the maximum tensile stress does not exceed some allowable value. The allowable strength value on the tension side is the quick break value derived from a cylinder burst test divided by a creep rupture factor of 3. The factor of 3 accounts for the fact that fabric under load for a period of time has a reduction in strength.

The allowable hoop tension strength value on the compression side is the quick break value derived from the cylinder burst test times 0.65 divided by 3. The factor of 0.65 accounts for the fact that the fabric in a cylinder burst test is loaded at a 2-1 stress ratio, while on the compression side of the fuselage is loaded in only one direction and consequently gets little or no help from the bias ply. The factor is based on a comparison of cylinder burst tests and strip tensile tests.

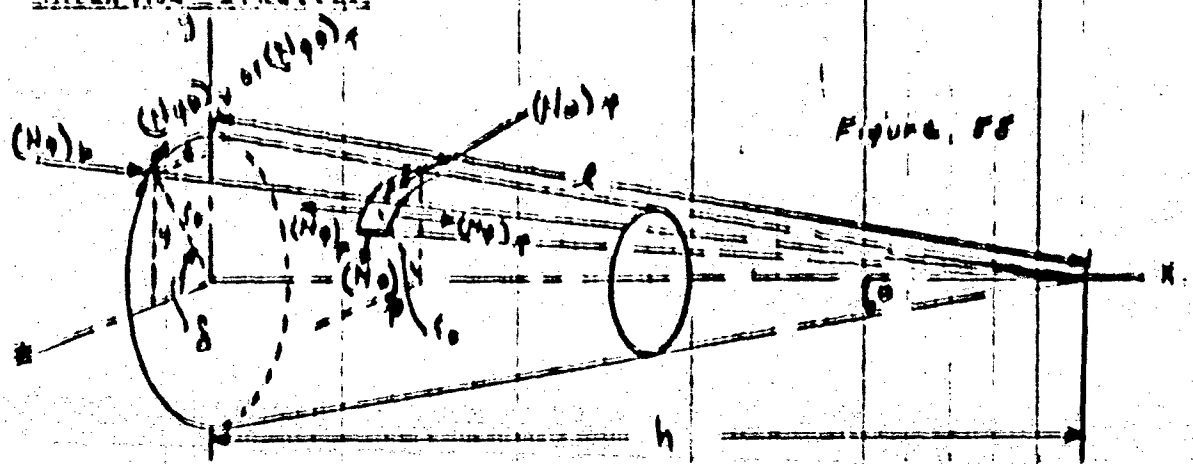
MEMBRANE STRESSES IN A CONE — FUSELAGE ANALYSIS

INFLATION STRESSES



FIGURE, F8

THE INFLATION STRESSES $(N_\phi)_p$ AND $(N_\theta)_p$ ARE GIVEN IN Ref. 6 Page 137.

$(N_\phi)_p = \frac{pr_0}{2\cos\theta}$, LB/IN = LONGITUDINAL INFLATION STRESS

$(N_\theta)_p = \frac{pr_0}{\cos\theta}$, LB/IN = HOOP TENSION

WHERE p = INFLATION PRESSURE, PSI
r_0 = RADIUS OF NORMAL SECTION, IN.
θ = ONE HALF OF ANGLE OF CONE.

BENDING STRESSES

IF THE BENDING STRESS $(N_\phi)_b$ IS ASSUMED TO ACT ALONG A GENERATOR OF THE CONE THEN ITS X-COMPONENT MUST SATISFY THE FLEXURE FORMULA

$N_x = \frac{h}{\ell} N_\phi = \frac{M_z y}{I}$ WHERE M_z IS THE MOMENT ABOUT THE z-AXIS.

OR $(N_\phi)_b = \frac{M_z y}{I}\frac{\ell}{h} = \frac{M_z y}{I\cos\theta}$

THE MAXIMUM VALUE OF $(N_\phi)_b$ IS

$(N_\phi)_{bm} = \frac{M_z}{\pi r_0^2 \cos\theta}$

218-03 (3-5)

BEAM SHEAR STRESS

FINERAGE ANALYSIS

IF THE NET SHEAR AT A SECTION IS ALONG THE Y-AXIS, THEN THE SHEAR STRESS IS GIVEN BY THE ELEMENTARY SHEAR STRESS FORMULA TO BE

$$(N_{\phi\theta})_V = \frac{V \cos\beta}{\pi r_0} \quad \text{LB/IN}$$

TORSIONAL SHEAR STRESS

THE TORSION OF THIN WALLED SHELLS GIVES

$$(N_{\phi\theta})_T = \frac{T}{2\pi r_0^2} \quad \text{LB/IN}$$

ENGINE MOUNT ANALYSIS

An engine saddle mount is attached to the top of the wing by lacing to patch attachments on the top surface of the wing. The saddle mount is also used to fasten the wing to the fuselage, at the trailing edge, by means of two short cable-patch attachments. The engine is attached to the pylon of the saddle structure through the four engine mount fittings. The mount is a weldment of 6061-T6 aluminum tubing heat treated after welding.

SUMMARY OF

EMPENNAGE, COCKPIT, AND LANDING GEAR ANALYSES

Section 6

Summary of Empennage, Cockpit, and Landing Gear

Description of Empennage

The horizontal tail is supported along its center line on the fuselage and by cables attached to outboard edges. The main support cables are the aft cables which are attached near the hinge line of the elevator while forward cables are added for stability. Thus half of the horizontal stabilizer acts as a cantilever beam supported at the end.

The vertical tail is hinged to the horizontal tail and to the fuselage and also supported by cables; the main cable being attached near the rudder hinge line and a forward cable added for stability is attached to the leading edge. As the largest tail loads are applied to the vertical tail and as the vertical tail is not supported as well as the horizontal tail, the vertical tail is the most critically loaded part of the empennage.

Description of Cockpit

The cockpit is made up of flat sections of Airmat, three inches thick, consisting of two side panels, a bottom panel, a seat bulkhead, and a rear bulkhead. These panels are joined to form the cockpit which attaches to the fuselage section. A hammock type seat is provided for the pilot, which is cemented to the top of the rear bulkhead and seat bulkhead.

Description of Landing Gear

A single wheel landing gear is used on the aircraft. The structure supporting the wheel is a weldment of 6061-T6 aluminum tubing heat treated after welding, and is attached by lacing to patch attachments on the forward end of the fuselage. This structure is designed to provide a shock absorber action during landing. The wing lower brace cables are attached to the channel support structure at the rear of the landing structure.

Stress Analysis of Empennage

The empennage is an Airmat structure and supports the external loads by making use of the tensile inflation stress. The pressure in the empennage should be large enough to prevent collapsing due to the applied compression stresses under ultimate loads. On the tension side the allowable strength value is the quick break strength derived from a cylinder burst divided by the reduction factors shown on page 1.00.110.

STRUCTURAL ANALYSIS OF EMPENNAGE

FROM PA 2.05.020 THE UNIT REACTION LOADS

SHEAR V = 1111 LB
MOMENT M = 2115 IN-LB
TORQUE T = 1111 IN-LB
SECTION WIDTH = 35.4 IN

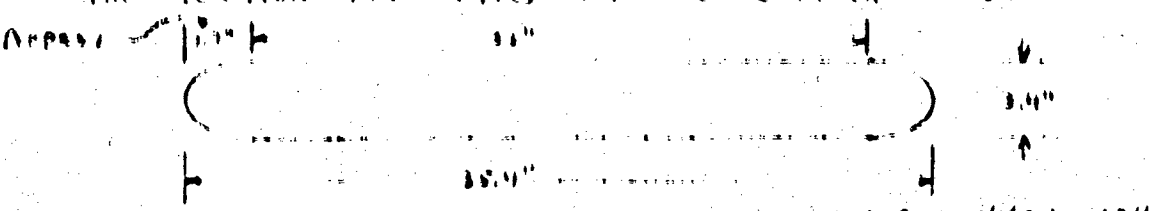
} FOR THE CRITICAL SECTION

FROM PA 2.05.060 THE CRITICAL LOAD, CORRECTED FOR VERTICAL TAIL INERTIA, IS 1161 LB ; HENCE, THE UNIT VALUES ABOUT BECOME :

CRITICAL CONDITION A II RUDDER NEG

V = 1.61 × 1111 = 1785 LB
M = 1.61 × 2115 = 3411 IN-LB
T = 1.61 × 1111 = 1111 IN-LB
P_c = 1.61 × 35.4 = 110.4 LB

THE SECTION PROPERTIES AT THE CRITICAL SECTION ARE :



$I = \frac{\pi}{2}(1.7)^3 + 31(1.7)^2(1.4) = 185.9 \text{ IN}^4$

$A = \pi(1.7)^2 - 4(1.4) = 11.7.9 \text{ IN}^2$

$S = 3.4\pi + (2)(11) = 74.7 \text{ IN}$

THE APPLIED STRESSES ARE :

$q_{max} = \frac{MC}{I} + \frac{P_c}{S} = \frac{3411(1.7)}{185.9} + \frac{110.5}{74.7} = 1111 \text{ LB/IN}$

$q = \frac{T}{2A} = \frac{1111}{2(1179)} = 3.2\% \text{ LB/IN}$

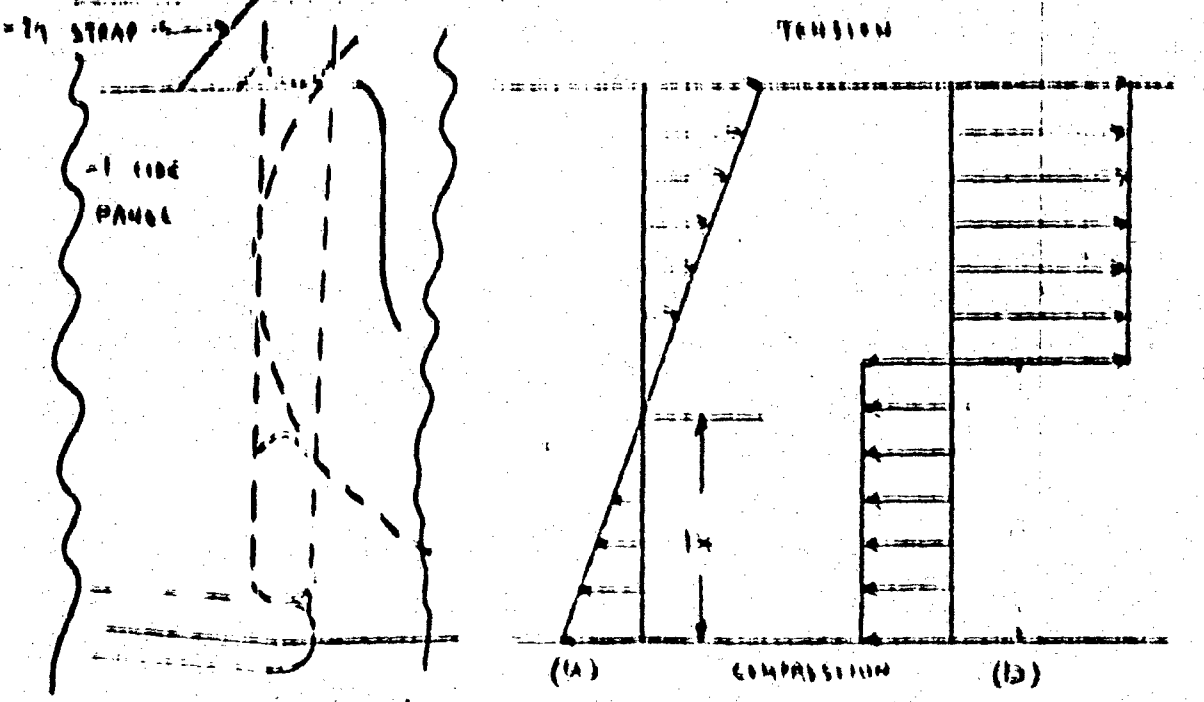
COCKPIT STRESS ANALYSIS

REF DWG 4474-060



STRESS DISTRIBUTION UP TO WRINKLING OF BOTTOM PANEL

STRESS DISTRIBUTION UP TO COLLAPSE OF COCKPIT

Figure 57

THE ORDINARY BEAM BENDING STRESS DISTRIBUTION IS ASSUMED UP UNTIL THE BENDING STRESSES IN THE BOTTOM PANEL EQUAL THE INFLATION STRESSES. AFTER THE BOTTOM PANEL WRINKLES IT CANNOT CARRY ANY ADDITIONAL COMPRESSIVE LOAD, SO THE SIDE PANELS BEGIN TO WRINKLE PROGRESSIVELY UPWARD. THIS SHIFTS THE NEUTRAL AXIS UP AS SHOWN IN THE SKETCH ABOVE. NEAR THE COLLAPSE LOAD OF THE COCKPIT IT IS ASSUMED THAT THE TENSILE STRESS DISTRIBUTION ABOVE THE NEUTRAL AXIS IS UNIFORM AS SHOWN IN FIGURE (b) ABOVE.

ON THE NEXT PAGE ARE MORE DETAILED SKETCHES SHOWING THE TRANSFER OF LOADS FROM THE COCKPIT SIDE AND BOTTOM PANELS TO THE BULKHEAD, WING, LANDING GEAR, AND FUSELAGE. AS LONG AS THE COCKPIT DOES NOT COLLAPSE, THE LOAD CAPABILITIES ARE DEPENDENT UPON THE FABRIC TENSILE STRENGTH AND THE PRESTRAIN.

SUMMARY OF EQUATIONS AND SAMPLE CALCULATIONS

STRESS DISTRIBUTION (a)

SEE PG. 6.01.060

CENTERLINE STRESS = $\frac{M \cdot C}{I_{aa}} = S$ LB/IN.

FABRIC STRESS = $\frac{S}{2}$, LB/IN.

INFLATION STRESS = $\frac{P \times \text{PANEL THICK}}{2}$

$= 1.5P$ LB/IN

NET FABRIC TENSION = $\frac{S}{2} + 1.5P$ LB/IN.

THE LIMIT MOMENT FOR CONDITION 1 PG 2.06.030 IS 11,125 IN-LB

$S = \frac{11,125 \times 15.87}{4345} = 40.2$ LB/IN

NET TENSION IN COCKPIT FABRIC $= \frac{40.2}{2} + 1.5(7) = 30.6$ LB/IN.

TENSION IN STRAPS BETWEEN BULKHEAD AND SIDE PANELS = 40.2 LB/IN

STRESS DISTRIBUTIONS (b) AND (c)

SEE PG 6.01.070

$P = (10W_1 + 6W_2)P$ LB

$\bar{X} = \frac{\pi.36 - 25.W_3 X - 3X^2}{12W_1 + 6W_2}$ IN.

$M = (36W_3 + 10P.5X)P$ IN-LB

$T_{aa} = \frac{P}{2(R\Sigma - \pi)}$ LB/IN.

= STRESS IN CONNECTIONS, IE. STRETCH (b) ARE DRAGGED BETWEEN BULKHEAD AND FUSELAGE CONNECTIONS

FABRIC TENSION IN SIDE PANEL $= \frac{T_{aa}}{2}$ LB/IN

NET FABRIC TENSION $= \frac{T_{aa}}{2} + 1.5P$

FOR $\theta = 10°$, $P = 7$ PSI

$P = 11496$ LB

$\bar{X} = 3.85$ IN.

$M = 17,260$ IN-LB

$T_{aa} = 62.0$ LB/IN

$\frac{T_{aa}}{2} = 31.0$ LB/IN

NET TENSION $= 31 + 13.5 = 44.5$ LB/IN

STRESS DISTRIBUTION (c)

SEE PG. 6.01.070

P AND $\bar{X}$ AS IN (b) AND (c)

$\theta = 7.5°\left[\frac{\text{NO. OF}}{\text{BAYS}} - \text{CONST.}\right]$

$R = 111.76 + 7.5\cos\beta$

$M = (36W_3 + 10.5W_2 - \bar{X})P$

$T_{aa} = \frac{P}{115\beta}$

FOR $\theta = 12.5°$ $P = 7$ PSI

$P = 11496$ LB

$\bar{X} = 3.85$"

$\cos\beta = -.0376$

$\beta = 180 - 70.4 = 109.6°$

$= \frac{109.6}{57.3} = 1.91$ RADIANS

$R = 5.80$"

$M = 15,600$ IN-LB

$T_{aa} = 42.3$ LB/IN.

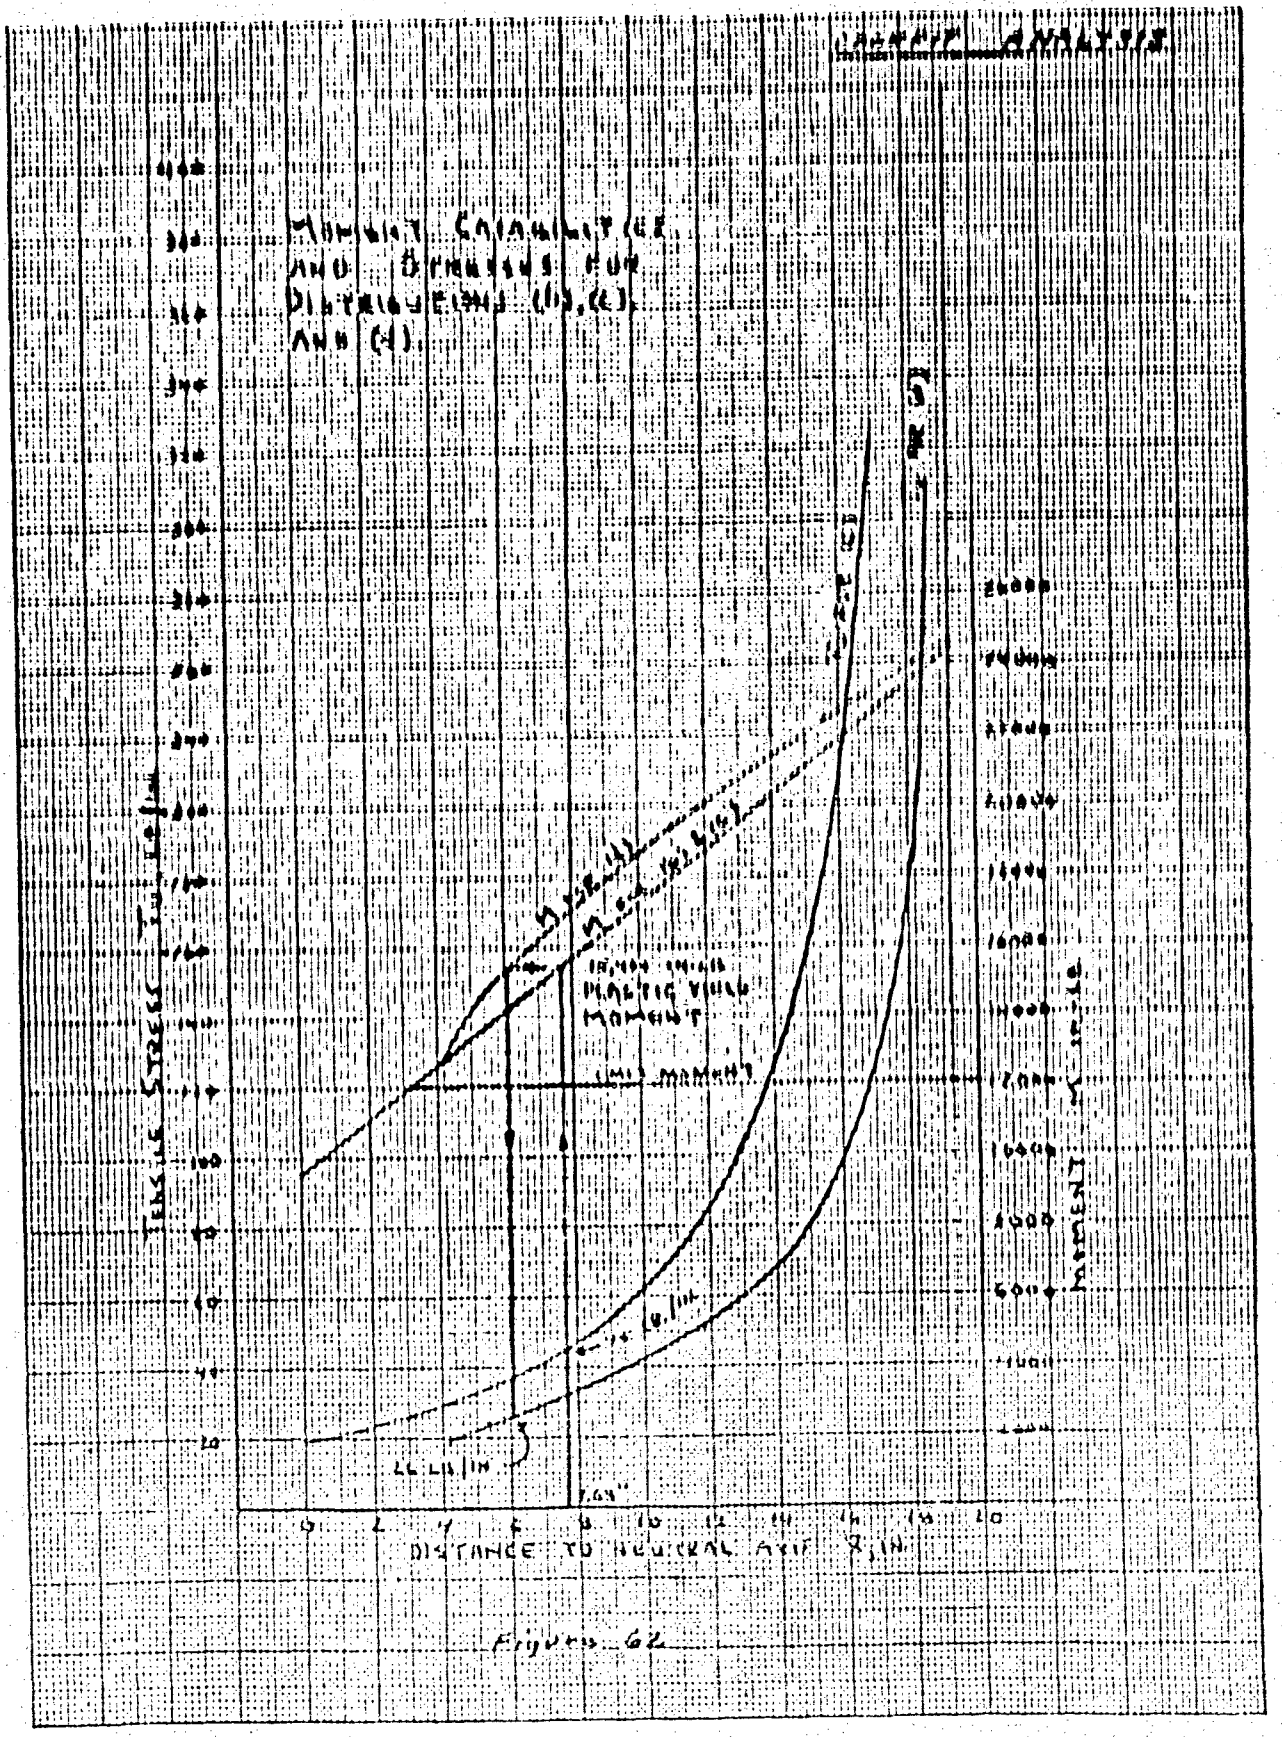

Figure 62

COCKPIT ANALYSIS

From page 6.01.000 the neutral axis for triangular stress distribution (a) is at $\bar{n} = 7.63$ in. The curves on page 6.01.130 give the moments and stresses vs. neutral axis location for plastic yield or uniform stress distributions (b), (c), and (d). Changing from stresses (a) to (b) or (c) at $\bar{n} = 7.63$ changes the limit moment 12,120 in-lb (page 6.01.120 to an initial plastic yield moment of 15,400 in-lb (page 6.01.120). Thus:

For $M \leq 12120$ in-lb - - - - - - - - stresses (a)
For $12120 \leq M \leq 15400$ in-lb - - - transition
For $M \geq 15400$ - - - - - - - - - - stresses (b) and (c)

} stresses (d)

The curves of page 6.01.140 are derived from those of page 6.01.120 by simultaneous values of M and T_u for $15400 \leq M \leq 23000$. The stresses $(T_u)_b$ are calculated from

$$(T_u)_b = \frac{1}{2}(T_u)_a + \frac{1}{2}(7) = \frac{1}{2}(T_u)_a + 10.5 \text{ lb/in.}$$

in which the stress 10.5 lb/in is the cockpit panels inflation stresses.

The fabric factors of safety are three on limit stress, 1.5 on stress at ultimate load, and four on inflation stress. The cockpit panels are made from Airmat fabric A35A with cylinder burst values of 150 x 150 lb/in warp and fill, the bulkhead is fastened to the side and bottom panels with MS13A105 fabric straps with strip tensiles of 200 x 100 lb/in warp and fill; and the bulkhead and side panels are fastened to the fuselage with ZX-300 fabric straps with 425 x 350 lb/in warp and fill strip tensiles.

The limit and ultimate moments are given in the table below.

Condition	1	5	6
Limit Moment	11,125	15,773	13,916
Ultimate Moment	19,440*	20,800**	18,400**

* $11,125 \times 1.75 = 19,440$ In-lb - - - - Using a factor of safety 1.75

** $15,773\sqrt{1.75} = 20,800$ In-lb - - - - Using a factor of safety of 1.75 on energy of absorption for landing, and noting that loads are proportional to $\sqrt{\text{energy}}$.
