March 1961

ABSTRACT

Aerodynamic flow parameters for isentropic expansions and flow through normal shocks, including real gas effects, have been calculated for total temperatures of 4000 to 10,000°K and for total pressures of 100 to 4000 atmospheres. Calculations assume equilibrium flow. Results indicate real gas effects vary from a few percent to more than two orders of magnitude.

SUMMARY

Aerodynamic flow parameters for isentropic expansions and flow through normal shocks, including real gas effects, have been calculated for total temperatures of 4000 to 10,000°K and for total pressures of 100 to 4000 atmospheres. Tables are presented in which flow parameters are listed for the throat of a nozzle and for Mach numbers at increments of 0.5 in the range of 2.0 to 30.0. Flow parameters presented include the usual Mach number, velocity, pressure, temperature and density relations plus other parameters useful in the analysis of real gas flows. Combinations of total pressure and temperature are such as to allow duplication of ambient atmospheric conditions at altitudes in the range of 100,000 to 350,000 feet at flow velocities of 10,000 to 24,000 feet per second.

MACH TABLES FOR REAL GAS EQUILIBRIUM FLOW OF AIR IN HYPERVELOCITY TEST FACILITIES WITH TOTAL TEMPERATURES TO 10,000°K

Introduction

The high flight speeds of today's aircraft result in high air temperatures in the immediate vicinity of the aircraft due to compression through shock waves and energy conversion through viscous effects. In many practical instances, air temperatures become high enough that the vibrational mode of energy is excited, the diatomic molecules dissociate, and the air becomes ionized. These deviations from perfect fluid characteristics result in considerable complication of aerodynamic analyses as compared to the case of low speeds where air temperatures are relatively low and many of the important nondimensional aerodynamic flow parameters are independent of air pressure and temperature.

Practical aerodynamic analyses require a detailed knowledge of flow fields. Since wind tunnels are basic tools for the aerodynamicist and cannot always be operated to provide exact simulation of flight, there is a need for detailed definition of flow parameters in wind tunnels in the range of desirable operating conditions. An early compilation of this type of information was made by the NACA in 1947 (Reference 1). Calculations for these early compilations were based on the assumption that air is a calorically and thermally perfect fluid, as defined under subscript p in the nomenclature.

In 1953 an extension of Reference 1 was published (Reference 2) which included effects of caloric imperfections of air and was thus applicable to higher flight speeds. In the range of air temperatures for which both caloric and thermal imperfections exist, no comprehensive compilation of aerodynamic flow parameters are available. In this range, calculations have been made of normal shock parameters at various altitudes (Reference 3). Also a few of the flow parameters for isentropic expansions in wind-tunnel nozzles have been published in Reference 4.

The purpose of this paper is to present a comprehensive compilation of aerodynamic flow parameters for wind tunnels operating at conditions which might be chosen for practical aerodynamic studies at hypervelocities. Wind-tunnel operating conditions included are total pressures of 100 to 4000 atmospheres and total temperatures of 4000 to 10,000°K. These conditions will allow duplication of ambient atmospheric conditions at altitudes in the range of 100,000 to 350,000 feet at flow velocities of 10,000 to 24,000 feet per second. Calculations include real gas effects and assume the air to be in equilibrium throughout the flow field. An IBM 704 computer was used in making the calculations.

Analysis

Range of Calculations

The range of wind-tunnel operating conditions included in the calculations herein are total pressures of 100 to 4000 atmospheres and total temperatures of 4000 to 10,000°K. The low total temperature limitation was

arbitrarily chosen in order to begin these calculations somewhat above the point where Reference 2 ends. The low pressure and high temperature limitations were selected from consideration of flow freezing of air in the nozzle (failure of the initially dissociated molecules to recombine during expansion to lower temperatures because the rate of cooling is too high). Data of Reference 4 and also results of unpublished work carried out at Sandia Corporation have indicated that flow freezing will become quite significant even before the low pressure limits are reached at temperatures of 6000°K and above. The result of flow freezing is a nonequilibrium mixture of molecules and atoms reaching the test section with severe effects on aerodynamic flow parameters indicated by Reference 4. The high pressure limitation corresponds to the maximum pressure for which high temperature data are available.

One other limit on the range of calculations has been the consideration of 100°K as the minimum-ambient temperature reached during expansions of the flow. This minimum temperature is considerably below the minimum temperature reached in the atmosphere at altitudes below 300,000 feet.

In the above-defined range of total conditions and ambient temperatures, calculations were made of isentropic flow parameters at a nozzle throat and of isentropic and normal shock flow parameters at Mach numbers of 2.0 to 30.0 in increments of 0.5.

Air Properties

A knowledge of air properties through a wide range of conditions is required for determination of the desired aerodynamic flow parameters. Extensive work toward the determination of air properties at high temperatures has been carried out by the National Bureau of Standards and the Cornell Aeronautical Laboratory (References 5-7). It was decided early in this analysis to use high temperature air properties from the latest publication of NBS work (Reference 7) as a basis for calculations.

The data of Reference 7 cover the temperature range of 1500 to 15,000°K. Since air flows of interest herein require a knowledge of air properties at lower temperatures, the next step was to define air properties at temperatures below 1500°K. Two sources were considered for definition of these lower temperature air properties. These were earlier results of NBS work (Reference 8) and equations from NACA work published in Reference 2. It was decided not to use data of Reference 8 because there are some discrepancies between the data therein and the higher temperature data of Reference 7 which would have caused artificial discontinuities in the flow parameters. The NACA work of Reference 2 presents equations for air properties in the desired temperature range which have been used extensively in practical aerodynamic analyses, and it was decided that these would be used in this analysis. Equations used from Reference 2 were those for a thermally perfect-calorically imperfect gas. The equations are as follows:

$$c_p = \frac{\gamma R}{\gamma - 1} \quad (1)$$

$$c_v = \frac{R}{\gamma - 1} \quad (2)$$

$$\gamma = 1 + \frac{\gamma_p - 1}{1 + (\gamma_p - 1) \left[\left(\frac{\theta}{T} \right)^2 \frac{e^{\theta/T}}{(e^{\theta/T} - 1)^2} \right]} \quad (3)$$

$$dH = c_p dT \quad (4)$$

$$dS = c_v \frac{dT}{T} - R \frac{d\rho}{\rho} \quad (5)$$

Reference 2 defines the constants of the above equations as $\theta = 3056^\circ\text{K}$, $R = 3089 \text{ ft}^2/\text{sec}^2\text{-}^\circ\text{K}$ and $\gamma_p = 1.4$.

An examination revealed that the value of the constant R of Reference 2 is quite consistent with that of Reference 7. However, the enthalpies of air presented in Reference 7 at 1500°K are not defined by Equations 3 and 4 when the above values of constants θ and γ_p are used. Consequently, new values of θ and γ_p were calculated which would make Equations 1, 3 and 4 consistent with the data of Reference 7 at 1500°K and also with the normally accepted low temperature value of $\gamma = 1.4$ at 273°K . The new values, $\theta = 2887.42$ and $\gamma_p = 1.40046$, were used in subsequent calculations of air properties at temperatures below 1500°K . A comparison of specific heat ratios obtained using the new constants with values from Reference 2 is presented in Figure 1.

The procedure then used in calculations of air properties was as follows: Equations 1 and 4 were combined to obtain

$$d\left(\frac{H}{R}\right) = \frac{\gamma}{\gamma - 1} dT. \quad (6)$$

Equations 2 and 5 were combined to obtain

$$d\left(\frac{S}{R}\right) = \frac{1}{\gamma - 1} \frac{dT}{T} - \frac{d\rho}{\rho}. \quad (7)$$

Then, using data of Reference 5 for 1500°K as a reference, numerical integrations of Equations 6 and 7 were performed on the IBM 704 to obtain values of enthalpy and entropy as a function of temperature and density. Value of γ were calculated at temperature increments no greater than 30°K from 80°K to 1500°K and values of $\frac{\gamma}{\gamma - 1}$ and $\frac{1}{\gamma - 1}$ were assumed to vary linearly through each increment of temperature.

Calculation Procedure

A decision was made to use an interpolation procedure within tables of air properties previously described to obtain the desired flow parameters. The Lagrangian interpolation formula of Reference 9 was chosen to be used. This formula accomplishes the interpolation on the basis of a curve passing exactly through a series of data points for which values are known. The degree of the polynomial used for curve fitting is $n - 1$ where n is the number of data points used in the interpolation.

In order to determine the degree of curve to be used in interpolations herein, curves of second to seventh degree were checked for interpolation accuracy at representative locations in the tables of Reference 7. The largest interpolation inconsistencies were found in interpolations of enthalpy versus temperature at low densities and at temperatures in the vicinity of 2000°K . For these conditions the enthalpy interpolation inconsistency decreased from about two-thirds percent with second degree interpolation to one-eighth percent with seventh degree interpolation. The consistency of interpolations for other air properties was considerably better than for enthalpy. It was decided that one-eighth percent consistency would be adequate and that seventh degree interpolation would be used.

To use the IBM 704 computer for required interpolations it is necessary that data in the range of interpolations be available to the machine. Examination revealed that the data storage capacity of the Sandia

Laboratory computer was not adequate for storage of the complete tables of air properties to be used in calculations. It was thus decided to store air properties data on magnetic tape and read it into the machine as required. Data were read into the machine in blocks of eight pages (temperatures) from Reference 7 and from results of previously described low temperature calculations. The program used for the calculations was such that eight data points would always be used for interpolation and where possible four of the data points would lie on each side of the value for which interpolation was required.

Isentropic Expansion

The first step of the program was to make interpolations to determine density, compressibility factor, enthalpy, and entropy at the selected stagnation temperature and pressure. Then, at each temperature below stagnation for which data were available, interpolations were made to determine density, compressibility factor, and enthalpy at the initial value of entropy. Values thus obtained correspond to an isentropic expansion from stagnation conditions to the pertinent temperature.

From the equation for continuity of energy,

$$H_t = H + \frac{1}{2} U^2, \quad (8)$$

together with the total enthalpy and the enthalpy after isentropic expansion to the pertinent temperature, a velocity was calculated. The speed of sound was calculated from the following equations from Reference 7:

$$a = \sqrt{\alpha R T Z} \quad (9)$$

where

$$\alpha = 1 + \frac{1}{Z} \left(\frac{\partial Z}{\partial \ln \rho} \right)_T + \frac{Z \left[1 + \frac{1}{Z} \left(\frac{\partial Z}{\partial \ln T} \right)_\rho \right]^2}{\left(\frac{\partial (E/R)}{\partial T} \right)_\rho} \quad (10)$$

$$E/R = T (H/RT - Z). \quad (11)$$

(Subscript T indicates the partial is evaluated at a specified temperature, and subscript ρ indicates the partial is evaluated at a specified density.)

In Equation 10 the partial derivatives were evaluated by using the interpolation routine to obtain values of Z or E/R at the value of the variable of interest and at one closely spaced interval on either side of this value, then calculating the slope from a second-degree curve passing through these three closely spaced points. From the velocity and speed of sound thus obtained, a Mach number was calculated.

After calculation of the above parameters at each temperature for which air property data were available, the air properties at the throat of a nozzle were calculated as follows. The point at which the velocity density product is maximum during the expansion was specified as the criterion for defining the nozzle throat. The velocity density product was calculated from previously defined flow parameters at the first temperature below stagnation and at each successively lower temperature. This procedure was repeated until the vicinity of the throat was determined. Values of ρU at eight temperatures in the vicinity of the throat were used to interpolate for determining three values of ρU at 10-degree temperature increments in the immediate vicinity of the throat. The temperature at maximum ρU was then obtained by calculating the point of zero slope of a second-degree curve passing through the three points thus obtained. Values of each of the previously defined flow parameters were then used for interpolation to determine the value at the throat temperature. A nozzle area ratio at each

temperature of the isentropic expansion was obtained from the equation for continuity of mass:

$$(\rho UA)^* = \rho UA. \quad (12)$$

Values of the various isentropic flow parameters at the desired Mach number were calculated by interpolation using values previously obtained.

Normal Shock

Normal shock flow parameters were obtained by using the basic equations for continuity of mass, momentum, and energy in conjunction with air properties data. Continuity of energy is defined by Equation 8a and continuity of mass and momentum are defined by Equations 12a and 13.

$$H_t = H_2 + \frac{1}{2} U_2^2 \quad (8a)$$

$$\rho_1 U_1 = \rho_2 U_2 \quad (12a)$$

$$p_1 + \frac{\rho_1 U_1^2}{g} = p_2 + \frac{\rho_2 U_2^2}{g}. \quad (13)$$

In early program checks it was found that the resolution of the enthalpy parameter (H/RT) presented in Reference 7 corresponds to a resolution of approximately 1000 to 3000 ft²/sec² in values of enthalpy. In some cases this resolution can result in significant inaccuracies in determining U_2 and inconsistencies in simultaneous solution of the three continuity equations. In order to reduce the magnitude of inconsistencies, an iteration process was used in conjunction with the usual interpolation routine. In these calculations a value of the density parameter $\log \rho/\rho_0$ to the nearest 10^{-5} was obtained for which the interpolation to obtain H/RT indicated satisfaction of Equations 8a and 12a. At this value of the density parameter the usual interpolation routine was used for calculating other air properties. Also at this point the difference between the pressure defined by the air properties and the pressure defined by continuity of momentum was calculated. This procedure was started at the first temperature below initial total temperature and repeated at successively lower temperatures until the pressure difference changed sign, indicating that the temperature corresponding to simultaneous solution of the three continuity equations had been crossed over.

After thus determining the approximate temperature at which the three continuity equations were satisfied, air properties at conditions satisfying continuity of mass and momentum were obtained by the above described procedure at eight temperatures in the vicinity of the crossover. A similar iterative interpolation routine was then followed to determine the temperature to the nearest 0.1°K which satisfied the continuity of momentum and thus complete solution of the flow through a normal shock. Interpolations were then made to determine the required air properties at this temperature.

The basis for determining total conditions downstream of a normal shock was the specification of a constant entropy compression from the conditions downstream of the shock to zero velocity at the initial total enthalpy. Beginning at the first temperature below initial total temperature, interpolations were made to obtain entropy at the initial total enthalpy. This process was repeated until the approximate temperature at which the entropy downstream of the normal shock was located. Air properties at the initial total enthalpy at eight temperatures in this vicinity were obtained by interpolation. Then another set of interpolations was made to obtain the properties at the desired entropy, representing total conditions downstream of the shock.

Reliability Checks

At several points in the calculations for each expansion or each final data point, checks were made to determine the consistency of results obtained from a series of interpolations. In all cases, the results indicated consistency of better than 0.1 percent. Consistency checks made were the following:

In the isentropic expansion at each temperature, a separate interpolation was made to obtain each of the air properties at the point where entropy was equal to the value at the selected total temperature and pressure. Properties thus obtained were used to calculate the velocity-density product (ρU). Values of velocity-density product thus obtained were used for determining the maximum value of ρU corresponding to the nozzle throat and the air temperature at this point. Another set of interpolations was made to determine the individual air properties at the throat temperature and another value of ρU obtained from these air properties. The two values of ρU at the throat were compared for consistency.

In the isentropic expansion, individual air properties obtained by interpolation at each temperature were used in a second interpolation routine to obtain air properties at each desired Mach number. The total enthalpy indicated by velocity and ambient enthalpy thus obtained at each Mach number was compared for consistency with total enthalpy calculated initially.

Following the procedure previously described for normal shock calculations, pressure and enthalpy from the individual air properties finally calculated were compared with values obtained from the continuity equations for consistency.

After completion of calculations of the desired aerodynamic flow parameters and the rounding off of these parameters for presentation herein, a final consistency check was made. Various tabulated pressure ratios were compared with values indicated by tabulated density, temperature, compressibility factor, and the equation of state. Also, tabulated total enthalpies were compared with values indicated by tabulated ambient enthalpies, tabulated velocities, and the energy equation. These checks indicated consistencies of better than 0.2 percent.

Ratios of many of the flow parameters presented herein to corresponding parameters for perfect gas were calculated. These parameters were then plotted versus Mach number in groups of all stagnation pressures for one stagnation temperature. These plots indicated consistent variations of the parameters with both Mach number and pressure.

In addition to the above-described internal checks, results were compared with available data from other sources.

In Reference 4 are presented calculations of equilibrium isentropic expansions from total temperatures of 4000 to 8000°K at some of the stagnation pressures considered herein. The ambient temperatures for which expansion calculations were made in Reference 4 in several cases correspond to similar calculations of this report. In these cases, including 224 expansions from 10 stagnation conditions, comparisons were made between the two sets of data. The maximum deviations of data contained herein from that of Reference 4 were as follows:

<u>Parameter</u>	<u>Maximum percent deviation</u>
ρ	-7.49 to +4.04
p	-7.53 to +4.14
U	-1.20 to +0.74
M	-0.96 to +1.89
A/A*	-3.84 to +8.16

An examination of the pattern of the deviations indicated two facts. At all stagnation temperatures, the larger deviations occurred in results for expansions to the lower temperatures. Deviations at the higher temperatures were not of significance except in the case of expansions from 8000°K. These facts are indicated by a comparison of the following table with the above table. The following table includes maximum deviations obtained when expansions from stagnation temperatures of 8000°K and expansions to temperatures below 800°K are eliminated:

<u>Parameter</u>	<u>Maximum percent deviation</u>
ρ	-1.19 to +1.35
p	-2.17 to +1.00
U	-0.31 to +0.49
M	-0.96 to +0.98
A/A*	-0.94 to +0.74

In the above table it can be seen that deviations are of little significance. The pattern of the deviations indicate that the air properties used for calculations of Reference 4 differ appreciably from those used herein at temperatures below 800°K and at 8000°K. As previously mentioned for calculations herein, the latest Bureau of Standards air properties data were used directly for calculating flow parameters at and above 1500°K and were used as a reference for defining lower temperature air properties required in the calculations.

In Reference 3 results of calculations of normal shock flow parameters are presented for flight through the atmosphere at several selected altitudes. Each of the 33 sets of stagnation conditions considered herein corresponds to flight simulation at some Mach number and altitude. Of these, 27 correspond to simulated altitudes in the range of Reference 3. For these cases, comparisons were made between data of Reference 3 and that contained herein. Results of these comparisons are as follows:

<u>Parameter</u>	<u>Maximum percent deviation</u>
p_2	-0.66 to +1.80
ρ_2	-1.42 to +2.08
T_2	-3.19 to +1.39
M_2	-1.99 to +0.94

Considering the fact that these comparisons required the use of faired curves of Reference 3, the above deviations are not considered significant. It is noted that air properties data used in Reference 3 were from Reference 5 in which the air model is not as exact as that of Reference 7 used herein.

Presentation of Results

Aerodynamic flow parameters obtained from calculations discussed herein are presented in Table I. An index to the table is presented on page 18, and definitions of flow parameters of the table are presented on page 19. Air properties at the selected temperature and pressure in the stagnation chamber are listed at the top of each page of the tables. The first line in the data list includes flow parameters at the nozzle throat. The following lines include isentropic expansion and normal shock flow parameters for Mach numbers of 2.0 and above in increments of 0.5. At the bottom of each page are presented the altitude and Mach number for which flow parameters of flight are duplicated in the wind tunnel with the selected total pressure and temperature.

In addition to the tables, representative plots have been prepared to illustrate the real gas effects on various aerodynamic flow parameters. Figure 2 illustrates the variation of ratios of real to perfect gas flow parameters with Mach number for various total temperatures at a total pressure of 500 atmospheres. Figure 3 illustrates variations of these ratios with Mach number for various total pressures at a total temperature of 7000°K.

An important point clearly indicated by data of Figures 2 and 3 is the wide range of variations of real gas effects on the various flow parameters. Of the parameters included in Figures 2 and 3, the real gas effects in the range of conditions considered vary from a few percent to more than two orders of magnitude.

LISTED IN TABLE I

T_t	Total temperature in stagnation chamber and in isentropic expansion, °K
p_t	Total pressure in stagnation chamber and in isentropic expansion, atmospheres
ρ_t	Total density in stagnation chamber and in isentropic expansion, atmospheres
H_t	Total enthalpy, ft ² /sec ² -°K
Z_t	Compressibility factor in stagnation chamber, mols of air at elevated temperature per mol of air at reference pressure and temperature
S/R_t	Ratio of entropy in stagnation chamber and in isentropic expansion to the universal gas constant
M	Mach number of the flow
U	Velocity of the flow
p/p_t	Ratio of static to total pressure
ρ/ρ_t	Ratio of static to total density
T/T_t	Ratio of static to total temperature
q/p_t	Ratio of dynamic to total pressure
A/A^*	Ratio of local cross-sectional area of nozzle to area at throat
H/H_t	Ratio of ambient to total enthalpy
ρU	Velocity density product, lb/ft ² -sec
Z	Compressibility factor at ambient conditions of the flow
M_2	Mach number downstream of a normal shock
U_2/U_1	Velocity ratio across a normal shock
p_2/p_1	Static pressure ratio across a normal shock
ρ_2/ρ_1	Static density ratio across a normal shock
T_2/T_1	Static temperature ratio across a normal shock
H_2/H_1	Static enthalpy ratio across a normal shock
Z_2	Compressibility factor at ambient conditions downstream of a normal shock
p_{t2}/p_t	Ratio of total pressures across a normal shock
ρ_{t2}/ρ_t	Ratio of total densities across a normal shock
T_{t2}/T_t	Ratio of total temperatures across a normal shock
Z_{t2}	Compressibility factor at total conditions downstream of a normal shock
p_{t2}/p_1	Ratio of total pressure downstream of a normal shock to static pressure upstream of the shock
S/R_2	Ratio of entropy downstream of a normal shock to universal gas constant

TABLE I
Mach Functions

 $T_t = 4000^\circ\text{K}$
