Processes of importance in the coloration of solids by x-radiation are discussed on the basis of Seitz's hypothesis that vacancies are created at jogs on dislocations or at other imperfections. The interaction between F centers and dislocations is calculated, and it is shown that F centers located within about 50Å of edge-type dislocations would experience measurable broadening and perhaps shifting of their absorption peaks, in contradiction of experiment. From the available energy in the form of point thermal pulses, it is shown that most vacancies freed from jogs or other sources probably make less than a thousand atomic jumps during x-irradiation at He temperatures and hence are unable to diffuse more than about 100Å from their sources. The tunneling of F-center electrons to positive-hole centers is calculated, and it is concluded that tunneling can occur with high probability over a distance of ~30Å by an electron in its ground state, ~40Å in its first excited state. Such tunneling is important in limiting local F- and V-center concentrations even at He temperature in the dark. Crystals achieving macroscopic concentrations of the order 10^{18} cm^{-3}, it is concluded, must contain very high densities of vacancy sources to be consistent with the requirements of both the large tunneling range and the small diffusion distance. THEORY OF CONCENTRATION QUENCHING IN INORGANIC PHOSPHORS, by D. L. Dexter and J. H. Schulman. Feb. 8, 1954 [8] p. incl. illus. refs. (In cooperation with Naval Research Lab., Washington, D. C.) (AFOSR-TN-54-23A) (AF 18(600)688) AD 42586
Unclassified

Also published in Jour. Chem. Phys., v. 22: 1063-1070, June 1954.

A theory is presented for concentration quenching in solid systems, based on the migration of excitation energy from one activator center to another and eventually to an imperfection which may act as an energy sink. Calculations are made on the dependence of the fluorescence yield on concentration, and to indicate typical activator concentrations at which appreciable quenching may be expected to occur. If the transition in the activator is of the electric dipole or electric quadrupole type, appreciable quenching may arise when the activator concentration is 10^{-3} to 10^{-2}; if it is a magnetic dipole transition, transfer will occur by exchange, rather than by overlapping of magnetic dipole fields, and the critical concentration will be of the order of a few percent. The implications of transfer phenomena upon the observed absence of luminescence in most "pure" inorganic crystals are discussed, and it is concluded that transfer rates are so high in strongly absorbing crystals that the energy can easily migrate to a very few sinks dispersed throughout the lattice. ON THE SHAPES OF ABSORPTION AND EMISSION LINES OF IMPURITIES IN SOLIDS, by D. L. Dexter. Aug. 1954, 5p. (In cooperation with Naval Research Lab. Solid State Div., Washington, D. C.) ([AF]OSR-TN-54-192) (AF 19(600)688) AD 46175 Unclassified

Also published in Phys. Rev., v. 96: 615-616, Nov. 1, 1954.

Existing ireatments of band shapes in solids, for the simplest impurity centers, predict Gaussian shape functions. These trealmenis assume for simplicity that the electronic matrix element is independent of the nuclear wave functions, and that the energy width of the band is negligible compared with ihe energy of the mtdpoint of the band. We estimate here the expected magnitude of the effect of correciing these assumptions in iypical cases, and find ihai the emtssion or absorption band may deviate from a Gausstan by iwenty per cent or more on the wings. TUNNELING OF ELECTRONS IN ALKALI HALIDES (Abstract), by D. L. Dexter. [1954] 1p. (AF 18(600)-688) Unclassifted

Presented at meeting of ihe Amer. Phys. Soc., Columbia U., New York, Jan. 28-30, 1954.

Published in Phys. Rev., v. 94: 771, May 1, 1954.

The tunneling of electrons from F-centers to hole-centers is calculated for the ground and excited states, and the accompanying bleaching is discussed. Tunneling ranges of 30 and 40 Å are found, corresponding to saturation concentrations of about 10^{19} per cm^3 if the F- and V-center distributions interpenetrate. The effect of an electric field is examined, and applications of the theory are made to experiments by Maurer and coworkers on optical and thermal bleaching in the presence of a field. Implications are discussed of tunneling phenomena on the x-ray coloration of crystals at low temperatures, and it is concluded that tunneling represents an important back-reaction for limiting local color-center concentrations. CRITERION FOR THE OCCURRENCE OF LUMINESCENCE, by D. L. Dexter, C. C. Klick, and G. A. Russell. May 1955, 4p. incl. diagrs. refs. (Technical rept. no. 9) (AFOSR-TN-55-174) (AF 18(600)688) AD 81839 Unclassifled

Also publtshed in Phys. Rev., v. 100: 603-605, Oct. 15, 1955.

A mechanism is suggested for the non-radiative quenching of excited states of simple impurity centers, namely, a cross-over to the ground electronic state of the center tmmedtately after excitation and before thermal equilibrium has had time to come about. It is proposed that this mechanism is responsible for the absence of strong luminescence in some impurity and color centers, e.g., the F-center in alkali halide crystals. The quenching process proposed here is applicable only for certain geometries of the configuration coordinate diagram, which are discussed with a view to a criterion for strong luminescence. The quenching mechanism is consistent with known configuration coordinate curves, and leads to a prediction which is experimentally verified, to the effect that the wavelength of emitted radiation is not more than twice that of the light absorbed by the center The same mechanism shows the possibility of photoconductivity arising from absorption in discrete lines even at low temperatures. Presented at meeting of the Amer. Phys. Soc., Pittsburgh, Pa., Mar. 15-17, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series tt, v. 1: 110-111, Mar. 15, 1956.

Also published in Jour. Opt. Soc. Amer., v. 46: 443-448, June 1956.

An tnvestigation was made of the spectral distrtbution in CdS crystals and the temperature dependence on the quenching of the photoconductivity in the crystals. Of the 2 quenching bands which are resolved at room temperature in pure crystals, the 1.4-μ band was no longer resolved at -75°C and lower, although some quenching was observed at -185°C. In Cu-doped crystals, only 1 quenching band was observed at 1.4μ, and this completely disappeared at temperatures below -80°C. Results implied that the quenching process at 1.4μ involves the excitation of trapped holes and the thermal ionization of excited holes. The quenching peak at 0.9μ remained at -185°C in pure crystals, and the quenching efficiency was reduced to some extent. The addition of tR radiation to green light on CdS crystals caused an initial transient increase in photoconductivity in the crystals followed by a decay. Data showed that the transient increase in photoconductivity on the application of IR radiation was caused hy the temporary increase of conduction electrons created by IR light which ejects trapped electrons from traps into the conduction band. ([AF]OSR-TN-55-402) (Technical note no. 11 under AF 18(600)688 and technical note no. 5 under AF 18(600)-193) AD 79513 Unclassified

Presented at meeting of the Amer. Phys. Soc., Pittsburgh, Pa., Mar. 15-17, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 113, Mar. 15, 1956.

Also published in Jour. Chem. Phys., v. 24: 161, Jan. 1956.

V-centers have been produced in thin films (300 Å to 600 Å) of KI and KBr by evaporating the alkali halide and a halogen simultaneously onto a quartz substrate held at low temperature. The concentration of these centers was of the order of $10^{20}/cm^3$. A study of the films shows that the V-bands depend only on the alkali halide, not on the halogen. As a result, KI + I_2 has the same band structure as KI + Br_2. This fact tends to support the vacancy models of the V-centers suggested by Seitz and others. (Contractor's abstract)

ABSORPTION CROSS SECTION FOR LIGHT IN PERFECT SOLIDS (Abstract), by D. L. Dexter. [1955] [1]p. [AF 18(600)688] Unclassified

Presented at meeting of the Amer. Phys. Soc., Mexico City (Mexico), Aug. 29-31, 1955.

Published in Phys. Rev., v. 100: 964, Nov. 1, 1955.

The interactions of an atom with its neighbors in an idealized solid are taken into account explicitly in treating the absorption of light, as contrasted with the usual introduction of an "effective" field and mass. It will be shown that in simple cases the total cross section of an atom in a given absorption line j is uninfluenced by the dipole coupling with the same transition in neighboring atoms of density n, although the transition probability per atom is increased by the factor

$$[1 + (\pi n/3)2e^2 \langle r_j \rangle^2 / e_j]^2.$$

Thus the "effective fields" for polarization, for absorption cross section, and for transition probability are all different. Additional correction terms arise from transitions $I \neq j$ in the neighbors, from exchange and overlap effects, and from higher multipole effects. These additional effects are in general important.

BITTER MAGNETS IN GRAPHITE SINGLE CRYSTALS, by N. N. Axelrod. Apr. 1956 [11]p. incl. diagrs. (Technical note no. 13) (AFOSR-TN-56-180) (AF 18-(600)688) AD 87053 Unclassified

Presented at meeting of the Amer. Phys. Soc., Pittsburgh, Pa., Mar. 15-17, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 119, Mar. 15, 1956.

A discussion is presented on the presence of screw dislocations, in single graphite crystals, with their axes along the direction of high resistivity. This anisotropy provides low resistivity paths in the c direction of these crystals. The magnetic field arising from a helical current flow was calculated by making use of a theorem by O. Bottema (Physica v. 8: 703, 1941) for the radial and vertical components of the magnetic field associated with currents in finite solenoids. A suggestion was made that it may be feasible to detect the magnetic field by using suspensions of ferromagnetic powders.

SOLID STATE LUMINESCENCE THEORY AND OSCILLATOR STRENGTHS IN KCl:Tl, by R. S. Knox and D. L. Dexter. June 1956 [32]p. incl. diagrs. tables, refs. (Technical note no. 14) (AFOSR-TN-56-405) (AF 18(600)688) AD 96213 Unclassified

Also published in Phys. Rev., v. 104: 1245-1262, Dec. 1, 1956.

The existing quantitative treatment by Williams (Jour. Chem. Phys. v. 19: 457, 1951) of the Seitz model (Jour. Chem. Phys., v. 6: 150, 1938) for the KCl:Tl luminescent system has been extended to include a prediction of the oscillator strengths of the 1960Å and 2475Å absorption lines. These f values are simply related to those of the associated free-ion transitions. In the course of the computations, it is found that the best available Tl+ wave functions are inaccurate for the free ion and are therefore not of great value for the KCl:Tl center. Free-ion oscillator strengths are (a) computed with these

functions, and are (b) estimated by analysis of experimental spectra. The results of both methods, when modified for KCl:Tl, are in poor agreement with experimental f values in the solid. A review and critique are given for the present Williams dynamical treatment of the Seitz-Williams model. It is concluded that a sensitive test for the model would be its successful prediction of the ratio of these (1960 and 2475Å) oscillator strengths in KCl:Tl. The observed values are from 3 to 5 times as large as the predicted value. It is decided that the KCl:Tl problem is not as well understood as it has been believed, since the existing quantitative theory: (a) is subject to considerable arbitrariness in the construction of excited-state configurational coordinate curves, (b) appears to be in fortuitous agreement with experiment insofar as its quantitative predictions depend on Tl^+ wave functions, and (c) does not, in this sample extension, predict the observed ratio of oscillator strengths corresponding to the electronic transitions assumed responsible for the behavior of the center. OSCILLATOR STRENGTHS IN THE KCl:Tl PHOSPHOR, (Abstract), by R. S. Knox and D. L. Dexter. [1956] 1p. (AF 18(600)688) Unclassified

Presented at meeting of the Amer. Phys. Soc., Pittsburgh, Pa., Mar. 15-17, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 112, Mar. 15, 1956.

Wave functions calculated by Hartree without exchange are used to compute energy levels and oscillator strengths in the $^{1,3}P_1 - {}^1S_0$ transitions in free Tl^+. The results will be compared with measured f values in the iso-electronic Hg atom and those of the corresponding transitions in the KCl:Tl luminescent center. In our perturbation approximation the ratio g of f(forbidden) to f(allowed) is independent of the dipole matrix element and is simply related to the spin-orbit matrix element H_1. Values of H_1 and f in Hg indicate that for the free ion the wave functions are too diffuse, i.e., too small at small distances and too large at distances of importance in luminescence theory ($\sim 3a_0$). Implications of the lack of agreement between calculated and observed values of f and g will be discussed with a view to assessing the validity of the usual model for the KCl:Tl center. RESISTIVITY FROM CLUSTERED VACANCIES IN COPPER (Abstract), by D. L. Dexter. [1956] 1 p. (AF 18(600)688) Unclassified

Presented at meeting of the Amer. Phys. Soc., Pittsburgh, Pa., Mar. 15-17, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 114, Mar. 15, 1956.

The excess resistivity and stored energy associated with clusters of vacancies, i.e., cavities, are calculated for copper on the basis of a simple model; the cavities are assumed spherical and shielding effects are neglected so that the results are valid only for clusters of more than 10^2 vacancies. The evidence for the existence of cavities, the results of the present calculations, and comparison with other scattering entities will be presented, and the implications discussed. It appears probable that, in copper heavily cold worked at nitrogen temperatures, a large fraction, of the order one-half, of the energy expended is stored in the form of vacancies, many of which cluster into cavities upon warming to room temperature. Vacancies formed by radiation damage seem to behave similarly. (Contractor's abstract)

METHOD OF INTEGRATION FOR SUPERSONIC FLOW BEHIND AN ATTACHED SHOCK-WAVE, by L. Broglio. Mar. 1955, 114p. incl. diagrs. tables. (Technical rept. no. 1; SIARgraph no. 3) [AFOSR-TN-55-450] (AF 61(514)431) AD 80172 Unclassified

The fluid field behind a shock wave attached to the sharp nose of a body of whatsoever form is analyzed. The solution is expanded into a series of powers r^n of the distance r from the apex: every term of the series is shown to be independent of the successive ones, and the solution results from the superposition, to a non-linear field (field around a cone), of successive linear fields (Part I). In particular, attention is devoted to a body little different from one of revolution, and the procedure is shown in this case to reduce to the step-by-step integration of a certain number of ordinary differential equations of the 2nd order (Part II). In Part III, the rules and the explicit formulas are given for the step-by-step integration of the equations that result from the analysis of Parts I and II. Finally, in Part IV, numerical examples are developed. Tables and graphs are included, (Contractor's abstract, modified)

A NOMOGRAPH ON THE PROBLEM OF COMBUSTION INSTABILITY IN LIQUID-PROPELLANT ROCKET MOTORS, by C. C. Ross and P. P. Datner. Final

rept. June 4-Dec. 31, 1953, 66p. incl. illus. diagrs. tables, refs. ([AF]OSR-TR-54-2) (AF 18(600)799) Unclassified

Published in part in Selected Combustion Problems, Cambridge U. (England) (Dec. 7-11, 1953), London, Butterworths Scientific Publications, 1954, p. 352-402.

Three different types of combustion instability in liquid-propellant rocket engines – the low-frequency "chugging," the high-frequency "screaming," and the low-frequency "divergent" type – are briefly described. The pertinent information available in the literature is reviewed, and the problems encountered in securing reliable experimental data on the phenomena, using conventional instrumentation, are discussed. A discussion of low-frequency instability, resulting from the interaction of propellant feed system oscillations and combustion gas vibrations, is given, based on available test results. Some data on high-frequency combustion oscillations are presented, indicating that the vibrations of the combustion gases correspond to the propagation of finite pressure disturbances in the combustion chamber, which appear to originate in the combustion zone. The modes of combustion gas oscillations of both high and low frequencies are described as similar to those of acoustic oscillations taking place in cavity resonators, and as maintained by the interaction between the rates at which propellants are consumed and fluctuations in combustion chamber pressure, resulting in strong reactive shock waves. It is noted that combustion oscillations may be excited by disturbances of the random noise type, inherent in the combustion, or by a shock such as a "hard start." It is pointed out that all published theories on the phenomena agree on two principles. (1) The oscillations of combustion gases are maintained by periodic variations in the propellant consumption rate, resulting in a periodicity in the rate of heat release. All theories are based on Rayleigh's principle that vibration in a confined mass of gas can be maintained by periodic heat release if variations in heat release and in pressure oscillations are in phase, but that the oscillations will be impeded if the fluctuations in heat release and pressure are out of phase. (2) The significance of the combustion time lag with respect to combustion instability is generally recognized, and the rocket engines under discussion are considered to be dynamic systems with delay reaction because of this inherent time lag. It is shown that the Nyquist criterion of stability could be applied successfully for predicting the dynamic behavior of rocket systems if sufficient data were available concerning the physical and chemical kinetics of the conversion of propellants into burned gases in the combustion chamber. (Contractor's summary)

COMBUSTION PROBLEMS IN LIQUID-FUEL ROCKET ENGINES, by S. S. Penner and P. P. Datner. [1955] [19]p. incl. diagrs. table, refs. (AF 18(18(700)799) Unclassified

Published in Fifth Symposium (International) on Combustion, Pittsburh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y., Reinhold, 1955, p. 11-29.

Brief discussions of theoretical estimates for motor performance based on thermodynamics, the relation between nozzle flow characteristics and performance, and general rocket engines introduce a review of fundamental studies investigating the burning characteristics of simple heterogeneous systems. Engineering problems in rocket engine combustion are then reviewed. The consideration of basic work on heterogeneous combustion discusses the burning of single droplets, of fuel sprays and of monopropellants in tubes, carbon formation, and laboratory measurements of ignition delay. The review of engineering problems treats the following: design difficulties associated with ignition failure, shutdown and flame-out problems regarding peak pressures during transient operation, combustion chamber volume requirements and their relation to possible rate-controlling reaction steps, combustion oscillations, as well as motor scaling and similarity analysis.

ON THE INFLUENCE OF THE GEOMETRY OF SLENDER BODIES OF REVOLUTION AND DELTA WINGS ON THEIR DRAG AND PRESSURE DISTRIBUTION AT TRANSONIC SPEEDS, by F. Keune and K. Oswatitsch. 1955, 34p. incl. diagrs. tables, refs. (Technical rept.) ([AF]OSR-TN-55-364) (AF 61(514)-811) AD 80178 Unclassified

A theory of the transition from subsonic to supersonic flow was applied to an entire body of revolution of finite length, and the lower and upper critical Mach numbers were calculated. These results were compared with supersonic values. The drag of the afterbody (behind the maximum thickness) at M = 1 is shown to be practically equal to the whole supersonic drag of this part. Even the linear supersonic theory holds for all supersonic Mach numbers. The small subsonic region on the tip at the upper critical Mach number has no appreciable influence.

LOCALIZATION ON SPHERES, by V. L. Shapiro. July 2, 1956, 15p. (AFOSR-TN-56-311) (AF 18(600)-1595) AD 94846 Unclassified

Also published in Trans. Amer. Math. Soc., v. 86: 212-219, Sept. 1957.

The main result is given by the following theorem:

Let $S \sum_{n=1}^{\infty} Y_n(x)$ be a series of surface spherical

RUT. 01:002 - RUT. 03:001

harmonics with $Y_n(x) = 0(n^\beta)$, $\beta \geq 0$, uniformly for x on Ω. Let F be the Riemann function associated with S. Then if F is of class C^{2w} on a domain D contained on Ω, S is uniformly (C, α) summable, $\alpha > p + 2w$, to $\Delta^w F$ in every closed domain contained in D. Before proving the main result, 3 lemmas dealing with trigonometric series, and 3 lemmas dealing with surface spherical harmonics are proved. The main theorem is proved by the Heine-Borel theorem, showing that if $D(x_0, h_1)$ is contained in D, then S is uniformly (C, α) summable $\Delta^w F$ for x in $D(x_0, h_1)$. The operator Δ^w is defined by $\Delta^w = \Delta(\Delta^{w-1})$, where Δ is the Laplace operator on Ω, the unit (k-1)-dimensional sphere in Euclidean k-space.

EFFECTS OF DIFFUSION ON FREE PRECESSION IN NUCLEAR RESONANCE EXPERIMENTS, by H. Y. Carr and E. M. Purcell. Jan. 19, 1954 [9] p. incl. illus. diagrs. (In cooperation with Harvard U. Lyman Lab. of Physics, Cambridge, Mass.) (In its Annual Research Report, no. 8, Sept. 1, 1954; AD 48577) [AFOSR-TN-54-27] (Sponsored jointly by Office of Naval Research, Atomic Energy Commission, The Radio Corp. of America, Rutgers U. Research Council, and [Air Force] Office of Scientific Research under AF 18(600)975) AD 48577(e) Unclassified

Also published in Phys. Rev., v. 94: 630-638, May 1, 1954.

Nuclear resonance techniques involving free precession are examined, and, in particular, a convenient variation of Hahn's spin-echo method is described. This variation employs a combination of pulses of different intensity or duration ("90-degree" and "180-degree" pulses). Measurements of the transverse relaxation time T_2 in fluids are often severely compromised by molecular diffusion. Hahn's analysis of the effect of diffusion is reformulated and extended, and a new scheme for measuring T_2 is described which, as predicted by the extended theory, largely circumvents the diffusion effect. On the other hand, the free precession technique, applied in a different way, permits a direct measurement of the molecular self-diffusion constant in suitable fluids. A measurement of the self-diffusion constant of water at 25°C is described which yields $D = 2.5\ (\pm 0.3) \times 10^{-5}$ cm^2/sec, in good agreement with previous determinations. An analysis of the effect of convention on free precession is also given. A null method for measuring the longitudinal relaxation time T_1, based on the unequal-pulse technique, is described. BLOCH EQUATIONS WITH DIFFUSION TERMS, by H. C. Torrey. May 8, 1956, 7p. (AFOSR-TN-56-182) (AF 18(603)6) AD 87055 Unclassified

Presented at meeting of the Amer. Phys. Soc., New Haven, Conn., June 21-12, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 282, June 21, 1956.

Also published in Phys. Rev., v. 104: 563-565, Nov. 1, 1956.

The phenomenological Bloch equations in nuclear magnetic resonance are generalized by the addition of terms due to the transfer of magnetization by diffusion. The revised equations describe phenomena under conditions of inhomogeneity in magnetic field, relaxation rates or initial magnetization. As an example, the equations are solved in the case of the free precession of magnetic moment in the presence of an inhomogeneous magnetic field following the application of a 90° pulse with subsequent applications of a succession of 180° pulses. The spin-echo amplitudes agree with the results of Carr and Purcell (Phys. Rev., v. 94: 630, 1954) from a random walk theory. (Contractor's abstract)

REDUCTION OF RELATIVISTIC TWO-PARTICLE WAVE EQUATIONS TO APPROXIMATE FORMS. II, by Z. V. Chraplyvy. Sept. 18, 1953, 18p. incl. diagrs. (Technical rept. no. 1) (AF 18(600)789) AD 18908 Unclassified

Also published in Phys. Rev., v. 92: 1310-1315, Dec. 1, 1953.

A method of reducing 2-particle relativistic wave equations is presented which is free of the mass restriction $m_1 m_2$. In a discussion of the matrices involved, the postulate of an even-even transformed Hamiltonian is dropped, and the less stringent requirement of a uU-separating or an 1L-separating H_{Tr} leads to a whole class of usable transformation is calculated in detail. Different transformations give different expressions for H_{Tr}, but they coincide after the Dirac matrices β^{I} and β^{II} are replaced by 1 or -1. Consequently, the reduced wave equation is the same in all cases. (ASTIA abstract)

REDUCTION OF RELATIVISTIC TWO-PARTICLE WAVE EQUATIONS TO APPROXIMATE FORM, by Z. [V.] Chraplyvy and F. [N.] Glover. Aug. 16, 1954, 85p. incl. diagrs. refs. (Technical rept. no. 2) (AF 18(600)789) AD 57906 Unclassified

In a system of 2 particles (even without an external field), the field by which they interact with each other plays an essential role; however, it is convenient to have at least an approximate description of this interaction in terms of quantities referring to the particles rather than to the field itself. A 2-particle equation (approximately relativistic), yielding such a description, has been established by Breit (Phys. Rev., v. 34: 553, 1929; Ibid., v. 36: 383, 1930; Ibid., v. 39: 616, 1932). More recently Salpeter and Bethe gave a 2-particle equation based on the Feynman formalism of quantum electrodynamics. Any of these 2-particle equations has 16 components which may be reduced to a simplified form consisting of only 4 components. The development of reduction method, analogous to that of Foldy and Wouthuysen (F-W) is the aim of this study. investigation indicated that this would entail more than just a formal generalization of the 1-particle method of (F-W). There is found to exist a whole class of applicable transformations, which, however, when followed by an adequate cut in the equations, furnish the same final form of the reduced equation. The search for such transformations must be based on a study of the properties of 16- by 16-matrices which is given in Chapter I. In Chapter II, a summary of the F-W method is presented in order to secure suitable starting points for the extensions and generalizations developed in Chapter III, "Transformation of a 2-Particle Equation," and in Chapter IV, "Reduction of the 2-Particle Case." In the remaining chapters of this study, the method is applied to the Breit equation, to the Salpeter-Bethe equation, and to an amplified Breit equation.

REDUCTION OF RELATIVISTIC TWO-PARTICLE WAVE EQUATIONS TO APPROXIMATE FORMS, by Z. [V.] Chraplyvy and F. [N.] Glover. Final rept. Aug. 16, 1955, 54p. incl. diagrs. tables, refs. (Technical rept. no. 3) ([AF]OSR-TN-55-238) (AF18-(600)789) AD 71406 Unclassified

Previous studies are continued on a reduction method for 2-particle equations analogous to that of Foldy and Wouthuysen (Phys. Rev., v. 78: 29, 1950). Consideration is given to the amplified Breit equation, and a new formulation of the large component method of reduction is presented. The new formulation permits a comparison of the large component reduction method for 1- and 2-particle problems with the method of successive canonical transformations of Foldy and Wouthuysen in the 1- and 2-particle cases. REDUCTION OF RELATIVISTIC TWO-PARTICLE WAVE EQUATIONS TO APPROXIMATE FORMS. III, by W. A. Barker and F. N. Glover. [1955] [8]p. incl. tables, refs. [AF 18(600)789] Unclassified

Published in Phys. Rev., v. 99: 317-324, July 1, 1955.

The interaction between two fermions of charge ϵ_I and ϵ_{II} and intrinsic magnetic moment μ_I and μ_{II} is described by a sixteen-component wave equation of the Breit type. The method of reduction of two-particle wave equations, as given in two previous papers by Chraplyvy, is used to convert this equation to an approximate four-component Pauli equation. A simple perturbation calculation is used to determine the contribution of the intrinsic magnetic moments to the fine and hyperfine structure of hydrogen and positronium. (Contractor's abstract)

INVESTIGATIONS ON COMPRESSIBLE FLUID FLOWS, by A. D. Wasel. Technical rept. Jan. 1955, 46p. incl. diagrs. tables, refs. ([AF]OSR-TN-54-360) (AF 18(600)1036) AD 52470 Unclassified

A summary is presented of some theoretical results and some applications resulting from investigations of 2-dimensional, steady, compressible fluid flows. The basic theory underlying this work is that which pertains to second-order linear partial differential equations of the form $\frac{\partial^2 v}{\partial z \partial \bar{z}} + b(z, \bar{z})\frac{\partial u}{\partial z} + c(z, \bar{z})\frac{\partial u}{\partial z} + d(z, \bar{z})u +$ $e(z, \bar{z}) = 0$, where $z = y + iy$ and $\bar{z} = x - iy$. Methods are developed for the evaluation of Bergman's formulas for the determination of compressible fluid flow patterns bounded by segments of straight lines and portions of free boundary. This requires a construction of a set of particular solutions of the equation satisfied by the stream function ψ in a certain plane and the orthonormalization of this set of solutions with respect to the boundary in that plane. Bergman's integral operator for generating solutions of equations of the above form is studied with regard to possible simplification. Comparisons are made between different forms of the operator. A form is developed which permits a theory concerning singularities of solutions to the stream function equation corresponding to singularities of the so-called associate functions. A new integral operator is introduced. It's domain of definition is determined, and forms of it are developed which could serve as a basis for theory concerning this operator analogous to that concerning the Bergman operator. Sample computing machine programs and a wiring diagram are appended.

STUDIES OF HIGH AMPLITUDE SOUND. A. MEASUREMENTS OF THE ACOUSTIC IMPEDANCE OF A RESONATOR AT LARGE AMPLITUDES. B. MEASUREMENTS OF THE ATTENUATION OF REPEATED SHOCK WAVES. C. A LOGARITHMIC AMPLIFIER, by O. B. Wilson, Jr. and D. A. Bies. Aug. 1954 [37]p. incl. diagrs. refs. (Report no. 79) ([AF]OSR-TN-54-276) (AF 18(600)495) AD 52274 Unclassified

The experimental investigation of the acoustic impedance of a Helmholtz-type resonator at very high amplitudes of excitation is presented. Sound levels up to 180 db and particle velocity amplitudes in the neck of the resonator up to 1.5×10^4 cm/sec were used. The results at lower levels are compared with those of previous investigators whose work has been confined to levels below 140 db and particle velocity amplitudes in the resonator neck below 4×10^3 cm/sec. Experimental work on the rate of attenuation of repeated shock waves in a 5-in. tube is reported. Qualitative agreement with theory is found, but there is at present no adequate explanation of quantitative discrepancies. The design and construction of a logarithmic amplifier is discussed. (Contractor's abstract)

STUDIES OF VERY HIGH AMPLITUDE SOUND, by O. B. Wilson, Jr. and D. A. Bies. Apr. 1955, 22p. incl. diagrs. table. (Rept. no. 82) ([AF]OSR-TR-55-10) (AF 18(600)495) AD 72433; PB 137707 Unclassified

A standing wave technique was used to investigate the acoustic impedance of a Helmholtz-type resonator over a wide range of sound levels. At large sound pressure levels above 150 db, the sound waves propagating down the impedance tube became essentially repeated shock waves so that it was necessary to use a filter in the monitoring system, and to consider only the behavior of the fundamental component in the repeated shock wave. In this way, a range of sound pressure levels in the resonator from 100 to 170 db was investigated. Two different methods of mounting the resonator were considered. In one case the resonator was mounted on the side of the impedance tube next to a solid end plate terminating the tube, and in the other case the resonator was mounted on the solid end plate coaxially with the impedance tube. At the higher levels of excitation a rise in resonant frequency and in acoustic resistance was noted in both cases, but the details of the effects in each case were quite different. With the resonator mounted on the side the rise in the acoustic resistance followed Sivian's formula (Jour. Acoust. Soc. Amer., v. 7: 94, 1935) while the mass end correction decreased only at very high sound pressure levels. With the resonator mounted on the end, the rise in acoustic resistance was at first more rapid, then less rapid than Sivian's formula would predict. The decrease in mass end correction with increasing sound pressure level began at a lower level and was more pronounced than in the former case.

AN INVERSION FORMULA FOR LAPLACE TRANSFORMS AND SEMI-GROUPS OF LINEAR OPERATORS, by R. S. Phillips. [1954] [32]p. (AF 18(600)163) Unclassified

Published in Ann. Math., v. 59: 325-356, Mar. 1954.

A discussion is presented of the conditions that a closed linear operator be the infinitesimal generator (i.g.) of a semi-group of bounded linear operators (b.l.o.) $T(s)$, $s > 0$, Abel summable to the identity at $s = 0$. It is proved, in section 2, that $F(\cdot)$ is the Laplace transform of a measurable submultiplicative function ($0 \neq \cdot(s_1 + s_2) \leq \cdot(s_1)\cdot(s_2)$ integrable near $s = 0$, if the following conditions are satisfied: (i) there exists a real $\cdot$ such that $F(\cdot)$ is completely monotonic in $(\cdot, \infty)$, (ii) $\lim \cdot \to \cdot F(\cdot) = 0$ and (iii) $G(k+m+1, \cdot) \leq G(k, \cdot)G(m, \cdot)$ for $G(n, \cdot) = (-1)^n(n!)^{-1}F^{(n)}(\cdot)$, and for integers k, $m \geq 0$. This result is applied, in section 3, to the class of semi-groups $T(s)$ satisfying $\int_0^1 T(s)x\, ds < \infty$ for each x. For those $T(s)$ strongly Abel summable to the identity at $s = 0$, the i.g. A defined by strong $\lim_{h \downarrow 0} h^{-1}(T(h) - I)x$ is not in general closed. The Laplace transform of such $T(s)$ is shown to be equal to the resolvent of $\bar{A}$, the smallest closed extension of A. A necessary and sufficient condition that $A = \bar{A}$ is that $T(s)$ be strongly Cesàro

SOC. 02:001 - SOC. 02:004

summable to the identity at s = 0. In section 4, similar results are obtained under the further hypothesis $\int_0^1 ||T(s)||ds$, specializing to give results concerning semi-group theory due to Hille, the reviewer and the author. In the final section is discussed the perturbation, by a b.l.o., of the i.g. of semi-groups of the above type. The method and the results are extensions of the author's previous paper (Trans. Amer. Math. Soc., v. 74: 199-221, 1953; Math. Rev., v. 14: 882). (Math. Rev. abstract)

A kinetic study of the reaction $ArSCl + CH_3OH \rightleftharpoons ArSOCH_3 + HCl$ (1), where Ar = 2,4-dinitrophenyl, in the absence of pyridine, with pyridine present, and with the highly hindered amine, N,N-dimethylmesidine leads to the conclusion that the powerful catalytic effect of pyridine on reaction 1 involves formation of the intermediate 2,4-dinitrobenzenesulfenylpyridinium chloride, $(ArSNC_5H_5)Cl^-$. The attainment of equilibrium 1 is measurably slow, and favors the reactants ($K_{28°} \sim 10^{-3}$), in ethylene chloride solution. An infrared technique was used to follow the kinetics. Other tertiary amines, e.g., triethylamine and acridine, also catalyze reaction 1. The results obtained with the special case of reaction 1, above, appear to apply also to the general case of reaction 1, involving other sulfenyl halides and alcohols. To evaluate the utility of 2,4-dinitrobenzenesulfenyl chloride for the characterization of more complex alcohols, the reactions with ethylene glycol, pinacol, allyl alcohol, cinnamyl alcohol, benzhydrol, triphenylcarbinol, 2-methyl-3-butyn-2-ol, and propargyl alcohol were studied. Several new examples of 2,4-dinitrobenzenesulfenate esters are reported, and the complexities which can be encountered with various of the above alcohols are illustrated and interpreted. THE ALCOHOLYSIS OF 2,4-DINITROBENZENESULFENYL CHLORIDE, by L. Goodman and N. Kharasch. [1955] [1]p. (AF 18(600)844) Unclassified

Presented at meeting of Organic Division of the Amer. Chem. Soc., Cincinnati, Ohio, Apr. 2, 1955.

Study was made of the strong catalytic effect of pyridine in the reaction $ArSCl + ROH \rightleftharpoons ArSOR + HCl$, with Ar = 2,4-dinitrophenyl and R = methyl (reaction 1). The rate of reaction 1 was studied in the absence of pyridine, with pyridine present and with the highly hindered amine, N,N-dimethylmesidine, in ethylene chloride as solvent. At 28°, the reaction approaches equilibrium at a measurably slow rate and the equilibrium favors the reactants ($K_{28°} \sim 10^{-3}$). With one mole, or with excess of pyridine present, however, reaction is practically instantaneous and complete. With excess N,N-dimethylmesidine (which is highly hindered, but slightly more basic than pyridine) reaction 1 also goes to completion, but again measurably slowly and at a rate dependent on the concentration of mesidine. The reaction in the latter case was found to be first order with respect to the sulfenyl chloride. The rates were followed by an infra-red technique. The above results suggest that the effect of pyridine of reaction 1 involves the intermediate formation of 2,4-dinitrobenzenesulfenylpyridinium chloride $[(NO_2)_2\text{-}C_6H_3\text{-}S\text{-}NC_5H]^+Cl^-$. Triethylamine, quinoline and acridine have similar effects. An attempt to isolate the pyridinium intermediate was, however, not successful. The synthetic utility of reaction 1 has also been extended to various examples, such as the 2,4-dinitrobenzenesulfenates of ethylene glycol, pinacol, allyl alcohol, cinnamyl alcohol and 2-methyl-3-butyn-2-ol. The complexities which can be encountered in these reactions are illustrated, as are also the difficulties which may arise in extending the reaction to benzhydrol, triphenylcarbinol and propargyl alcohol. The reactions of 2, 4-dinitrobenzenesulfenyl chloride (I) with selected 1, 2-epoxides or chlorohydrins have been examined. These latter reactants include: ethylene oxide; 2-chloroethanol; cyclohexane oxide; trans-1, 2-chlorocyclohexanol; propylene oxide; 1-chloro-2-propanol; styrene oxide; 2-chloro-2-phenylethanol; 2-chloro-1-phenylethanol; and the nonreactive cis- and trans-stilbene oxides. The tabular data given present reactants, product, % yield, mp, % unreacted I in the absence of pyridine, and calculated and found C, H, and N. In all cases in which pyridine was used, varying amounts of the highly insoluble bis(2, 4-dinitrophenyl) disulfide were precipitated. Since the hydrolysis of the sulfenyl chloride occurs very rapidly in the presence of pyridine, and the disulfide is known to be the major product, it is believed that the disulfide results from a reaction with H_2O present in the system. As a result, the yields of products obtained are probably determined by the amounts of moisture in the reaction mixtures, rather than by the course of the main reactions with the epoxides or chlorohydrins. It is probable that the effect of pyridine in the reactions of I with epoxides involves reactions of the epoxides with the pyridine-sulfenyl complex, previously formulated as 2, 4-dinitrobenzenesulfenylpyridinium chloride. This mechanism explains the catalytic role of pyridine and is similar to the one suggested by Steward and Cordts (Jour. Amer. Chem. Soc., v. 75: 2658, 1953) for an analogous reaction with episulfides in which the addition of 1-chloro-2-propanesulfenyl chloride to propylene sulfide gave bis(1-methyl-2-chloroethyl) disulfide.

CONVERSION OF A 1, 4-DIOL TO A LACTONE BY RANEY NICKEL, by J. A. Berson and W. M. Jones. June 1956, 4p. incl. diagr. (AFOSR-TN-56-268) (AF 18(600)1544) AD 88988 Unclassified

Also published in Jour. Org. Chem., v. 21: 1325-1326, Nov. 1956.

$LiAlH_4$ (I) (10 g) and 250 cc anhydrous Et_2O was refluxed with stirring and the condensate passed through 28.5 g endonorbornane-2, 3-dicarboxylic anhydride in a Soxhlet apparatus, the resulting mixture cooled, treated dropwise with 81 cc iso-PrOH (II) and then 66 cc saturated NaCl solution, stirred 30 min, and filtered, the filter cake washed with 2:3 II-Et_2O, and the filtrate evaporated to give 21 g gummy solid, distilled at 148-50°/1.5 mm and recrystallized from C_6H_6-C_6H_{14} (III) to give 9.5 g 2, 3-bis(hydroxymethyl)norbornane (IV), melting at 61-2°; bis(p-tolluenesulfonate), melting at 128-9°. Raney Ni (freed of H_2O by washing with EtOH and of EtOH by azeotropic distillation with C_6H_6) (10 g), 50 cc C_6H_6, and 1 g IV was refluxed 3 hrs, filtered, the filter cake washed with C_6H_6, and the filtrate evaporated. Crystallization of the residue from C_6H_{14} gave 0.83 g solid, melting at 42-4°; purification by solution in 5% NaOH, reprecipitation with acid, and recrystallization from C_6H_{14} gave the pure lactone (V), melting at 145-6° (shrinking

at 135-40°), insoluble in bicarbonate and cold NaOH, negative test with $KMnO_4$ and 2,4-$O_2NC_6H_4NH$-NH_2. V (0.570 g) in 25 cc absolute Et_2O, was added to 0.30 g I in 50 cc Et_2O with vigorous stirring, refluxed 3 hr, and worked up with 3.3 cc II and 3.3 cc saturated NaCl as above. Evaporation of solvents and recrystallization of the residue from III gave 0.450 g IV, melting at 59-61°. IV (1.0 g), 2 cc 10% NaOH, and 100 cc ice was treated with 135 cc 1% $KMnO_4$ with stirring, allowed to stand overnight, filtered, and the filtrate acidified and extracted with $CHCl_3$. The extract was dried over $MgSO_4$, filtered, evaporated, the residue leached with 3 cc hot 5% NaOH, and the insoluble gummy residue filtered off. The precipitate obtained on acidification of the filtrate was washed with 5% $NaHCO_3$ and H_2O to give 0.11 g V, melting at 139-41°, identified by infrared spectrum. (C. A., 1950: 5305f)

ON POINCARÉ RECURRENCES, by H. L. Frisch. [Aug. 9, 1956] 15p. refs. (Technical rept. no. 1) (AFOSR-TN-56-374) (AF 18(603)122) AD 95810 Unclassified

Also published in Phys. Rev., v. 104: 1-5, Oct. 1, 1956.

In connection with the tracing of the origin of the apparent irreversibility exhibited by a class of simple mechanical systems, namely all multiply or conditionally periodic Hamilton Jacobi systems, estimates are obtained for the Poincaré recurrence time of such a system in terms of the preassigned limits of error of the mechanical recurrence, ε. By applying the theory of diophantine approximations, the asymptotic fraction of the time a system spends in such recurrence is found exactly. These results allow further deductions concerning the fraction of time a given system obeys a strict version of the Second Law of Thermodynamics as well as the existence and order of magnitude of the average Poincaré recurrence time of the Gibbsian ensemble of such systems whose degrees of freedom are indistinguishable. The relation of the results obtained for this important class of mechanical systems and the resolution of the paradoxes of heat theory propounded by Zermelo Loschmidt, etc. due to Boltzmann and von Smoluchowski is discussed. An especially easily visualized model, the one-dimensional gas of hard spheres, is treated, in particular, in some detail (Contractor's abstract)

THE TIME LAG IN NUCLEATION, by H. L. Frisch. [1956] [21]p. incl. diagrs. refs. (Technical rept. no. 3) (AFOSR-TN-56-557) (AF 18(603)122) AD 110377 Unclassified

Also published in Jour. Chem. Phys., v. 27: 90-94, July 1957.

A theory of the time lage of nucleation L based on the Zeldovich modification of the Becker-Döring theory of nucleation of a new phase (B) from a pure old phase (A) is presented in accord with the L used in diffusion theory. The complete spectrum of embryos f(g, t) or the flux of embryos is attributed a hypothetical time lag which is validated without explicit knowledge of f(g, t) over the whole range of values of g and t. The "memory effects" of the time lag are able to account for certain nucleation processes involving condensed phases (and the reversal processes).

AN INVESTIGATION OF SHOCK WAVE — BOUNDARY LAYER INTERACTION, by R. L. Chuan. Aug. 1955, 46p. incl. illus. diagrs. (USCEC rept. no. 40-201) ([AF]OSR-TN-55-299) (AF 18(600)1145) AD 72049 Unclassified

Experimental results are presented for an investigation of the characteristics of separating and reattaching boundary layer flow over a compression corner on a flat plate for M 2.54 and Re (based on 1 in.) 6×10^5. Detailed measurements of the boundary layer structure showed that in transitional interaction the flow can be characterized in terms of the mean temperature and mean velocity by 2 separate curves, one for the laminar separating flow and the other for the turbulent reattaching flow; while in turbulent interaction the entire flow can be characterized by one such curve. The rate at which momentum is transported from the free stream to the viscous region was determined for the transitional and turbulent cases, and was found to be highly dependent on the Reynolds number (based on a boundary layer momentum thickness). FLOW IN A VISCOUS VORTEX, by C. D. Pengelley. Mar. 16, 1956, 59p. incl. diagrs. tables. (Rept. no. 494C-1) (AFOSR-TN-56-126) (AF 18(600)1540) AD 86002 Unclassified

Equations have been derived for velocity, temperature and pressure distribution in a 2-dimensional viscous vortex with a steady state component of radial flow. Radial velocity has been assumed small compared with the tangential component, and heat transfer has been neglected. The equations have been based, upon the following well-established principles: (1) the Navier-Stokes equation in its most general form, (2) the first law of thermodynamics, and (3) the gas laws. A reference radius has been defined where viscous stress is zero; using this, nondimensional forms have been set up and generalized charts prepared for ready visualization and numerical applications. Due to the classical concept of viscosity as used in the Navier-Stokes equation, results are strictly applicable to laminar flow only; a discussion is presented regarding possible application to turbulent flow. THEORETICAL CONSIDERATIONS ON PERFORMANCE CHARACTERISTICS OF SOLAR FURNACES, by E. Loh, P. Duwez and others. Jan. 16, 1956, 27p. incl. diagrs. (Technical rept. no. 1; Rept. no. 3) (AFOSR-TN-56-69) (AF 18(600)1499) AD 81521 Unclassified

This study contains a theoretical discussion of the parabolic-type solar furnace. Calculations of the heat flux and the maximum temperature obtainable at the focus are presented for furnaces of different diameter-to-focal-length ratios. The analysis is extended to the California Institute of Technology lens-type furnace. The calculations indicate that the upper practical limit of a parabolic furnace has a rim angle θ between 50° to 60° or a diameter-to-focal-length ratio of about 2.0. Above a rim angle of 60° there is very little increase in the maximum temperature obtainable at the focus. In addition, the difficulty of constructing an accurate parabolic surface increases with increasing rim angle. The results presented here indicate that a paraboloid of relatively low quality is capable of achieving temperatures over 2000°K with a low heat flux of about 20 cal/sec/sq cm. On the other hand, a research furnace capable of attaining temperatures in the range of 3600° to 4200°K, or a furnace capable of high heat flux values above 230 cal/sec/sq cm, would have to have a paraboloid of very high quality.

THE OPERATION AND USE OF THE CALIFORNIA INSTITUTE OF TECHNOLOGY LENS-TYPE SOLAR FURNACE, by N. K. Hiester, E. Loh, and T. E. Tietz. Apr. 24, 1956, 24p. incl. illus. diagrs. Technical rept. no. 2; rept. no. 5) (AFOSR-TN-56-248) (AF 18(600)1499) AD 88368 Unclassified

A description is given of the lens-type solar furnace. The concentration of solar energy is accomplished by using converging lenses. The 19 large lenses, with their axes pointed toward the sun, are arranged with one in the center, 6 surrounding this, and then 12 around the central 7. The converging rays from the sun are brought to these lenses by 18 oblique mirrors. The concentration efficiency, η_c, defined as the ratio of the power received within the smallest sun image to the total power passing through the optical system, was calculated to be 45%. The concentration ratio, C, which is the ratio of heat flux per unit area at the sun image to the actual flux per unit area received at the furnace site, was calculated to be 19.7×10^3. The computed maximum-attainable temperature, Tm, for a cavity receiver under ideal conditions was 4700°K. These theoretical values of η_c, C, and Tm are for the case where the target plane is perpendicular to the rays coming from the sun.

ECONOMIC AND DESIGN STUDY OF SOLAR FURNACES, by R. E. De La Rue, Jr., T. E. Tietz, and N. K. Hiester. June 21, 1956, 52p. incl. diagrs. tables, refs. (Rept. no. 6; Technical rept. no. 3) (AFOSR-TN-56-382) (AF 18(600)1499) AD 95818 Unclassified

Also published in Jour. Solar Energy Science and Engineering, v. 1: 28-43, Apr.-July 1957.

Investigation was continued on the feasibility of adapting a lens-type solar furnace for research on solids at high temperatures. The theoretical and practical factors which affect the specific performance characteristics and costs of solar furnaces are reviewed. Technical and economic considerations indicated that the best design for a large solar furnace should incorporate: (1) a parabolic concentrator consisting of adjustable curved-mirror segments; (2) a stationary concentrator with its axis horizontal, with an auxiliary movable mirror to follow the sun; (3) a 50° to 70° angle between the image area and the rim of the concentrator; and (4) a reflecting surface consisting of back-silvered glass. The actual heat flux available at the target was expressed as $p = 46.1 \times 10^3 E p_o \sin^2 \theta$, where E is the over-all efficiency factor of the solar furnace, p_o is the solar constant, and θ is the rim angle. Consideration was given to the factors which affect the performance characteristics and their effect on the size requirements of a furnace. The specifications to allow operation at 2 flux levels and image diameters were evaluated with respect to cost by the use of 3 possible methods to meet the requirements. A preliminary structural design and cost estimate for a solar furnace system having a 100-ft parabolic concentrator with a

STR. 01:004 - STA. 01:001

movable auxiliary mirror to follow the sun is presented. The study results were extrapolated to give cost curves for furnace systems with 50- to 200-ft-diam concentrators. Comparison between flat-plate and parabolic concentrator segments showed that the parabolic concentrator was most economical.

HEAT FLUX MEASUREMENTS AT THE SUN IMAGE OF THE CALIFORNIA INSTITUTE OF TECHNOLOGY LENS-TYPE SOLAR FURNACE, by E. Loh, N. K. Hiester, and T. E. Tietz. Sept. 14, 1956, 17p. incl. diagrs. tables. (Rept. no. 8; technical rept. no. 5) (AFOSR-TN-56-587) (AF 18(600)1499) AD 110383 Unclassified

Also published in Jour. Solar Energy Science and Engineering, v. 1: 23-26, Apr.-July 1957.

Flux measurements were made at the focus of the CIT lens-type solar furnace using two U. S. Naval Radiological Defense Laboratory (NRDL) water-cooled radiometers. Maximum flux values were obtained for three cases: central lens only operating, central seven lenses operating, and finally, all lenses operating. For each of these cases, flux profiles were obtained by traversing the radiometer through the sun image. A maximum flux value of 220 cal/sec/sq cm was recorded with all lenses operating. The direct solar radiation received at the furnace site at this time was about 1.04 cal/min/sq cm. Under these conditions the furnace operating efficiency was found to be 47.2%. The losses of 52.8% are ascribed to transmission losses in the lenses, reflectivity losses at the mirrors, the geometrical imperfection of the individual lenses and mirrors, and lack of perfect superposition of the nineteen images. EXTENSIONS OF A THEOREM OF LOEWNER ON INTEGRAL OPERATORS, by D. C. Benson. Apr. 16, 1954. 41p. (Technical note no. 1) ([AF]OSR-TN-54-59) (AF 18(600)680) AD 29641 Unclassified

Extensions are considered of a result of Loewner (Ann. Math., v. 49: 316-332, 1948) which gives a necessary and sufficient condition that a function k(t), L-integrable on [0, 1] have the property that, for every continuous function x(t) of period 1, the closed curve in the x-y plane, $x = x(t)$, $y = y(t) = -\int_0^1 k(\tau)x(t-\tau)d\tau$ has non-negative index with respect to every point of the x-y plane not lying on this curve. The extensions considered include: (1) the function k(t) is Lebesque integrable on the half line $[0,\infty]$. The operator $y(t) = -\int_0^\infty k(\tau)x(t-\tau)d\tau$ is applied to functions x(t), which are continuous in $(-\infty, \infty)$ and such that $\lim_{t \to \pm\infty} x(t) = 0$. Then $\lim_{t \to \pm\infty} y(t) = 0$ and $x = x(t)$, $y = y(t)$ may be considered as a representation of a closed curve. The curve $x = x(t)$, $y = y(t)$ is considered, and the question is asked as to which functions k(t) generate only curves of non-negative circulation. (2) Consideration is given to the original problem when all of the integrations are taken in the sense of the Cauchy principal value. Assume that $k(t) = \frac{\varphi(t)}{t^\alpha(1-t)^\alpha}$ where $\varphi(t)$ is L-integrable on the interval $[0, 1]$ and $0 < \alpha < 1$. The integral operator $y(t) = P\int_0^1 k(\tau)x(t-\tau)d\tau$ is applied to a class of functions x(t) which satisfy a suitable Holder condition (to insure the existence and continuity of y(t)). The symbol P denotes that the integration is taken in the sense of the Cauchy principal value. The above question is again asked. (ASTIA abstract)

ON SOME CRITICAL POINTS OF HIGHER ORDER, by C. Loewner. Nov. 30, 1954 [25]p. (Technical note no. 2) ([AF]OSR-TN-54-309) (AF 18(600)680) AD 48583 Unclassified

The report contains a study of critical points of functions or mappings defined for sufficiently differentiable functions. The simplest critical points are stationary points of a differentiable function. In general, a critical point is defined by a system of differentiable relations containing derivatives up to an order k, which is then called the order of the critical points under consideration. Several theorems are proved about existence of critical points under conditions regarding the boundary values and the qualitative behavior of the functions involved. (Contractor's abstract)

ON FREE BOUNDARY PROBLEMS AND CONFORMAL MAPPING, by R. Finn. Mar. 11, 1955, 63p. incl. diagrs. refs. (Technical note no. 3) ([AF]OSR-TN-55-44) (AF 18(600)680) AD 58419 Unclassified

A study is made of existence, uniqueness, and stability questions for the 2-dimensional steady flow of a perfect fluid with formation of a free boundary at an interface of discontinuity. The first proof is given of the existence of a flow through an asymmetric nozzle into a medium of constant pressure. Also, it is shown that for symmetric nozzles the restrictions on total curvature of the boundary which have appeared in previous literature are of no mathematical significance. The existence of multisheeted flows is demonstrated, and boundaries are characterized which do not admit nonsingular flows. Several related problems are also considered, e.g., the flow of fluid past a boundary with formation of an infinite wake. (Contractor's abstract)

ON SOME CONVEX CONES AND ASSOCIATED MONOTONE FUNCTIONS, by D. P. Squier. July 29, 1955, 57p. (Technical note no. 4) ([AF]OSR-TN-55-224) (AF 18(600)680) AD 70391 Unclassified

The concept of a monotone function is defined for any linear space S by means of a convex cone K in S. A function $f(\xi)$ which maps a subset of S into S is called monotone increasing on the subset if it preserves the order of the elements so that $\alpha \geq \beta$ implies $f(\alpha) \geq F(\beta)$ for every α and β in the domain of definition of $f(\xi)$. Attention is given to spaces of real binary forms in x and y with the requirement that the convex cones are closed and invariant under linear transformations on the variables x and y. The analysis shows that in spaces of odd degree forms the whole space is the only closed cone. In spaces of even degree, any closed cone is contained in either the set of nonnegative forms or the set of nonpositive forms, and also contains a certain closed cone or its opposite which is the smallest. For binary quartics, all closed cones are determined and characterized by means of an invariant of the positive definite forms. Elements in the smallest closed cone in the space of forms of degree 2m are characterized by means of the matrix of coefficients of a quadratic form in m + 1 variables. In special spaces with special convex cones, functions are defined on the space by means of a scalar function f(t) defined on an interval together with a generalized concept of eigenvalues. Those functions f(t) are determined which yield a monotone function on the space.

HOMOLOGY AND FLOWS ON MANIFOLDS, by T. Frankel. Mar. 28, 1956, 19p. (Technical note no. 5) (AFOSR-TN-56-141) (AF 18(600)680) AD 86018 Unclassified

Also published in Ann. Math., v. 65: 331-339, Mar. 1957.

An investigation is made of the manner in which the homology of a manifold influences the vector and tensor fields on that manifold. The vector fields give rise to 1-parameter groups of point transformations on the manifold and interest is focused on those transformations which conserve a volume element. Such divergence free vectors and their associated transformations are called flows. For flows which are also isometries of a Riemannian metric, a proof is presented that the homology class of any possible closed trajectory is essentially determined by means of De Rham's theorem; this is not true if the isometry requirement is not met. A homological form of a theorem of Cartan (Ann. Soc.

STA. 01:007 - STA. 03:002

Polon. Math., v. 8: 181-225, 1929) is proved for flows on a homogeneous space, and the theorem that the homology class of any possible closed trajectory is essentially determined by De Rham's theorem is interpreted within the framework of homogeneous spaces. An extension is given by Weyl's theorem for compact semi-simple Lie groups.

ON SOME TRANSFORMATION SEMIGROUPS, by C. Loewner. [1956] [14]p. (AF 18(600)680) Unclassified

Published in Jour. Rational Mech. and Analysis, v. 5: 791-804, Sept. 1956.

Semigroups projection transformations or transformations of the Moebius group are considered in this paper. D is an open convex domain of the n-dimensional projective space which can be associated with a semigroup of projective transformations. Analogously in Moebius geometry a semigroup M_D of transformations transforms the domain D into itself. The first section derives distortion theorems for the semigroup P_D for arbitrary domains D and M_D in spherical domains. In section two, finer distortion theorems for M_D are obtained but only for circles in the plane. Section three holds group-theoretical considerations giving a group-theoretical considerations giving a group-theoretical characterization of some of the semigroups P_D and M_D.

SOME THEOREMS ON DISCONTINUOUS PLANE FLUID MOTIONS, by R. Finn. [1955/1956] [46]p. incl. diagrs. refs. (AF 18(600)680) Unclassified

Published in Jour. Analyse Math., v. 4: 246-291, 1955/1956.

Proofs are given of results stated in an earlier note (Proc. Nat'l. Acad. Sciences, v. 40: 983-987, 1954; Math. Rev., v. 16: 296). The demonstrations are based on the well-known Levi-Civita representation for free boundary flows, and make use of the method of continuity. In addition to the work reported in the earlier note, the author also studies by the same method the classical problem of free-boundary flow past a polygonal obstacle. For this problem, a local uniqueness theorem is proved for concave obstacles (especially significant in that no restrictions are placed on total curvature), and an existence theorem is obtained for both symmetric and asymmetric convex obstacles, again with no restriction on curvature. Finally, the existence theorems are extended to apply to curved nozzles and obstacles. (Math. Rev. abstract)

THE COMPUTATION OF THE LAMINAR COMPRESSIBLE BOUNDARY LAYER, by I. Flügge-Lotz. Final rept. June 15, 1954 [65]p. incl. diagrs. tables, refs. ([AF]OSR-TN-54-144) (AF 18(600)586) AD 40185 Unclassified

A difference method was developed for computing shear stress and enthalpy $i = c_pT$ as functions of the coordinate x along the wall and the velocity u parallel to the wall. Pressure gradient and temperature distribution along the wall are given continuous finite functions of the coordinate x. Density and viscosity coefficients depend on the local temperature in the boundary layer. The method is tested in regions of pressure decrease and increase. Various examples are included to show the influence of the pressure gradient on skin friction and heat transfer.

INTERPRETATION OF ELECTRON SCATTERING EXPERIMENTS, by L. I. Schiff. June 24, 1953, 16p. diagrs. refs. (Technical rept. no. 1) (AF 18(600)545) AD 16169 Unclassified

Also published in Phys. Rev., v. 92: 988-993, Nov. 15, 1953.

The results of electron scattering experiments are interpreted with the aid of the first Born approximation. These experiments imply nuclear charge distributions that are peaked at the center and taper off smoothly. The rms radii of the charge distributions, and the nuclear Coulomb energies, are in approximate agreement with those computed from the usual uniform charge distribution. The effect of radiation loss and nuclear excitation are discussed qualitatively, and the effect of a nuclear electric quadrupole moment is considered quantitatively. The over-all conclusion is that these effects cannot account for the discrepancy between the observed scattering cross section which decreases monotonically with increasing angle and the diffraction minima and maxima expected from a uniform charge distribution with a sharp or moderately rounded edge. Theoretical improvements on the first Born approximation are being undertaken. (ASTIA abstract)

LATTICE-SPACE QUANTIZATION OF A NONLINEAR FIELD THEORY, by L. I. Schiff. Aug. 6, 1953, 30p. diagrs. refs. (Technical rept. no. 2) (AF 18(600)545) AD 15602 Unclassified

Also published in Phys. Rev., v. 92: 766-779, Nov. 1, 1953.

A method is developed for the approximate diagonalization of certain types of quantum field Hamiltonians which is not limited to weakly nonlinear systems. It consists of omitting the gradient terms in zero order and diagonalizing the resulting Hamiltonian by replacing the field defined in a continuum space by a field defined in a lattice space. This unperturbed system is equivalent to a countably infinite number of uncoupled nonlinear oscillators, which are then coupled together when the gradient terms are included as a perturbation. The method is applied to the quantization of the classical nonlinear meson theory previously introduced (L. I. Schiff, Phys. Rev., v. 84: 1, 1951) to give a qualitative explanation of the saturation of nuclear forces, according to which a positive φ^4 term is added to the field Hamiltonian. Although the quantized theory is manifestly noncovariant, a single-particle solution exists that has an approximately relativistic relation between energy, momentum, and rest mass. It is essential that the lattice constant be kept finite, as all computed physical quantities become meaningless in the continuum limit (in which the lattice constant approaches zero). These particles obey Einstein-Bose statistics, and they scatter from each other. Nucleons are introduced as classical sources for the meson field, and calculations are made on the nucleon isobaric state, interaction mesons with nucleons and heavy nuclei, and nucleon-nucleon interaction. A brief discussion is given of the possibility of extending the method to the quantization of both meson and nucleon fields when they are strongly coupled together. (ASTIA abstract)

PHOTOPRODUCTION OF π-MESON PAIRS, by R. D. Lawson. Aug. 27, 1953, 15p. diagrs. refs. (Technical rept. no. 3) (AF 18(600)545) AD 18727
Unclassified

Also published in Phys. Rev., v. 92: 1272-1279, Dec. 1, 1953.

A perturbation study of the photoproduction of π-meson pairs by γ-rays incident on portions is made for both pseudoscalar and pseudovector coupling. Expressions are derived for the possible cross sections, assuming that the nucleon is infinitely heavy. The effect of first-order nucleon recoil on the (π^+, π^-) cross section, assuming pseudoscalar coupling, is considered. Curves illustrating the results are given. The possibility of obtaining information on the type of interaction operative between mesons and nucleons from a study of the pair production cross sections is discussed. (Contractor's abstract)

PHASE SHIFT CALCULATION OF HIGH ENERGY ELECTRON SCATTERING BY NUCLEI, by D. R. Yennie, R. N. Wilson, and D. G. Ravenhall. Oct. 1953, 3p. diagrs. (Technical rept. no. 4) (AF 18(600)545) AD 18892
Unclassified

Also published in Phys. Rev., v. 92: 1325-1326, Dec. 1, 1953.

A numerical phase shift calculation was performed to examine the accuracy of the Born approximation. The results disagreed with those of Parzen (Phys. Rev., v. 80: 355, 1953). Generally, the calculation followed the methods of Acheson (Phys. Rev., v. 82: 488, 1951) and Parzen. The details of the calculation are to be published. The phase shift relative to that of the Coulomb was calculated for the first nine partial waves; the last shift was less than 0.003° in all cases. All the phase shifts were negative and tended monotonically to zero. Uniform and exponential charge distributions were used for Au and Cu. Scattering angle vs differential cross-section curves are given for the phase shift analysis of Au and Cu, as well as the Born approximation.

ON THE EXPRESSION FOR THE TOTAL CROSS SECTION, by L. I. Schiff. Jan. 8, 1954, 5p. (Technical rept. no. 5) ([AF]OSR-TN-54-7) (AF 18(600)545) AD 27412
Unclassified

Also published in Prog. Theoret. Phys., v. 11: 288-290, Mar. 1954.

A simple derivation is presented for the well-known expression for the total cross section in terms of the imaginary part of the coherent forward scattered amplitude. The derivation shows that there is a shadow remnant beyond the actual shadow, within which the forward coherent scattering intensity is diminished, of approximate radius $(r/k)^{1/2}$, where r is the distance from the scattering center and $k = 2\pi/\lambda$ is the wave number. A qualitative understanding of the shadow remnant is obtained in terms of the uncertainty principle. (ASTIA abstract)

NUCLEAR MULTIPOLE TRANSITIONS IN INELASTIC ELECTRON SCATTERING, by L. I. Schiff. July 1954, 24p. incl. table, refs. (Technical rept. no. 7) ([AF]OSR-TN-54-191) (AF 18(600)545) AD 41720
Unclassified

Also published in Phys. Rev., v. 96: 765-772, Nov. 1, 1954.

Expressions are obtained for the differential cross sections for inelastic scattering of fast electrons with excitation of various nuclear multipole transitions. The most probable transitions are those that involve collective motion of many nucleons, and in this case the term

STA. 03:007 - STA. 03:010

arising from the transition charge density dominates those that come from the current and magnetization densities. There is then a close relation between the probability for inelastic electron scattering and the probability for the corresponding radiative electric multiple transition, although an assumption must be made as to the shape of the transition charge density. This is illustrated with a detailed discussion of the collective electric quadrupole transitions, using the model of Bohr and Mottelson. When the transition is produced by one or a small number of nucleons, or when it is of magnetic multipole type, there is likely to be little relation between inelastic scattering and radiation probabilities. The electric moncpole transition ($0+ \longrightarrow 0+$) is also discussed. It is shown how the elastic scattering can be corrected for unresolved inelastic scattering, as well as elastic quadrupole scattering, before an analysis is made in terms of the spherically symmetric part of the static nuclear charge density, and also how the strength, as well as the shape of the transition charge density, can be determined experimentally when only relative measurements of inelastic scattering are available. RESULTS OF A PHASE SHIFT CALCULATION OF HIGH ENERGY ELECTRON SCATTERING, by D. G. Ravenhall and D. R. Yennie. Aug. 1954, 4p. diagrs. (Technical rept. no. 8) ([AF]OSR-TN-54-209) (AF 18(600)545) AD 41801 Unclassified

Also published in Phys, Rev., v. 96: 239-240, Oct. 1, 1954.

The results of a phase shift analysis of the scattering of 84, 126, 154, and 183 mev electrons on gold are described. For "smoothed uniform" charge distributions, characterized by a central region of almost constant density and a surface region in which the density drops to zero, it is found that at these energies the surface structure is unimportant. The best fit with the experimental data is given by a distribution with rms radius $\sqrt{3/5}\ A^{1/3} \times 1.20 \times 10^{-13}$ cm, and surface thickness 1.65×10^{-13} cm. PHASE SHIFT CALCULATION OF HIGH ENERGY ELECTRON SCATTERING, by D. R. Yennie, D. G. Ravenhall, and R. N. Wilson. Mar. 1954, 29p. diagrs. tables, refs. (Technical rept. no. 6) ([AF]OSR-TR-54-11) (AF 18(600)545) AD 30601 Unclassified

Also published in Phys. Rev., v. 95: 500-512, July 15, 1954.

The details of a phase shift calculation of high energy electron scattering by nuclei are given, together with some preliminary results. A new method for summing the Legendre series for the Coulomb scattering amplitude is described. The results indicate that the first Born approximation does not give cross sections accurate enough for a reliable interpretation of the experiments. From a comparison of the few theoretical cross sections already obtained with the experiments in gold at 125 mev, very tentative conclusions about the nuclear charge distribution are drawn. It is pointed out that an analysis of results at two or more energies will be a much more sensitive test of possible charge distributions. (Contractor's abstract)

PHASE SHIFT CALCULATION OF HIGH-ENERGY ELECTRON SCATTERING BY NUCLEI, I (Abstract), by D. R. Yennie, R. N. Wilson, and D. G. Ravenhall. [1954] [1]p. [AF 18(600)545] Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 28-30, 1953.

Published in Phys. Rev., v. 93: 948-949, Feb. 15, 1954.

The computational program for calculating the elastic scattering of electrons from spherically symmetrical charge distribution is described, and in the following paper the results are presented and compared with experiment. The calculation follows in general the methods given by Parzen and Acheson, with some modifications in the details. To calculate the phase shifts, the radial wave functions inside the nucleus are integrated numerically and fitted to Coulomb functions (obtained by series expansion about the origin) outside the nucleus. In order to obtain relatively accurate differential cross sections for large angles ($> 90°$), it is necessary that the phase shift errors be kept small (less than 10^{-4} radian). In this angular region it is also necessary to know the Coulomb scattering amplitude very accurately. A new method of summing the series for this amplitude will be given. (Contractor's abstract)

PHASE SHIFT CALCULATION OF HIGH-ENERGY ELECTRON SCATTERING BY NUCLEI, II (Abstract), by D. G. Ravenhall, D. R. Yennie, and R. N. Wilson. [1954] [1]p. [AF 18(600)545] Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 28-30, 1953.

Published in Phys. Rev., v. 93: 949, Feb. 15, 1954.

For gold, $Z = 79$, differential cross sections for uniform exponential and intermediate charge distributions have been calculated. Compared with the first Born approximation, the maxima and minima given by the uniform charge distributions are smoothed out, the

first minimum appearing only as a point of inflection. The slope of the cross section for the exponential distribution is greater than that given by the first Born approximation; this effect can be understood qualitatively as being due to the increase of the electron's wave number inside the attractive potential of the nucleus. For comparison, some distributions for copper ($Z = 29$) have also been obtained. The maxima and minima are more pronounced and are shifted to smaller angles relative to the Born approximation, an effect explainable qualitatively in terms of the effect wave number. Further calculations now in progress will be reported and compared with the experimental results of Hofstadter, Fechter, and McIntyre. (Contractor's abstract)

SECOND BORN APPROXIMATION TO THE SCATTERING OF FAST ELECTRONS AND POSITRONS BY NUCLEI (Abstract), by R. N. Wilson. [1954] [1]p. [AF 18(600)-545] Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 28-30, 1953.

Published in Phys. Rev., v. 93: 949, Feb. 15, 1954.

The scattering of a Dirac particle in an electrostatic potential is calculated in second Born approximation. A charge distribution of the form $\rho(r) = (Ze/8\pi a^3)\exp(-r/a)$ is chosen because the integrations can be performed exactly and because it is of interest to compare the result with an exact calculation by phase shift analysis. In the imaginary part of the second-order contribution to the scattering amplitude there appear divergent terms which are to be interpreted as phase corrections to the first-order contribution. A comparison is made of the results of this calculation with the first Born approximation and with the exact phase shift calculation. (Contractor's abstract)

THE SIGN OF THE PHASE SHIFT IN THE ELASTIC SCATTERING OF ELECTRONS, by D. R. Yennie, D. G. Ravenhall, and E. Baranger. [1954] [2]p. [AF 18-(600)545] Unclassified

Published in Phys. Rev., v. 93: 1128-1129, Mar. 1, 1954.

The total phase shift, in the phase-shift analysis of the scattering of electrons from a nuclear charge distribution, can be expressed as the sum of 2 terms: $\eta_l = \eta_l^c + \delta_l$, with η_l^c being the phase shift of the l^{th} partial wave for a pure Coulomb field and δ_l the additional phase shift due to the modification of the Coulomb field inside the nucleus. The assertion that for large l, δ_l approaches zero through positive values is found incorrect. Proof is given that for all reasonable charge distributions inside the nucleus $\delta_l < 0$.

NUCLEAR DISPERSION CONTRIBUTION TO HIGH-ENERGY ELECTRON SCATTERING, by L. I. Schiff. Jan. 1955, 16p. (Technical rept. no. 9) ([AF]OSR-TN-55-27) (AF 18(600)545) AD 55259 Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Berkeley, Dec. 28-30, 1954.

Also published in Phys. Rev., v. 98: 756-760, May 1, 1955.

An expression for the contribution of virtual intermediate states of the nucleus (nuclear dispersion) to the elastic and inelastic scattering of high-energy electrons is obtained. The closure relation for the nuclear states is used to put this in a form which depends only on the properties of the initial and final states. An estimate of this contribution in comparison with the first-order scattering shows that it is expected to be small but not negligible for the light elements and somewhat larger for the heavy elements, when the electronics have several hundred mev energy. The estimate is only valid for large scattering angles. More detailed knowledge of the 1- and 2-proton transition charge densities would be required in order to extend the range of validity. It seems likely that the bulk of the dispersion correction would be taken into account if the correct electron wave functions in the static Coulomb field were to be used in place of plane waves. ELECTRIC MONOPOLE TRANSITIONS IN C^{12} AND AND O^{16}, by L. I. Schiff. Feb. 1955, 16p. refs. (Technical rept. no. 11) ([AF]OSR-TN-55-41) (AF 18(600)545) AD 55261 Unclassified

Also published in Phys. Rev., v. 98: 1281-1285, June 1, 1955.

The matrix element (ME) was calculated for electric monopole transitions ($0^+ \longrightarrow 0^+$) between the ground and 7.68-mev states in C^{12}. The calculations were based on jj-coupling independent-particle model in which 2 nucleons undergo transitions between the $p_{3/2}$ shell and the $p_{1/2}$ shell. Pair forces were included to first order, and the sum-over configurations were performed exactly by means of a Green's function. (For simplicity an infinitely deep square-well independent-particle potential was assumed.) The calculated ME was -1.58×10^{22} CR cm^2, with R measured in cm and C in mev-cm^3. By using R 3.0×10^{-13} cm and the experimental value of ME (3.8×10^{-26} cm^2) of

STA. 03:015 - STA. 03:018

Oppenheimer and Schwinger (Phys. Rev., v. 56: 1066, 1939) and Dalitz (Proc. Roy. Soc. (London), v. 206A: 521, 1951), the neutron-proton interaction value, $C = 8.0 \times 10^{-36}$ mev-cm^3 was obtained. Since this is about 6 times the volume integral of the triplet neutron-proton interaction when it is assumed to be of Gaussian form, a model is required which is more collective than the independent-particle model (with pair interactions) and less collective than the α-particle or elastic-fluid models in order to account for the experimental value of ME. LATTICE SPACE QUANTIZATION OF COUPLED MESON AND NUCLEON FIELDS, by D. H. Holland. Jan. 1955, 17p. (Technical rept. no. 10) ([AF]OSR-TN-55-42) (AF 18(600)545) AD 55260 Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Berkeley, Dec. 28-30, 1954.

Also published in Phys. Rev., v. 98: 788-792, May 1, 1955.

The lattice space quantization method of Schiff (Phys. Rev., v. 92: 766, 1953) for treating nonlinear mesons is used to quantize coupled mesons and nucleon fields. Neutral pseudoscalar mesons with pseudoscalar coupling to neutral Dirac nucleons are assumed, and only the fields at the lattice points of a cubic lattice are considered. A lattice space Hamiltonian is found, and momentum terms are treated as petrurbations. To zero order, the lattice points are uncoupled so that the state function is written as a product of functions describing a single point. Finding a particular point function requires the solution of a set of coupled differential equations. Linear combinations of zero-order solutions are found which diagonalize the perturbation to the lowest order and which can be interpreted as 1-particle momentum eigenstates. Linear combinations of 2-particle momentum states are obtained which approximately diagonalize the perturbation, and, from these, scattering cross sections are calculated. The lattice constant, l, appears in the final results and must be regarded as a parameter of the theory. This constant must be much larger than the meson Compton wave-length for the perturbation approximation to be valid.

DEUTERON MODEL CALCULATION OF THE HIGH-ENERGY NUCLEAR PHOTOEFFECT, by K. G. Dedrick. May 1955 [26]p. incl. diagrs. tables, refs. (Technical rept. no. 13) ([AF]OSR-TN-55-135) (AF 18(600)545) AD 63957 Unclassified

Also published in Phys. Rev., v. 100: 58-66, Oct. 1, 1955.

The high-energy nuclear photoeffect has been calculated according to the "deuteron model" of Levinger. In this model, the photo process occurs when a neutron and a proton which are scattering one another inside the nucleus absorb the energy of the incident photon and escape from the nuclear potential well into the laboratory. The nuclear photoeffect cross section is then obtained by averaging the cross section for the above process over all possible neutron-proton pairs in the nucleus, assuming a nucleon momentum distribution. The electric dipole and quadrupole interactions of the radiation field with the neutron and proton are included, and the magnetic terms are neglected. The averaging over all neutron-proton pairs is performed by means of a random flight formulation of the problem. The analytical work involved may conveniently be done using either a zero temperature Fermi ground state nucleon momentum distribution or a Gaussian distribution. Numerical results for the energy and angle distributions of photoneutrons and photoprotons are presented in the case of the Gaussian distribution, for 4 photon energies between 50 and 125 mev. ELECTRIC QUADRUPOLE EFFECTS IN SCATTERING OF HIGH-ENERGY ELECTRONS BY HEAVY NUCLEI (Abstract), by B. W. Downs, D. G. Ravenhall, and D. R. Yennie. [1955] [2]p. [AF 18(600)545] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Berkeley, Dec. 28-30, 1954.

Published in Phys. Rev., v. 98: 277-278, Apr. 1, 1955.

Using a modified Born approximation, calculations have been derived of the contributions to the differential scattering cross section which arise from the static quadrupole moment and from the collective electric quadrupole transitions (excitation of low-lying collective rotational states of the target nucleus). For nuclei having large intrinsic quadrupole moments these contributions partially smooth the diffraction wiggles in the scattering curves calculated by the method of Yennie et al.; the theoretical curves are thus brought into better agreement with the experimental data. The quadrupole charge distribution and the extent to which its details affect the scattering cross section are discussed. Results are presented for scattering of 183 mev electrons by tantalum. ELECTRODISINTEGRATION OF THE DEUTERON (Abstract), by V. Z. Jankus. [1955] [1]p. [AF 18(600)545] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Berkeley, Dec. 28-30, 1954.

Published in Phys. Rev., v. 98: 278, Apr. 1, 1955.

Calculations have been made on the disintegration of the deuteron in high-energy electron impact. With increase of momentum transfer the inelastic cross section increases at the expense of the elastic, while the sum of the two remains approximately equal to the Mott cross section. The energy spectrum of the scattered electron has been obtained using the Møller potential. In this calculation it was necessary to take account of the proton-neutron interaction in the final S state. The influence of this interaction on the states of higher angular momentum has been found to be much smaller. The results indicate that the cross section is sensitive to the effective range of proton-neutron forces, especially at high momentum transfers, such a produced by 300 mev electrons scattered at 60°. EXCITED STATES OF C^{12} AND O^{16} (Abstract), by L. I. Schiff. [1955] [1]p. [AF 18(600)545] Unclassified

Presented at meeting of Amer. Phys. Soc., Chicago, Ill., Nov. 26-27, 1954.

Published in Phys. Rev., v. 98: 235, Apr. 1, 1955.

The matrix element for the electric monopole transition in O^{16} computed from the pair emission lifetime has roughly the same magnitude as the matrix element between the ground and 7.68-mev states in C^{12} estimated from inelastic electron scattering, assuming that the latter is also electric monopole. Both matrix elements are much smaller than would be expected on the basis of an alpha particle model, an elastic fluid model, or a $1S \rightarrow 2S$ transition of a single proton. It seems possible that this can be explained on the independent particle model (IPM) if two particles change their states. The transition is then forbidden if the IPM is taken literally, but becomes allowed if some interaction between particles is admitted in addition to that which is included on the average in the IPM. An estimate of the magnitude of this residual interparticle interaction that is required to explain the matrix elements are presented. (Contractor's abstract)

HIGH-ENERGY ELECTRON SCATTERING AND THE CHARGE DISTRIBUTIONS OF SELECTED NUCLEI (Abstract), by B. Hahn, D. G. Ravenhall, and R. Hofstadter. [1955] [1]p. [AF 18(600)545] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Berkeley, Dec. 28-30, 1954.

Published in Phys. Rev., v. 98: 278, Apr. 1, 1955.

Recent improvements in experimental technique have made it possible to measure more accurately the angular distribution of high-energy electrons (180 mev) scattered by heavy and medium nuclei. Small differences in scattering cross sections of two nuclei can be established by measuring ratios of counting rates at each scattering angle. Scattering ratios of gold with respect to hydrogen have been measured, as well as ratios with respect to Rh, Ta, W and U. Ta, W, and U definitely show less pronounced diffraction wiggling in the angular distribution than Pb^{208}, Au, and Bi. It is fairly difficult to fit the experimental results for Ta, W, and U with phase shift calculations to a spherically symmetric charge distribution. A possible explanation of these relatively smooth angular distributions may involve nuclear-quadrupole effects. (Contractor's abstract)

STA. 03:023 - STA. 03:026

It has been shown previously that for heavy elements the Born approximation is inadequate for calculating high-energy electron scattering. However, after the problem of scattering in a central potential has been solved exactly (by numerical methods), additional effects can be treated by perturbation theory. Since the unperturbed scattering waves are known only through their partial wave decomposition, this method leads to a tedious, though straightforward, computation. An analytic approximation to the complete unperturbed scattering wave has been found which restores the perturbation calculation to the simplicity of the Born approximation; the approximation is good in the neighborhood of the nucleus. In this region the approximate function is very nearly a plane wave with normalization and wave number altered from that of the incident wave; in addition the wave fronts are slightly curved. This modified Born approximation is used to estimate the sensitivity of electron scattering to small changes in the radial charge distribution. (Contractor's abstract)

PHASE SHIFT ANALYSIS OF HIGH-ENERGY ELECTRON SCATTERING (Abstract), by D. G. Ravenhall and D. R. Yennie. [1955] [1]p. [AF 18(600)545] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Berkeley, Dec. 28-30, 1954.

Published in Phys. Rev., v. 98: 277, Apr. 1, 1955.

Results of a phase shift analysis of high-energy electron scattering is reported. Previously, experimental data on gold at several energies have been compared with cross sections obtained by using a "smoothed uniform" charge distribution. The effect of altering the central charge density has now been investigated, in an attempt to improve the agreement with these experiments, and in order to examine the extent to which the experiments determine the charge distribution. Some results are also presented for other nuclei whose distortion (i.e., intrinsic quadrupole moment) is small enough that the assumption of a spherically symmetrical charge distribution is justified. W. K. B. APPROXIMATION TO PHASE SHIFTS (Abstract), by S. P. Heims, D. R. Yennie, and D. G. Ravenhall. [1955] [1]p. [AF 18(600)545] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Berkeley, Dec. 28-30, 1954.

Published in Phys. Rev., v. 98: 278, Apr. 1, 1955.

The computing time required to evaluate exactly the phase shifts for the nuclear electron scattering at very high energies increases roughly as the square of the energy. For this reason the W. K. B. approximation for the phase shifts is being reconsidered. Using this approximation, E. Baranger has obtained cross sections at 150 mev for mercury that agree well with those obtained by the exact method, and the accuracy of the W. K. B. approximation improves as the energy increases. The phase integral is evaluated numerically rather than by the analytic approximation used by Baranger. Phase shifts and cross sections obtained by this method are compared with those obtained by the exact method. (Contractor's abstract)

THE EFFECTS OF SHORT-RANGE CORRELATIONS [IN POSITION] BETWEEN TWO PROTONS IN THE ELASTIC SCATTERING OF HIGH-ENERGY ELECTRONS BY HEAVY NUCLEI, by B. W. Downs. [Oct. 3, 1955] [21]p. incl. diagr. [AF 18(600)545] Unclassified

Also published in Phys. Rev., v. 101: 820-825, Jan. 15, 1956.

An expression is obtained for the leading term in the 2-proton contribution to the scattering cross section with a 2-proton charge density which is a Yukawa function of the separation between 2 protons. The cross section for scattering from more complicated charge distributions can be generated from this basic result by differentiation with respect to the Yukawa range parameter. The 2-proton cross section is evaluated for a charge density in which short-range correlations in position between 2 protons appear. Results are given for the scattering of 600-mev electrons by heavy nuclei. (Contractor's abstract)

INELASTIC ELECTRON SCATTERING BY CARBON (Abstract), by D. G. Ravenhall. [1955] [2]p. [AF 18(600)545] Unclassified

Presented at meeting of the Amer. Phys. Soc., Southern California U., Los Angeles, Dec. 28-30, 1955.

Published in Phys. Rev., v. 100: 1797-1798, Dec. 15, 1955.

The experimental results of Fregeau and Hofstadter on the scattering of 187-mev electrons by carbon contain differential cross sections for both elastic and inelastic processes. The former can be related to the charge distribution of the nucleus in its ground state, and the latter are associated with nuclear excitation, in this case to each of the first three levels, at 4.43, 7.68, and 9.61 mev. The spins and parities of the first two levels are known to be 2^+ and O^+ respectively, and the experimental results relating to these levels and to the ground state are in qualitative agreement with the predictions of the shell model. In this paper a discussion is given of the excitation to the 9.61-mev level, and of the information it gives concerning the spin and parity of this level. Further experiments which could assist in giving an unambiguous assignment are also discussed. (Contractor's abstract)

CALCULATION OF ELECTRON-DEUTERON SCATTERING CROSS SECTIONS, by V. Z. Jankus. Feb. 1956 [20]p. incl. diagrs. refs. (Technical rept. no. 14) (AFOSR-TN-56-48) (AF 18(600)545) AD 80560 Unclassified

Also published in Phys. Rev., v. 102: 1586-1591, June 15, 1956.

Elastic and inelastic cross sections for electron-deuteron scattering with large momentum transfers were investigated. The calculations were performed in the first Born approximation. The neutron-proton interaction was described by a phenomenological potential, and the nucleons were represented by point charges and point magnetic moments. The finite size of nucleons caused major corrections to the results. The calculations treated the deuteron nonrelativistically, while the electron was considered extremely relativistic. Thus the wave functions for incident and scattered electrons were represented by plane waves, and the deflection of the electrons generated Møller potentials to act upon the charge and current distributions in the deuteron. The calculations showed that the elastic cross section is sensitive to the presence or absence of the hard core in the interaction and that the inelastic cross section is sensitive to the presence or absence of the neutron-proton interaction in the final ^3P state. The calculations used bare nucleons to represent the proton and the neutron.

THE ZERO-ZERO TRANSITION IN CARBON 12, by B. F. Sherman and D. G. Ravenhall. Mar. 1956 [18]p. refs. (Technical rept. no. 15) (AFOSR-TN-56-152) (AF 18(600)545) AD 86311 Unclassified

Also published in Phys. Rev., v. 103: 949-955, Aug. 15, 1956.

The electric monopole transition density between the ground state and the 7.68 mev level of C^{12} is examined on the basis of the nuclear shell model. It is found to vanish for all stages of intermediate coupling if only the $(1p)^8$ configuration is involved. A nonzero value is obtained by including states of the $(1p)^7$ (2p) configuration, which are the results of a residual central internucleon interaction. For computational simplicity, both this and the spin-orbit interaction are first treated as perturbations about the L-S limit. Since the results show that the residual interaction is probably too large for this to be reliable, an attempt is made to diagonalize the Hamiltonian exactly, but the severe restriction on the number of states considered makes the result rather unsatisfactory. It is concluded that if all of the possible states of the low-lying configurations were to be included in the diagonalization, agreement with experiment might result, but that in this case some semi-collective model might better be applied. AN APPROXIMATION METHOD FOR HIGH-ENERGY POTENTIAL SCATTERING, by L. I. Schiff. Apr. 1956, 24p. refs. (Technical rept. no. 16) (AFOSR-TN-56-162) (AF 18(600)545) AD 86582 Unclassified

Also published in Phys. Rev., v. 103: 443-453, July 15, 1956.

An approximation method for high-energy potential scattering is developed that expresses the scattered amplitude in terms of a quadrature, similar to the Born approximation but superior to it in accuracy. It is valid when the potential is slowly varying compared to a wavelength, $|V|/E'$ is small compared to unity, is either small or large compared to $(kR)^{-1/2}$, and $|V|R/\hbar v$ is unrestricted in magnitude, where E', , k, and v are the kinetic energy, scattering angle, wave number, and speed of the scattered particle, respectively, and V and R are rough measures of the strength and range of the scattering potential, which may be complex. For comparison, the Born approximation requires that $|V|R/\hbar v$ be small compared to unity.

STA. 03:031 - STA. 03:034

The procedure consists in summing the infinite Born series after approximating each term by the method of stationary phase. Both the Schrödinger and Dirac equations are treated, and it is expected that the method can be extended to the scattering theory of other wave equations. The relation of the present work to previous work of others is discussed, and the limitations of WKB or eikonal-type approximations are explored. The method is expected to be especially useful for calculating the scattering of fast electrons, neutrons, and protons from nonspherical nuclei. (Contractor's abstract)

APPROXIMATION METHOD FOR SHORT-WAVELENGTH OR HIGH-ENERGY SCATTERING, by L. I. Schiff. Sept. 1956 [16]p. (Technical rept. no. 17) (AFOSR-TN-56-407) (AF 18(600)545) AD 96215 Unclassified

Also published in Phys. Rev., v. 104: 1481-1485, Dec. 1, 1956.

The approximation method developed recently is extended to the scattering theory of Maxwell's equations, and of the Schrödinger equation with spin-orbit interaction. Both of these situations are more complicated than the Schrödinger and Dirac cases considered earlier. While the electromagnetic case yields the earlier type of result in which the Born formula is modified by the inclusion of an additional phase factor, the Schrödinger spin-orbit case cannot be put in such a simple form. Brief mention is also made of the tensor interaction, which is even more complicated than the spin-orbit interaction, and of the space-exchange interaction, which can only be treated by this method if the potential is symmetric with respect to inversion. PION PRODUCTION IN ELECTRON-PROTON COLLISION, by R. H. Dalitz and D. R. Yennie. Nov. 1956 [59]p. incl. diagrs. tables, refs. (Technical rept. no. 18) (AFOSR-TN-56-533) (Sponsored jointly by [Air Force] Office of Scientific Research under (AF 18(600)-545), Office of Naval Research, and Atomic Energy Commission) AD 110352 Unclassified

Also published in Phys. Rev. v. 105: 1598-1615, Mar. 1, 1957.

The close relationship between photo-pion and electro-pion production from protons allows an unambiguous first estimate (the standard value) for the ratio of these cross sections, based on assumptions very close to those of the Weizsäcker (Zeitschr. Phys., v. 88: 612, 1934)-Williams (Phys. Rev., v. 45: 729, 1934; Kgl. Videnskab. Selskab, Mat-fys. Medd. Danske, v. 13: 4, 1935) method. Deviations of the ratio from this estimate arise from pion production by the longitudinal components of the field of the scattered electron and from the variation of the off-diagonal transverse excitations from their on-diagonal photoproduction values. The dependence of these deviations on the physical processes contributing to the electromagnetic excitation of pions is discussed in terms of matrix elements specified in the pion-nucleon center of mass system, both for various phenomenological contributions and for specific meson theories. The experimental values reported are interpreted as an indication of the smallness of longitudinal production, in qualitative accord with the fixed source theory. These features may also be investigated by study of the energy spectrum of inelastically scattered electrons and of the azimuthal variation of pion production relative to the scattering plane, which are also discussed here. ELECTROMAGNETIC STRUCTURE OF NUCLEONS, by D. R. Yennie, M. M. Lévy, and D. G. Ravenhall. Nov. 1956, 1v. incl. diagrs. refs. (Technical rept. no. 20) (AFOSR-TN-56-559) (AF 18(600)545) AD 110379 Unclassified

Also published in Rev. Modern Phys., v. 29: 144-157, Jan. 1, 1957.

The extent to which the results of the separate experiments performed upon phenomena of the nucleon electromagnetic interaction type can be combined into a consistent picture of nucleons as charge-current distributions. Neutron scattering by atoms gives information about the volume integral of the electron-neutron interaction. An interpretation is made in terms of a simple meson model of nucleon structure in which the "physical" nucleon is made up of "bare" nucleons and pions interacting in a charge-symmetrical manner. Other speculative ways of interpreting results are commented upon.

SHORT WAVELENGTH SCATTERING APPROXIMATIONS (Abstract), by L. I. Schiff. [1956] [1]p. [AF 18(600)545] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 66, Jan. 30, 1956.

The Born series for the exact scattering amplitude associated with the Schrödinger equation is simplified by applying the stationary phase approximation in the short wavelength case. The series can then be summed in two ways. One of these leads to an expression already obtained by Glauber, who used the WKB approximation for the wave function in the integral equation for the scattered amplitude. The other yields a superficially different expression first derived by the author with the help of a WKB approximation for the Green's function. The two expressions are equivalent, but Glauber's seems to be slightly more convenient for numerical computation. This point, and the extension to the Dirac equation, is discussed. SCATTERING OF CLASSICAL ELECTRONS BY NUCLEI, by S. P. Heims, D. G. Ravenhall, and D. R. Yennie. [1956] [19]p. incl. diagrs. refs. [AF 18(600)545] Unclassified

Published in Amer. Jour. Phys., v. 24: 568-573, Nov. 1956.

In connection with recent research at Stanford University on the scattering of high-energy electrons by atomic nuclei, a study is made of the scattering of extremely relativistic classical charged particles by a distribution of charge. The approximation is made that the mass of the scattered particle can be neglected; this is valid for the energies used in the experiments (between 100 and 200 mev). In the case of the point charge, orbits appear in which the particle encircles the nucleus many times before emerging. Cross sections are obtained for this case, for the spherical shell, and for the "smoothed uniform" charge distribution. From these results, it is clear that the experimentally interesting region is completely inaccessible to classical particles, and that the process observed corresponds more to the diffraction of waves. THE SOLUTION OF COMPRESSIBLE LAMINAR BOUNDARY LAYER PROBLEMS BY A FINITE DIFFERENCE METHOD. PART I. DESCRIPTION OF THE METHOD, by I. Flügge-Lotz and D. C. Baxter. Sept. 30, 1956, 81p. incl. diagrs. tables, refs. (Technical rept. no. 103) (AFOSR-TN-56-544) (AF 18(600)1488) AD 110363 Unclassified

The differential equations of the boundary layer can be conveniently treated by the described method. Such a method will allow the determination of boundary layer behavior under any combination of pressure gradient and wall temperature of heat transfer rate variation. The stability of the finite difference solution of the boundary layer equations, and of parabolic equations in general, has been investigated and found to place certain restrictions on the mesh sizes which may be used. Series expansions in powers of the velocity for the dependent variables τ^2 and $i_\mu \tau$ (pertaining to shear stress and enthalpy, respectively) can be used to allow determination of the wall conditions. The finite difference solution of the boundary layer equations has been programmed for the IBM 650 digital computer, and the computation of an extensive series of examples under various combinations of heat transfer rate and pressure gradient has been started. THE ANALYSIS AND SYNTHESIS OF GROUND-GRID AMPLIFIER TRANSFER FUNCTIONS, by W. A. Christopherson. May 12, 1952, 110p. incl. illus. refs. (Technical rept. no. 46) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) U22181; ATI-154480 Unclassified

The need for wide-band (50 to 75 megacycles), band-pass amplifiers operating at center frequencies in the ultra-high frequency range (above 300 megacycles) and having voltage gains of at least one thousand cannot be satisfied through the use of present day pentode tubes. However, such amplifiers can be designed by incorporating presently available ultra-high frequency triode types in grounded-grid operation if stagger tuning is employed to preserve gain band-width product and to produce the necessary selectivity. An alternative method is to use a traveling-wave tube, though this has several practical disadvantages having to do with noise-figure, selectively, and physical size. This investigation was undertaken to develop techniques of analysis and synthesis that would make possible the systematic design of a stagger-tuned cascade of grounded-grid triode amplifiers having a prescribed gain-magnitude response. The first part of this report is concerned with the analysis of grounded-grid cascades. It is shown that the cascade is not unilateral and that the equivalent circuit is a passive ladder

STA. 05:002 - STA. 05:003

network. However, series resistors in the equivalent ladder network allow the sections corresponding to the stages of the cascade to behave as though they are nearly unilateral. Deviations from unilateral behavior are defined as interaction. The tubes act as impedance transformers having low input-impedance and high output-impedance. It is necessary to obtain gain by employing only four-terminal interstages that act as current transformers. Thus, the choice of interstages is restricted. The second part of the report is concerned with the synthesis of prescribed gain-magnitude functions of grounded-grid cascades. A simple interstage network is selected with which it is possible to obtain a band-pass response. The resultant amplifier transfer function has three clusters of poles (points of infinite gain) on the band-pass complex-frequency plane. There is a pole in each cluster for each stage of the amplifier. The problem of arranging the poles to obtain the desired gain-magnitude response is solved by transforming it to a low-pass complex-frequency plane where there is only one cluster of poles. The solution of the problem in such a low-pass plane is known for a variety of gain-magnitude responses. Hence, the problem is solved if the inverse transformation from the low-pass plane to the high-pass plane can be carried out. This problem is actually by-passed, and the alignment data (center frequency and three -db bandwidth) for each stage are obtained directly from the low-pass plane solution. This is accomplished by using a plot of the correspondence of the imaginary axes of the low-pass and band-pass planes. Since the alignment data is obtained directly in the synthesis procedure, only approximate design equations are needed for the interstage networks. These are developed in the third part of the report. The final adjustment is performed experimentally. Throughout the development of the synthesis procedure, interaction is assumed to be negligible in order to simplify the problem. Thus it is necessary to investigate methods of reducing interaction so that this assumption is justifiable. It is shown that the order of the stagger-tuned stages is a very important factor in reducing interaction. In the final part of the report, the design of a low-frequency-analog amplifier (eight megacycle center frequency, one megacycle bandwidth) is described in order to illustrate the use of the synthesis and design techniques. The experimental results obtained with this amplifier check closely with the results predicted by the theory. (Contractor's abstract)

HELIX IMPEDANCE OF TRAVELING WAVE TUBES, by P. K. Tien. June 27, 1952, 26p. incl. diagrs. (Technical rept. no. 50) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) U23274; ATI-159659 Unclassified

The impedance parameter $E^2z/2\beta^2P$ of a circular helix was investigated for a tape-helix model in which a helix of width δ and pitch p is assumed to be wound of infinitely thin conducting tape. (E_z is the maximum value of the axial electric field on the axis of a helix carrying power P and with a phase constant β.) The results indicate that the impedance has a smaller value than for the sheath-helix model and is considerably reduced at larger values of ka, the ratio of the helix circumference to the free-space wave length. Analysis of a tape helix surrounded by a dielectric medium established that the impedance of a helix of circular wire, supported by a dielectric structure, can be estimated on the basis of the phase velocity reduction. The estimates using this procedure were in agreement with measurements on various tube designs. Two ways of improving the helix design for use in traveling wave tubes were indicated: (1) to increase the dielectric loading factor and (2) to reduce the space harmonic component fields. The dielectric loading factor can be raised by using dielectric supports so that most of the dielectric material is away from the helical surface; the space harmonic component fields can be reduced either by using a larger ratio of δ/p or a smaller value of ka.

THE MECHANISM OF RADIO REFLECTIONS FROM METEORIC IONIZATION, by V. R. Eshleman. July 15, 1952, 128p. incl. diagrs. table, refs. (Technical rept. no. 49) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) U23268; ATI-163933 Unclassified

A theory of radio reflections from cylinders of ionization is presented in an attempt to explain the characteristics of radio echoes from meteor trails. The theoretical approaches to the problem were (1) solution of the electromagnetic-wave equation for dielectric columns with cylindrical symmetry and (2) a summation of the fields scattered by the individual electrons in the column. Neither method was easily applicable for finding reflections from a column of arbitrary properties; however, consideration of both led to approximate expressions for the reflections as a function of size, number of electrons, and radial variation of electron density. A meteor-trail model which is proposed to explain conflicting experimental results consists of a column with a dense core surrounded by a larger, more dilute region of ionization. This model would produce the observed increase in the number and amplitude of meteor echoes with wave length as well as the difference in polarization effects measured at different wave lengths. High electron densities in the dense core of the column appeared responsible for the small percentage of long-duration echoes; these durations were believed to be enhanced by the sharp boundaries of this inner core. The amplitude fluctuations observed in long-duration echoes were attributed to (1) upper atmosphere winds and turbulence and (2) expansion of the sharply bounded inner core of ionization. A theoretical treatment of forward scattering from meteor trails indicated that the duration of meteor echoes is expected to increase markedly with the distance between the transmitting and receiving locations.

GRID-MODULATED TRAVELING WAVE TUBE FOR LOW-PASS AMPLIFICATION, by J. T. Mendel. July 31, 1952, 92p. incl. diagrs. tables. (Technical rept. no. 47) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) U23203; ATI-166259
Unclassified

The fundamental limitations of conventional wideband low-pass amplifiers using triodes and pentodes preclude the possibility of extending the gain-bandwidth performance of these devices much beyond present day standards. The network approach to extremely large bandwidths is seriously hampered by the difficulties encountered in the physical realization of the component parts. Parasitic inductances and capacitances, and the effects of conventional networks are virtually impossible to eliminate. To circumvent the limitations of vacuum tube networks, the inherent broadband high-gain properties of the traveling-wave tube have been utilized to achieve low-pass video amplification. The video signal is used to modulate the beam current of a helix type TWT, and consequently the effective gain of the table varies according to the input signal. A microwave local oscillator supplies a carrier signal to the input of the helix and the modulated output of the TWT is fed into a grounded-grid microwave triode which serves as a plate detector. Following the detector is a low-pass filter which rejects the microwave frequency components appearing at the plate of the detector. At the output of the low-pass filter the original video signal appears at an amplified level. Thus, the basic principles of modulation, amplification, and detection are combined in a system to accomplish low-pass amplification. The analysis that a video gain of 36 db over the pass band 0-1000 mc is possible with components which are easily realized in view of modern construction techniques. A gain of 60 db with the same video bandwidth is possible if a second unmodulated TWT is employed to serve as a linear power amplifier. With respect to gain and bandwidth, the indicated performance of this system is better by an order of magnitude than other more conventional broadband amplifiers available at this time. An experimental system has been constructed and tested to verify the predicted behavior. The experimental measurements of bandwidth and video gain were in close agreement with the analytic results. It was found that with the proper level of input carrier power the output power of the TWT was a linear function of beam current over a wide range, and consequently the system could be made linear for much larger input video powers than the analysis indicated. Although the grounded-grid triode detector used in the experimental system was adequate for measurement purposes, a tube of larger power capabilities would be needed for a practical high gain amplifier. The overall video noise figure is shown to be several db larger than that of the modulated TWT when operating as a microwave amplifier. If a representative low noise TWT were used the video noise figure would be of the order of 15 db. (Contractor's abstract)

TRAVELING WAVE AMPLIFICATION OF MILLIMETER, by H. Heffner. July 31, 1952 [118]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 51) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) U24219; ATI-169726
Unclassified

An investigation of the helix and certain heavily loaded waveguides is made to determine their suitability as slow wave structures of millimeter wave amplifiers. Fundamental mode interaction in these circuits is found to be unsuitable because of the minuteness of the dimensions involved and the excessive close tolerances required in their construction. The periodically loaded guide is shown to exhibit space harmonics of the fundamental mode whose velocities may be made many times lower than that of the fundamental. Interaction with these space harmonics is investigated particularly with regard to the finned rectangular guide and is shown to lead to practical millimeter wave amplifiers if the impedance magnification around either the high or low frequency cut-off regions is utilized. The advantages of low frequency cut-off operation are pointed out. A detailed analysis of the expected gain in the vicinity of the low frequency cut-off including the effects of loss and space charge for the first space harmonic of the fin-opposite-fin and fin-opposite-slot corrugated guide is made. Interaction with backward waves is investigated and is shown to form a high gain, narrow band, regenerative-type amplifier, and, at higher beam currents, a continuously voltage tunable oscillator suitable for use in the millimeter wave region. The start-oscillation conditions including the effect of space charge are quoted. The probable occurrence of backward wave oscillations in forward wave space harmonic amplifiers is pointed out and methods for their elimination proposed. The easitron, consisting of a resonant wall surrounding an electron beam, is analyzed and shown to form a high gain narrow band amplifier. Circuits of both cylindrical and rectangular geometry are proposed for millimeter wave easitrons and curves of expected gain are drawn. The problems of circuit excitation are pointed out. The results of a representative sample of nine experimental tubes of both the space harmonic and easitron type are given and compared with the theory presented. (Contractor's abstract)

STA. 05:007 - STA. 05:009

Superregeneration is a method of operation whereby the tendency of a traveling-wave amplifier to oscillate is utilized to obtain high gain and improved sensitivity. In superregenerative operation the traveling-wave tube is allowed to oscillate periodically. The conditions of operation are such that the amplitude of oscillation is greatly increased when a signal is received. Conventional operation, in which attenuation is added to the helix structure, and superregenerative operation are compared. Gain is increased from 18 to 50 db and sensitivity is improved by at least 5 db during superregenerative operation. Superregenerative amplification is not, however, amplification in the true sense. Many frequencies other than those contained in the signal are present at the output. (Contractor's abstract)

SCATTER-SOUNDING: A TECHNIQUE FOR STUDY OF THE IONOSPHERE AT A DISTANCE, by O. G. Villard, Jr. and A. M. Peterson. Aug. 1952, 16p. incl. illus. tables, refs. (Technical rept. no. 54) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) U24482; ATI-169853 Unclassified

Presented at URSI-IRE meeting, Nat'l. Bur. Standards, Washington, D. C., Apr. 21-24, 1952.

Also published in I. R. E. Trans. of Professional Group on Antennas and Propagation, v. PGAP-3: 186-201, Aug. 1952.

Echoes arising through back-scattering when radio waves strike the ground at oblique incidence are readily detectable even with low power and provide a useful means for studying the ionosphere at a distance. Use of a rotatable directional antenna, with PPI display of the back-scattered echoes is convenient. The techniques, called scatter-sounding, permits systematic investigation of geographical variations in F-layer MUF, and makes possible for the first time study of the detailed spatial distribution of sporadic-E clouds and other anomalies. The characteristics of F-layer back-scatter echoes are reviewed from the standpoint of their usefulness in ionospheric research. As an aid in interpretation, the following relationships, calculated on the basis of a parabolic model of the F-layer, are presented in graphical form: (1) echo amplitude and pulse width, (2) echo delay time and distance to the edge of the skip zone, and (3) equivalent transmission path length and the corresponding vertical angle. Experimental verification of the pulse width-echo amplitude relationship is found to agree well with the simple theory. Examples of some practical uses of scatter-sounding are given. SYNTHESIS OF DISTRIBUTED AMPLIFIERS FOR PRESCRIBED AMPLITUDE RESPONSE, by A. D. Moore. Sept. 1, 1952, 95p. incl. diagrs. tables, refs. (Technical rept. no. 53) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) U24220; ATI-171341 Unclassified

The purpose of this investigation is the development of synthesis techniques for distributed amplifiers in order to produce amplitude characteristics which approximate specified functions of frequency, using the concepts of modern network theory. Conventional distributed amplifiers are designed by an extension of the principles of image-parameter filter synthesis; this study shows that it is possible to combine the more effective insertion loss method of filter design with an interactive process to achieve prescribed amplitude characteristics for distributed-amplifier stages in specified circuit configurations. The relationship between this problem and the more complete one of general active network synthesis is described. Amplifiers with resistively terminated ladder-like reactive structures in the plate and grid networks are analyzed. It is shown that the number of degrees of freedom available for approximation purposes in the gain function of a distributed-amplifier stage is usually less than the number apparent in the degree of the function. For this reason, it is generally impossible to match exactly an arbitrarily specified function of the same degree if the corresponding circuit is to be physically realizable. In order to satisfy the requirements of approximation and realizability simultaneously, an interative procedure is introduced; variation of the gain function to meet each of the two requirements in turn produces a converging solution. Although no formal proof of convergence is given, the examples show that the method can give useful results after very few steps. The solutions are not unique; a number of discrete choices must be made during the design, so that a finite number of different circuits can be obtained, all in the specified configuration. Some of the available degrees of freedom are not used in the method and must be determined from other considerations. Design techniques for maximally-flat and equal-ripple types of amplitude response are considered in detail. The maximally-flat specification is most easily satisfied; methods are described for numerous special cases, including some which reduce the number of choices which must be made. Modifications applicable to multi-stage amplifiers are described. Illustrative examples are presented for two- and three-tube stages in various configurations, with greatest emphasis on the maximally-flat designs. The principle difficulty in all cases is the necessary factorization of polynomials of high degree; suggestions for simplifying this problem are included. Although the principle remains the same for more elaborate designs, the numerical computation becomes excessive for the usual desk calculator. For this particular form of active network, the iterative solution to the approximation and realization problems presents a new technique in network synthesis. (Contractor's abstract)

EXTENDED-RANGE RADIO TRANSMISSION BY

OBLIQUE REFLECTION FROM METEORIC IONIZATION, by O. G. Villard, Jr., A. M. Peterson and others. Oct. 1, 1952, 23p. incl. illus. diagrs. tables. (Technical rept. no. 55) ([Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research] under N6onr-25107) U24483; ATI-169854 Unclassified

It has been found that radio communication between relatively low-power stations operating at 14 megacycles and separated by distances of roughly 1200 km may be maintained at times when no layer transmission to any point on the earth's surface can be demonstrated to be present. The signal obtained is subject to considerable fading, but some signal is nearly always detectable. The contribution of overlapping oblique-incidence meteor reflections to the observed signal is considered in the light of some preliminary theoretical and experimental findings. It is clearly important to assess the meteoric contribution with care, since the possibility that meteoric reflections alone could account for the signal does not seem unreasonable. Suggestions for futher investigation are given. (Contractor's abstract)

THE POTENTIAL ANALOGY AS APPLIED TO A DRIVING POINT IMMITTANCE FUNCTION, by E. M. Goldfarb. Dec. 1, 1952, 81p. incl. illus. refs. (Technical rept. no. 56) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 3548 Unclassified

The principles and techniques of synthesizing a 1-terminal pair (which is useful in interstage and feed-back networks) are developed with the object of presenting a practical approach to the synthesis of an immittance with a magnitude that is almost constant over a specified band of frequencies. The 1-terminal pair is considered to have a constant value which may be approximated in either a Tchebycheff or Butterworth manner. The potential analogy is used to relate the magnitude and phase functions to the scalar potential and stream functions about filaments of charge. The maximum number of poles and zeros (positive and negative charges) which are needed for the accuracy of the approximation are established. They are then located so that the absolute value approximates a constant value along the pass band. When the negative charge is properly quantized, a constant k is added to the exponential of the complex function which will move the negative charges to the positive charges along odd π lines of flux. For some k k_c, the charges will be located to be analogous to the magnitude squared of a positive real immittance which is approximately constant over a band of frequencies. Graphical root locus techniques are used to locate the minimum permissible value of the constant. The ultimate limiting factors to a full realization of the driving point immittance in a physical form are the wiring and physical components. (ASTIA abstract)

RADIO COMMUNICATION BY SCATTERING FROM METEORIC IONIZATION, by V. R. Eshleman and L. A. Manning. Dec. 1, 1952 [41]p. incl. illus. tables, refs. (Technical rept. no. 57) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force of Scientific Research] under N6onr-25107) AD 3587 Unclassified

By a consideration of the amplitude and duration of echoes forward-scattered from individual meteor ionization trails, and of the probability of detecting randomly oriented trails over an oblique radio propagation path, an estimate of the contribution of meteoric ionization to extended range HF and VHF radio transmission has been obtained. It has been concluded that meteoric ionization alone would give a virtually continuous signal for a transmission path of about 1000 km at frequencies near 15 megacycles. For the very-high frequencies, scattering from meteor trails has been found to be at least an important contributing factor to the propagation of a signal over an oblique path. A precise evaluation of the role of this process must await a better determination of the number of trails as a function of their ionization density. (Contractor's abstract)

THE EFFECT OF RADAR WAVELENGTH ON METEOR ECHO RATE, by V. R. Eshleman. Feb. 1, 1953, 16p. incl. refs. (Technical rept. no. 59) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 3549 Unclassified

A new theory is given for the way in which the number of echoes received from sporadic meteor ionization trails varies with radar wavelength and other system parameters. Previously published explanations of the echo rate dependence on wavelength are critically examined. The present explanation of echo rate variations is based on a more complete analysis of the radio reflection process than is afforded by the Lovell-Clegg theory. A number of apparent conflicts in earlier investigations are reconciled by the new theory. (Contractor's abstract)

STA. 05:014 - STA. 05:017

An experimental study of new synthesis techniques resulted in a stagger-tuned, double-tuned amplifier which has a center frequency of 30 mc, an 18.2-mc bandwidth, a maximally flat gain characteristic, and a midband gain of 43.2 db. An exact low-pass to band-pass transformation was employed which permits utilization of both double-tuned interstages and staggering techniques. The design, tuning, and limitations of the physical networks to produce such an amplifier are discussed together with the measured characteristics of the experimental amplifier. The staggering technique permits cascading stages without narrowing the overall bandwidth. An amplifier was designed without staggering to obtain a comparison of staggered and nonstaggered double-tuned amplifiers. Methods of obtaining the transient response are reviewed, and the need for a simple method of obtaining the transient response is demonstrated. An analog circuit containing only single-tuned RLC and RC circuits is described. The analog has the advantages of precision and ease of tuning. The results obtained from the analog are oscillograms which show the envelope of the transient response of 2, very-wide-band, stagger-tuned, double-tuned amplifiers. The analog can also be used to measure the rejection of transient signals with carrier frequencies outside of the pass band of the analog. Results of measurements of the transient selectivity are included. (ASTIA abstract)

ON THE APPROXIMATION OF ARBITRARY PHASE-FREQUENCY CHARACTERISTICS, by V. H. Grinich. May 1, 1953, 102p. incl. illus. diagrs. refs. (Technical rept. no. 61) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 12808 Unclassified

Design methods were achieved for obtaining an approximation to any given phase-vs-frequency function. The Taylor series approximation in the low-interval case is discussed for its value as a final solution to the approximation problem and as an aid in obtaining Chebyshev approximations. Darlington's approximation method (Bell System Tech. Jour., v. 31: 613-655, 1952) employing a Chebyshev polynomial series is discussed, particularly with respect to conformal transformations and the linear low-interval phase. Taylor approximations were made for an arbitrary band-interval phase and the simultaneous band-interval and phase problem. Elliptic transformations were used to apply Taylor approximation techniques to the nearly equal-ripple (Chebyshev) approximations. Examples of band-interval Chebyshev approximations are presented for the linear phase, the wide-band phase discriminator, standard and direct-approach constant-phase-difference networks, phase equalization for a coaxial cable, and the simultaneous constant attenuation-and-linear phase problem. A discussion is included of (1) the symmetric functions which occur in the Taylor approximations and (2) the expansion of an arbitrary function in a series of elliptic dn functions.

A TRAVELING-WAVE ELECTRON DEFLECTION SYSTEM, by R. C. Honey. May 1, 1953, 58p. incl. illus. refs. (Technical rept. no. 63) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 12598 Unclassified

A detailed study is made of a slow-wave structure whose transverse electric fields may be utilized for

deflecting an electron stream. It is a special case of parallel zig-zag lines since it does not propagate a mode whose transverse electric fields are zero along the plane of symmetry. The phase velocity of such lines as a function of frequency is determined both theoretically and experimentally for a wide range of geometries. A theoretical analysis of the interaction of electrons with purely transverse fields is included which takes into account the deflection occurring within the deflection space as well as within the drift space. The results are applied to traveling-wave structures, and the electron velocities are determined which produce the maximum deflection as a function of frequency, phase velocity, and geometry of structure and drift space. A tube utilizing a zig-zag line deflection structure 9 in. long was built and its phase velocity measured from 100 to 2700 mc. The tube exhibited a maximum sensitivity of over 1 mm total deflection for an input power 20 db below 1 mw. The deflection sensitivity is discussed from several theoretical viewpoints. A matching section tapering from coaxial line to line-over-plane transmission line is described in detail. It is concluded that such zig-zag line structures, in either the form of a line over a plane or of parallel lines, show promise for use in traveling-wave deflection devices. (ASTIA abstract)

Fourier and Laplace methods are reviewed for obtaining low-pass filter functions. The first method describes the input signal as a Fourier series in which frequency components are known, and the second describes the signal as the Laplace transform of the time variable. The signal described by a time-function power series is designated as the quasi-distortionless method. Low-pass filter functions are obtained by this method which exhibit either delay or prediction. Quasi-distortionless functions of increasing complexity are listed, and a discussion is given of their network realizations. Second-, third-, and fourth-order amplitude functions are plotted for comparison with a maximally flat function. Specific networks discussed include the shunt-peaked, linear-phase, and series-peaked circuits. The general quasi-distortionless network is derived in an appendix on the basis of the central moments of pulse-like input and output functions.

SOME PROPERTIES OF A SHEATH HELIX WITH A CENTER CONDUCTOR OR ELECTRICAL SHIELD, by G. W. C. Mathers and G. S. Kino. June 17, 1953, 34p. incl. illus. (Technical rept. no. 65) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 14909
Unclassified

This report outlines the theoretical analysis of a cylindrical helix with either an external shield or a center conductor. The current sheath model of the helix is used in the analysis. The results are presented in the form of equations and graphs which give the ratio of the square of the electric field to the power flow, (modified by appropriate normalizing factors) as a function of frequency for various ratios of the helix-to-conductor radii. The electric fields used in these graphs are the longitudinal electric field at the center of the helix and at the helix, and the radial electric field at the conductor and at the helix. In addition, the input impedance (defined on a power-current basis) for such helical transmission systems has been evaluated and plotted as a function of frequency. These results show that it is possible to obtain a wideband match from a coaxial line to a helical transmission system with a closely spaced shield or center conductor. Several simple matching techniques are briefly explained. (Contractor's summary)

METEORIC RADIO ECHOES, by L. A. Manning. July 15, 1953, 29p. illus. diagrs. refs. (Technical rept. no. 66) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 16402
Unclassified

Also published in I. R. E. Trans. of Professional Group on Antennas and Propagation, v. AP-2: 82-90, Apr. 1954.

A summary of progress in radio meteoric detection is presented which classifies the accomplishments under the headings of astronomical properties, tools for determining properties of the atmosphere, and contributions to radio propagation. Methods of radiant determination are discussed as well as velocity measurements. Velocity measurements made by the Doppler meteor-whistle technique for thousands of meteors indicate that the meteors are members of the solar system. The need for a satisfactory technique to measure the rate of occurrence and distribution in size of meteoric particles is indicated as well as a reliable theory relating meteoric mass and ionization production to augment present information concerning the distributions of the smaller meteoric masses. Various theories are described which attempt to explain the processes in the ionization trail. An important problem remains in relation to the recombination coefficient applicable to meteoric ionization. Meteor studies of wind motion utilize body-Doppler and double-Doppler techniques. The former technique yields information concerning the radial velocity component of the wind, the speed and

STA. 05:021 - STA. 05:025

direction of the average translation of the air mass, and the rms wind speed. The results of both theory and experiment indicate that meteors should be considered as possible transmission mechanisms at frequencies above the normal layer criticals.

COUPLED-HELIX ATTENUATORS FOR TRAVELING-WAVE TUBES, by O. G. Owens. Aug. 26, 1953, 44p. incl. illus. tables. (Technical rept. no. 68) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 18468 Unclassified

An investigation was made of the problem of constructing a coupled-helix device which would operate over a wide range of frequencies. The attenuator is intended for use with a high-power hollow-beam traveling-wave tube operating over the 70- to 300-mc range. A theoretical analysis of the problem is presented. Tests of experimental helices indicated that attenuation by such devices is possible, and that a terminated low-loss coupled helix can be made to have a broad range of attenuation. By taking into account the dielectric loading of the tube envelope, an outer helix with synchronous velocity can be designed on the basis of an equivalent unloaded inner helix. The positions of attenuation maxima and the shape of the attenuation curve can be predicted in this way with fair accuracy.

THE DISTRIBUTED PAIR, by D. O. Pederson. Oct. 5, 1953, 21p. incl. diagrs. tables. (Technical rept. no. 70) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 19061 Unclassified

An analysis is presented for the distributed amplifier (distributed pair) in which the grid and plate networks are simple ladders without any node bridging. The shunt elements of the networks are restricted to a complexity no greater than parallel combinations of resistance and capacitance, and the series elements are restricted to series combinations of resistance and inductance. Design procedures include either rigorous mathematical synthesis and approximation techniques or intuitive cut-and-try methods based on an understanding of the pair. Two amplifiers were built by means of the latter method. On a gain-magnitude basis these simple amplifiers compare favorably with cascades of conventional interstages for bandwidth requirements of about 10 mc. However, the distributed pairs become more advantageous as the bandwidth requirement is increased. The pair also provides a greater available output voltage and will have a more linear input-output voltage characteristic. The frequency or transient characteristic of the pair can be modified (by simple changes in the values of the network elements) to obtain a desired characteristic with little or no change in the gain level. RESONANCE PHENOMENA IN TIME-VARYING CIRCUITS, by M. C. Herrero. Oct. 15, 1953, 97p. incl. illus. diagrs. tables, refs. (Technical rept. no. 69) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 20154 Unclassified

Also published in I. R. E. Trans. of Professional Group on Circuit Theory, v. CT-2: 35-41, Mar. 1955.

A study was made of the sweeping-filter and its applications to panoramic receivers. The latter were defined as receivers which display their responses as functions of the receiver frequency setting. The envelope of the steady-state solution of the sweeping filter was obtained directly. The method of solution utilized a system transfer function defined as the ratio of amplifier output to input as both vary exponentially with time. The case of a variable inductance in a parallel RLC filter was studied in detail. A combination of parameters small compared to unity was indicated for a quasi-steady-state solution. A comparison was made between the sweeping-filter and the gliding-tone problems in panoramic receivers of the sweeping-local-oscillator type. In the gliding-tone problem the peak of the solution for the system output decreased with increasing sweeping frequency, and instability could not occur. In the sweeping filter the peak magnitude was almost constant, and instability occurred under some conditions. Experimental results are included for a backward-wave amplifier used as a sweeping filter at 2000 mc. Analogies and differences of this case with previous cases are tabulated. Various types of parametric excitation are compared, and the resulting solutions are interpreted physically.

THEORY OF RADIO REFLECTIONS FROM ELECTRON-ION CLOUDS, by V. R. Eshleman. Dec. 1, 1953, 37p. incl. diagrs. tables, refs. (Technical rept. no. 72) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 24168 Unclassified

Also published in I. R. E. Trans. of Professional Group on Antenna Propagation, v. AP-3: 32-39, Jan. 1955.

Approximations to the reflection coefficients of electron-ion clouds of various sizes, shapes, and densities are determined. A simplified approach to the problem is employed, wherein the total reflection from the low-density clouds is computed by summing the scattered wavelets from the individual electrons, while the high-density clouds are treated as total reflectors at the critical density radius. Some of the limitations of this method are discussed. While more elaborate determinations should be used in certain regions of cloud size and density, the method used here provides an over-all, first-order approximation of the effects of size, shape and density on the reflecting properties of electron-ion clouds. Several possible applications of the theoretical results are outlined. (Contractor's summary)

LARGE SIGNAL THEORY OF THE TRAVELING-WAVE TUBE (INCLUDING THE EFFECTS OF LOSS, SPACE CHARGE AND FINITE "C"), by H. C. Poulter. Jan. 28, 1954, 87p. incl. diagrs. tables. (Technical rept. no. 73) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 47136 Unclassified

An extension is made of the large signal theory of Nordsieck (Proc. Inst. Radio Engineers, v. 41: 630-637, 1953) of the traveling-wave tube to include the effects of circuit loss, finite C (Pierce's gain parameter), and space charge. The effect of loss is included by considering the equivalent transmission line to be lossy. The effect of finite C is included by retaining all the terms involving C which were neglected in the small C theory, and under conditions of finite C there is an additional term which did not appear in the earlier theory. Space-charge effects are included by considering the field acting upon the electrons to consist of a circuit field and a space-charge field. The latter is evaluated by expanding the charge distribution of the beam in a Fourier series in the time domain. The electric field associated with each of the Fourier components of charge is approximated, and a weighting function is derived which relates the space-charge field at a particular electron to the distribution of charge about that electron. Equations are developed which allow for the computation of cases where the electric field is not constant across the beam, but calculations based on these equations are impractical at present. The numerical calculation procedure for thin beams is described, and results are presented in the form of graphs for thin beams for C = 0.2, d = 0.0, b = 1.5 and 2.2; d is Pierce's loss parameter, and b is defined by $v_0 = \frac{u_0}{1 + bc}$, where v_0 is the wave velocity on the helix in the absence of a beam, and u_0 is the beam velocity.

THE INFLUENCE OF POSITIVE IONS OF ELECTRON-BEAM PROFILES, by B. H. Wadia. Jan. 28, 1954, 66p. incl. illus. diagrs. (Technical rept. no. 74) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 27028 Unclassified

The presence of residual gas within the envelope of an electron tube leads to the formation of positive ions by collision with electrons. Because of the nature of the fields in the drift space, the ions formed are in continuous motion toward the cathode and a variation of ion density in the drift space results. This distribution of positive ions determines the net negative charge effective at each point in the drift space, and hence controls the shape of the beam. This work concerns the possibility of controlling the positive-ion distribution in such a manner as to obtain a nondiverging electron beam. The loss of positive ions to the cathode may be counteracted in two ways. First, by increasing the pressure, one may obtain such a high rate of production of ions that complete neutralization is possible despite

STA. 05:029 - STA. 05:031

the losses. Alternatively, the flow of ions toward the cathode may be eliminated by interposing a positive hump of potential in their path. Both these methods of control have been known for some time, but their simple theory has not found any consistent experimental support. Consequently it is necessary to enlarge upon the simple principles and to modify them in order to obtain a full understanding of the phenomenon and to correlate theory with experiment. The results of the investigation indicate that both methods of control involve more complicated phenomena than are accounted for in the prevailing simple theory. The first method cannot be widely applied because of practical considerations, but the second, which avoids these disadvantages, should find some application. The investigation also shows that the design of the second method, called ion trapping, is only possible by a process of trial and error. Qualitative suggestions are made which can be of help in designing an acceptable trapping system. (Contractor's summary)

STUDY OF MICROWAVE NOISE IN BEAM-TYPE DEVICES, by G. Wade. Apr. 21, 1954, 164p. incl. illus. diagrs. refs. (Technical rept. no. 75) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 32043 Unclassified

The microwave noise properties of electron beams and of certain devices which employ beams were investigated. An approach to the problem of analyzing the noise characteristics of beams is presented which accounts for the multivelocity nature of beams. The approach embodies a set of simultaneous equations whose solutions give the variations of the magnitude of the ac current and the velocity for an arbitrary number of modulated beams which are mixed at an input plane and then allowed to travel together. The multivelocity approach gave results which were in close agreement with those of the Rack approach (Bell System Tech. Jour., v. 17: 592-619, 1938). An analysis of the rectification characteristics and the noise behavior is presented for a traveling-wave tube modified for use as a video detector. The analysis indicated that such a detector would have a smaller minimum detectable signal than do crystal detectors. The noise and amplification properties were examined for a traveling-wave amplifier which employs a coupled helix structure as a slow-wave circuit. An analysis of the interaction between lightly coupled helices and an axial beam includes a derivation of the equations for the propagation constants. (ASTIA abstract)

NEW METHODS OF DRIVING-POINT AND TRANSFER-FUNCTION SYNTHESIS, by R. H. Pantell. July 19, 1954, 101p. incl. diagrs. refs. (Technical rept. no. 76) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 35057 Unclassified

New methods are presented for accomplishing driving-point and transfer-function synthesis by means of passive, linear, bilateral elements without including coupled coils. Two new approaches to driving-point synthesis are discussed: decomposition of the even part of the impedance function and nonladder realizations. In the former, the even part of the specified function is expressed as the sum of even functions that individually satisfy the conditions for being the even part of a positive-real function. The impedance corresponding to each even function was determined and synthesized by Brune procedure (Jour. Math. and Phys., v. 10: 191-236, 1931). By decomposition of the even functions the impedances can be made to have zeros on the $j\omega$-axis and reduced to expressions that are simpler to realize than the Brune procedure. The nonladder realizations require one less reactive element per reduction cycle than the Bott-Duffin (Jour. Appl. Phys., v. 20: 816, 1949), realization requires. A new method for RLC transfer-function synthesis presents a means for realizing a minimum-phase function H(p) to within a constant multiplier provided that H(p) has no poles on the $j\omega$-axis including infinity. Synthesis is illustrated for resistance termination at input and output and for an RC termination at both ends. The synthesis problem, regardless of the complexity of H(p), can always be reduced to the problem of synthesizing driving-point functions that are no more complicated than the ratio of quadratic polynomials in p. NOISE AT THE POTENTIAL MINIUM IN THE HIGH-FREQUENCY DIODE, by D. A. Watkins. July 29, 1954 [3]p. incl. diagrs. refs. (Technical rept. no. 89) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD C8068 Unclassified

Also published in Jour. Appl. Phys., v. 26: 622-624, May 1955.

Noise quantities at the potential minimum in the high-frequency diode are analyzed by means of a relatively simple model which assumes that the transit angle from the cathode to the potential minimum is small and that the transit angle from the potential minimum to the anode is large. The mean-square convection current is found to be about half full shot noise for a typical case and the mean-square velocity is found to be the same as in the temperature-limited case. Application of this result to an analysis of the minimum obtainable noise figure of klystrons and traveling-wave tubes using velocity-jump noise reduction shows that their noise figure can be reduced without theoretical limit by increasing the current density at the cathode.

HELIX MILLIMETER-WAVE TUBE, by W. V. Christensen and D. A. Watkins. Aug. 23, 1954, (rev. Nov. 1, 1954) [4]p. incl. illus. (Technical rept. no. 82) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 61074 Unclassified

Also published in Proc. Inst. of Radio Engineers, v. 43: 93-96, Jan. 1955.

The experimental results of a program to extend helix backward-wave oscillator techniques to the 4.5- to 6.0-millimeter range are described. The design of a tube capable of cw output over this range is presented together with operating characteristics. The tube employs a tungsten helix wound with 0.002-in. by 0.005-in. tape with a 0.025-in. inner diameter. The helix voltage is tuned from 2,400 to 850 volts to cover the range, and the cathode current is 4.0 ma. The tube with its all-glass envelope is believed to be a relatively inexpensive millimeter-wave signal source. Power output is estimated to be greater than 1 milliwatt.

JUNCTION-TRANSISTOR CIRCUITS FOR SQUARE-WAVE GENERATION, by C. Martin, Aug. 24, 1954, 47p. incl. illus. diagrs. refs. (Technical rept. no. 78) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 54848 Unclassified

This work comprises a review of junction transistor multivibrators with the aim of finding a practical frequency-controllable square-wave generator. Two circuits appear to offer the best possibilities as far as a good waveform and a good percentage of utilization of the supply voltage are concerned. Of these two circuits, the emitter-coupled multivibrator gives broader possibilities of frequency control. This circuit has been built and tested, and it operates over a range of 50 cps to 20 kc/s, the frequency being adjustable by a single control knob. An output amplitude of 15 v is obtained using a 19 v dc supply. Analysis of the different multivibrators is developed in a manner similar to that used for vacuum-tube multivibrators. The transistor is replaced by equivalent passive T networks, the element values of which are taken from the characteristic curves or from measurements at the proper operating points. BACKWARD-WAVE OSCILLATOR EFFICIENCY, by R. W. Grow. Nov. 2, 1954, 129p. incl. illus. diagrs. refs. (Technical rept. no. 80) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 48897 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 43: 848-856, July 1955.

Backward-wave oscillators are new and interesting devices which have characteristics different from those of other microwave tubes. This report contains the results of a study conducted for the purpose of obtaining information concerning the factors which determine the oscillation level in a backward-wave oscillator and which will permit the design of an oscillator to produce a given amount of r-f power. All of the theoretical results contained in this report are based on linear theory restricted by an arbitrary specification of the degree of saturation of the device. A large-C theory of backward-wave oscillators is derived as a basis for beginning the efficiency study. It is shown that values of large C obtained to date cannot produce any additional significant differences in the operating characteristics than would be expected from small-C theory. The efficiency of backward-wave oscillators is influenced by space charge, circuit loss, beam thickness, and velocity spread and the effect of each of these factors is presented in the report in such a manner as to provide results which can be easily applied to the understanding of backward-wave oscillators and to their design. Poor terminations at the ends of the circuit of backward-wave oscillators are shown to produce sinusoidal variations in the starting current and power-output vs frequency curves. The magnitude of the variations is determined in analytic form as a function of the reflections at the ends of the tube and the circuit loss. An additional forward-wave mode existing simultaneously with the backward-wave mode of an oscillator is shown to produce no effect with perfect matches even when both modes have identical spacial variations. It is possible that the combination of two modes and imperfect matches will affect the operating characteristics. (Contractor's summary)

ON THE THEORY OF JUNCTION TRANSISTORS, by R. D. Middlebrook. Dec. 16, 1954, 132p. incl. diagrs. tables, refs. (Technical rept. no. 79) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 50323 Unclassified

The theory is prefaced by a qualitative discussion of solid-state physics and crystal structure. A general qualitative development is given of the p-n-p junction transistor by way of the p-n junction rectifier and a brief discussion of crystal structure. A more detailed treatment of crystal structure is followed by the idea of energy bands which leads to the distinction between insulators, conductors, and semiconductors. Definitions are given of the Fermi level and of an intrinsic semiconductor. Equations are obtained for carrier densities in intrinsic and in impurity semiconductors, and the modification of the Fermi levels because of injected carriers is discussed. A qualitative discussion of the energy diagram is followed by a discussion of the p-n junction under applied forward dc potential. A solution is given of the continuity equation for minority carriers which leads to the rectifier characteristic of the p-n junction. The equations for carrier currents are obtained for a p-n junction under applied reverse potential. The continuity equation is solved for minority carriers in the base region, and this leads to an explanation of the power gain of a transistor. Emitter and collector minority currents are discussed, and an LF equivalent circuit is set up. The qualitative effects of feedback and capacitance in the transistor are summarized.

A FLIP-FLOP CIRCUIT BASED ON FREQUENCY MEMORY, by H. C. Lee. Jan. 30, 1955, 42p. incl. diagrs. (Technical rept. no. 81) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 56611 Unclassified

The present report is intended to introduce the idea of counting in multi-mode oscillatory systems by use of a beat-frequency technique. To demonstrate this idea, a binary counting system which employs a balanced frequency mixer to switch from one frequency to the other is studied. The analysis is based on a bistable oscillator with two degrees of freedom, forced with an external signal. The corresponding behavior is described by a simultaneous pair of second-order nonlinear differential equations for which no general solution is known. Graphical solutions for different values of the external voltage have been obtained with the aid of the IBM computer. Conditions for switching are analyzed and discussed. It is found that for satisfactory switching it is necessary that the external voltage must exceed a certain critical value. An experimental system which has the property of a binary counter is described. The experimental results confirm the prediction of the analysis. To extend this idea, a ten-frequency decimal counter based on beat-frequency techniques is discussed. Finally, a new technique for frequency switching based on a single variable impedance is introduced and studied in terms of the behavior of the roots in the complex frequency plane. NORMAL MODE THEORY IN PERTURBED TRANSMISSION SYSTEMS, by G. S. Kino. May 2, 1955, 229p. incl. diagrs. refs. (Technical rept. no. 84) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 63628 Unclassified

The reciprocity theorem is used to derive the orthogonality properties of the modes of transmission systems that are either uniform or periodic in the Z direction. Certain of the conditions are valid for modes that are not pure TE or TM, even when there is loss present, and there are several conductors passing through the cross section. It is also shown that, in a lossless system, the propagation constants of the modes (or fundamental space harmonics) are pure real or pure imaginary and the corresponding power flows are pure imaginary or pure real. The perturbation of the modes of a uniform or periodic system by change in permittivity, permeability or the current at some point, is considered by making use of normal mode expansions derived from the orthogonality conditions. It is shown that the expansion derived by Pierce for pure TM modes is valid for the non-θ-varying modes of a general circular system. A combination of Birdsall's impedance matching method and the normal mode expansion is used to derive $E^2/_{\beta}{}^2P$ at any point of a uniform transmission system. The change in the propagation constant caused by the insertion of a dielectric rod or uniform conductor into a transmission system is also calculated, and it is shown how $E^2/_{\beta}{}^2P$ may be determined from measurement of this effect. Pierce's factors C and Q for a hollow electron beam inside a sheath helix are derived from the normal mode or expansion and by a method known to be accurate; good agreement is obtained between the results. Fletcher's derivation of these parameters is discussed, and it is shown that some of the assumptions made are not valid, so that values of Q obtained are too low. The normal mode method is used to estimate QC^3 for a sheath helix or tape surrounded by dielectric. It is demonstrated that the correct value of $E^2/_{\beta}{}^2P$ has been applied in the past to periodic systems but the value of QC^3 in the presence of dielectric is somewhat lower than for the system with no dielectric. The completeness and convergence of the expansions for a sheath helix are checked by comparing with direct derivations of identical expansions from the field theory of Mittag-Leffler's method. In all important cases the expansions are convergent but are complete for the shielded helix, only when certain fast and cut-off modes that do not appear in the unshielded helix system are taken into account. These

modes form a continuum in Γ in the so-called forbidden region of the unshielded sheath helix and may be included in the normal mode expansion in the form of an integral Such an integral is shown be valid for a simple parallel plate transmission system when one plate is removed to infinity. A JUNCTION-TRANSISTOR HIGH-FREQUENCY EQUIVALENT CIRCUIT, by R. D. Middlebrook. May 2, 1955, 231p. incl. illus. diagrs. tables. (Technical rept. no. 83) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 65767 Unclassified

A new junction transistor equivalent circuit, derived from theoretical principles and valid up to and beyond the alpha cut-off frequency, is presented. Two main results are achieved: first, it is shown how the behavior of a practical transistor depends on the geometry and physical properties of the transistor materials (of use to transistor designers); second, it is shown how the element values in the practical equivalent circuit may be determined numerically from six measurements made on a completed transistor (of use to circuit designers). The final equivalent circuit takes into account collector space-charge capacitance, collector space-charge-layer widening, and base resistance, and is in the form of four short-circuit admittances. Each admittance can be represented by a network of lumped elements each of which is constant with frequency. The results are obtained for the ground-base connection, but are easily modified for grounded-emitter or grounded-collector configurations. Experimental verification of the practical equivalent circuit is presented for fifteen commercial transistors of various makes and types, and it is concluded that the theoretical results obtained are substantiated both qualitatively and quantitatively. ITERATIVE METHODS IN AMPLIFIER INTERSTAGE SYNTHESIS, by G. A. Caryotakis. May 2, 1955, 95p. incl. diagrs. refs. (Technical rept. no. 86) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 65768 Unclassified

A discussion is given of the design of low-pass video amplifiers for specified amplitude or phase response. This is accomplished by stagger tuning similar to that used for narrow-band amplifiers except that the problem is complicated by the presence of finite zeros in the amplifier gain function. The method used is an iterative process by means of which the elements in the predetermined amplifier configuration can be adjusted so that the gain function may approximate the desired response. The designs obtained by this method exhibit a marked increase in gain-bandwidth product over the all-pole designs. The iterative method can be applied to synthesis for prescribed phase as well as amplitude response.

SOME PROPERTIES OF OBLIQUE RADIO REFLECTIONS FROM METEOR IONIZATION TRAILS, by O. G. Villard, Jr., A. M. Peterson and others. May 31, 1955, 33p. incl. diagrs. tables. (Technical rept. no. 85) (In cooperation with Stanford U. Radio Propagation Lab.) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 68059 Unclassified

Also published in Jour. Geophysical Res., v. 61: 233-247, June 1956.

Certain characteristics of radio signals propagated by reflection from meteor ionization trails from a low-power continuous-wave transmitter 960-km distant are studied at radio frequencies of 23.2, 46.4, and 92.8 megacycles. In particular, the percent of the total time that meteor reflections were detectable at each frequency is presented, and shown to be in qualitative agreement with theoretical expectations. Simultaneous recordings were also made of signals from a second remote transmitter operated at 23.1, 46.2 and 92.4 megacycles, and located at variable distances up to 180 km from the first. Based on the percent time signals received from the second transmitter were coincident with those from the first, it is concluded that reradiation from the numerous, low density trails is highly directional, and that the fading, long-enduring echoes from the relatively-infrequent, high-density trails are considerably less directional. When the transmitters were spaced in a direction perpendicular to the propagation path, the signal coincidence decreased much more rapidly with transmitter spacing than when the transmitters were spaced along the propagation path. ON THE STATISTICAL DESIGN OF DEMODULATION SYSTEMS FOR SIGNALS IN ADDITIVE NOISE, by J. B. Thomas. Aug. 1, 1955, 140p. incl. diagrs. refs. (Technical rept. no. 88) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 68067 Unclassified

Demodulation system to recover message signals corrupted by additive noise are discussed with the assumption that the amplitudes of the message and the noise have Gaussian probability distributions. The maximized posterior probability density function of the

STA. 05:043 - STA. 05:045

message is given by 2 integral equations which contain as known functions the autocorrelation functions of the message and of the noise and the functional form of the modulated wave. Solutions of these equations result in receivers which are optimum on a maximum likehood basis. For the assumed Gaussian statistics, this is equivalent to being optimum on a minimum mean-square-error basis. The analysis shown that for the case of simple filtering, the optimum filter is Wiener's minimum mean-square-error filter. In the AM case the optimum receiver is a cross-correlation detector followed by a form of the Wiener filter. A more appropriate criterion than that of the mean-square error for high noise level reception is the loss of correlation between the message part of the input and the output of various AM receivers. Specification of the optimum AM receiver requires a knowledge of message and noise power spectra and of carrier amplitude and phase. The error introduced when the carrier phase and magnitude are unknown is given, and the optimum receiver is shown to be relatively insensitive to such errors. Within the limits of certain approximations, the optimum PM receiver is a lock-oscillator type of detector. (ASTIA abstract)

RADIO COMMUNICATION AND SCATTER PROPAGATION, by J. D. Mitchell, Jr. Aug. 15, 1955, 49p. incl. illus. diagrs. (Technical rept. no. 87) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 68060 Unclassified

This report discusses the communication capabilities of ground-scattered propagation. It is shown that radio communication may be practical using frequencies several megacycles higher than the conventional great-circle-path maximum usable frequency (MUF). To make use of ground-scattering it will be necessary that transmitting and receiving antennas be directed towards distant scattering areas on the earth's surface which can be commonly illuminated rather than along the great-circle-path between stations. A number of experiments which demonstrate the characteristics of ground scattered propagation are discussed. The scatter-path MUF is calculated and compared with the conventional great-circle-path MUF for a number of different transmission path lengths and orientations. Possible limitations of ground scatter communications are outlined and recommendations are made for further study of this propagation mode. (Contractor's summary)

PRINCIPLES AND CONCEPTS OF RELIABILITY FOR ELECTRONIC EQUIPMENT AND SYSTEMS. PART I. INTRODUCTION TO ELECTRONIC RELIABILITY, by W. F. Luebbert. Aug. 18, 1955, 62p. incl. diagrs. tables, refs. (Technical rept. no. 90) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 73482 Unclassified

General concepts, principles, and mathematical techniques are to be presented for the analysis of reliability in electronic equipment. Electronic reliability is pointed out as one of a number of important aspects of the broad general problem of achieving most efficient and effective performance from electronic equipment. A rationale for the development of reliable systems is developed and presented in the form of a system development check-list. A discussion is given on the term reliability and some of the meaning that might be given to it. A few of the figures-of-merit are discussed which can be used to measure the basic property akin to dependability, trustworthiness, and failure resistance. A brief, simplified introduction is given to life curves of reliability vs time description. The initial discussion is qualitative; various simple patterns of failure are introduced and described with emphasis being given to the degree of randomness in time of occurrence, to variation with time of the instantaneous hazard of failure to an individual, and to presentation, when applicable, of a simple mechanism of failure which might lead to such a pattern of failure. An analogy between equipment life patterns and human mortality is demonstrated and explained. This analogy leads to an approach which indicates that differential (or integral) equations of probability such as are used in queueing (waiting line) theory, renewal theory, and even in Gompertz-Makenham actuarial mathematics may be useful in reliability problems.

PRINCIPLES AND CONCEPTS OF RELIABILITY FOR ELECTRONIC EQUIPMENT AND SYSTEMS. PART II. SIMPLE MODELS FOR FAILURE OF COMPLEX EQUIPMENT, by W. F. Luebbert. Aug. 18, 1955, 62p. incl. illus. diagrs. tables, refs. (Technical rept. no. 91) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 73483 Unclassified

Further analysis was conducted on simple models for the failure of complex systems. Basically, 2 types of systems are considered: (1) cascade systems, in which the failure of any essential element of the system causes failure of the system; and (2) parallel redundant systems, in which there is duplication of essential elements, so that the system remains successful as long as any of the elements remain successful. Most practical equipment systems can be broken down into combinations of these basic types. The models considered assume either complete success or complete failure of function, and hence are drastic simplifications of reality; yet, when applied realistically, with due attention to their limitations and capabilities, they are considered quite useful. REGULARLY OBSERVABLE ASPECT-SENSITIVE RADIO REFLECTIONS FROM IONIZATION ALIGNED WITH THE EARTH'S MAGNETIC FIELD AND LOCATED WITHIN THE IONOSPHERIC LAYERS AT MIDDLE LATITUDE, by A. M. Peterson, O. G. Villard, Jr. and others. Sept. 30, 1955, 25p. incl. illus. diagrs. table, refs. (Technical rept. no. 93) (In cooperation with Stanford U., Radio Propagation Lab. under Office of Ordnance Research, DA 04-200-ORD-181) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 74945 Unclassified

Aspect-sensitive radio reflections in the frequency range from 6 to 30 mc have been regularly obtained from scattering sources located within the ionosphere at locations quite far south of the auroral zone. Observations have been made at two locations on the West Coast of the United States (Stanford, Calif., geomagnetic latitude 43.75°, and Spokane, Wash., geomagnetic latitude 55°). With few exceptions, the echoes occur when the line of sight from the transmitter intersects a magnetic field line at perpendicular incidence at heights corresponding to those of the E- and F-layers. Thus the E-layer echoes are obtained from areas in the immediate vicinity of the observing stations. The echoes may be detected with relatively low-power radars during the majority of the hours of darkness on almost every night. The reflection geometry and the characteristics of the echoes themselves — occurrence frequency, fading rate, etc., — all suggest that the observed low-latitude phenomenon is caused by the same general type of particle bombardment which is believed to cause the aurora. SYNTHESIS OF MULTITERMINAL TWO-ELEMENT-KIND NETWORKS, by F. S. Boxall. Nov. 1, 1955, 122p. incl. diagrs. (Technical rept. no. 95) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 76262 Unclassified

A method is given by which all the realizations of a given immittance matrix may be obtained by a sequence of elementary transformations on an initial realization which is usually nonphysical. The labor involved in passing from one realization to another is small, and the designer is guided at each step of the transformation by the form of the current realization. A useful by-product of the method is the generation of equivalent networks. Since any terminal-pair voltage can be expressed as the difference of 2 terminal-to-ground voltages and since any terminal pair current can be expressed as 2 equal and opposite terminal-to-ground currents, the synthesis procedure can be applied to terminal-pair networks. The theoretical development and examples are phrased in terms of RC networks, but the results are valid for RL and LC networks after a simple change of variable. (ASTIA abstract)

THEORY AND APPLICATION OF UNIFORM ELECTROSTATIC FOCUSING OF HOLLOW ELECTRON BEAMS, by C. B. Crumly. Nov. 1, 1955, 78p. incl. illus. diagrs. refs. (Technical rept. no. 457-1) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107 and DA 36-039-sc-63189) AD 79834 Unclassified

A method of focusing hollow electron beams is investigated which eliminates the need for a magnetic field. The method uses a radial electric field to counterbalance the space-charge divergence forces in axially symmetric, spinning hollow beam. The analysis shows that the nonuniform-charge-density distribution requirement is not critical for beams that are not thick. An experimental traveling-wave amplifier tube, operating in the UHF region, was designed and built, and the results confirmed the practicality of this focusing method.

Also published in Proc. Inst. Radio Engineers, v. 43: 923-931, Aug. 1955.

Double-tuned amplifier stages have a greater gain-bandwidth factor than single-tuned stages, and by stagger tuning the double-tuned stages the gain-bandwidth factor is better preserved as stages are cascaded than if identical stages were used. This paper presents the results of a study which has yielded accurate design curves for the wide-band case permitting straightforward synthesis of maximally-flat staggered pairs and triples. The theory leading to the design curves is described in the Appendix. (Contractor's summary)

THE SINGLE-LAYER SOLENOID AS AN RF TRANSFORMER, by W. A. Edson. Nov. 30, 1955 [5]p. incl. diagrs. (Technical rept. no. 97) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 79929 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 43: 932-936, Aug. 1955

A set of curves is presented which makes it relatively easy to design air-core transformers satisfying a majority of engineering needs. Inductances in the range 0.1 μh to mh, coupling coefficients in the range 0.001 to 1.0, and inductance ratios up to 100:1 are covered directly. Certain arbitrary restrictions are placed upon the proportions in order to obtain a single set of charts, but the available electrical characteristics are not limited thereby. The proportions of the resulting coils are compatible with large values of Q, but this is seldom important because heavy damping must usually be provided by associated resistors. The derivation and use of the curves is explained. (Contractor's summary)

RADIO ECHOES FROM AURORAL IONIZATION DETECTED AT RELATIVELY LOW GEOMAGNETIC LATITUDES, by R. L. Leadabrand. Dec. 9, 1955, 191p. incl. illus. diagrs. refs. (Technical rept. no. 98) (In cooperation with Stanford U., Radio Propagation Lab. under Office of Ordnance Research, DA 04-200-ORD-181) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 82494 Unclassified

Radio echoes were discovered which are the result of reflection from ionization aligned with the earth's magnetic field lines. The echoes between 1400 and 4700 km correspond to reflection from ionization in the zone of maximum auroral occurrence north of Stanford. Ionization formation is attributed to the bombardment of the upper atmosphere by high-speed charged particles emitted from the sun. The echoes have great amplitudes with duration times between 1 sec and 1 hr. Their appearance and disappearance is similar to the behavior of visual aurorae; the occurrence of the echoes is related to geomagnetic disturbances. The heights of deflection are between 300 and 1200 km above the earth's surface. The paths which the auroral signals travel are greatly influenced by the presence of the normal ionospheric layers. The echoes were observed at ranges and bearings which indicate reflection from ionization at points along the auroral zone from eastern Canada to Alaska. The echoes at ranges between 220 and 1800 km correspond to reflection at points where a straight-line path from Stanford intersects the earth's magnetic field lines at perpendicular incidence. The low-latitude auroral effect appears regularly and can be detected at Stanford almost nightly. Frequently, the echoes last throughout the night. The occurrence of the low-latitude auroral echoes has little correlation with geomagnetic disturbances. The heights of reflection are restricted within the E and F layers of the ionosphere. The E-region echoes are associated with the formation of sporadic E ionization. The F-region echoes are related to spread F and F-layer irregularity appearing on the vertical-incidence sounding records.

COMMON-BASE TRANSISTOR EQUIVALENT CIRCUITS FOR WIDEBAND AMPLIFICATIONS, by J. M. Mathias. Dec. 12, 1955, 45p. incl. diagrs. (Technical rept. no. 94) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 79930 Unclassified

The problem of choosing a transistor equivalent circuit of practical usefulness for wideband, low-pass (video) amplifiers is studied experimentally. Measurements of amplitude and phase response up to and beyond a cutoff are made on a single transistor in the grounded-base, resistance-loaded configuration. The calculated responses of several equivalent circuits of varying complexities are compared with the actual measured response. A simple T circuit, having collector capacitance and a single pole expression for α as frequency dependent elements, is found to fit the measurements as well as some of the more complicated forms. Approximate formulas are then found, which enable the cutoff frequency of such an amplifier to be calculated for all values of source and load resistance. An instrument was developed to measure accurately the phase response of the transistor amplifier. This resulted in a device, with high input impedance, that could measure the relative phase shift between a reference signal and the low-[illegible] collector signal at frequencies from the audio r[illegible]p to 10 mc. COUPLED HELICES FOR USE IN TRAVELING-WAVE TUBES, by G. Wade and N. Rynn. Dec. 20, 1955 [10]p. incl. diagrs. refs. (Technical rept. no. 99) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 81064 Unclassified

Also published in I. R. E. Trans. of Professional Group on Electron Devices, v. ED-2: 15-24, July 1955.

Previous theoretical treatments concerning coupled helices in the absence of a beam, while useful for predicting approximate behavior, are not satisfactory for many tube applications because the presence of a beam can substantially modify the behavior. This paper presents a theory of propagation for coupled concentric helices in the presence of a coaxial beam and computes therefrom properties pertaining to coupler and attenuator applications. Included are curves of the propagation constants as functions of coupling coefficient and beam velocity, curves of the inner and outer helix voltages as functions of the physical dimensions, and curves which permit the frequency response for various designs of input and output couplers to be calculated. Sample calculations show that the proper length for input and output couplers is greater than the length for complete energy transfer between helices in the absence of the beam (a criterion commonly used in design work). Calculations also illustrate the related fact that the frequency for maximum transmission through a coupler is lower when the beam is turned on than when off. Only preliminary work has been done to date in computing the properties of a coupled-helix attenuator. (Contractor's summary)

THE ROLE OF METEORS IN EXTENDED-RANGE VHF PROPAGATION, by O. G. Villar, Jr., V. R. Eshleman and others. Dec. 20, 1955 [9]p. incl. diagrs. refs. (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] as Technical rept. no. 100 under N6onr-25107, and Air Force Cambridge Research Center as Scientific rept. no. 3 - AFCRC-TN-55-399, AD 88666 under AF 19(604)1031) AD 81457 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 43: 1473-1481, Oct. 1955.

The main factors influencing the propagation of continuous radio signals by reflection from meteoric ionization trails are reviewed and summarized. A procedure is given for calculating the system parameters required to maintain the signal received over a given path above the cosmic background noise level for 95% of the time. It is pointed out that the variation of signal level with frequency and path length measured for certain "ionospheric forward scatter" circuits, agrees well with calculations based on the assumption that the propagation is entirely by scattering from meteor ion trails. It is suggested that ionospheric scatter is predominantly meteoric at night in the lower latitudes. To the extent that this is true, the minimum performance level of existing circuits could be improved by use of antennas designed to maximize the meteoric component of the signal. Present designs actually tend to discriminate against meteors. (Contractor's summary)

A MEAN-SQUARE ERROR ANALYSIS OF SEVERAL DEMODULATION SYSTEMS, by B. F. Ludovici. Jan. 31, 1956, 50p. incl. diagrs. (Technical rept. no. 101) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 85618 Unclassified

Four different methods of extracting the intelligence from amplitude-modulated carrier in the presence of noise are analyzed on a mean-square error basis. Assumed is band-limited white Gaussian noise and a noise-like modulating intelligence of uniform power spectrum ranging from d-c to an upper limiting frequency equal to two-thirds of the carrier frequency. Included in the analysis are the square-law, autocorrelation, two-amplifier and crosscorrelation demodulators. As an important result, this investigation shows that the autocorrelation demodulator offers no significant improvement over the simple square-law demodulator. Improvements of approximately 3 db and 6 db can be expected from the two-amplifier and crosscorrelation demodulators, respectively. The results agree essentially with those of the other authors who carried out similar analyses on a signal-to-noise ratio basis. (Contractor's summary)

INVESTIGATION OF A TRAVELING-WAVE TUBE WITH INTERCHANGEABLE EXTERNAL SLOW-WAVE STRUCTURES, by A. R. Matthews. Feb. 7, 1956, 158p. incl. illus. diagrs. refs. (Technical rept. no. 102) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 85155 Unclassified

An investigation was conducted on a TWT using an external slow-wave structure consisting of lumped circuit elements connected as conventional filters. The tube for maximum beam coupling is discussed along with the practical considerations for the use of lumped-circuit elements as the slow-wave structure. Electron beam focusing by means of a uniform magnetic field and by periodic electrostatic focusing voltages is briefly examined theoretically and verified experimentally. Cold tests were conducted on the m-derived low-pass

STA. 05:058 - STA. 05:060

filter. Determinations were made of the characteristic impedance, phase shift, attenuation, cutoff frequency, phase and group velocity, and the effective magnitude of circuit elements. An extension was made on the circuit characteristics of the filter for TWT space-harmonic operation. Derivations are presented for the Brillouin diagram, space-harmonic phase and group velocities, space-harmonic voltage-tuning curves, impedance parameter K, and gain parameter C. Results indicated that the external filter slow-wave structure can be developed for a practical tube having the desirable features of small size and voltage tuning in the VHF and UHF range. Periodic electrostatic focusing is demonstrated for backward-wave oscillator operation; it offers further advantages, particularly if large beam currents can be electrostatically focused. The tube is a convenient device for instructional purposes and for further theoretical investigation of such factors as the effects of a large gain parameter. The versatility of changing slow-wave structures while using the identical electron beam is unique to this tube.

SOME NEW HIGH-FREQUENCY EQUIVALENT CIRCUITS FOR JUNCTION TRANSISTORS, by R. M. Scarlett. Mar. 20, 1956, 188p. incl. illus. tables. (Technical rept. no. 103) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 91300 Unclassified

A description is given of the physical processes in an idealized 1-dimensional junction transistor, leading to the fundamental equation for minority carrier motion and its appropriate boundary conditions. The small-signal solution to this equation was stated in the form of 4 short-circuit admittance (or y-) parameters. Rational function approximations are developed for the theoretical short-circuit admittance parameters. An actual transistor is assumed to be composed of the intrinsic transistor in combination with the collector space charge layer capacitance and base spreading resistance. On this basis, a derivation was undertaken, on a reasonably simple and approximate basis of small-signal equivalent circuits and 4-pole parameters representing junction transistor common-emitter and common-collector configurations. Results are presented on the development of methods for the measurement of the small-signal HF properties of junction transistors. A number of fundamental properties involving maximum single-frequency gain and potential instability were obtained for the 3 transistor configurations. Design theory for band-pass and low-pass amplifiers were presented. Discussions are appended on the electric circuit analogy for minority carrier flow in the base region, the effects of surface recombination, and the comparison of y-parameters with those given in a previous report, item no. STA. 05:039. (ASTIA abstract)

ANALYSIS OF COUPLED-STRUCTURE TRAVELING-WAVE TUBES, by N. Rynn. May 7, 1956, 167p. incl. illus. diagrs. refs. (Technical rept. no. 104) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 94037 Unclassified

An analytical procedure was developed for predicting the effect of the electron beam on the coupling between the distributed circuit of a traveling-wave tube and a second transmission system placed adjacent to it and outside the vacuum envelope. Emphasis is placed on the design of couplers and attenuators for traveling-wave tubes. A theory is reviewed which includes the effect of the beam. The theory is applied to predicting the active characteristics of the couplers and one type of attenuator. The theory is extended to include loss in the coupled structure and space-charge in the beam. The coupled-mode theory is summarized and extended to the coupled-structure traveling-wave tube. A root equation is derived, the 4 complex roots of which are plotted as functions of the beam velocity parameter for many combinations of coupling, loss, space-charge, and velocity parameters. The operation of a commercial traveling-wave tube with a coupled-helix attenuator under beam-saturation conditions is determined experimentally. A comparison is made of the saturation properties of 2 different coupled-helix attenuations and a lossy-wall attenuator. Curves are presented which show that a small diameter, tightly coupled helix attenuator has more effect on the electron beam than the equivalent lossy-wall attenuator. An outline is given of the procedure to calculate the passive properties of coupled structures.

AMPLIFIERS EMPLOYING POTENTIALLY UNSTABLE ELEMENTS, by G. S. Bahra. May 7, 1956, 100p. incl. diagrs. tables, refs. (Technical rept. no. 105) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 95920 Unclassified

The tendency toward oscillation which is caused by internal feedback in practical amplifying devices was studied along with the conditions under which this internal feedback may cause the device to oscillate. Studies were also made to establish the maximum gain that may be obtained from a device with circuit conditions that provide freedom from oscillation. Several types of amplifier situations employing various representative types of tubes and transistors are considered. By means of the Nyquist diagram, F(p), the characteristic function, for each of these stages is explored. The extent to which any set of termination provides freedom oscillation is indicated by a stability margin. The use of external feedback or neutralization circuits was not considered. Solutions for a wide range of representative

situations were obtained by means of an electronic computer. Design charts were prepared from the resulting data. Based on the admittances measured for 3 representative junction transistors, several amplifier stage designs were completed. These designs indicate that the gain obtained when stability is insured through control of the terminating admittances is comparable with the gain delivered by the same units in neutralized circuits. The measured gain for an actual amplifier was within 0.8 db of the design value. When the original transistor was replaced by various unselected units of the same type, the amplifier remained stable and exhibited gain variations of not greater than 2 db.

THE DESIGN OF ALIGNABLE TRANSISTOR AMPLIFIERS, by J. F. Gibbons. May 7, 1956, 83p. incl. diagrs. (Technical rept. no. 106) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107) AD 94554 Unclassified

A method is presented for designing easily alignable multistage transistor amplifiers when the individual stages are not unilateral. The method consists in first describing the transistor through measurement of its Y parameters at a set of discrete frequencies in the desired amplifier passband. This definition of the device is then used to determine its maximum available gain vs frequency properties, thus providing a criterion of amplifier performance. The sensitivity of the transistor's input admittance variations is mathematically defined and given the symbol δ. This definition is used as a criterion of alignability and as a measure of the feasibility of partially or wholly neutralizing the transistor in any given application. Power gain formulas are developed in terms of δ and the measured transistor parameters. Specification of the desired power gain and sensitivity at each frequency then serves to determine the frequency behavior appropriate for the amplifier load and coupling networks. Synthesis of these networks completes the amplifier design. Several video amplifier designs are given in the text to illustrate the design procedures. Measurement of the characteristics of these amplifiers provides experimental verification of the theory. (Contractor's summary)

ANALYSIS OF A NEW TYPE OF RADIO SCATTERING FROM THE IONOSPHERIC E-REGION, by P. G. Gallagher. May 7, 1956, 145p. incl. illus. diagrs. tables, refs. (Technical rept. no. 107) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25107; continued by Nonr-22524) AD 95546 Unclassified

A discussion is presented on direct scattering originating in the ionospheric E-region. An attempt was made to deduce the nature of the scattering region and its relation to known properties of the ionosphere from the characteristics of the scatter echo. Special importance is attached to the fading characteristics and the typical geometrical shape of the radar echo in developing a physical model of the scatter region. Various proposals are made to account for the scattering effect, and each is analyzed theoretically. The recurrent behavior of the new scatter echo suggests that field-aligned ionization in the ionospheric E-region should be considered a part of normal ionospheric behavior. The origin of the field-aligned scatter forms can be attributed to a hydrodynamic rearrangement of ionization existing in the affected (E-layer) region, rather than to ionization by high-energy charges originating external to the affected region. A close association exists with sporadic-E but not with geomagnetic, meteoric, auroral or various solar events. The data lead to the hypothesis that in most cases sporadic-E and the new radio scattering are different manifestations of a common phenomenon; both manifestations can be observed simultaneously under a specified (but not unusual) set of conditions. The ultimate source of ionization for the new scattering cannot be determined as yet.

ANALYSIS OF EXTERNAL CIRCUIT TRAVELING-WAVE TUBES, by C.-T. Sah. June 1, 1956, 141p. incl. diagrs. refs. (Technical rept. no. 1) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22524; continuation of N6onr-25107) AD 100249 Unclassified

A theoretical investigation is presented of traveling-wave tubes using external slow-wave circuits of either the lumped elements or a combination of the lumped and the distribution elements. A review is given of several known methods for solving the traveling-wave-tube problem. An exact field analysis by using Maxwell's equation can give useful information only for the simplest geometries and only after making some approximations to the solutions. The best method of solution is that of the normal-mode expansion which provides accurate results in normalized forms for any slightly perturbed transmission system. An approximate method for a planar model which uses the concept of an equivalent current generator is discussed which takes into consideration all the space harmonics and gives relatively simple expressions for the solution of the problem; results cannot be reduced to a simple normalized form for application to a general transmission system with large perturbations. For small perturbations, the results give the same normalized results as those given by the normal-mode expansion method. Electronic equations are obtained for the gridless gaps by Fourier analysis of the space harmonic field. The cases are considered for interaction in the longitudinal and the transverse interaction structures. The electronic equations are obtained for uniformly

STA. 06:002 - STA. 06:005

periodic transverse and longitudinal interaction gaps with grids. The circuit relations of a filter circuit are revised. The electronic and circuit equations are combined for the 2 types of interaction gaps. The characteristics of the slow-wave circuits are compared to illustrate the best circuits for certain types of operation such as forward-wave amplification or backward-wave oscillation.

ITERATIVE SYNTHESIS OF A LINEAR-PHASE NETWORK, by C. Y. Chang. June 25, 1956, 44p. incl. diagrs. refs. (Technical rept. no. 3) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22524) AD 100245 Unclassified

The procedure is described for using the iterative method of Moore (Synthesis of Distributed Amplifiers for Prescribed Amplitude Response; item no. STA. 05:008) to synthesize a linear-phase transfer function with an equal-ripple approximation to a constant phase slope. It is economical to adopt a linear-phase network and the rate of fall of the phase slope of this transfer point will be steeper. A cascade should be arranged which consists on n/2 different second-order all pass networks if n (the number of polar or zeros) is even, or n-1 different second-order all-pass networks and 1 first-order all-pass network is n is odd so that the overall transfer will have n equal maximum phase slope points in the desired frequency band (-1 ... 1). The computation in the iterative method is aggravated as n increases.

SOME PROPERTIES OF LUMPED-FILTER CIRCUITS FOR TRAVELING-WAVE TUBES, by C.-T. Sah and G. A. Loew. July 20, 1956, 159p. incl. diagrs. (Technical rept. no. 4) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22524) AD 104566 Unclassified

A family of curves is presented of the properties of lumped-filter circuits which are useful as slow-wave circuits for external-circuit traveling-wave tubes or as approximate equivalent circuits for traveling-wave tubes with distributed or lumped and distributed circuits. The characteristics presented include phase-frequency, the phase velocity, the group velocity, the circuit impedances and the interaction impedance characteristics as a function of frequency. These characteristics are obtained for the uniformly periodic geometry, i.e., equal lengths for all the cylinders and equal lengths for all the gaps; the gap reduction factor is not taken into consideration in the interaction impedance calculations. The circuits are assumed to be lossless. The circuits considered in this report represent only a small number of the various possible types of lumped-filter circuits that can be used as slow-wave circuits for external-circuit traveling-wave tubes. However, they do represent the simplest types of circuits. Other more complicated circuits may have more desirable properties for traveling-wave tube operation. (Contractor's summary)

TRANSIENT PHENOMENA IN TRAVELING-WAVE TUBES, by A. V. Brown. July 30, 1956, 113p. incl. illus. diagrs. refs. (Technical rept. no. 6) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22524) AD 104569 Unclassified

When the r-f input signal to a traveling-wave tube is pulsed on, and the electric beam in the tube is in a steady-state conditions, the rise time of the tube's output signal can be calculated with a knowledge of the tube's steady-state response versus frequency characteristics. This calculation is performed for both the forward-wave and the backward-wave amplifier. For the case with the r-f signal applied continuously to the circuit of a helix-type forward-wave amplifier and the electron beam pulsed on, transient effects of a time duration of 0.2 μ sec have been observed experimentally. It is shown that the pulse beam impresses a video signal on the helix, which causes the helix to ring. Due to the ringing phenomenon, the beam is placed out of synchronism with the circuit wave, thereby distorting the r-f output signal. Under suitable operating conditions a minimum rise time of less than 20 mμ sec was obtained. No theoretical investigation of this phenomenon was undertaken. Calculations of the beam-front distortion due to its transit down the length of the circuit were carried out. They predicted, for most conventional tubes, a collector-current rise time of less than a fifth of a beam transit time. Experimental results agreed with the theory to within a fraction of two. An investigation of the build-up process in backward-wave oscillators was performed. The theoretical results, based on a small-C linear theory, show reasonable agreement with the experimental results. The experimental results indicated build-up times of 2.5 to 0.1 μ sec for an S-band oscillator, as the tube's beam current was varied from 1.1 to 2.4 times its start-oscillation value. Fourier and Laplace transformation methods were used in the theoretical investigations. The difficulties, usually encountered when applying transformation calculus methods to distributed circuits, were considerably reduced by approximately the tube's response function before evaluating the inversion integral. A REPRESENTATION OF D-C CHARACTERISTICS AND TRANSIENT RESPONSE OF COMMERCIAL SEMICONDUCTOR DIODES, by F. S. Barnes. Aug. 30, 1956, 43p. incl. diagrs. refs. (Technical rept. no. 8) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22524) AD 106051 Unclassified

An attempt is made to present in one place a reasonably complete analysis of the characteristics of commercial semiconductor diodes. The first portion of the paper analyzes the ideal p-n junction and the resulting distribution of carriers in the bulk of the diode. The analysis is based on a relatively simple model of the crystal structure of germanium and silicon from which the mechanisms by which currents are carried is developed and related to the case of a p-n junction. The second portion of the paper analyzes the deviations of the d-c characteristics of commercial diodes from the ideal p-n junction. The discussion of these deviations includes the effect of ohmic voltage drop through the bulk of the diode, the effect of high currents, and of the leakage currents. The final portion of the paper analyzes the transient response of these diodes in both the forward and reverse direction. The results of measurements on commercial diodes of both the forward and inverse transient response are presented and compared with the theory. (Contractor's summary)

SOME RESULTS IN THE ESTIMATION OF SIGNAL PARAMETERS, by R. D. Bennion. Sept. 10, 1956, 19p. incl. diagrs. (Technical rept. no. 10) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22524) AD 109752 Unclassified

This memorandum summarizes some results obtained in the study of certain aspects of signal reception in the presence of noise. Two types of difficulties are considered. First, the problem of obtaining best estimates of pulse-heights occurring with certain non-Gaussian distributions is treated. The solution in each case implies some nonlinear filtering operation. Second, pulse trains with Gaussian statistics but interdependence between adjacent pulses are considered. The "best" estimate of any pulse height is found to be a certain linear combination of the present and previous signal samples. Some suggestions for extending this result to the case of interdependence between an arbitrary number of pulses are included. (Contractor's summary)

THE TRANSVERSE-CURRENT TRAVELING-WAVE TUBE. [PART I] THEORY OF THE TRANSVERSE-CURRENT TRAVELING-WAVE TUBE. [PART II] AN EXPERIMENTAL TRANSVERSE-CURRENT TRAVELING-WAVE TUBE, by D. A. Dunn, W. A. Harman and others. Sept. 25, 1956 [18]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 12) (In cooperation with General Electric Microwave Lab.) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22524) AD 109757 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 44: 879-887, 888-89C, July 1956.

Part I. An analysis is presented of a traveling-wave tube in which unmodulated dc current is continuously introduced along the length of the tube and is removed after traveling a fixed distance in the presence of the circuit field. This change in the dc current distribution as compared with that of a conventional traveling-wave tube results in three forward growing waves instead of one; one growing exponentially as in the conventional tube, one growing linearly, and one growing as the square of distance. Expressions for the over-all gain of a forward-wave amplifier of this type are derived as a function of the usual parameters plus an additional parameter related to the distance traveled by electrons in the interaction space. The power output of this device is found to depend on saturation of individual current elements rather than of the beam as a whole, with the result that, after saturation is once reached, the power output is independent of input power. An estimate of the value of the saturation power level is obtained from the linear analysis. Part II. A transverse current traveling-wave tube employing a flat helix and a skew beam has been built and tested both as a forward wave amplifier and as a backward wave oscillator. The tube operates as an amplifier over the frequency range from 1 to 2 kmc with a power output of the order of 30 milliwatts. Tests on the tube indicated a gain vs voltage characteristic markedly different from that obtained with a conventional traveling-wave tube, particularly with respect to the wide range of current and voltage over which a large amount of attenuation in excess of the cold insertion loss of the circuit was observed. The general shapes of the curves of gain vs current and the gain and saturation power level vs frequency are as predicted from theory and display significant differences from calculated curves for an equivalent conventional tube. The nonlinear behavior of the tube, as a function of input signal level, follows the general pattern predicted from qualitative arguments. The output power is constant to within 0.05 db over an input power range of 20 to 30 db. With two signals of different frequencies supplied to the input of the tube, a region of operation was observed in which, with the input amplitude of one signal fixed, the output amplitudes of both signals were independent of the amplitude of the other (variable) input signal. NEGATIVE-IMPEDANCE CONVERTER DESIGN, by A. I. Larky. Oct. 30, 1956, 50p. incl. diagrs. tables. (Technical rept. no. 11) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22524) AD 109753 Unclassified

An active device with the property that the driving-point immittance at one terminal-pair is the exact negative of the load immittance connected to the other terminal-pair is called a negative-impedance converter. This work describes the external or circuit properties of the ideal negative-impedance converter and relates them to certain ideal amplifier combinations. The necessary and sufficient conditions that a given device be an ideal negative-impedance converter are derived. The properties of the non-ideal negative-impedance converter are discussed and a method shown by which the non-ideal device may be made ideal by the addition of passive elements. Practical circuits are never ideal and are also subject to changes in performance due to drifts in their elements. Sensitivity criteria are developed which indicate which of the external parameters of the device most affect the negative-impedance conversion process. These are the parameters which must be most stable and this fact leads to the statement of the characteristics of a good negative-impedance converter circuit. Two transistor negative-impedance converter circuits are analyzed and compared. One of these has been published previously and the other is new. The new circuit is shown to be superior in frequency response and to have less distortion at a given signal level. The predicted behavior of these circuits is checked experimentally. LITERATURE GUIDE ON FAILURE CONTROL AND RELIABILITY, by W. F. Luebbert. Dec. 31, 1956, 1v. incl. refs. (Technical rept. no. 13) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22524) AD 122983 Unclassified

A literature guide is presented on failure control and reliability of electronic components and equipment to show what information is available and where it can be found. References are arranged alphabetically by author by using a special IBM card format. This format may be used as a conventional annotated bibliography or as the foundation of a rapid-access, edge-punch card file. Two subject classification schemes are used. The conventional subject guide is of the type which is designed for isolation of desired articles from the list of references. The following subject headings are used in the guide, but they differ from those used for edge punching of the cards: (1) general material; (2) definition and quantification of reliability; (3) administrative aspects of reliability; (4) reliability and design;

(5) reliability and manufacture; (6) reliability versus utilization, maintenance, and repair; (7) reliability testing; (8) mathematical theory of reliability; (9) mathematical-statistical tools useful in study of reliability; (10) electron tube reliability; (11) semiconductor device reliability; (12) component reliability; (13) guided missile and airborne electronic reliability; and (14) computer reliability. The unconventional type of subject guide is a key to the edge-punching code for use with the card format. The subject classification scheme which was prepared for use with the punched cards, contains classification by author, topic, type of equipment, type of circuit, type of component, type of construction, critical environmental factor, and type of service. HIGH ENERGY ELECTRON SCATTERING AND NUCLEAR STRUCTURE DETERMINATIONS [1], by R. Hofstadter, H. R. Fechter, and J. A. McIntyre. Aug. 1953, 23p. diagrs. refs. (Rept. no. HEPL-205) (Sponsored jointly by Office of Naval Research under N6onr-25116, [Air Force] Office of Scientific Research under AF 18(600)646, and Atomic Energy Commission)
AD 16168 Unclassified

Presented in part at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-May 1, 1953.

Also published in Phys. Rev., v. 92: 978-987, Nov. 15, 1953.

An investigation was made of the elastic scattering of fast electrons with energies of 125 and 150 mev by several elements. The relative angular distributions were measured for Be, Ta, Au, and Pb. The data indicated that these nuclei have charge distributions tapering off gradually from near the center to the outside. The best fit of first Born approximation form factors (Born and L. M. Yang, Nature, v. 166: 399, 1950) suggests an exponential charge distribution with rms radii 12 to 22% larger than conventional radii. The radii show considerable dependence on the function assumed for the charge-density taper. Among the tapers (Gaussian, half-uniform and half-Gaussian, uniform, and uniform with exponential) which were tried, all were definitely poorer than the exponential in representing the experimental data.

INTENSITY FLUCTUATIONS IN SCINTILLATION COUNTERS, by J. A. McIntyre. [1954] [33]p. incl. table, refs. (Sponsored jointly by Office of Naval Research under N6onr-25116, [Air Force] Office of Scientific Research under AF 18(600)646, and Atomic Energy Commission) Unclassified

The statistical effects inherent in a scintillation-counter system are examined theoretically and the sources of statistical spread noted. Comparison is then made between the theory developed and the rather meager experimental data available, and the necessity for more experiments is made evident. It is also pointed out that a yet unexploited method for determining scintillator efficiencies is possible and that an improvement in the precision of gamma-ray energy measurements seems feasible. HIGH-ENERGY ELECTRON SCATTERING AND NUCLEAR STRUCTURE DETERMINATIONS, II, by R. Hofstadter, B. Hahn and others. [Mar. 15, 1954] [21]p. incl. diagrs. table, refs. (Sponsored jointly by Office of Naval Research under [N6onr-25116], [Air Force] Office of Scientific Research under AF 18(600)646, Atomic Energy Commission, and Research Corp., New York) Unclassified

Presented in part at meeting of the Amer. Phys. Soc., New York, Jan. 28-30, 1954.

Published in Phys. Ref., v. 95: 512-515, July 15, 1954 1954.

Elastic scattering measurements have been carried out with electrons in Au^{197} at energies of 84, 126, 154, and 183 mev and in Pb^{208} at 84, 153, and 186 mev. Diffraction effects are observed which appear to vary with momentum and angular position as if a fundamental parameter $p \sin \frac{\theta}{2}$ were equal to a constant for a given diffraction feature. Such a behavior would be predicted by the Born approximation. A comparison of the scattering in Au^{197} and Pb^{208} suggests that inelastic scattering does not materially influence the scattering curves presented. The appearance of diffraction effects indicates a model more nearly uniform in charge density than early tentative conclusions based on Born approximation calculations. (Contractor's abstract)

ELECTRON SCATTERING FROM HYDROGEN, DEUTERIUM, AND CARBON AT 190 MEV (Abstract), by J. A. McIntyre and R. Hofstadter. [1954] [1]p. (Sponsored jointly by Office of Naval Research under [N6onr-25116], [Air Force] Office of Scientific Research under [AF 18-(600)646], and Atomic Energy Commission) Unclassified

Presented at meeting of the Amer. Phys. Soc., Seattle, Wash., July 7-10, 1954.

Published in Phys. Rev., v. 96: 854, Nov. 1, 1954.

The recoil of the proton or deuteron permits solid targets of light and heavy polyethyiene to be used in studying the elastic scattering of high energy electrons from the nuclei of hydrogen and deuterium, as distinguished from the elastic scattering from carbon nuclei. Inelastic electron scattering peaks have been observed in carbon at 4.5 mev and 9.7 mev and add a background below the carbon elastic peak which must be substracted from the hydrogen and deuterium peaks. Angular distributions of the elastic electron scattering have been observed in hydrogen between 35° and 100° at 190 mev in the laboratory frame. The proton appears to be a point charge since the experimental points fit the Mott formula. The deuteron definitely appears as not a point charge. Its finite size is exhibited by a fivefold reduction from the Mott formula at 105° in the center-of-mass system. The rms radius of the observed charged distribution is $1.5 \pm 0.2 \times 10^{-13}$ cm. This "radius" is a measure of the rms distance between the center of mass of the deuteron structure and the position of the proton. (Contractor's abstract)

ELECTRON SCATTERING IN HYDROGEN AND HELIUM (Abstract), by R. Hofstadter, R. [W.] McAllister, and E. Wiener. [1954] [1]p. (Sponsored jointly by Office of Naval Research under [N6onr-25116], [Air Force] Office of Scientific Research under [AF 18(600)646], and Atomic Energy Commission) Unclassified

Presented at meeting of the Amer. Phys. Soc., Seattle, Wash., July 7-10, 1954.

Published in Phys. Rev., v. 96: 845, Nov. 1, 1954.

To investigate the elastic scattering of high-energy electrons from hydrogen, helium, and other gases we have constructed a stainless steel scattering chamber containing gas at high pressure. The target is a right cylinder of length 2-t/2 in., diameter 3/4 in. with walls 15 mils thick and end windows of thickness 5 to 10 mils. Operation at 1000 psi has proved quite convenient. The end effects are easily subtracted out by emptying the gaseous contents and are not important except at small angles (~35°). Studies of the angular distribution in hydrogen and helium have been carried out at 190 mev in the laboratory frame of coordinates and show agreement with the Mott point-charge formula for hydrogen but distinct deviations from the Mott formula for helium. These studies thus demonstrate the finite size of the helium nucleus (the alpha particle). A preliminary estimate of the size of the alpha particle gives $1.40 \pm 0.2 \times 10^{-13}$ cm for the rms radius of the alpha particle. The rm radius is taken with respect to charge. HIGH-ENERGY ELECTRON SCATTERING IN Rh, Ta, W, and U (Abstract), by B. Hahn and R. Hofstadter. [1954] [1]p. (Sponsored jointly by Office of Naval Research under N6onr-25116, [Air Force] Office of Scientific Research under AF 18(600)646, Atomic Energy Commission, and Research Corp., New York) Unclassified

Presented at meeting of the Amer. Phys. Soc., Berkeley, Calif., Dec. 28-30, 1954.

Published in Phys. Rev., v. 98: 278, Apr. 1, 1955.

Recent improvements in experimental technique have made it possible to measure more accurately the angular distribution of high-energy electrons (180 mev) scattered by heavy and medium heavy nuclei. Small differences in scattering cross sections of two nuclei can be established by measuring ratios of counting rates at each scattering angle. Scattering ratios of gold with respect to hydrogen have been measured, as well as ratios with respect to Rh, Ta, W, and U. Ta, W, and U definitely show less pronounced diffraction wiggling in the angular distribution than Pb^{208}, Au, and Bi. It is fairly difficult to fit the experimental results for Ta, W, and U with phase shift calculations to a spherically-symmetric charge distribution. A possible explanation of these relatively smooth angular distributions may involve nuclear-quadrupole effects. (Contractor's abstract)

SCATTERING OF 192-MEV ELECTRONS FROM DEUTERIUM, by J. A. McIntyre and R. Hofstadter. Jan. 1955, 10p. diagrs. (Rept. no. HEPL-37) [AFOSR-TN-55-20] (Sponsored jointly by Office of Naval Research under N6onr-25116, [Air Force] Office of Scientific Research under AF 18(600)646, and Atomic Energy Commission) AD 52928 Unclassified

Also published in Phys. Rev., v. 98: 158-161, Apr. 1, 1955.

Elastic scattering of 192-mev electrons from deuterium has been studied using both solid (CD_2) and high-pressure gas targets. The results obtained by these 2

methods are in agreement and yield the following conclusions: (1) the range of the neutron-proton potential is between 1 and 4 x 10^{-13} cm if a square potential well is assumed, and if the deuteron wave functions predicted by the binding energy of the deuteron are used; and (2) it is, however, impossible with the present data to eliminate the possibility of other charge distributions for deuterium such as uniform or Gaussian. Inelastic electron scattering from deuterium was also investigated, and promises to give independent information on the deuteron structure. (Contractor's abstract)

HIGH-ENERGY ELECTRON SCATTERING ON NUCLEAR STRUCTURE DETERMINATIONS. III. THE CARBON 12 NUCLEUS, by J. H. Fregeau and R. Hofstadter. May 1955 [30]p. incl. diagrs. tables, refs. (Rept. no. HEPL-49) ([AF]OSR-TN-55-134) (Sponsored jointly by Office of Naval Research under [N6onr-25116], [Air Force] Office of Scientific Research under AF 18(600)-646, and Atomic Energy Commission) AD 63843 Unclassified

Also published in Phys. Rev., v. 99: 1503-1509, Sept. 1, 1955.

The elastic scattering peak in C^{12} is accompanied by a number of additional peaks corresponding to inelastic scattering of electrons from the various excited levels of the C nucleus. Three levels have been investigated by this method and correspond to the 3 known states at 4.43 mev, 7.68 mev, and 9.61 mev. Angular distributions of the inelastically-scattered electrons have been obtained, as well as the angular distribution of the elastically-scattered electrons. The angular distributions of the inelastic peaks fall off less steeply with angle than the elastic peak. By comparing the scattering from C with scattering from the proton, and using the theoretical value of the cross section of electrons scattered from the proton, it is possible to obtain "absolute" values for the elastic and inelastic scattering cross sections. From the elastic scattering curve, information about the size and charge distribution in the C^{12} nucleus may be derived. The charge distribution lies approximately half way between a Gaussian and a uniform model. The rms (root mean square) radius of the resultant charge distribution is 2.40 ± 0.25 x 10^{-13} cm. Experimental results are presented of electron scattering by Ca, V, Co, In, Sb, Hf, Ta, W, Au, Bi, Th, and U, at 183 mev and (for some of the elements) at 153 mev. For those nuclei for which asphericity and inelastic scattering are absent or unimportant, i.e., Ca, V, Co, In, Sb, Au, and Bi, a partial wave analysis of the Dirac equation has been performed in which the nuclei are represented by static, spherically symmetric charge distributions. Smoothed uniform charge distributions have been assumed; these are characterized by a constant charge density in the central region of the nucleus, with a smoothed-out surface. Essentially 2 parameters can be determined, related to the radius and to the surface thickness. An examination of the Au experiments shows that the functional forms of the surface are not important, and that the charge density in the central regions is probably fairly flat, although it cannot be determined very accurately. An analysis of the experiments on the nuclei Ca, V, Co, In, Sb, Au, and Bi, assuming for convenience the Fermi smoothed uniform shape, then leads to the following results: The radial parameter c (the distance to the midpoint of the surface) scales as $A^{1/3}$ for the nuclei examined and is (1.07 ± .02) $A^{1/3}$ x 10^{-13} cm; the surface thickness t (0.9 ρ_0 to 0.1 ρ_0 distance) is constant for all of these nuclei, to within the estimated error, and is (2.4 ± 0.3) x 10^{-13} cm. Presented at meeting of the Amer. Phys. Soc., Southern Calif. U., Los Angeles, Dec. 28-30, 1955.

Published in Phys. Rev., v. 100: 1797, Dec. 15, 1955.

Using techniques developed in this laboratory, the elastic scattering of electrons by Li^6 and Li^7 has been studied, with emphasis on the comparison of their cross sections. With high resolution, the inelastic scattering by the 0.477-mev state of Li^7 appears as a broadening of the main scattering peak, and its small contribution (~10%) is determined by comparison with the Li^6 peak. At 187 mev, $\sigma_7/\sigma_6 = \rho$ varies smoothly from 1.00 (35°) to 1.17 (80°). The magnetic contribution to ρ is estimated from the values ρ (187 mev, 65°) = 1.07 and ρ (117 mev, 118°) = 1.12; the two conditions involve equal momentum transfers; a crude interpretation of Rosenbluth's formula indicates that the effect adds 2% at 80° and less at smaller angles. For both isotopes the angular distribution at 187 mev indicates a charge distribution between the uniform and the Gaussian, with a rms radius $(2.38 \pm 0.05) \times 10^{-13}$ cm, the ratio of rms radii being $r_7/r_6 = 0.99 \pm 0.01$. INELASTIC AND ELASTIC SCATTERING OF 187-MEV ELECTRONS FROM SELECTED EVEN-EVEN NUCLEI, by R. H. Helm. Feb. 1956, 73p. incl. diagrs. tables, refs. (Rept. no. HEPL-40) (AFOSR-TN-56-11) (Sponsored jointly by Office of Naval Research under N6onr-25116 and Air Force Office of Scientific Research under AF 18(600)646) AD 85909 Unclassified

Also published in Phys. Rev., v. 104: 1466-1475, Dec. 1, 1956.

A survey has been made of the differential scattering cross sections for 187-mev electrons on the even-even nuclei $_{12}Mg^{24}$, $_{14}Si^{28}$, $_{16}S^{32}$, $_{18}A^{40}$, and $_{38}Sr^{88}$. It has been possible to separate the elastic scattering from the inelastic in all cases, and to resolve the inelastic groups from specific nuclear levels for at least one level in all cases. A simple Born-approximation analysis of the elastic data yields values of the effective radii and surface thicknesses of the nuclear charge densities which (if suitably corrected for failure of the Born-approximation) are in substantial agreement with the results of Hahn, Ravenhall and Hofstadter, i.e., a radius parameter (for the heavier elements) of $c = 1.08A^{1/3} \times 10^{-13}$ cm (radius of half-maximum of the charge distribution) and a surface thickness of $t = 2.5 \times 10^{-13}$ cm (thickness from 10 to 90% of the maximum of the charge distribution). Phenomenological analysis of the inelastic scattering along the lines laid down by Schiff yields some tentative multipolarity assignments, and application of some results of Ravenhall yields estimates of (radiative) partial level widths; for the E2 transitions these correspond to lifetimes of $\sim 19 \times 10^{-13}$ sec [Mg (1.37 mev)] to $\sim 1.4 \times 10^{-13}$ sec [Sr (1.85 mev)]. The observed strengths of the transitions are compared to those predicted by Weisskopf theory. (Contractor's abstract)

ELASTIC SCATTERING FROM THE PROTON AND THE ALPHA PARTICLE, by R. W. McAllister and R. Hofstadter. Feb. 1956 [23]p. incl. diagrs. (Rept. no. HEPL-73) ([AF]OSR-TN-56-73) (AF 18-(600)646) AD 81525 Unclassified

Also published in Phys. Rev., v. 102: 851-856, May 1, 1956.

The elastic scattering of 188-mev electrons from gaseous targets of H and He has been studied. Elastic profiles have been obtained at laboratory angles between 35° and 138°. The areas under such curves, within energy limits of ± 1.5 mev of the peak, have been measured and the results plotted against angle. In the case of H, a comparison has been made with the theoretical predictions of the Mott formula for elastic scattering, and also with a modified Mott formula (due to Rosenbluth) taking into account both the anomalous magnetic moment of the proton and a finite-size effect. The comparison shows that a finite size of the proton will account for the results, and the present experiment fixes this size. The rms radii of charge and magnetic moment are each 0.74×10^{-13} cm $\pm$ 0.24×10^{-13} cm. In obtaining these results, it is assumed that the usual laws of electromagnetic interaction and the Coulomb law are valid at distances less than 10^{-13} cm and that the charge and moment radii are equal. In He large effects of the finite size of the α particle are observed and the rms radius of the α particle is found to be 1.6×10^{-13} cm $\pm$ 0.1×10^{-13} cm. (Contractor's abstract)

THE STRUCTURE OF THE PROTON, by E. E. Chambers and R. Hofstadter. Apr. 1956 [45]p. incl. diagrs. tables, refs. (Rept. no. HEPL-78) ([AFOSR]-TN-56-151) (Sponsored jointly by Office of Naval Research under [N6onr-25116], Air Force Office of Scientific Research under AF 18(600)646, and Atomic Energy Commission) AD 86310 Unclassified

The structure and size of the proton have been studied by means of the methods of high-energy electron scattering. The elastic scattering of electrons from protons in polyethylene has been investigated at the following energies in the laboratory system: 200, 300, 400, 500, and 550 mev. The range of laboratory angles examined has been 30° to 135°. At the largest angles and the highest energy, the cross section for scattering

shows a deviation below that expected from a point proton by a factor of about nine. The magnitude and variation with angle of the deviations determine a structure factor for the proton, and thereby determine the size and shape of the charge and magnetic-moment distributions within the proton. An interpretation, which is consistent at all energies and angles and agrees with previous results obtained, fixes the rms radius at 0.77 ± 0.10 x 10^{-13} cm for each of the charge and moment distributions. The shape of the density function is not far from that of a Gaussian with rms radius 0.70 x 10^{-13} cm or an exponential with rms radius 0.80 x 10^{-13} cm. An equivalent interpretation of the experiments would ascribe the apparent size to a breakdown of the Coulomb law and the conventional theory of electromagnetism. (Contractor's abstract, modified)

Also published in Phys. Rev., v. 104: 225-236, Oct. 1, 1956.

The scattering of 187-mev electrons from C^{12}, reported previously, has been extended to 138°. It has been possible to separate the elastic scattering from the inelastic scattering and to resolve the inelastic groups from the 4.43-, 7.65-, and 9.61-mev nuclear levels. "Absolute" values were obtained by comparing the scattering from carbon with the scattering from hydrogen and computing the proton cross section. The angular distribution of the elastically-scattered electrons falls off more steeply than the angular distribution of the inelastically-scattered electrons. Analysis of the data, using the Born approximation, shows that the root-mean-square radius of C^{12} (corrected for breakdown of the Born approximation) is (2.37 ± 0.05) x 10^{-13} cm with a surface thickness of (2.0 ± 0.4) x 10^{-13} cm. The corresponding value of r_0 the "classical" radius parameter, is (1.33 ± 0.02) x 10^{-13} cm which is larger than that found from electron-scattering measurements for the heavy nuclei and is in agreement with the trend for light nuclei. The scattering from the 4.43-mev and 7.65-mev levels is larger than that predicted by some shell-model calculations. The transition from the ground state to the 9.61-mev level appears to be either quadrupole or electric monopole, which gives a spin and parity assignment of either 2^+ or 0^+. AN ABSOLUTE CROSS SECTION FOR ELECTRON SCATTERING FROM PROTONS, by R. W. McAllister. Oct. 1956 [1]p. (Rept. no. HEPL-109) (AFOSR-TN-56-518) (Sponsored jointly by Office of Naval Research under N6onr-25116, Air Force Office of Scientific Research under AF 18(600)646, and Atomic Energy Commission) AD 110333
Unclassified

Also published in Phys. Rev., v. 104: 1494, Dec. 1, 1956.

Scattering is reported of 189.6-mev electrons through 60° in the laboratory frame from polyethylene and carbon targets, using apparatus previously described in part (Phys. Rev., v. 92: 978, 1953; v. 95: 512, 1954; v. 99: 1503, 1955). A preliminary analysis of the experimental data yields a differential cross section of (1.20 ± 0.07) x 10^{-30} cm^2. Application of the radiative correction which is calculated as 0.836 to the Rosenbluth formula for a diffuse proton, assuming a magnetic moment rms radius of 0.77 x 10^{-13} cm yields an rms radius of 0.75 x 10^{-13} cm for the charge. This radius is consistent with existing values.

The charge distribution of the deuteron has been studied by electron-scattering experiments using 188-mev and 400-mev electrons. Both deuterated-polyethylene foils and deuterium gas targets were used. Two different scattering apparatuses were also used. The charge of the deuteron was found to be extended over a larger volume than that inferred from low-energy neutron-proton scattering. Specifically, the effective range of the neutron-proton potential was found to be at least $(2.18 \pm 0.15) \times 10^{-13}$ cm as compared with the n-p scattering result of $(1.70 \pm 0.03) \times 10^{-13}$ cm. It is possible also to fit the data using a 1.70×10^{-13} cm effective range, and a deuteron consisting of a point neutron and a proton with a rms radius of $(0.82 \pm 0.17) \times 10^{-13}$ cm. This procedure, however, violates the assumption of the charge independence of the internal structure of nucleons. Finally, the 1.70×10^{-13} cm effective range could be preserved by suitably modifying the Coulomb law at small distances. (Contractor's abstract)

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 10, Jan. 30, 1956.

Electron scattering has been observed from helium gas a high pressure with the new semi-circular double-focusing magnetic spectrometer. At an energy of 400 mev in the incident beam the elastic scattering has been studied at angles between 45° and 70° in the laboratory frame. Besides the sharp elastic peaks, prominent inelastic continua have been observed at several angles. At a given scattering angle the inelastic continuum shows a strong peak at an energy approximately 20 mev below the position corresponding to scattering from the free proton. The inelastic continua also exhibit thresholds about 20 mev below the elastic scattering peaks of the alpha particle, corresponding to the ejection of a single particle from the alpha particle. Theoretical treatment of the elastic data furnishes new information on the size and shape of the alpha particle. Preliminary analysis using the Born approximation gives a rms charge radius of 1.55×10^{-13} cm if the shape is Gaussian and 1.4×10^{-13} if a uniform shape is assumed. The best fit lies between these models. The new data are thus in excellent agreement with an earlier determination. (Contractor's abstract)

A new semi-circular double- focusing magnetic spectrometer with 36" radius of curvature has recently been placed in operation at electron energies up to 400 mev. Detection of the scattered electrons after magnetic deflection is accomplished with a Čerenkov counter enclosed within a ten-ton shield located on the magnet and moving with it. Sharp elastic peaks corresponding to electrons scattered from protons in polyethylene are observed at energies and angles consistent with relativistic kinematics. The areas under such peaks are measured as a function of scattering angle. As observed previously at lower energies the cross section falls below the scattering expected from a point proton and (subject to the validity of the Coulomb law) indicates that the proton has a diffuse structure. By fitting the observed cross section with a phenomenological form factor corresponding to exponential charge and magnetic moment distributions a proton size can be determined. Preliminary values are $r_e = r_m = 8 \times 10^{-14}$ cm where r_e and r_m are respectively rms radii of charge and magnetic moment distributions. These results are in excellent agreement with the earlier determinations. (Contractor's abstract)

SCATTERING OF 187-MEV ELECTRONS FROM CARBON (Abstract), by J. H. Fregeau. [1956] [1]p. (Sponsored jointly by Office of Naval Research under N6onr-25116, Air Force Office of Scientific Research under AF 18(600)646, and Atomic Energy Commission) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 9, Jan. 30, 1956.

The scattering of 187-mev electrons from carbon, reported previously, has been extended to larger angles. Measurements of the elastic scattering cross section and the cross section for inelastic scattering corresponding to the 4.43-mev excited state have been extended to 138° (the present limit of the equipment).

The absolute values have been obtained by comparison with previous results. The angular distribution of the 4.43-mev scattering falls off less rapidly with increasing angle than the elastic scattering. At angles greater than ~90°, the inelastic scattering of the 4.43-mev level is larger than the elastic; for example, at 130° the elastic scattering is 4.3×10^{-34} cm^2/sterad while the 4.43-mev scattering is 6.7×10^{-33} cm^2/sterad. Some measurements have also been made of the inelastic scattering corresponding to the 7.65-mev and 9.61-mev excited states. (Contractor's abstract)

RESUMÉ OF TALK GIVEN AT AMSTERDAM CONFERENCE ON NUCLEAR REACTIONS (Abstract), by R. Hofstadter. [1956] 5p. incl. tables. [Rept. no. HEPL-IP-12] [AF 18(600)646] Unclassified

Presented at Conference on Nuclear Reactions, Amsterdam (Holland), June 1956.

A report is presented of studies on the charge distribution of nuclei of various elements between calcium and bismuth, investigated at Stanford U., by electron scattering methods employing energies near 180 mev. The experiments showed mainly that spherical nuclei could be represented by a model in which the skin thickness t of all such nuclei approximately equaled 2.4×10^{-13} cm, and in which the distance to the half-central-density point varied as $A^{1/3}$, i.e. $c = 1.08 \times A^{1/3} \times 10^{1/3}$ cm. The distance t is measured between points such that their values are 90 and 10 of the central density. Data are tabulated for r_o, r_1, $cA^{-1/3}$, and t determinations of the lighter nuclei of C^{12}, Mg^{24}, Si^{28}, S^{32}, and Sr^{88}; skin thickness and half-density distance relations were found to apply to a good approximation. Redefinition of r_o is given and values of an equivalent $r_o = RA^{-1/3}$, t, c, and r_1 for C^{12}, Mg^{24}, Si^{28}, S^{32}, Ca^{40}, V^{51}, Co^{59}, In^{115}, Sb^{122}, Ta^{181}, Au^{197}, Pb^{208}, Bi^{209}. Thus r_o is not a constant but equals 1.19 for heavy elements and 1.34 for lighter elements, with a gradual variation probably occurring in between. Other studies of the momentum distribution of nucleons within nuclei are briefly noted.

ČERENKOV COUNTERS (Abstract), by R. Hofstadter. [1956] [1]p. [Rept. no. HEPL-IP-10] [AF 18(600)646; continued by N6onr-25116] Unclassified

Presented at CERN Symposium on High Energy Accelerators and Pion Physics, Geneva (Switzerland), June 11-23, 1956.

Published in Proc. CERN Symposium on High Energy Accelerators and Pion Physics, v. 2: 75, 1956.

In attempting to study the inelastic scattering of electrons from deuterium at high energy (500 mev) and large angles (90°-135°), it was found that scattered electrons must be carefully distinguished from mesons having the same momentum and coming from the target in the same direction as the electrons. Usually, the counting was carried on with a lucite Čerenkov counter after the scattered particles were momentum-analyzed magnetically. At electron energies (or momenta) well below the value corresponding to scattering from a free proton, a very large peak was observed. This peak has a sharp threshold on the low-energy side and fell off gradually at higher energies. As the scattering angle was varied, the threshold remained constant but the intensity changed. This fact suggested that the particles were not electrons. The threshold coincided with the energy π mesons should have if they were just to give pulses in a lucite (n = 1.50) Čerenkov counter. The counting material was, therefore, changed to the liquid $C_8F_{16}O$, which has an index of refraction of 1.276 and a density of 1.76 g/cc. The large peak disappeared and with it the threshold too. Twenty channel-discriminator runs taken with both lucite and the fluoroliquid indicate that this interpretation is correct. The present counting technique is carried on with the liquid which appears to be quite suitable for electron counting in a very high neutron and gamma-ray background. (This work was carried out by R. Blankenbecler, R. Hofstadter, and M. R. Yearian.) A total absorption TlCl crystal with a 5½-in. length and a 5½-in. diameter was used in conjunction with a Schaetti-10½-in. -diameter photomultiplier to study the properties of this counter for energetic electrons and gamma rays. Experiments were carried out with electrons of energies 200, 250 and 300 mev and definite total-absorption peaks were observed. The total widths of the pulse-height distributions at half-maximum were approximately 26% at all the energies. The positions of the maxima of the pulse-height distributions varied linearly with the energy. It appears, therefore, that TlCl will make a very successful total absorption spectrometer. (This work was carried out by A. Knudsen and R. Hofstadter.) (Contractor's abstract)

PION PRODUCTION IN ELECTRON-PROTON COLLISIONS, by R. H. Dalitz and D. R. Yennie. [Nov. 5, 1956] [17]p. incl. diagrs. tables, refs. (Rept. no. HEPL-118) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Atomic Energy Commission under N6onr-25116; continuation of AF 18(600)646) Unclassified

Published in Phys. Rev., v. 105: 1598-1615, Mar. 1, 1957.

The close relationship between photopion and electropion production from protons allows an unambiguous first estimate (the standard value) for the ratio of these cross sections, based on assumptions very close to those of the Weizäcker-Williams method. Deviations of the ratio from this estimate arise from pion

STA. 09:001 - STA. 10:002

production by the longitudinal components of the field of the scattered electron and from the variation of the off-diagonal transverse excitations from their diagonal photoproduction values. The dependence of these deviations on the physical processes contributing to the electromagnetic excitation of pions is discussed in terms of matrix elements specified in the pion-nucleon center-of-mass system, both for various phenomenological contributions and for specific meson theories. The experimental values reported are interpreted as an indication of the smallness of longitudinal production, in qualitative accord with the fixed source theory. These features may also be investigated by study of the energy spectrum of inelastically scattered electrons and of the azimuthal variation of pion production relative to the scattering plane, which are also discussed here. ANALYSIS OF A RESONANT-CAVITY MEASUREMENT OF THE VELOCITY OF LIGHT, by D. H. Janney. Technical rept. Oct. 1956, 123p. incl. illus. diagrs. tables, refs. (Rept. no. 343) (AFOSR-TN-56-325) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1593 and Office of Naval Research under N6onr-25123) AD 95201 Unclassified

Methods of overcoming the major sources of uncertainty in the Hansen-Bol and Essen measurements of the velocity of light by microwave resonant cavities were analyzed by theory or experiment and the potential accuracy of this type of measurement was evaluated. The procedure given by Heimer to eliminate the effects of dimensional imperfections in the cavity was extended. This experiment uses a cavity consisting of a circular cylinder of variable length. The velocity of propagation can be deduced from measurements of a single change in cavity length and the resonant frequencies of several modes. The effect of a nonvanishing cavity surface impedance was analyzed theoretically. The Q-correction which is usually used to relate the measured frequencies to the frequencies of a lossless resonator of the same dimensions is not valid for the general case in which the real and imaginary parts of the surface impedance are unequal. Specifically, the surface reactance must be known. No independent experiment is presently available for measuring the surface reactance with the desired accuracy. A combination of theory and experiment showed that if the resonant frequencies are in the range of 2000 mc to 4000 mc, the cavity length changes can be measured interferometrically with an uncertainty of about 3 parts in 10^7. At the specified frequencies the low-order TE_{Omn} modes will have Q's in the range of 50,000 to 100,000, hence the resonant frequencies probably can be detected with an uncertainty of about 1 to 2 parts in 10^7. Thus, length and frequency measurements do not preclude an uncertainty in the velocity of propagation of 1 part in 10^6. The measurement of the surface reactance limits the accuracy of the experiment. Unless this difficulty can be overcome, either by direct measurement or by use of several modes, no resonant cavity measurement of the velocity of light can have an uncertainty of less than 2 or 3 parts in 10^6. Several experiments which eliminate the effects of a nonvanishing surface impedance were analyzed theoretically and were found to have an excessively large final uncertainty. Two subsidiary problems were considered. One problem was a theoretical analysis of the effects of modes close to the one on which measurements are made, and the other was a brief experimental investigation of methods of electroforming high Q cavities. ACCURACY OF A MICROWAVE RESONANT-CAVITY MEASUREMENT OF THE VELOCITY OF LIGHT, by D. H. Janney. Nov. 13, 1956, 3p. incl. illus. [AFOSR-TN-56-550] [AF 18(600)1593] AD 110369 Unclassified

Also published in Phys. Rev., v. 105: 1138-1140, Feb. 15, 1957.

Most of the problems involved in a measurement of the velocity of light by a microwave resonant cavity are discussed briefly on the basis of work reported elsewhere. A more nearly complete theoretical analysis of the effects of the cavity-surface impedance is given. In general, the surface reactance and resistance must both be known to relate the measured resonant frequency to the normal-mode frequency. This problem limits the accuracy of the experiment to an uncertainty of no less than about 2 parts in 10^6. The formal requirements for reducing this uncertainty are states, but no experiment is suggested. (Contractor's abstract)

Also published in Proc. Inst. Radio Engineers, v. 42: 1508-1511, Oct. 1954.

A method is described for determining the circuit impedance of a slow-wave structure from experimental measurements of the perturbation in the resonant frequencies caused by passing beads through the interaction region. From these measurements the gain parameter C of such a structure, when used as a traveling-wave tube, can be determined. The results agree with measured experimental gains as well as with theoretical calculations. The method is limited to periodic structures which can be short-circuited and hence made resonant. The principles involved are not new, but their adaptation to traveling-wave tubes is not generally known.

A METHOD OF IMPROVING THE EFFICIENCY OF KLYSTRONS, by R. H. Winkler. May 1, 1954, 46p. incl. illus. (ML rept. no. 235) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25123) AD 35052 Unclassified

A collector device was designed which was capable of recapturing energy from the electron beam following the output gap of a klystron and feeding this energy into the pulse transformer such that the over-all efficiency of the klystron was increased. For a 2-electrode collector, the highest efficiency was 24%, a gain of 1% over a single-electrode type. Theory indicated a collector efficiency of 49% for a 3-electrode collector, but measurement failed to detect any change. Beam spreading of low-velocity electrons and collector length were cited as possible causes of low efficiency. Testing indicated that a beam-power recovery of 30% could be realized by a single-electrode collector. The optimum collector voltage (about 75% of beam voltage) is tapped from the pulse transformer with pulse tubes.

CROSS-WOUND TWIN HELICES FOR TRAVELING-WAVE TUBES, by M. Chodorow and E. L. Chu. Oct. 1954, 64p. incl. illus. table. (ML rept. no. 349) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25123) AD 51403 Unclassified

Also published in Jour. Appl. Phys., v. 26: 33-43, Jan. 1955.

This report describes a structure, namely a cross-wound twin helix which overcomes the disadvantages of a conventional helix for high-voltage traveling-wave tubes. The disadvantages of a single helix suitable for high voltages are: (1) the impedance for electron interaction is reduced because of the energy content of the noninteracting space harmonics; and (2) the high impedance of some of the space harmonics can result in backward-wave oscillation. In a structure consisting of helices wound in opposite directions, the symmetry of the fields results in most of the electric energy being stored in the fundamental component and most of the magnetic energy in the space harmonics. This results in a higher impedance for the fundamental component and a reduced impedance for the space harmonics. Typical numbers for dimensions suitable for 10 kv operation are an increase of a factor of 2 in the fundamental impedance and a reduction of a factor of about 20 in the -1 space harmonic for the twin helix as compared to the single helix. ELECTROFORMING OF COPPER FOR HIGH-VACUUM APPLICATIONS, by L. H. LaForge, Jr. Feb. 1955, 19p. incl. illus. (ML rept. no. 255) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-22506 and N6onr-25123) AD 60423 Unclassified

STA. 11:006 - STA. 11:008

Electroforming, an old process in typemaking and phonograph record reproduction, is being successfully used in a new and different field, namely, fabrication of vacuum-tube envelopes. Special requirements of this latter application are vacuum tightness and high electrical conductivity. Standard industrial processes are not suitable for this work, though well-known electrochemical procedures are used. Work yet to be done is concerned mainly with control of the operations. Waveguides and similar microwave components are formed to a thickness of 0.150 in. on stainless steel mandrels in an acid copper bath at room temperature with current density of 10 amp/ft^2, after suitable cleaning of the mandrel. Linear-accelerator sections are formed on a base of alternated copper disks and aluminum spacers by cleaning the stack of disks and spacers, silver striking and thin-silver-plating the stack, electroforming approximately 3/8 in. of copper from an acid bath at room temperature at 10 amp/ft^2 (about 5 wk plating time) and etching out the aluminum spacers with hot NaOH. Massive properties of the electroformed material are very similar to those of commercial OFHC copper, but there are microscopic differences, principally in grain structure. Voids and inclusions in the electroformed material are of the same order of magnitude as in the OFHC material. The compositions and operation of the various solutions are given in detail, and many of the significant variables are mentioned. Further work is required along these lines, but fairly consistent results can now be expected. (Contractor's summary)

APPLICATION OF CERAMIC SECTIONS IN HIGH-POWER PULSED KLYSTRONS, by L. H. LaForge [Jr.]. [Apr. 1955] [7]p. incl. illus. [ML rept. no. 263] (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research under [N6onr-25121], DA 36-039-sc-63189, Norr-22512, and Nonr-22505) AD 115468 Unclassified

Published in Bull. Amer. Ceramic Soc., v. 35: 117-122, 127, Mar. 15, 1956.

Early work with klystron tubes for the Stanford linear accelerators showed the need for rf windows of material having better electrical and mechanical properties than those of glasses. Several ceramic bodies in a variety of shapes and sizes were tried on these klystrons which handle peak powers up to 30 megawatts at microwave frequencies. High-alumina compositions proved superior to other formulations for these applications. Currently several metallizing techniques are in use, with one basic modification of the molybdenum-manganese method being of broad usability. This modified molybdenum-manganese system is especially efficacious on materials of high refractoriness, working well even on sapphire. Suitable brazing materials permit direct soldering of the metallized surfaces without the intervening step of nickel plating or its equivalent. (Contractor's abstract)

DESIGN AND OPERATION OF MAGNETIC UNDULATORS, by W. H. Thon. May 1955, 114p. incl. illus. tables, refs. (ML rept. no. 262) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N6onr-25123 and N6onr-25107) AD 66505 Unclassified

Two magnetic undulators were constructed and connected to suitable sources of bunched electron beams. The first undulator received 100-mev electrons and confirmed the theoretical prediction of radiation in the visible spectrum. A photomultiplier tube served as a radiation detector. The second undulator was designed for electrons in the range of a few mev. Radiation was detected by crystal detectors and thermistors; frequency measurements indicated about 1-mm wavelengths. A theoretical study is presented of cascade prebunching at low energy levels by 2 microwave resonators, followed by RF acceleration of the bunches in high-power microwave devices like resonators and linear accelerators. The system indicates the possibility of much tighter bunching than that employed in the millimeter-wave experiment.

Also published in Proc. Inst. Radio Engineers, v. 44: 649-659, May 1956.

This paper discusses the problems involved in designing traveling-wave tubes in the range of pulsed powers of the order of a megawatt. Suitable circuits are described, together with their advantages and limitations. In general, the all-metal structures described are capable of dissipating high average powers, have good impedances at the required voltages (100-kv range), but at a sacrifice in bandwidth. Nevertheless, this class of traveling-wave tube is useful where bandwidths of 10 to 20 per cent, not obtainable from klystrons of equivalent power outputs, are of interest. The problems of tube construction and tube design are discussed. Results of tests on an experimental model tube are described, showing good agreement with available theory. A gain uniformity of 3 db over a 9 per cent bandwidth, with power outputs of 300 kw pulsed have been obtained using attenuators of nonoptimum design. Better performance should be obtainable with further improvements in beam focusing and coupler design. Higher power levels with same efficiency should be possible by designing the tube to operate at higher potentials.

Also published in Jour. Appl. Phys., v. 28: 212-215, Feb. 1957.

Two maser oscillators have been constructed and operated. The behavior of one maser has been observed under various operating conditions by comparing it with the second maser which is used as a reference standard. The experimental setup is shown and experimental results are given. The frequency-pulling effects of the beam and the oscillation amplitude as a function of cavity-tuning are compared with the theoretically expected behavior. It is shown that the simple behavior predicted by the theory exists only for oscillation frequencies which are well removed from line center. The theoretical curves are obtained from a new analysis which included the velocity distribution in the beam. A comparision is made between the velocity-distributed and uni-velocity theories. It is shown that the introduction of the velocity distribution drops the maximum beam efficiency from 1 to 0.76 and cause a region of stability to appear in the beam frequency-pulling function. Published in Electromagnetic Wave Theory Symposium, [1956] p. 374-384.

During the past few years several authors have suggested applications of the radiation properties of electron beams to the problems of mm wave generation and some experiments have been carried out. Some investigators have succeeded in generating coherent waves in a range below one mm wave length. It is suggested to call these waves "Interwaves" or "Zwischenwelien" as they lie between the infra-red and microwaves. A separate name might be appropriate as to the techniques for generation and detection are likely to be very different from microwave techniques. The use of Čerenkov radiation has been suggested by Abele, Danos, and Linhart, and tried, and the radiation from fast electron beams has been investigated theoretically (Ginsburg, Coleman, Motz, Combe and Felx, and Landecker) and experimentally. In this paper the theory underlying these devices will be examined from a unified point of view and the relationship between different approaches will emerge. It is hoped that the understanding of this rapidly increasing field will thereby be advanced. A related field, coherent light generation, will also be touched upon.

CONTRIBUTIONS TO THE THEORY OF MARKOV CHAINS [PART I], by K. L. Chung. [1953] [6]p. [Research paper no. 2411] [AF 18(600)760]
Unclassified

Published in Jour. Res. Nat'l. Bur. Standards, v. 50: 203-208, Apr. 1953.

The random variables X_n, $n = 0, 1, \ldots$, form a discrete Markov chain with states, i, j, ... and stationary transition probabilities $P_{ij}^{(m)} = P(X_{m+n} = j \mid X_m = i)$, Let

$$F_{ij}^{(n)} = P(X_n = j,\ X_r \neq j,\ 1 \leq r < n \mid X_0 = i).$$

The subscript k prefixed to a symbol means that the state k is not visited during the passage, exclusive of both terminals. Q^* means $\sum_{n=1}^{\infty} Q^{(n)}$. The author proves a large number of relations of which only some can be given here. (1) $\lim_{N\to\infty} \sum_{n=0}^{N} P_{ii}^{(n)} / \sum_{n=0}^{N} P_{jj}^{(n)}$ equals any of the three expressions $(1+{}_jP^*_{ij})/(1+{}_iP^*_{jj})$, $F^*_{ij}/{}_iP_{ij}{}^*$, $(F^*_{ij})({}_jF^*_{ji})/(F^*_{ji})({}_iF^*_{ij})$, the first always, the second if $i \neq j$, the third if $F^*_{ij}F^*_{ji} > 0$. Doeblin proved that the existence of the limit (Bull. Soc. Math. France, v. 66: 210-220, 1938); the expressions for it are new. (2) Suppose the states form a single positive recurrent class. If $j \neq k$, then

$m(i, j \cup k) = m_{ij} - {}_jF^*_{ik}m_{kj}$, $m(i, j \cap k) = m_{ij} + {}_kF^*_{ij}m_{jk}$, where m_{ij}, $m(i, j \cup k)$, and $m(i, j \cap k)$ are the mean first-passage times from i to j, i to j or k, and i to both j and k; then $m_{ik} + m_{kj} - m_{ij} = {}_kF^*_{ij}(m_{jk} + m_{kj})$. As an application certain quantities involved in the central limit theorem for Markov chains are evaluated. (3) Formulas analogous to Poincaré's formula (Feller, Introduction to probability theory ..., Wiley, New York, 1950, p. 61; Math. Rev., v. 12: 424) are given for mean first-passage times to unions or intersections of an arbitrary number of states. (4) If i, j, and k (not necessarily distinct) belong to the same positive class, $\sum_{n=1}^{\infty} (P_{ik}^{(n)} - P_{jk}^{(n)}) = (m_{jk} - m_{ik}) / m_{kk}$. There are some connections with work of the reviewer (Trans. Amer. Math. Soc., v. 73: 471-486, 1952; Math. Rev., v. 14: 567). (Math. Rev. abstract)

CONTINUOUS PARAMETER MARKOV CHAINS, by K. L. Chung. Sept. 1954, 41p. incl. refs. ([AF]OSR-TN-54-250) (AF 18(600)760) AD 45116 Unclassified

A systematic discussion is presented of continuous parameter Markov chains for the case where all of the states are stable. Proofs are presented of the following theorems which completely describe the sample functions in such a chain: (1) there is a set $\Omega_0 \in B$ with $P(\Omega_0) = 1$ such that if $w \in \Omega_0$, then the sample function $x(\cdot, w)$ defined in the half-line $(0, \infty)$ has the following properties; the set of its discontinuities D(w) is closed and of Lebesgue measure zero; in each of the open intervals whose union is the open complement D' of D with respect to $(0, \infty)$, $x(\cdot, w)$ is a constant; in 2 adjacent intervals separated by a point of D the 2 constant values of $x(\cdot, w)$ are different; and (2) there is a set $\Omega_1 \in B$ with $P(\Omega_1) = 1$ such that if $w \in \Omega_1$, then for every finite $T > 0$, and every i, the sample function $x(\cdot, w)$ contains only a finite number of i-intervals in (0, T). The notation is as follows: Ω is a probability space with the generic point w, B is a Borel field of w-sets which includes Ω itself, and P is a complete probability measure defined on B. Recurrence and ergodicity properties are discussed which extend known results in the discrete parameter case.

ON A THEOREM OF DOOB AND DIFFERENTIABILITY PROPERTIES OF MARKOV TRANSITION PROBABILITY FUNCTIONS, by D. G. Austin. Sept. 1954, 17p. incl. ref. ([AF]OSR-TN-54-251) (AF 18(600)760) AD 45117 Unclassified

The following generalization to spaces of infinite measure of a fundamental lemma of J. L. Doob (Stochastic Processes, p. 56, New York, 1953) is proved: let E be a collection of sets in F containing at least one set of finite measure, then there is a countable collection of sets $E_i \in F$ such that for any $E \in F$, $\mu\{E' \cap [\cap_i E_i]\} = 0$. The notation is that of an abstract space Ω which contains a Borel field of sets F with a measure function μ defined on the sets F. Various theorems on the differentiability and related properties of the transition probability functions $p_{ij}(\cdot)$ in a Markov chain are presented including a generalization of a theorem of Auerbach (Fundamenta Mathematica, v. 11: 196-197, 1928). A report is made of 3 outlines published recently in Russian which presented a new approach to problems of finding the distributions associated with several distances between 2 empiric distribution functions. The papers are: (1) "On the Maximal Difference Between Two Empirical Distributions," by Gnedenko and Korolook (Doklady Akad. Nauk SSSR, v. 80, no. 4: 1951); (2) "On a Problem of Comparison of Two Empirical Distributions," by Gnedenko and Rvaceva (ibid., v. 82, no. 4: 1952); and (3) "Some Results on the Maximum Discrepancy between Two Empirical Distributions," by Gnedenko (ibid., v. 82, no. 5: 1952). The method is presented in detail, computations omitted from the original papers are included, and some errors in the original are corrected. Asymptotic relations with precise estimates of the errors are obtained in addition to precise formulas for finite cases. (ASTIA abstract)

CONTRIBUTIONS TO THE THEORY OF MARKOV CHAINS, II, by K. L. Chung. [1954] [23]p. incl. refs. [AF 18(600)760] Unclassified

Published in Trans. Amer. Math. Soc., v. 76: 397-419, May 1954.

Theorems on Markov chains are discussed and proved. Theorem 1 demonstrates a type of solidarity among the states of a recurrent class, generalizes a classical result due to Kolmogorov and permits a classification of recurrent states and classes. Theorem 2 is a generalized ergodic theorem which applies to any recurrent class, positive or null. In a null class a set of numbers occurs which plays the roll of stationary absolute probabilities. These numbers are all equal to one in the case of a recurrent random with independent stationary steps and the result is simple. Theorem 3 shows the type of solidarity exhibited in theorem 1 to persist in such a sequence. The weak and strong laws of large numbers, the central limit theorem, the law of the iterated logarithm, and the limit theorems for the maxima of the associated sequence are proved very simply. It is shown that Kolmogorov's conditions are not sufficient for the validity of the central limit theorem. Conditions of validity for the strong limit theorems and the limit theorems for the maxima are obtained by strengthening of corresponding conditions for the weak limit theorems. The connection between these conditions and martingale theory is considered.

SOME NEW DEVELOPMENTS IN MARKOV CHAINS, by K. L. Chung. Sept. 1955, 24p. ([AF]OSR-TN-[55-351]) (AF 18(600)760) AD 75294 Unclassified

Also published in Trans. Amer. Math. Soc., v. 81: 195-210, Jan. 1956.

Some new connections are pointed out between sample-function behavior and analytical properties of the transition probability functions of a continuous parameter Markov chain with stationary probabilities. The new concept of a post-exist process imbedded in a continuous parameter Markov chain is introduced. This process has the same transition probabilities as the original chain, but its initial distribution is of a novel kind. An imbedded renewal process is also studied. Together they yield various relations which imply the differentiality of the transition probability functions and certain generalized Kolmogorov differential equations. (ASTIA abstract)

ON THE ANALYTIC STRUCTURE OF A MARKOFF MATRIX, by D. G. Austin. Sept. 1955, 34p. refs. ([AF]OSR-TN-[55-355]) (AF 18(600)760) AD 75932 Unclassified

Also published in Ann. Math. Stat., v. 27: 532-536, June 1956.

The analytical properties are studied of a matrix of real nonnegative functions $p_{ij}(t)$ on $0 < t \leq \infty$ ($i, j = 1, 2, \ldots$) satisfying: (1) $\sum_j p_{ij}(t) = 1$, and (2) $p_{ij}(t + s) = \sum_k p_{ik}(t)p_{kj}(s)$. A general differentiability criteria which does not require that $\lim_{t \to 0} p_{ij}(t) = \delta_{ij}$ for all i, j, is applied to the case where the initial state is stable $q_i < \infty$. A study of the case of a stable terminal state, $q_j < \infty$, shows that for this condition the transition function, $p_{ij}(t)$, has continuous derivatives. The asymptotic limits of $\sum_j |Dp_{ij}(t)|$ are considered and several conditions are found which guarantee that this sum tends to zero as t tends to ∞. The problems of second and higher order derivatives and abstract spaces are also studied. (ASTIA abstract)

INTEGRAL OPERATORS AND MARKOV PROCESSES, by S.-T. C. Moy. Aug. 1956, 12p. [Wayne U. technical rept. no. 2] (AFOSR-TN-56-520) (In cooperation with Wayne U. under DA 20-018-ORD-14025) (AF 18(600)760) AD 110338 Unclassified

SYR. 01:012 - SYR. 01:013

An investigation is made of the integral operators on the space M' of countably additive set functions. Let P(x, X) be the conditional probability that a moving point x is transferred into a region X after the elapse of a unit time. The probability distribution F_1 of the point at the end of a unit time can be obtained from the initial distribution F_0 of the point at the beginning of the unit time by $F_1(X) = \int P(y, X)F_0(dy)$. This formula defines an operator on M' into itself if F_0 is any bounded countably additive set function. If f(x) is any bounded function of the point x, the conditional expectation $g(x_0)$ of f at the end of a unit time (given that the position of the point is x_0 at the beginning of unit time) is given by $g(x_0) = \int f(y)P(x_0dy)$. This formula defines an operator on the space M of bounded functions into itself. The mystery tie between spaces M and M' by an integral operator is then solved. If the domain of the integral operator to the space M* of bounded additive set functions is enlarged, an integral operator on M* is simply the adjoint of any linear operator on M. A study of the weak star topology on M* shows that sequential compactness and compactness are not equivalent for subsets of M*. Proof is given that any integral operator on M* has nonzero fixed points if it has a nonzero fixed point in M. The consequences of this theorem to the existence of a stationary absolute distribution of a Markov process is discussed. (ASTIA abstract)

TWO ERGODIC THEOREMS FOR MARKOV CHAINS, by K. L. Chung. Aug. 1956, 8p. [AFOSR-TN-58-521] (AF 18(600)760) AD 113732 Unclassified

Let $\{X_n,\ n \geq 0\}$ be a Markov chain with denumerable state space I; let $\{p_i,\ i \in I\}$ be the initial distribution, let p_{ij} be the stationary transition matrix, and let f be any function from I into the reals. Consider the functional $y_n = f(x_n)$, $n \geq 0$. Set $S_n = \sum_{v=0}^{n} y_v$, $A_n = S_n/n$. The ergodic mean of $\{f(x_n)\}$ is defined to be $\bar{A} = A(f) = \sum_{i \in I} \pi_i f(i)$ if and only if $A(|f|) < \infty$. Theorem 1: $\lim_{n \to \infty} E|A_n - \bar{A}| = \lim_{n \to \infty} E|A_n - E(A_n)| = 0$. The τ_n's are well-defined random variables; w denotes the sample point and the value of t(n) at w is t(n, w); $Y_v = \sum_{n=\tau_v}^{\tau_{v-1}-1} y_n$. The following dissection formula is basic: $S_n = Y'(n) + \sum_{v=1}^{t(n)-1} Y_v + Y''(n)$, where $Y'(n) = \sum_{s=0}^{\tau_1-1} y_s$, $Y''(n) = \sum_{s=\tau_{t(n)}}^{n} y_s$; $U_v = \sum_{n=\tau_v}^{\tau_{v+1}-1} |y_n|$. $M_i = \pi_i E(Y_v)$ if $E(Y_v) < \infty$ so that $M_i = \bar{A}$ if $A(|f|) < \infty$; $Z_v = Y_v - M_i(\tau_{v+1} - \tau_v) = \sum_{n=\tau_v}^{\tau_{v+1}-1} (y_n - M_i)$; $m_{ii}^{(2)} = E\{(\tau_{v+1} - \tau_v)^2\}$; $\sigma_i^2 = E(Z_v^2)$; $B_i = \pi_i \sigma_i^2$. Since the values of M_i and B_i as well as the validity of conditions $m_{ii}^{(2)} < \infty$ and $E(U_1^2) < \infty$ do not depend on the choice of i, M and B can be written for M_i and B_i respectively. Theorem II: If $m_{ii}^{(2)} < \infty$ and $E(U_1^2) < \infty$, then $\lim_{n \to \infty} \frac{1}{n} E\{(S_n - Mn)^2\} = \lim_{n \to \infty} \frac{1}{n} E\{[S_n - E(S_n)]^2\} = B < \infty$. SOME THEOREMS ON CONTINUOUS PARAMETERS MARKOV CHAINS, by R. Chacon. Sept. 1956, 21p. refs. [AFOSR-TN-56-522] (AF 18(600)760) AD 113734 Unclassified

Let (Ω, B, P) be a probability triple where P is a complete measure defined on the sets of the Borel field B of subsets of Ω. The defining properties of a Markov chain y(.,.), a positive-integer valued function of $T \times \Omega$, where $T = [0, \infty]$ are that for all $n \geq 1$ if $t_1 < \ldots < t_n$ and for any integers $\nu_1, \ldots, \nu_\eta$, $P\{y(t_\eta, w) = \nu_\eta | y(t_{(\eta-1)}, w) = \nu_{(\eta-1)} \ldots, y(t_1, w) = \nu_1\} = P\{y(t_\eta, w) = \nu_\eta | y(t_{(\eta-1)}w) = \nu_{(n-1)}\}$. The probability must be a function of ν_η, $\nu_{(\eta-1)}$, and $t_\eta - t_{(\eta-1)}$. The stationary transition probability functions are defined by $p_{ij}(t) = P\{y(t+s, w) = j | y(s, w) = i\}$ $s \geq 0$, $t > 0$, i, j = 1, 2, ... and they satisfy the following conditions: (1) $p_{ij}(t) \geq 0$; (2) $\sum_j p_{ij}(t) = 1$; and (3) $p_{ij}(s+t) = \sum_k p_{ik}(s) p_{kj}(t)$ for s, $t \in (0, +\infty)$. The initial probabilities are $p_i = P\{y(0, w) = i\}$ which satisfy condition (4) $p_i \geq 0$ and $\sum_j p_j = 1$. Given the stationary Markov transition matrix function, $\{p_{ij}(t)\}$, and a sequence of numbers $\{p_i\}$ which satisfy condition (4) then there exists a Markov chain so that the $p_{ij}(t)$ are its stationary transition probabilities and p_i the initial probabilities. A theorem stated by Doob (Trans. Amer. Math. Soc., v. 52: 1942) and 2 new theorems are proved. These theorems are used to establish the limiting properties of discrete parameter Markov transition probability functions. Proof is given for the limiting behavior of the transition probabilities in the continuous parameter case. Another theorem states that if equations 1, 2, and 3 are satisfied for s, $t \in (-\infty, +\infty)$, and if the transition probabilities are

each either identically zero or never zero, then the transition probabilities are constant. (ASTIA abstract)

A NOTE ON NONRECURRENT RANDOM WALKS, by C. Derman. [1956] [4]p. (AF 18(600)760) Unclassifled

Published in Proc. Amer. Math. Soc., v. 7: 762-765, Oct. 1956.

Let $\{X_i\}$, $i = 1, \ldots$, be a sequence of independent and identically distributed random variables with density function $f(x)$ and with $EX_i = \mu > 0$ assumed. Let $\{S_n\}$, $n = 1, \ldots$, be the sequence of cumulative sums $S_n = \sum_{i=1}^{n} X_i$; and let $H(x) = \sum_{n=1}^{\infty} P(S_n \leq x)$ and $h(x) = H'(x)$; $h(x)$ is defined for almost all x as $H(x)$ is nondecreasing. With A any Borel set of positive real numbers and $m(A)$ its Lebesgue measure, proof has been presented that (1) $P(S_n \in A$ infinitely often (i. o.)) = 0 when $m(A) < \infty$, and (2) $P(S_n \in A$ i. o.) = 1 when $m(A) = \infty$, if $0 < \lim_{x \to \infty} \inf h(x) \leq \lim_{x \to \infty} \sup h(x) < \infty$, and if $\lim_{x \to -\infty} h(x) = 0$ is assumed; this assumption can easily be removed. Proof is developed that if $\mu < \infty$ and $\lim_{x \to \infty} \sup h(x) < \infty$, then $\lim_{x \to \infty} \inf h(x) > 0$, and (1) and (2) hold; if $\lim_{x \to \infty} \inf h(x) > 0$, then (1) holds; if $\mu < \infty$, and if a constant $a > 0$ and an interval (a, b) exists so that $f(x) \geq a$ for $X \in (a, b)$, then $\lim_{x \to \infty} \inf h(x) > 0$.

SOME DIFFERENTIATION PROPERTIES OF MARKOFF TRANSITION PROBABILITY FUNCTIONS, by D. G. Austin. [1956] [11]p. (AF 18(600)760) Unclassified

Published in Proc. Amer. Math. Soc., v. 7: 751-761, Oct. 1956.

Differentiation properties are developed for the stationary, transition, probability functions of a denumerable Markoff chain by use of a purely analytic method. Two problems are considered, the question of the existence of derivatives and the question of analytical relations. Theorem I establishes the bounds on the difference quotient and Theorem II establishes that the $p_{ij}(t)$ has a first derivative everywhere. The existence question is shown to have a rather complete solution by the results obtained.

Also published in Phys. Rev., v. 97: 39-52, Jan. 1, 1955.

The evidence for the existence of an appreciable deformation of the charge distribution about the atoms during lattice vibration is discussed. This deformation is shown to lead to a second-order electric moment as well as to a modification of the first-order moment. An analysis is made of the IR absorption in diamond, Si, and Ge. Part of the absorption is intrinsic, and the remainder is explained as an impurity-induced first-order moment. The second-order electric moment can also be used to explain the side-bands in the absorption and reflection spectra of the alkali halides.

ON LOCALIZED PERTURBATIONS, by M. Lax. Feb. 1954, 4p. (Technical rept. no. 2) ([AF]OSR-TN-54-46) (AF 18(600)651) AD 37507 Unclassified

Also published in Phys. Rev., v. 94: 1391-1392, June 1, 1954.

The procedure used to solve problems in physics characterized by a strong local perturbation on an otherwise solvable problem is presented in its most general

SYR. 02:003 - SYR. 02:006

and abstract form. The problem is that of finding the eigenvector x and eigenvalues λ of the matrix A + b: $\Sigma_j(A + b)_{ij}x_j = \lambda x_i$, where the matrix $A = A_{ij}$ has elements i, j = 1, 2, ..., N, and all elements of the matrix b_{ij} vanish except b_{rs} for r, s = 1, 2, ..., k. The eigenvectors S_p and eigenvalues E(p) of A are assumed to be known: $\Sigma_j A_{ij}S_{jp} = E(p)S_{ip}$. A discussion is presented of the special case where the matrix b has only one nonvanishing element, $b_{ij} = b_o \delta_{io} \delta_{jo}$. (ASTIA abstract)

THE INFLUENCE OF LATTICE VIBRATIONS ON ELECTRONIC TRANSITIONS IN SOLIDS, by M. Lax. Oct. 1954 [55]p. incl. diagrs. refs. ([AF]OSR-TN-54-274) (Sponsored jointly by Office of Naval Research as technical rept. no. 5 under Nonr-66904 and [Air Force] Office of Scientific Research as technical rept. no. 3 under AF 18(600)651) AD 43570 Unclassified

A summary is presented of the present state of knowledge concerning optical and thermal transitions of electrons or holes trapped in solids. Among the topics covered are integrated intensities for absorption, the breadth of absorption lines, and the rates for thermal ionization and capture. The configurational coordinate model is discussed in the light of a generalized Frank-Condon principle quoted from M. Lax (Jour. Chem. Phys., v. 20: 1752, 1952). An attempt was made to explain the observation by C. C. Vlam ("The Structure of the Emission Bands of Luminescent Solids," Thesis, University of Groningen, July 1953) that total intensities of absorption (or emission) are essentially independent of temperature.

THERMAL IONIZATION AND CAPTURE OF ELECTRONS TRAPPED IN SEMICONDUCTORS, by H. Gummel and M. Lax. Oct. 1954, 5p. incl. refs. (Technical rept. no. 4) ([AF]OSR-TN-54-275) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under AF 18(600)651) AD 45115 Unclassified

Also published in Phys. Rev., v. 97: 1469-1470, Mar. 15, 1955.

The use of Coulombic wave functions rather than plane waves for the free electron states is found to increase the calculated rate of capture of electrons by a factor of about 200 at liquid helium temperatures. Results calculated for shallow traps in Ge and Si are now found to be consistent with the upper limit set on the photoconductive lifetime by the experiment of Burstein, Overly and Davisson. The Born-Oppenheimer and Hartree approximations used in the calculations were found to yield identical results at low temperatures in these materials. (Contractor's abstract)

MOLECULAR FIELD IN THE SPHERICAL MODEL, by M. Lax. Aug. 30, 1954 [12]p. incl. diagrs. tables refs. (Technical rept. no. 5) ([AF]OSR-TN-[55]-56) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under AF 18(600)651) AD 76985 Unclassified

Also published in Phys. Rev., v. 97: 629-640, Feb. 1, 1955.

The Heisenberg model of ferromagnetism is replaced by a classical model in which the interaction between a pair of neighboring atoms is $-2JS(S + 1)\epsilon_i \epsilon_j$, where S is the spin of any atom, J is the exchange integral, and the ϵ_i are classical unit vectors. The spherical model is then used to evaluate the molecular field acting on any atom i. This effective field is found to have the generalized Weiss form, $H + W(T)M + W'(T)M'y_i^{\Pi}$, where H is the magnetic field, M the magnetization, and M' the antiferromagnetic order (in units of magnetization). The coefficient y_i^{Π} changes sign from one sublattice to another. The "Weiss" coefficients W(T) and W'(T) are slowly temperature-dependent and obey $dW/dT > 0$; $dW'/dT > 0$. A phase transition is found in 3 dimensions, but not in 1 or 2 dimensions. For spin $\frac{1}{2}$ lattices of simple-cubic (sc), body-centered cubic (bcc), and face centered-cubic (fcc) type, the ferromagnetic transition temperature T_c in units kT_c/J is found to be 1.98, 2.87, and 4.45, respectively. Corresponding values for the simple cubic case due to P. R. Weiss and V. Zehler are 1.85 and 1.93, respectively. The susceptibility and the paramagnetic temperature θ are found for the 3 lattices. The ratio θ/T_c is found to be independent of spin with the values 1.52, 1.39, and 1.34 for the sc, bcc, and fcc lattices, respectively. Corresponding results for the transition temperatures, susceptibility, etc., are obtained for the antiferromagnetic cubic lattices. (Contractor's abstract)

BROADENING OF IMPURITY LEVELS IN SILICON, by M. Lax and E. Burstein. Mar. 1955, 36p. diagrs. refs. ([AF]OSR-TN-55-69) (Sponsored jointly by Office of Naval Research as technical rept. no. 8 under Nonr-66904 and [Air Force] Office of Scientific Research as technical rept. no. 7 under AF 18(600)651) AD 56509 Unclassified

Also published in Phys. Rev., v. 100: 592-602, Oct. 15, 1955.

Sharp absorption lines have been observed in p and n type silicon whose absolute and related positions lead to their interpretation as optical transitions between bound states of trapped holes or electrons that are approximately hydrogenic in character. These lines have a finite breadth of the order of 0.001 ev at liquid helium temperatures. This breadth is determined by the zero-point vibrations of the lattice. At higher temperatures, the squared breadth increases in proportion to the mean squared amplitude of oscillation of those lattice modes that contribute significantly to the broadening. The theory indicates that the modes of importance have wave lengths of the order of the Bohr radius of the trapped carrier state. These are rather long wavelength acoustic modes whose energy $\hbar\omega$ corresponds to 80°K. Thus, the squared broadening is expected to increase by a factor of 2 from helium to nitrogen temperatures — and this increase is confirmed experimentally. This confirms the hypothesis that the broadening results from the interaction of the trapped electron with the acoustic lattice vibrations. The form of the electron-lattice interaction is taken to be that of the Bardeen-Shockley deformation potential, and its strength is determined from the experimental mobility. Thus, the theory contains no adjustable parameters. In absolute magnitude, the theoretical line breadth turns out to be several times too large. Possible reasons for the discrepancy are discussed. THERMAL CAPTURE OF ELECTRONS IN SILICON, by H. Grummel and M. Lax. [June 1955] [56]p. incl. diagrs. refs. (Rept. no. 8) ([AF]OSR-TN-55-185) (Bound with its TR-58-13; AD 148100) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under AF 18(600)651) Unclassified

Also published in Ann. Phys., v. 2: 28-56, July 1957.

The thermal processes in semiconductors which depend on the excitation of trapped electrons (or holes) into the conduction band (or valence band) and the reverse process, capture are studied. The correlation to experimental observation of the calculation of the capture cross section for donors in Si is attempted through Born-Oppenheimer (for low temperatures and K phonons) and other approximations, dealing with the perturbations arising from phonon emission and absorption in the electron-lattice systems of the crystal. Sections II and III develop the formal theory and Section IV studies the capture of electrons into the ground state of P impurities in Si. Section V contains speculation on trapping into deep traps.

INERTIAL EFFECTS AND DIELECTRIC RELAXATION, by E. P. Gross. Sept. 1954 [50]p. incl. tables, refs. (Technical note no. P-1) [AFOSR-TN-54-287] (Also bound with its TR-58-15) (AF 18(600)1124) AD 43114 Unclassified

Also published in Jour. Chem. Phys., v. 23: 1415-1423, Aug. 1955.

The response to an alternating electric field of a dilute solution of dipolar molecules in a nonpolar compressed gas was studied. The dipoles are described by a classical distribution function which is a function of angular velocity, orientation, and time. The assumption is made that the duration of collision can be neglected, compared to the time between collisions, the period of the applied field, and the mean thermal period. The distribution function satisfies a kinetic equation, and the effects of collisions are described by a collision kernel. The solutions of the kinematic equation are studied for a variety of kernels. One model is a soft-impact theory which is a generalization of Debye's Brownian-motion treatment to include inertial effects. Other models involve strong collisions and partial specular reflection. The Debye relaxation shape is found in all the models at high pressures. Another common feature is the way in which discrete rotational lines are linked with the Debye spectrum. At lower pressures, the main contribution to the polarization arises from dipoles rotating with the angular frequency close to that of the applied field. Equations constructed for the transport of various physical quantities permit a detailed picture of the transfer of energy and angular momentum from the electric field to the dipole system, and then to the reservoir.

A MODEL FOR COLLISION PROCESSES IN GASES. II. SMALL AMPLITUDE OSCILLATIONS OF CHARGED TWO COMPONENT SYSTEMS, by E. P. Gross and M. Krook. June 1955, 37p. (Technical note no. P-2) ([AF]OSR-TN-55-165) (Also bound with its TR-58-15) (AF 18(600)1124) AD 65384. Unclassified

Also published in Phys. Rev., v. 102: 593-604, May 1, 1956.

The general features of the small amplitude oscillations of a 2-component ionized gas are discussed; the effects of the random thermal motions of ions and electrons are described by distribution functions.

SYR. 03:003 - SYR. 03:006

When collisions are neglected there are 2 types of waves for a given wavelength. One is a high frequency electron plasma oscillation, slightly modified by ionic motions. The other is the Touks-Langmuir positive-ion oscillation which is shown to be undamped when the electron temperature is considerably greater than the ion temperature. The effects of collisions are treated by a kinetic model which satisfies the conservation laws and provides for energy and momentum exchange between components. The low pressure waves are damped with increasing collision frequency and decreasing electron temperature. The validity of transport treatments is investigated. At high density and high frequency one finds the correct sound wave for a mixture of gases. Study of the frequency as a series of inverse powers of the collision frequency shows that the first power term yields absorption independent of the electric charge. Higher powers give contributions to the absorption and dispersion which depend on electrical polarization as well as on diffusion, viscosity, and heat conductivity. The behavior at low frequency and high pressure depends on the electric charge more directly. (For part 1 see item no. MIT. 08:021) (Contractor's abstract)

SMALL OSCILLATION THEORY OF THE INTERACTION OF A PARTICLE AND SCALAR FIELD, by E. P. Gross. [1955] 25p. refs. [Technical rept. no. P-3] [AFOSR-TN-55-305] (Also bound with its TR-58-15) [AF 18(600)1124] AD 107155
Unclassified

Also published in Phys. Rev., v. 100: 1571-1578, Dec. 15, 1955.

The interaction of a nonrelativistic particle with a scalar field is studied with particular application to the theory of polarons. The approach is based on a general classical method for the integration of equations of motion. The Hamiltonian is transformed by successive canonical transformations, the first corresponding to describing the motion relative to special solutions of the equations of motion. This stage as applied to suitably ordered Heisenberg equations of motion is identical with intermediate coupling theory. The second transformation treats the coupled small oscillations of particle and field oscillators about the chosen special solution. This affords a natural extension of intermediate coupling theory for this problem. Differences between the classical and quantum theories arise in the ordering of operators. The differences play a crucial role in determining the effective cutoff in wave vector space. (Contractor's abstract)

THEORY OF MAGNETIC RESONANCE SATURATION (Abstract), by E. P. Gross. [1955] 1p. [AF 18 (600)1124]
Unclassified

Published in Phys. Rev., v. 99: 622-623, July 15, 1955.

We use equations which are generalizations of the Karplus and Schwinger type to study saturation in magnetic resonance absorption. Spin-spin interactions are in the Liouville term, while spin lattice interactions are represented by the stochastic term. For gases, the magnetization satisfies equations differing from those of Bloch in that the transverse components tend to relax to the instantaneous value of applied field. When spin-spin interactions are important, a solution is obtained for line width small compared to the Larmor frequency. The solution agrees with Redfield's postulate that the density matrix is canonical in the rotating coordinate system for circularly polarized rf fields. The defects of Bloch's equations are traced to using perturbation theory in analyzing the statistical behavior of a system in weak interaction with a reservoir. We develop a generalization of the Weisskopf-Wigner approach and find generalizations of the equations used in the foregoing. The restriction to processes near equilibrium made in irreversible thermodynamics is artificial. It is required that the line width due to reservoir interaction be small compared to the separation of combining system levels; the spin system can deviate arbitrarily from equilibrium. BOUNDARY VALUE PROBLEMS IN KINETIC THEORY OF GASES, by E. P. Gross, [E.] A. Jackson, and S. Ziering. Oct. 1956, 38p. incl. tables, refs. [AFOSR-TN-56-527) (AF 18(600)1124) AD 110346
Unclassified

Also published in Ann. Phys., v. 1: 141-167, May 1957.

The state of a gas, flowing between 2 parallel plates, is analyzed from the viewpoint of kinetic theory. When the mean free path is greater than the distance between the plates, the exact solution shows that the distribution function is discontinuous in velocity. Distinction must be made between molecules impinging on a plate and those leaving. The problem is investigated of finding a theory valid for arbitrary ratio of mean free path distance, and of plate speed to sound speed. This is most easily achieved by splitting the distribution function into the above mentioned parts, and expanding each part in polynomials in velocity space, which is orthogonal over half the velocity range. In every approximation, exact account is given of (1) the microscopic boundary conditions, (2) the conservation laws, and (3) the behavior in the low pressure region. The method, which can be applied to the Boltzmann equation is here developed for the kinetic model of Bhatnagar, Gross, and Krook (Phys. Rev., v. 94: 511-525, May 1954). Variational principles are stated by noting the similarity of the linearized version of this theory to the Milne equation of radiative transfer. For the nonlinear, high speed case, a new approach in the low pressure region is indicated. The relationship to alternative methods is discussed. When the distribution function is expanded in full range orthogonal polynomials it is necessary to go to high order to obtain an adequate representation of the low pressure region, and of the boundary layer. Very simple half range distribution functions yield an accurate description of the state of the gas. (Contractor's abstract)

QUANTUM THEORY OF DIELECTRIC RELAXATION, by E. P. Gross and J. L. Lebowitz. [Oct. 1956] 12p. [Technical rept. no. P-5] [AFOSR-TN-56-528] (Also bound with its TR-58-15) [AF 18(600)1124) AD 110347 Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Abstract published in Phys. Rev., v. 99: 623, July 15, 1955.

Also published in Phys. Rev., v. 104: 1528-1531, Dec. 15, 1956.

The statistical behavior of a system coupled to a reservoir at temperature T is discussed. The interactions are assumed to be impulsive. (The meaning of impulsive is that the system evolves under the influence of its own Hamiltonian, except for infinitesimal time intervals when the state is abruptly changed by interactions with the reservoir.) Kinetic equations are written for the classical distribution function and quantum density operator. The class of operators admitted leads to a proper description of the irreversible behavior of the system. Construction of the collision operator for a given Hamiltonian of system and reservoir is not treated. Application is made to the quantum theory of dielectric relaxation with the further assumption that the position coordinates of the system are unchanged by collisions. An explicit solution is found for the behavior in an external alternating field of 2-dimensional dipole of moment of inertia I subject to strong collisions with the reservoir. For low collision frequency $1/\tau$, discrete rotational lines of width $1/\tau$ are found, while at high collision frequencies there is a continuous Debye spectrum with relaxation time $\tau = 1/\tau I/kt$. At intermediate collision times, the absorption and dispersion are governed by an interplay of quantum and inertial effects. (Contractor's abstract)

KINETIC THEORY OF COUETTE FLOW (Abstract), by E. P. Gross, E. A. Jackson, and S. Ziering. [1956] [1]p. [AF 18(600)1124] Unclassified

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 227, Apr. 26, 1956.

Investigation was made on the kinetic theory of plane shear flow, i.e., two infinite flat plates at a distance d, moving with a relative velocity U. For this simplest flow problem, exact solutions of the Navier-Stokes equations yielding flow pattern, temperature distribution, drag for arbitrary U are known. The theory of the infinite mean free path comparable to d and high speeds. An intuitive two stream constant free path model which links properly the known limits and which yields explicit and reasonable results in general was developed. The model is related to a discrete ordinate method of solving the Boltzmann equation. The features of several interaction methods which give solutions satisfying the microscope boundary conditions and which start from either Knudson or Navier-Stokes limits were studied. An analysis is made of the linearized (low speed) solutions of Chang and Uhlenbeck and Mott-Smith. (Contractor's abstract)

MAGNETIC RESONANCE IN SPIN SYSTEMS (Abstract), by A. Zahlan and E. P. Gross. [1956] [1]p. [AF 18 (600)1124] Unclassified

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 216, Apr. 26, 1956.

Two spins coupled to external magnetic fields and to each other by exchange and dipolar energies were considered. The Liouville equation, obeyed by the density matrix, is multiplied by the dipole moment operator to yield the tract. This provides an equation

for the rate of change of the magnetization which is the cross product of magnetization and field, plus traces containing two spin operators which arise from the dipolar energy. Equations for the change of the traces are obtained in like manner; the process terminates because of the properties of the spin matrices. For spins of 1/2 there are nine coupled linear equations. If the equations are completed by an instantaneous field relaxation term, a full discussion of line positions, widths, and of coherence, saturation and thermodynamic aspects is possible. The introduction of spin lattice relaxation by the method of Bloembergen, Purcell, and Pound requires in the general case solution of equations with stochastically varying coefficients. VAPOR-LIQUID TRANSITIONS IN A CLOSED SYSTEM (Abstract), by C. Willis and H. L. Frisch. [1953] [1]p. [AF 18(600)459] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 30-May 2, 1953.

Published in Phys. Rev., v. 91: 465, July 15, 1953.

A formal nonlinear kinetic scheme for the formation of subcritical nuclei of a liquid from a supersaturated vapor in a closed system was formulated without the assumption that the actual distribution does not depart appreciably from canonical distribution. The average number of subcritical nuclei as a function of size and time is presented as a power series in a parameter ϵ which is the ratio of the average rate constant for accretion to the average decay constant. If the condition that the system be closed is relaxed and if all elementary steps involve either the accretion or loss of a single "vapor" molecule, then the equations governing the process reduce to the linear equations derived by Becker and Döring. Comparisons between the linear and nonlinear equations of the two theories are presented. (Contractor's abstract)

GRAND CANONICAL ENSEMBLES, LAPLACE TRANSFORM, AND THE DARWIN-FOWLER CONTOUR INTEGRALS (Abstract), by P. G. Bergmann and E. Newman. [1953] [1]p. [AF 18(600)459] Unclassified

Presented at meeting of the Amer. Phys. Soc., Rochester, N. Y., June 18-20, 1953.

Published in Phys. Rev., v. 92: 856, Nov. 1, 1953.

Let the Hamiltonian of a thermodynamic system depend upon some parameter (s) such as volume or number of particles. Then the mean of the partial derivative of the Hamiltonian with respect to such a strain parameter represents the associated stress. If we combine ordinary (petit) canonical ensembles with different values of the strain parameter, weighting each ensemble with an appropriate exponential factor, then this Laplace transformation leads to the grand canonical ensemble. This transition interchanges, in a certain sense, the respective roles of strain and stress. A return to the petit ensemble is possible, by means of an inverse Laplace transformation, the integration to be carried out in the complex plane. The well-known Darwin-Fowler method for obtaining partition functions for fixed particle numbers is precisely such an inverse Laplace transformation. (Contractor's abstract, modified)

Also published in Phys. Rev., v. 97: 395-403, Jan. 15, 1955.

Vleck and Weisskopf and Frohlich have derived a microwave line-shape by studying the interruption by collisions of the motion of a classical oscillator. They assume that after the instantaneous impact the oscillator variables are distributed according to a Boltzmann distribution appropriate to the value of the applied field at collision. In contrast to the earlier theory of Lorentz, they obtain the correct static polarization. The procedure involves an assumption of very large velocity during collision. This is criticized on the grounds that the duration of collision is short compared to the resonant period, and energy exchanges are of the order of kT. We have derived a line shape formula assuming that the positions are unchanged after impact. Two extreme models are studied. In one the oscillators have a Maxwellian distribution of velocities after impact; the second is a Brownian motion treatment. The resulting line-shape in both cases is that of a friction damped oscillator. For collision frequency much less than the resonant frequency, the polarization postulated by the above authors is reached as a result of kinematic motion between collisions and the line shaper agree. However, to obtain equal line widths and peak absorptions the collision frequency is twice as large for the present theory. For collision frequency comparable to resonant frequency a less distorted line-shape results. For testing the theories, experiments on foreign-gas broadening in the microwave region at pressures of the order of an atmosphere are required. Differences between the theories are small for conditions accessible experimentally at present. (See also item no. MIT. 08:036) (Contractor's abstract)

ON N-PARTICLE DISTRIBUTION FUNCTIONS, by H. L. Frisch. Apr. 1954, 17p. incl. refs. (Technical note no. P-4) ([AF]OSR-TN-54-85) (AF 18(600)-459) AD 37506 Unclassified

Also published in Jour. Chem. Phys., v. 22: 1713-1717, Oct. 1954.

An investigation was made of a certain class of approximate solutions of the Yvon-Born-Green recurrence relations for the lower dimensional molecular distribution functions. The analysis was based on a particular mechanism of exclusion of interactions among clusters composed of successively larger numbers of molecules. This mechanism leads to a chain of equations for the approximate distribution functions which (1) converge to the exact molecular distribution function after a finite number of approximations, (2) are linear in the dependent variable just like the Yvon-Born-Green recurrence relations, and (3) are time-reversible. The connection between these equations and certain natural generalizations of Boltzmann's equation to other than binary collisions is obtained. (ASTIA abstract)

SIMPLIFIED MODEL OF A STATIONARY NONEQUILIBRIUM PROCESS (Abstract), by H. L. Frisch and J. L. Lebowitz. [1954] [1]p. [AF 18(600)459] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-May 1, 1954.

Published in Phys. Rev., v. 95: 643, July 15, 1954.

A Gibbs ensemble will describe a stationary process if the Liouville equation of the system is modified by additional terms describing the stochastic interaction with surroundings, provided the surroundings are at different temperatures. In that case there will be a flux of energy through the system whose ensemble average does not vanish. Probably the simplest model of such a process is a single one-dimensional particle traveling back and forth between two large pistons having different mean energies of vibration. Because even this model leads to a rather involved integral equation, it has been simplified further by assuming that some of the reflections from the pistons are as from rigid walls, with the remainder (a fixed percentage of all reflections) leading to a redistribution of velocity independent of the incident velocity. This redistribution may be thought of as a surface adsorption with subsequent release. This new model is mathematically so simple that the solutions of the integro-differential equation can be obtained in full by relatively elementary methods. The results are presented. NEW APPROACH TO NONEQUILIBRIUM PROCESSES, by P. G. Bergmann and J. L. Lebowitz. Mar. 1955, 30p. (Technical note no. P-7) [AFOSR-TN-55-81] [AF 18(600)459] AD 58012 Unclassified

Also published in Phys. Rev., v. 99: 578-587, July 15, 1955.

A new model is proposed for the description of irreversible processes, which permits the construction of a Gibbs-type ensemble and the employment of the general techniques of statistical mechanics. The internal dynamics of the system that is engaged in the process is assumed to be described fully by its Hamiltonian. Its interaction with the driving reservoirs is described in terms of impulsive interactions (collisions). The reservoirs themselves possess definite temperatures, are inexhaustible, and free of internal gradients. The ensemble obeys an integrodifferential equation in Γ space, containing both the terms of the Liouville equation and a stochastic integral term that describes the collisions with the reservoirs. It is shown that: (1) the ensemble will approach canonical distribution in the course of time in the presence of a single driving reservoir; (2) it will approach a stationary non-equilibrium distribution in the presence of several reservoirs at different temperatures; and (3) in the latter case, and for small temperature differences, Onsager's reciprocal relations are satisfied by the stationary distribution. IRREVERSIBLE GIBBSIAN ENSEMBLES, by J. L. Lebowitz and P. G. Bergmann. Nov. 1956, 43p. (Technical note no. P-8) (AFOSR-TN-56-566) (AF 18-(600)459) AD 110387 Unclassified

Also published in Ann. Phys., v. 1: 1-23, Apr. 1957.

It is shown that it is not required to assume the "direct symmetry" of K for an equilibrium approach. The argument of a weaker requirement is derived from a general theorem which states that regardless of symmetry assumptions on K, (1) $\partial \mu(x,t)/\partial t + (\mu(x,t), H_S(x)) = \int x, [K(x, x^1)\mu(x^1,t) - K(x^1, x)\mu(x,t)] dx^1$ possesses at most one stationary solution, which infers the ensemble approaches this state in the course of time. A weaker condition to be obeyed by $K(x, x^1)$, which is both necessary and sufficient for an asymptotic approach to canonicity, is investigated and the Onsager relations are proved under these conditions with more than one reservoir. The physical model of impulsive interactions between the system and its surroundings is used to derive Equation (1). The kernels are constructed directly from the physical model where the properties are assumed, necessary for the different symmetry conditions on K to hold. The formalism is extended to more general types of reservoirs. An originally generalized canonical ensemble reservoir and systems which exchange particles with a reservoir are studied.

WEAKENED SYMMETRY CONDITION ON STOCHASTIC KERNELS (Abstract), by J. L. Lebowitz. [1956] [1]p. [AF 18(600)459] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 73, Jan. 30, 1956.

A model for an irreversible process, in which a thermodynamic system of arbitrary structure interacts impulsively with inexhaustible reservoirs. It obeys in its γ space a Liouville equation, augmented by a stochastic integral term. The kernel of this term was postulated to possess a certain symmetry. This

symmetry condition has been found to be unnecessarily severe. It can be weakened to a condition somewhat similar to "semidetailed balance." This new condition is both necessary and sufficient to yield these properties: (1) If driven by a single reservoir, the distribution function of the system approaches the canonical distribution asymptotically. (2) With several reservoirs, the Onsager reciprocal relations are satisfied for near-equilibrium conditions. (Contractor's abstract)

GENERALIZATION OF OUR MICROMODEL OF IRREVERSIBLE PROCESSES (Abstract), by J. L. Lebowitz and P. G. Bergmann. [1956] [1]p. [AF 18(600)459] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 221, Apr. 26, 1956.

The model of a system that exchanges energy with its surroundings stochastically (and thereby approaches canonical distribution if the surroundings are at a definite temperature) has been extended to the exchange of other physical variables, including the number of (identical) particles. For suitably constructed reservoirs the system will then approach a generalized canonical or grand canonical distribution. If the system interacts with several reservoirs whose intensive parameters have different values, a stationary irreversible process will result. Among the possible applications of the extended model is the treatment of electric currents and other particle fluxes. The validity of Onsager's reciprocal relations for such situations is verified. STOCHASTIC BOUNDARY CONDITIONS IN IRREVERSIBLE PROCESSES (Abstract), by H. Salwen, W. [L.] Sadowski, and P. G. Bergmann. [1956] [1]p. [AF 18(600)459] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 221, Apr. 26, 1956.

Bergmann and Lebowitz described the time-dependent interaction of open systems with their surroundings by introducing stochastic terms on the right-hand side of the Liouville equation in Γ space. Realistically, such interaction ordinarily takes place only in certain regions of physical space and thence also in limited domains of the Γ space. Accordingly, investigation is made of the extreme case in which the causal Liouville equation is satisfied everywhere except on certain hypersurfaces. The dynamics of the stochastic integral operator is then replaced by "stochastic boundary conditions," integral conditions on the density function on the hypersurfaces. The form of the boundary conditions may be ascertained either by a transition to the limit of the region in which the original integral operator is non-zero or by the formal requirement that the Helmholtz potential of the ensemble decrease monotonically with time. A STUDY OF THE PHYSICAL PROPERTIES OF FERRITES AND RELATED MATERIALS. PART I. MAGNETIC DIPOLAR INTERACTIONS IN ORDERED FERRITES, by W. L. Sadowski, R. A. Johnson, and D. W. Healy, Jr. Final rept. no. I. Dec. 1955, 41p. incl. diagrs. tables, refs. (Rept. no. EE250-55I2F1) (AF 18(600)754) Unclassified

The effects of classical magnetic dipole - dipole interactions in an ordered ferrite crystal structure are examined. It is assumed that the ferrites are completely inverted and the term ordered refers to a long range ordering of the metallic cations on the various available octahedral sites of the crystal. A quantitative calculation of the magnitude of these effects is made and the dipole interaction energies are found to be of the order of 10^6 ergs/cc. At least two ferrites, magnetite, and lithium ferrite are believed to occur physically in an ordered state. Predictions are made concerning the result of microwave resonance experiments on lithium ferrite and explanations are offered for the experimental results obtained on magnetite below its transition temperature. MAGNETIC DIPOLE EFFECTS IN FERRITES, by D. W. Healy, Jr. and R. A. Johnson. [1956] [17]p. incl. tables, refs. (AFOSR-TN-56-224) (AF 18(600)754) AD 88032 Unclassifted

Also published in Jour. Chem. Phys., v. 26: 1031-1035, May 1957.

An analysis is made of the role which classtcal magnetic dipole-dipole interactions may play in the physical behavior of ferrites espectally its magnetic anistropy. In magnetite, the ordering takes the form of 1:1 ordering in the B sites in which successive (001) layers of B sites are occupied by Fe^{++} and Fe^{+++} ions, respectively. In $Li_{0.5}Fe_{2.5}O_4$, the orderting is a 3:1 ordering in the B sites where every row of B sites in the [110] direction contains a Li ton every fourth site. The dipolar contribution to the internal field is calculated at each lattice site for the general case of perfect long range order. When evaluated for the specific orderting postulated for magnetites and Li ferrite, these results predicted a large dipolar contribution to the anisotropy energy. In most ferrites of interest in which long range order is absent, the magnetic cations are statistically distributed on the available B sites. The statistical properties of the resulting local dipole field are discussed.

A STUDY OF THE PHYSICAL PROPERTIES OF FERRITES AND RELATED MATERIALS. PART 2. MAGNETIC DIPOLAR INTERACTIONS IN DISORDERED FERRITES, by R. A. Johnson. Final rept. no. 2. Feb. 1956, 16p. incl. table, refs. (Rept. no. EE250-563F2) (AF 18(600)754) Unclassified

The statistical properties of the local dipole field resulting from a disordered arrangement of metallic ions in the ferrite crystal structure are discussed. Quantitative results are obtained for limiting distributions of ions on the available octahedral sites. For nickel ferrite, the rms dipole field is nearly 2000 oersteds for random ordering and somewhat larger if short range order exists. With this model the expected line width in magnetic resonance is of the order of 20 oersteds. The results also predict a small (about 7%) cubic anisotropy in the line width with the narrower line obtained when the equilibrium position of the magnetization is along a body diagonal. Since thermal motion of the spins is not considered, the theory is only applicable at low temperatures. An experimental test of the theory on a single crystal of lithium ferrite which can be prepared in either the ordered or disordered phase is suggested. (Contractor's abstract)

A STUDY OF THE PHYSICAL PROPERTIES OF FERRITES AND RELATED MATERIALS. PART 3. ELECTRONIC RESONANCE IN NICKEL FERRITE AT LOW TEMPERATURES, by D. W. Healy, Jr. and R. A. Johnson. Final rept. no. 3. Mar. 1956, 23p. incl. dtagr. tables, refs. (Rept. no. EE250-563F3) (AF 18(600)754) Unclassifted

An experimental study of the g value and magnetic anisotropy constants of a stngle crystal of nickel ferrite is reported. These constants were measured over a temperature range from room temperature (298°K) to liquid helium temperature (4.2°K) and over a frequency range from 6,000 to 11,000 megacycles. The prtnctpal study was made on a stngle crystal of nickel ferrtte on which measurements at the K band frequencies had been made at the Bell Telephone Laboratories. The results of measurements taken at the X band frequency were found to be consistent with those taken at the K band frequency when the X band data was extrapolated according to the following equation: $w = \gamma'(H_{eff} - H_i)$.

DYNAMIC EQUATIONS OF DONNELL'S TYPE FOR CYLINDRICAL SHELLS WITH APPLICATION TO VIBRATION PROBLEMS, by Y.-Y. Yu. Oct. t956, 22p. (Rept. no. ME390-56t0TNt) (AFOSR-TN-56-526) (AF t8(603)5) AD tt0345 Unctassified

SYR. 08:00t

Presented at Ntnth International Congress of Appl. Mech., Brussels (Belgium), Sept. 5-t3, 1956.

A set of dynamic equations was previously derived which corresponds to the original Donnell (NACA Tech. rept. no. 479, 1933) static equations used in bending and buckling problems of cylindrtcal shells. In this note 2 more sets of Donnell-type dynamic equations for cylindrical shells are presented. The ftrst set ts derived from the well-known Flügge equations, which, like the previous set, do not tnclude transverse shear and rotational tnertia effects. The 2nd set ts derived from equations which do include these effects. It is shown that the 2nd set may be reduced to the first, which may tn turn be reduced to the one given tn the previous paper. On the basts of the Donnell-type equations which do not tnclude transverse shear and rotational tnertia effects, the free vibration problem of cylindrical shells with freely supported edges ts first tnvestigated. By further making use of Galerkin's method, the cases of shells with clamped and flexibly supported edges are also dtscussed. The last case of flexibly supported edge has never been tnvestigated before and comprises the other 2 of freely supported and clamped edges as special limiting cases. As exemplified, one advantage of using Donnell-type equations tn the vibration studies of cylindrtcal shells is that the natural frequency and mode may now be calculated from separate equations. Another important application feature, also illustrated, ts that the Galerkin method may be used effectively and conveniently. (Contractor's abstract)

The catalyzed hydration-enolization of quinone in hydroquinone developers produced hydroxyhydroquinone which appears to be the fogging and accelerating developer of infectious development. Hydrazine was considered to act as a catalyst for the hydration-enolization and also to hold the hydroxyhydroquinone in the reduced state until the hydrate-enolate reacts with a Ag halide grain. The catalyzed hydration-enolization of the quinoid states of the developers composing a superadditive developer was considered the primary cause of superadditivity. The reduced developers also serve to hold the hydrate-enolates in the reduced state until they react with Ag halide. This evidence points to the first hydrate-enolate as being the active agent in these processes. This does not eliminate the possibility of the hydrate-enolate semiquinones also acting on the charge barrier. The antifoggants, such as benzotriazole, 6-nitrobenzimidazole, and phenosafranin, all react with hydroxyhydroquinone or its oxidation products. The nature of this reaction was not determined. The action of amidol is discussed on the basis of its relation to hydroxyhydroquinone.

CHROMATOGRAPHIC SEPARATION AND IDENTIFICATION OF PHOTOGRAPHIC DEVELOPERS (Abstract), by J. H. Pannell and J. E. LuValle. [1954] [1]p. (AF 18(600)371) Unclassified

Published in Anal. Chem., v. 25: 1566, Oct. 1953.

In the course of a study of reactions of photographic developers, methods for the separation and identification of the developers and their oxidation product were devised. Knowledge of the reactions of developers was seriously limited by a dearth of information on such separations. A method based on paper chromatography was evolved which should be of value as it has the advantages of simplicity and specificity. However, it is probably applicable only to substances which are moderately stable to air. The method employs standard chromatographic equipment and a solvent composed of butanol, acetic acid, and water mixed in the volume proportion 4 to 1 to 5, from which the organic layer is separated and used. As spray reagent, a 2% solution of ammoniacal silver nitrate gives the highest sensitivity. A 5% solution of phosphomolybdic acid, while less sensitive, produces chromatograms which do not darken with time. Best results are obtained when 10 γ amounts of developers are used, although 1 γ can be detected. The following table shows Rf values obtained by descending development on Whatman No. 2 paper using butanal-acetic acid-water solvent at room temperature (22°C) where the solvent front moved 40 cm:

Hydroquinone disulfonate	0.00
p-Methylaminophenol monosulfonate	0.09 ± 0.01
Hydroquinone monosulfonate	0.15 ± 0.01
Quinone monosulfonate	0.34 ± 0.02
p-Aminophenol hydrochloride	0.43 ± 0.03
p-Phenylenediamine hydrochloride	0.55 ± 0.03
p-Methylaminophenol sulfate	0.61 ± 0.02
Hydroquinone	0.80 ± 0.02.

PRODUCTION OF BLUE COLOR IN IRRADIATED PLASTIC SCINTILLATORS, by J. H. Pannell and B. Manning. [Apr. 1955] 2p. incl. diagr. ([AF]OSR-TN-55-83) [AF 18(600)1134] AD 73220 Unclassified

Also published in Jour. Chem. Phys., v. 23: 1368-1369, July 1955.

An intense blue color is produced at room temperature in polystyrene and polyvinyltoluene containing certain fluors when they are subjected to β irradiation in the absence of light. At dry ice temperatures (-70°C), production of this color is apparently accelerated, i.e., decay is decelerated, and becomes obvious in many plastic scintillators, being most noticeable in those containing the following: terphenyl; terphenyl + diphenylstilbene; diphenylbutadiene; tetraphenylbutadiene; diphenylstilbene; and tetraphenylethylene. On warming the plastics to room temperature, a considerable amount of phosphorescence is evident; this phosphorescence, associated with thermal bleaching of color, indicates that the color is associated with trapped electrons. Light absorption measurements were made using a Beckman model DU spectrophotometer. Absorption curves are plotted for terphenyl-tetraphenylbutadiene polystyrene plastic after 16 hr irradiation. It is proposed that the phenomenon described might be most easily explained by an "F-center" theory, but in a noncrystalline structure.

THE INDEX OF REFRACTION EFFECT ON ABSOLUTE FLUORESCENCE MEASUREMENTS, by A. Shepp. Apr. 1956, 8p. incl. diagr. (Technical rept. no. 1; rept. no. TOI 56-12) (AFOSR-TN-56-184) (AF 18(600)1134) AD 87057 Unclassified

Also published in Jour. Chem. Phys., v. 25: 579, Sept. 1956.

A detailed analysis is given of the effect of the index of refraction (n) of the crystal on the luminescent light escaping from within a pure crystal. The spatial distribution and the total quantity of light escaping from a phosphor depend on geometric shape and index of refraction. The recommendations for crystal or cell shape when making absolute fluorescence measurements are as follows: (1) those based on a reading of total light output should utilize a rectangular crystal; (2) those based on a reading taken far out along the normal to a plane face should utilize a cylindrical or rectangular crystal; (3) for readings taken far out off the normal to a plane face, a rectangular crystal should be used; (4) measurements should never be taken close to the crystal; and (5) measurements on powders must in some way (comparing with a pure crystal) take account of the possibility of light loss. An analysis of previous efficiency measurements is presented. Most of them were subject to complex, though probably small corrections.

TOWARDS A THEORY OF WOOD'S ANOMALIES, by B. A. Lippmann and A. K. Oppenheim. Final rept. June 30, 1954 [33]p. incl. diagrs. refs. (Rept. no. TRG-951-1) ([AF]OSR-TR-54-25) (AF 18(600)954) AD 42673 Unclassified

The Rayleigh-Artmann theory of Wood's anomalies is shown to be limited, by an implicit approximation, to the region $b/\lambda << 1$, where b = groove depth and λ = wavelength. Since the observation of P anomalies seems to be associated with $b/\lambda \sim 1$, a more general theory of grating anomalies is required. It is suggested that such a theory can be constructed by analyzing the influence of kinematical, groove, and edge effects individually. In this study, a calculation is made of the kinematical effects associated with a grating. The results lend support to the view that kinematical effects are, in part, responsible for grating anomalies. (Contractor's abstract)

"SHIMMING" AN INHOMOGENEOUS MAGNETIC FIELD IN NUCLEAR RESONANCE EXPERIMENTS BY PULSES, by B. Nelson and L. Goldmuntz. July 1, 1956, 1v. incl. diagrs. tables. (AFOSR-TN-56-368) (AF 18(600)1313) AD 95804 Unclassified

A mathematical investigation is presented in connection with the possible use in radar design of nuclear magnetic resonance in the development of a narrow-band, low-noise figure filter capable of operating at r-f frequencies. The chief result obtained is that there is a combination of "shimming" pulses that can be applied to a liquid sample that can make the line width of the sample independent of the degree of homogeneity of the external static magnetic field. Initially, a simplified discussion is given of certain nuclear resonance experiments and the modifications necessary to make them useful in filter circuits. This is followed by a general discussion of the matrix solution of Bloch's equations describing the behavior of the net nuclear magnetization. The methods covered in the discussion are then used in the analysis of the series of "reclustering" pulses applied to the nuclear sample to obtain the desired narrow line width. Finally, there is considered the integral of the transients caused by this shimming technique. The report is restricted in discussion to shimming systems which operate only transiently over the longitudinal relaxation time of the nuclear sample.

ON ISOTROPIC TENSOR FUNCTIONS AND THE MEASURE OF DEFORMATION, by M. Hanin and M. Reiner. [1955] 18p. refs. (Part 2 of its AFOSR-TN-56-114; AD 82510) [AF 61(514)871] AD 82510(b) Unclassified

Also published in Zeitschr. Angew. Math. Phys., v. 7: 377-393, 1956.

A theoretical understanding is provided for a centripetal-pump effect which was recently observed in air. An isotropic relation between 2 symmetric tensors of second rank can be expressed in the form

$$y_s^r = (F_0 + \sum_{n=3}^{\infty} F_n C_n)\,\delta_s^r + (F_1 + \sum_{n=3}^{\infty} F_n B_n)x_s^r + (F_2 + \sum_{n=3}^{\infty} F_n A_n)x_\alpha^r x_s^\alpha, \text{ where } F_n = \sum_{p,q,r}^{(n)} k_{p,q,r}$$

$I^p II^q III^r$, and the A_n, B_n, and C_n are similar power series in the principal invariants of x_s^r. The constants k must be determined by means of suitable experiment between the physical quantities represented by x_s^r and y_s^r. The F_n will be a constant when x_s^r and y_s^r are different measures of deformation, and the logarithmic Hencky measure can then be expressed through the Almansi measure. When this is done, a quasi-linear stress-flow relation reveals certain second order effects in viscous liquids, even when elasticity is absent and the viscosity is low. (Contractor's abstract)

RESEARCH ON THE PHYSICS OF AIR VISCOSITY, by M. Reiner. Research progress summary rept. July 15, 1955-Jan. 15, 1956, 1v. incl. illus. tables, refs. (AFOSR-TN-56-114) (AF 61(514)871) AD 82510 Unclassified

The Weissenberg effect is described, and its possible mechanisms are analyzed in terms of simple shear. They are reduced to cross-stresses which may be due either to a quasilinear or a general elasticity involving a second order term, or to cross-viscosity. A mathematical expression is given which shows an isotropic relation between 2 symmetric tensors of second rank. The expression led to a quasilinear stress-flow relation which reveals certain second order effects in viscous liquids, even when elasticity is absent and the viscosity is low. This may provide a theoretical understanding for the recently observed centripetal pump effect in air. An instrument is described which permits the determination of the Weissenberg effect and the viscosity of a small sample in one operation. Data obtained from 218 experiments performed with a centripetal airpump instrumental setup are given, confirming that the effect found in very viscous liquids is also present in air. RESEARCH ON THE PHYSICS OF AIR VISCOSITY, by M. Reiner, J. F. T. Blott, and B. Poppen. Research progress summary rept. Jan. 15, 1956 - July 14, 1956, 1v. incl. illus. diagrs. refs. (AFOSR-TR-56-42) (AF 61(514)871) AD 97075 Unclassified

This report is divided into three parts. Part I, A Centripetal Pump Effect in Air, is a revision of and has been abstracted as Part 4 of AFOSR-TN-56-114, item no. TIH. 01:004. Part II is an addenda to Part I and contains a number of graphs which illustrate results which were not included in Part I. The graphs refer mainly to cylinder III which behaved differently from the other four cylinders. This probably some resonance-effect which awaits an explanation. Part III, A Centripetal Airpump, describes an instrument consisting of two circular metal plates; one stationary, the other rotating opposite it with a very narrow gap between both. At certain high speeds the air is drawn in a centripetal direction into the gap.

ON SUPERSONIC ROTATIONAL FLOW BEHIND STRONG SHOCK WAVES. I. FLOW PAST AIRFOILS, by A. Kogan. Technical research progress note July 15, 1955-Jan. 15, 1956 [58]p. incl. diagrs. table, refs. (AFOSR-TN-56-165) (AF 61(514)870) AD 86586 Unclassified

A method of successive approximations to the ideal flow past airfoils at high supersonic Mach numbers is developed, based on the concept of Crocco's stream function. When the undisturbed stream is taken as zero-order approximation to the actual flow, the second approximation to the pressure coefficient $C_p(x)$ at the airfoil surface coincides with the well known results obtained by Busemann. But contrary to potential flow theory, the present method yields good results also at a distance from the airfoil and approximates correctly the shock wave profile. Then taking the uniform flow behind a plane shock wave as zero-order approximation, both the shock wave curvature and its derivative, and the first and second derivatives of $C_p(x)$ on the airfoil surface are evaluated at the leading edge in terms of the airfoil curvature and its derivative at the leading edge. (Contractor's abstract)

THEORETICAL AND EXPERIMENTAL INVESTIGATIONS ON SWEPT- AND DELTA WINGS IN SYMMETRICAL FLOW, by E. Truckenbrodt, tr. by H. Schltchttng. Ftnal rept. Apr. 30, t954, 91p. tncl. tllus. dtagrs. tables. (Rept. no. 54/7a) ([AF]OSR-TR-54-23) (AF 6t(5t4)426; continued by AF 6t(514)-649-C) AD 7089t Unclasstfted

Also published in Zettschr. Flugwissensch., v. 2: t85-20t, Aug. t954.

Also published in Jour. Aeronaut. Sctences, v. 2t: 637-638, Sept. t954.

Systematic 3-component measurements were conducted on swept- and delta wtngs tn tncompresstble flow. There were 5 swept wtngs of constant chord and 5 delta wtngs, both with aspect rattos between 1 and 5, wtth the swept wtngs havtng a constant angle sweep, $\Lambda = 45°$, and the delta wtngs a constant taper ratto, $\lambda = t/8$. For the swept wtngs, the aerodynamtc center was about 10% of the wtng chord tn front of the geometrtc center. For the delta wtngs, tt was about 6 to tt% of the wtng chord behtnd the geometrtc center. The curves of the profttle drag coefftctent vs the ltft coefftctent cotnctded well for all aspect ratios at moderate ltft coefftctents, C_L, up to approxtmately 0.5. Except for small aspect rattos beyond maxtmum ltft, the pttchtng moment at htgh C_L was tatl-down for the swept wtngs and nose-down for the delta wtngs. Theorettcal calculattons of the spanwtse and chordwtse ltft dtstrtbutton accordtng to a new ltfttng-surface theory proposed by Truckenbrodt (Beträge zur Tragflächentheorte bei tnkompresstbler Strömung [Contrtbutton to the Ltfttng-surface Theory in Incompresstble Flow], Jahrbuch der wtssenschaftlichen Gesellschaft für Luftfahrt, t953) were carrted out for atl wtng planforms. For swept wtngs, wtth large aspect rattos there was a constderable breakdown tn the spanwtse ltft dtstrtbutton resultlng from the ktnk near the mtddle sectton. For all delta wtngs, the spanwtse ltft dtstrtbutton was nearly elltptical. For all planforms, the local aerodynamtc center was tn front of the quarter-chord ltne at the outer parts of the wtng and behtnd the quarter-chord ltne at the tnner parts of the wtngs.

SOME PROBLEMS OF CASCADE FLOW, by H. Schltchttng. [t955] [t3]p. tncl. dtagrs. refs. (AF 6t(5t4)649-C) Unclasstfted

Published in Proc. Conference on High-Speed Aeronautttcs, Polytechnic Inst. of Brooklyn, N. Y. (Jan. 20-22, 1955), p. t75-187.

In the course of systemattc research work on cascade flow whtch has been conducted tn recent years new soluttons have been estabtlshed for the "Dtrect Problem" and the "Inverse Problem" of the two-dtmenstonal tncompresstble frtctionless flow through cascades. These soluttons together wtth the boundary layer theory have been used for systemattc theorettcal calculattons of the loss coefftctents of two-dimenstonal cascades. Both soluttons are based on the method of stngularttties, and each blade sectton of the cascade ts replaced by certatn conttnuous chordwtse dtstrtbuttons of vorttces and sources stnks. While the solutton of the "Inverse Problem" has been publtshed, tn thts paper an outltne of the solution of the "Dtrect Problem" ts gtven. This solution allows each of the geometrtc parameters of the cascade (e.g. soltdtty ratto, angle of stagger, blade sectton) to be altered separately. In order to calculate the pressure dtstrtbutton of a gtven cascade, a system of six ltnear equattons has to be solved. The amount of numertcal work tnvolved

has been reduced considerably by tabulating certain "Influence Functions," which are independent of the blade section and depend on the solidity ratio and the angle of stagger only. Pressure distributions, as well as loss coefficients, as obtained from theory are in good agreement with experiments. (Contractor's summary)

A SIMPLE APPROXIMATE METHOD FOR CALCULATING THE LAMINAR BOUNDARY LAYER WITH SUCTION, by E. Truckenbrodt. Final rept. May 21, 1955, 62p. incl. diagrs. tables, refs. (Rept. no. 55/6a) [AFOSR-TR-55-21] (AF 61(514)639-C) AD 74986 Unclassified

A simplified approximate method was developed which compares satisfactorily with the exact solution and which presents no difficulties such as those associated with the approximate methods of H. Schlichting and T. P. Torda. The new method can be used to calculate the boundary layer in plane and axial symmetrical flow and the arbitrarily distributed suction velocity along the body. The point of separation at various suction velocities can also be obtained. Examples are given for plane and axially symmetrical flow with a stagnation point, a flat plate at zero incidence with homogeneous suction, and a semi-body of revolution with the suction beginning in one case at the stagnation point and in the other case at the point of maximum velocity. RESULTS OF SYSTEMATIC INVESTIGATIONS ON SECONDARY FLOW LOSSES IN CASCADES. PART I. SECONDARY FLOW LOSSES IN COMPRESSOR CASCADES OF PROFILE NACA 8410, by K. Gersten. June 28, 1955, 33p. incl. diagrs. tables. (Rept. no. 54/29a) [AFOSR-TN-55-451] (AF 61(514)650-C) AD 92866 Unclassified

Experimental investigations of secondary flow losses have been carried out on a compressor cascade with blade profile NACA 8410. The solidity was $t/l = 1$, the blade angle $\beta_S = 135°$, and the ratio of blade chord $h/l = 3$. The Reynolds number, based on the outflow velocity, is $Re_2 = w_2 l/\nu = 4 \times 10^5$. On comparison with previous investigations concerning turbine cascades, these measurements indicate a completely different behavior of secondary flow effects for turbine and compressor cascades. In the case of the turbine cascade having a blade length ratio $h/l = 3$, there exists a zone in the middle of the blade which is almost uninfluenced by secondary flow effects; however, in the case of the compressor cascade, the middle zone is strongly disturbed. Also, in the latter instance there exists an additional acceleration of the flow in the middle zone, owing to secondary flow effects, which results from the blocking of the cross section at the side walls. This additional pressure drop gives: (1) an unfavorable decrease of the total pressure rise across the compressor cascade, and (2) a favorable influence on the total losses of the cascade.

RESULTS OF SYSTEMATIC INVESTIGATIONS ON SECONDARY FLOW LOSSES IN CASCADES. PART II. SECONDARY FLOW LOSSES OF A TURBINE CASCADE FOR DIFFERENT VELOCITY PROFILES OF INFLOW, by K. Gersten. Dec. 20, 1955, 29p. incl. diagrs. (Rept. no. 54/12a) (AFOSR-TN-56-137) (AF 61(514)650-C) AD 86013 Unclassified

Measurements on a turbine cascade between parallel plane walls have been carried out with different inflow velocity profiles to investigate the influence of the boundary layer thickness on the flow characteristics. The solidity ratio was $t/l = 1$, 0, where t is the distance the ratio of blade length to blade chord $h/l = 5$, and the angle of inflow $\beta_1 = 135°$. Two values of blade loading were investigated with blade angle $\beta_S = 35°$ and 45°. The values of the displacement thickness of the boundary layer of the inflow velocity profile were $\delta_1^*/l = 0.03$; 0.09 and 0.23, and the Reynolds number based on the outflow velocity $Re = w_2 l/\nu = 9 \times 10^4$. These are the main results: For moderate acceleration in the cascade ($\beta_S = 45°$) and small values of the boundary layer thickness, the coefficient of total loss increases slowly with increasing boundary layer thickness, but becomes independent of it for larger thickness of the boundary layer. For larger values of acceleration in the cascade ($\beta_S = 35°$), the ratio of secondary flow loss to total decreases and is independent of the boundary layer thickness of the inflow velocity profile. RESULTS OF SYSTEMATIC INVESTIGATIONS ON SECONDARY FLOW LOSSES IN CASCADES. PART III. SECONDARY FLOW LOSSES OF A TURBINE CASCADE FOR DIFFERENT SHAPES OF BLADE TIP AND BLADE FOOT, by E. G. Feindt. May 15, 1956, 32p. incl. diagrs. (Rept. no. 54/32a) (AFOSR-TN-56-301) (AF 61(514)650-C) AD 90014 Unclassified

Measurements on a turbine cascade have been carried out to investigate the influence of the shape of the blade foot and the blade tip on the secondary flow

THB. 04:004 - TEM. 01:001

losses in incompressible flow. The solidity ratio, the ratio of blade length to blade chord, and the gap were kept constant. The blade profile was NACA 8410. Three different shapes of the blade tip and of the blade foot have been investigated; the blade tip was bluntly cut off, and obliquely cut off to the pressure and to the suction side of the blade; the blade foot was without a fillet, with a fillet of small radius, and with a fillet of large radius. The blade loading was altered by altering the blade angle. The main results of these investigations indicate that: (1) for the gap used here, the secondary flow losses at the blade tip and at the blade foot are nearly of the same magnitude; (2) the secondary flow losses at the tip and at the foot depend very little on the blade loading; and (3) the secondary flow losses depend very little on the shape of the blade tip and the blade foot. [SECONDARY FLOW LOSSES IN COMPRESSOR CASCADES] Randverluste in Pumpengittern, by H. Schlichting. [1956] [6]p. incl. illus. diagrs. refs. [AF 61(514)650-C] Unclassified

Published in Zeitschr. Flugwissensch., v. 4: 35-40, Feb. 1956.

Several results from tests regarding the losses of flow in compressor cascades for incompressible flow are discussed. For the ratio of blade length to blade chord h/l = 3 the effect of the secondary flow along the walls is considerable, not only on the deflection of the flow but also on the pressure rise in the cascade. In order to separate these effects of the secondary flow the same cascade was also tested in two-dimensional flow. The two-dimensional flow was obtained by applying suction to the walls resulting in a good agreement of deflection of flow and pressure rise in two dimensional flow with potential theory. The available measurements indicate that the secondary flow effect in compressor cascades is much greater than in turbine cascades. A splitting-up of the total losses into two-dimensional losses and additional secondary flow losses is possible in many cases of turbine cascades but not so in most cases of compressor cascades. (Contractor's summary)

THEORETICAL AND EXPERIMENTAL INVESTIGATIONS ON WING-BODY COMBINATIONS WITH DELTA WINGS IN SYMMETRICAL FLOW, by K. Gersten and E. Truckenbrodt. June 4, 1956, 45p. incl. diagrs. tables, refs. (Rept. no. 56/20a) (AFOSR-TR-56-36) (AF 61(514)875) AD 96505 Unclassified

Three-component measurements have been made of fourteen wing-body combinations of a Delta wing. The influence of body length and shape (nose rounded or pointed) has been investigated, keeping constant the ratios of wing aspect and of body width/wing span. A method and its applications in the present study are given for the theoretical calculation of the shift of the aerodynamic center due to the influence of the body. This shift is considerably dependent on the wing aspect and the body width/wing span ratios. Agreement between theoretical and experimental results is satisfactory. (Contractor's abstract, modified)

THE COMBUSTION OF CARBON SUBNITRIDE, C_4N_2, AND A CHEMICAL METHOD FOR THE PRODUCTION OF CONTINUOUS TEMPERATURES IN THE RANGE OF 5000-6000° KELVIN OR 9000-11000° RANKINE, by A. V. Grosse and A. D. Kirshenbaum. Dec. 15, 1955, 37p. incl. illus. diagrs. tables, refs. (Technical note no. 1) (AFOSR-TN-56-13) (AF 18-(600)1475) AD 84316 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 2020, May 20, 1956.

A chemical method for producing continuous flame temperatures in the range of 5000° to 6000°K is described. In this method, C_4N_2 is combusted with O_2, O_3, or O_2-O_3 mixtures to CO and N_2. The vapor pressure curve of the compound was determined, and preliminary values were obtained for the heats of vaporization (6875 cal/mol), fusion (3700 cal/mol), and sublimination (10,575 cal/mol). The thermochemical equations of combustion of C_4N_2 with O_2 and O_3 are: (C_4N_2) gas + $2O_2 \rightarrow 4CO + N_2$ + 254.6 kcal at 25°C, and (C_4N_2) gas + 1-1/3 $O_3 \rightarrow 4CO + N_2$ + 299.9 kcal at 25°C. From these equations and the heat content of the products of combustion, the actual temperatures attainable at various pressures can be calculated with a high degree of accuracy. A flame temperature of 5260°K was obtained by premixing gaseous C_4N_2 with O at the stoichiometric point. This is the highest continuous temperature attained so far by chemical means. At superatmospheric pressure which markedly suppresses the dissociation of CO and N_2, temperatures above 5500°K should be obtainable. A temperature slightly above 5500°K can be obtained at 1 atm by using pure O_3 instead of O_2. The effect of ionization on flame temperatures was calculated by using Saha's formula for thermal ionization (Phil. Mag., v. 1: 1025, 1920). Results indicated that ionization does not lower the calculated flame temperatures.

CHEMICAL BEHAVIOR OF VARIOUS SUBSTANCES AT TEMPERATURES IN THE RANGE 4000 to 5000°K, by C. S. Stokes. [Feb. 1956] 2p. (Technical note no. 3) (AFOSR-TN-56-90) (AF 18(600)1475) AD 82017 Unclassified

A report is made of the behavior of 9 mil tungsten wire and of carbon filaments in a helium or argon atmosphere at temperatures of 4000° to 5000°K produced by use of an oxy-cyanogen flame which develops 4800°K at the CO stoichiometric point ($C_2N_2 + O_2 \rightarrow 2CO + N_2$) and at 1.0 atm pressure. The temperature range is produced by addition of helium to the entry gases or by use of pressure in multicone or other torches developed, with flame adjustment effected by use of a photoelectric cell. The tungsten wire rapidly oxidized to a blue oxide of some intermediate composition below WO_3 at a temperature of 4800°K produced by a 55 mol % oxygen-45 mol % cyanogen flame. Oxidation was slow and the wire melted and evaporated if the flame was slightly oxygen rich. With the flame at the stoichiometric point the tungsten remained intact and carbon deposited on the wire growing down the outside of the flame cone to form the semblance of a cap. Tungsten carbide formation, which could only occur initially, prior to carbon deposition, will be investigated later. Similar tests with carbon filaments produced like results, except that the carbon oxidized when the flame was even slightly oxygen-rich; carbon growth was noted in the flame at the stoichiometric point. Other materials such as iron and nickel simply boiled away at 4800°K. (Contractor's abstract, modified)

THE PURE OZONE TO OXYGEN FLAME, by A. [G.] Streng and A. V. Grosse. [1956] [30]p. incl. diagrs. tables, refs. [Technical note no. 2] (AFOSR-TN-56-104) (AF 18(600)1475) AD 82018 Unclassified

Published in Sixth Symposium (International) on Combustion, Yale U., New Haven, Conn., (Aug. 19-24, 1956) N. Y., Reinhold, 1957, p. 264-273.

A report is made of high temperature studies involving direct conversion of O_3 to O_2 to produce a steady flame. At first, the burning of pure O_3–O_2 was observed in horizontal glass tubes, open at one end and varying in inner diameter from 4 to 12 mm, and of a length of about 100 cm. A mixture was ignited at the open end by means of a hot platinum wire and its burning velocity measured. It was found that below 16 mol % O_3 and at 1 atm total pressure and 25°C the O_3–O_2 mixtures did not ignite in a 12mm tube. After these preliminary experiments an apparatus was set up for continuous burning of O_3 to O_2. It consisted essentially of a cylinder of the desired O_3–O_2 mixtures, from which it could be passed on at a constant and preset rate to a straight vertical pyrex glass tube. The mixture was ignited by a hot platinum wire. Below about 20 mol % O_3 the flame can be observed only with difficulty by the naked eye, but the burning cone can be readily observed by the Schlieren method. For example, a 27.5 mol % O_3–O_2 mixture has a normal burning velocity of 50 cm/sec (at 1 atm and 20°C). The pure O_3–O_2 mixtures burn with a faint blue flame with a characteristic pink cast. A flashback may cause explosion or even detonation of the O_3-supply and the system must therefore be handled with care. After the technique of burning O_3–O_2 was developed it was used to combust hydrogen, carbon monoxide, cyanogen and others in a diffusion type flame. In general appearance and color the three O_3 flames do not differ from the corresponding O_2 flames. (Contractor's abstract, modified)

THE PREMIXED HYDROGEN CYANIDE-FLUORINE-OXYGEN FLAME (Abstract), by C. S. Stokes. [1956] 2p. incl. table. (AFOSR-TN-56-131) (AF 18-(600)1475 AD 86003 Unclassified

Temperatures in excess of 4500°K have been produced in this laboratory by various flames including cyanogen and oxygen. The materials used, however, are not commerically available. Hydrogen cyanide, fluorine and oxygen are available in quantity and a flame of these constituents produces a temperature of approximately 4000°K. Hydrogen cyanide and a fluorine-oxygen mixture of 1:1 molar ratio has been successively premixed in all concentrations. Burning velocities have been measured and compared to the hydrogen cyanide oxygen flame. Studies have been made to determine the exact chemical composition of the HCN fluorine-oxygen flame at the stoichiometric point. The proposed equation

$$2HCN + F_2 + O_2 \longrightarrow 2HF + 2CO + N_2$$

has been proved correct. Theoretical flame temperatures have been calculated and are as follows:

Flame Temp. °K for the Above Stoichiometric Point	Pressure Atm
3930	1
4275	10
4860	100

Some correlation of the hydrogen atom concentration with burning velocity has been noted. (Contractor's abstract)

THE PURE OZONE FLAME ON THE COMBUSTION OF VARIOUS FUEL GASES IN PURE OZONE, by A. G. Streng and A. V. Grosse. [Dec. 25, 1956] 11p. incl. illus. diagr. table. (AFOSR-TN-56-599) (AF 18(600)-1475) AD 115026 Unclassified

Presented at International Ozone Conference, Chicago, Ill., Nov. 28, 1956.

High temperature research involving combustion of various gases including ozone are briefly reviewed and findings presented of the burning characteristics of pure ozone as well as mixtures of ozone and hydrogen, carbon monoxide, cyanogen, methane, or in ethylene. The burning velocity of ozone, found to be 270 cm/sec at -78°C, appears to be a straight-line function of temperature. As mixtures of 100% O_3 and H_2, C_2H_2, or CH_4 did not spontaneously ignite during the diffusion flame tests, further tests were made of the stability of such mixtures. All were found stable at dry-ice temperatures; CH_4 reacted noticeably at room temperature, while H_2 and C_2H_2 caused no change in pressure. Ozone - C_2N_2 mixtures in long 1.6 mm id tubes, at room temperature and atmospheric pressure, burned without detonation; the mixture in wider tubes exploded. The stoichiometric 1.5 C_2N_2 + O_3 mixture burns very rapidly with a bright flame without explosion or detonation. A corresponding C_2N_2 + O_2 mixture burns somewhat slower with a less bright flame under similar conditions, while pure O_3 burns with a fallow flame without explosion or detonation. The possibility of burning C_2N_2 - O_3 mixtures from burner tips is noted, and production of instantaneous high temperatures through detonation of solid C_2N_2 or CO mixtures with solid O_2 or O_3 is discussed.

[GRIGNARD REAGENTS AND UNSATURATED ETHERS] I. THE REACTION OF GRIGNARD REAGENTS WITH α-, β-UNSATURATED ETHERS, by C. M. Hill, R. A. Waler, and M. E. Hill. [1951] 2p. incl. tables. [AF 18(600)466] Unclassified

Published in Jour. Amer. Chem. Soc., v. 73: 1663-1664, Apr. 1951.

Theoretical considerations of the electron displacement tendencies in α-, β-unsaturated ethers indicate a possibility of reaction with Grignard reagents as indicated in I. The formation of a Grignard complex with the ether oxygen would render the electron deficiency on the α-carbon more acute, thus favoring an α-γ migration of the aryl group of the Grignard with its eleciron pair as shown in the scheme:

INVESTIGATION OF THE USE OF GRIGNARD REAGENTS WITH UNSATURATED ETHERS, by C. M. Hill, M. E. Hill and others. Final rept. Oct. 1, 1954, 16p. incl. tables. (Technical rept. no. 1) ([AF]OSR-TR-54-32) (AF 18(600)466) AD 50350 Unclassified

A summary is given of investigations concerning the reaction of alkyl and aryl Grignard reagents with unsaturated ethers, including both open-chain and cyclic unsaturated ethers. Unsubstituted and alky- and aryl-substituted α-, γ-unsaturated ethers and unsubstituted and alkyl-substituted dihydropyrans and furans were included. The results demonstrated that Grignard reagents react with both open-chain unsaturated and cyclic unsaturated ethers to form saturated and unsaturated alcohols, phenols, aldehydes, methyl ketones, and olefins in acceptable yields. The mode of cleavage apparently depends upon certain electrical and steric effects imparted to the unsaturated ether molecule by substituents attached to it.

GRIGNARD REAGENTS AND UNSATURATED ETHERS. V. REACTION OF GRIGNARD REAGENTS WITH ALPHA AND GAMMA-SUBSTITUED ALLYL ETHERS, by C. M. Hill, M. E. Hill and others. [1954] [12]p. incl. tables. (Pt. 3 of its Technical rept. no. 1; AD 50350) [AF 18-(600)466] AD 50350(a) Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 3889-3892, July 20, 1955.

Substituents suspected of imparting electrical or sterically hindered effects were attached to the α and γ positions of allyl ethers, and their reaction with aryl and alkyl Grignard reagents was investigated. The substituted ethers included were of the type $R\text{-}CH=CH\text{-}CH_2O\text{-}R'$, where R is H and phenyl and R' is n- butyl, and phenethyl; and $R\text{-}CH=CH\text{-}\underset{R'}{CH}\text{-}O\text{-}R''$, where R is methyl, R' is n- and tert-butyl and benzyl, and R'' is n- and tert-butyl. The nature of the group attached to the γ position of the allyl ether apparently influenced the mode of cleavage by certain Grignard reagents. In experiments in which n-heptyl- and n-octylmagnesium bromides were added to tert-butyl-1-benzyl-3-methylallyl ether, no reaction occurred at the refluxing temperature of diethyl ether or benzene. All the aryl Grignard reagents reacted with 3-methyl- and 3-phenylallyl ethers to yield olefinic hydrocarbons and alcohols, which indicated 1, 2-cleavage only of the ethers; similar results were obtained when ethyl- and n-hexylmagnesium bromides were used. The electrical effect upon the ether molecule caused by electron-releasing groups in the γ position appeared to facilitate 1, 4-addition when the Grignard reagent was an n-heptyl or n-octylmagnesium bromide.

VIBRATIONAL STRUCTURE OF THE ELECTRONIC SPECTRA OF SIMPLE MOLECULES. I. EVALUATION OF CONDON OVERLAP INTEGRALS FOR THE BENT XY_2 MOLECULE, by J. K. Ward and J. B. Coon. July 1954 [11]p. incl. diagrs. ([AF]OSR-TN-54-181) (AF 18(600)439) AD 38856 Unclassified

A method is outlined for evaluating the Condon overlap integral associated with any vibronic band of a UV absorption system of an XY_2 molecule. All necessary formulas are included. For the small vibration problem, the geometry of the molecule as well as its vibrational frequencies must be given for both of the electronic states involved. A relation between coordinates of the normal state and those of the excited state must be found in order to evaluate the Condon overlap integrals.

APPLICATION OF THE FRANCK-CONDON PRINCIPLE TO THE BENT XY_2 MOLECULE (Abstract), by J. B. Coon and J. K. Ward. [1954] [1]p. [AF 18(600)439] Unclassified

Presented at meeting of the Amer. Phys. Soc., Austin, Tex., Feb. 26-27, 1954.

Published in Phys. Rev., v. 94: 805, May 1, 1954.

A method is described for comparing the experimental intensities of vibronic bands of an XY_2 molecule with Condon overlap integrals calculated to the harmonic approximation. Using the vibrational frequencies and the apex angle for a given electronic state, normal coordinates Q_i may be calculated by known methods. Three independent Cartesian coordinates x_i of the nuclei for the ground electronic state are related to similar coordinates x_i' for the excited state by $x' = x + C$, where C is a three-element column matrix determined by the equilibrium bond distances and angles of both states. This leads to the relation $Q' = \zeta Q + K$, where ζ is a 3 x 3 matrix in which the elements ζ_{13}, $\zeta_{23} \neq 0$ unless $\theta' = \theta$. The Condon overlap integral takes the form

$$I = N'(v_1'v_2'v_3')N(v_1v_2v_3)\int\int\int \prod_i H_{v_i'}(\alpha_i'Q_i') \times \exp(-\tfrac{1}{2}\alpha_i'^2Q_i'^2)\prod_j H_{v_j}(\alpha_jQ_j) \exp(-\tfrac{1}{2}\alpha_j^2Q_j^2)dQ_1dQ_2dQ_3,$$

where $\alpha_i^2 = (4\pi^2/h)c\omega_i$, and $H_{v_i}(\alpha_iQ_i)$ are Hermite polynomials. This is easily evaluated for any special case. The ratio of the overlap integrals for two vibronic bands is known to be related to the integrated molecular extinction coefficients ϵ_i for these two bands by $(I_1/I_2)^2 = \exp[hc(G_1 - G_2)/kT](\nu_2/\nu_1) \times (\int_1 \epsilon_1 \delta\nu / \int_2 \epsilon_2 \delta\nu)$, where G_i is the ground state vibrational level associated with band i. Sufficient data are available for ClO_2 to evaluate these integrals.

VIBRATIONAL ANALYSIS OF THE 3400-4000A ABSORPTION SPECTRUM OF SO_2 (Abstract), by R. K. Russell. [1954] [1]p. [AF 18(600)439] Unclassified

Presented at meeting of the Amer. Phys. Soc., Austin, Tex., Feb. 26-27, 1954.

Published in Phys. Rev., v. 94: 805, May 1, 1954.

A preliminary analysis is reported of the 3400-4000A absorption spectrum of SO_2, based on wave numbers measured on spectrograms obtained with absorbing paths up to 18 meter-atmospheres. Within an average deviation of about 2 cm^{-1}, 23 bands fit the formula $\nu = \nu_0 + (G_0' - G_0'')$, where $\nu_0 = 25,776.0\ cm^{-1}$ and $G_0'(v_1'v_2'v_3') = 938.3v_1' + 362.8v_2' + 1119.65v_3' - 34.60v_1'^2 - 1.95v_2'^2 - 25.77v_3'^2 + 1.82v_1'^3 - 5.9v_1'v_2' - 21.55v_1'v_3' - 9.1v_2'v_3'$. Ground-state levels G_0'' given by Nielsen (Phys. Rev., v. 91: 235, 1953) were used. Previously, in a brief report, Metropolis and Beutler (Phys. Rev., v. 57: 1078, 1940) assigned the $(0,0,0,)' \leftarrow (0,0,0,)''$ band and gave approximate values of ν_1' and ν_2' that are essentially in agreement with the above formula. The G_0' (2, 1, 0) and the G_0' (0, 0, 2) excited state vibrational levels appear to perturb each other, the shift being about 33 cm^{-1}. It is expected that spectrograms to be

made with still longer absorbing paths will reveal more bands, thus providing additional data needed to confirm or improve the analysis. (Contractor's abstract)

GROUND-STATE POTENTIAL CONSTANTS OF ClO_2 (Abstract), by J. K. Ward. [1954] [1]p. [AF 18(600)439] Unclassified

Presented at meeting of the Amer. Phys. Soc., Seattle, Wash., July 7-10, 1954.

Published in Phys. Rev., v. 96: 845, Nov. 1, 1954.

Sufficient information is available to compute the four harmonic potential constants of the ground state of ClO_2. Coon's ultraviolet rotational structure analysis furnishes $2\bar{B}'' = 0.612 \pm 0.003$, $(2\bar{B}' - \bar{B}'') = -0.0615 \pm 0.001$, and $2(A' - A'') = -(1.250 \pm 0.006\ cm^{-1}$; at least-square treatment of Nielsen and Woltz 's infrared rotational structure data yields $2(A'' - \bar{B}'') = 2.831 \pm 0.01\ cm^{-1}$. From this data one obtains $2\theta'' = 117.4 \pm 0.2^{o}$, $r_o'' = 1.472 \pm 0.005A$, $2\theta' = 107.4 \pm 0.4^{o}$, $r_o' = 1.620 \pm 0.015A$. By using $2\theta''$ in conjunction with $\omega_1'' = 964.8$, $\omega_2'' = 451.8$, and $\omega_3'' = 1127.3\ cm^{-1}$ given by Coon and Ortiz, and one isotope shift $\Delta\omega_1'' = -6.41\ cm^{-1}$, the ground-state valence potential constants are determined: $k = 6.990$, $k_\theta = -0.649$, $k_1 = -0.191$, $k_2 = -0.035 \times (10)^5$ dyne-cm^{-1}. Poor agreement exists with potential constants determined using three ground-state frequencies and the criterion of Glockler and Tung: $k = 7.411$, $k_\theta = 0.803$, $k_1 = 0.230$, $k_2 = 0.930 \times (10)^5$ dyne-cm^{-1}. Disagreement also exists with the prediction of Duchesne and Nielsen that k_1 and k_2 should be positive. (Contractor's abstract)

A VIBRATIONAL ANALYSIS OF THE 3000-5000A ABSORPTION OF ClO_2, by J. B. Coon and E. Ortiz. May 1955, 19p. incl. diagrs. tables. ([AF]OSR-TN-55-119) (AF 18(600)439) AD 63489 Unclassified

Presented at meeting of the Amer. Phys. Soc., Mexico City (Mexico), Aug. 29-31, 1955.

Abstract published in Phys. Rev., v. 100: 963, Nov. 1, 1955.

Also published in Jour. Molecular Spectroscopy, v. 1: 81-94, Sept. 1957.

A critical list of 143 vibronic bands in the visible and ultraviolet absorption spectrum of ClO_2 vapor has been compiled. Vibrational quantum number assignments have been made for 117 of these bands. This vibrational analysis ytelds the following values of the zero order frequenctes ω'_i and the anharmonicity constants X'_{ij} for the excited electronic state. In wave numbers,

$\omega_1' = 711.4$ $\quad X_{11}' = -2.44$ $\quad X_{13}' = -7.40$

$\omega_2' = 298.0$ $\quad X_{12}' = -4.36$ $\quad X_{23}' = -6.9$

$\omega_3' = 756.1$ $\quad X_{22}' = -1.4$ $\quad X_{33}' = +10.2$

Combining the information obtained for the ground state with existing infrared data, the best resulting constants for this state are:

$\omega_1'' = 962.8$ $\quad X_{11}'' = -4.4$ $\quad X_{13}'' = -14.4$

$\omega_2'' = 455.4$ $\quad X_{12}'' = -3.0$ $\quad X_{23}'' = -13$

$\omega_3'' = 1128.2$ $\quad X_{22}'' = 0.0$ $\quad X_{33}'' = -2.0$

VIBRATIONAL STRUCTURE OF THE ELECTRONIC SPECTRA OF SIMPLE MOLECULES IV. THE GEOMETRY OF AN EXCITED STATE OF SO_2 AND THE FRANK-CONDON PRINCIPLE, by M. L. Coffman, J. M. Corgan and others. Aug. 1956, 29p. incl. diagrs. tables, refs. (AFOSR-TN-56-370) (AF 18(600)439) AD 95806 Unclassified

Presented at meeting of the Amer. Phys. Soc., Houston, Tex., Feb. 24-25, 1956.

Also published in Bull. Amer. Phys. Soc., Series II, v. 1: 90, Feb. 24, 1956.

The geometry of the excited electronic state associated with the 3800 Å absorption system of SO_2 is determined using the Frank-Condon principle. The normal coordinated Q_i of the ground electronic state and Q'_i of the excited electronic state are calculated from the known vibrational frequencies of these states. The excited state angle is assumed to be the same as that known for the ground state from microwave studies. The transformation relating Q_i to Q'_i involves 2 parameters c_1 and c_2 which specify the difference in geometry of the 2 states. This transformation permits evaluation of the Condon overlap integrals R_i in terms of c_1 and c_2. The harmonic approximation is made. Comparison of band intensities measured photographically with the squares of the overlap integrals allows evaluation of c_1 and c_2 and hence the excited state geometry. Four excited state models are consistent with the observed intensities, but only one of these is consistent with the partially resolved rotational structure of the bands. The S-O distance and the O-S-O angle for the resulting model of the excited electronic state are $r' = 1.492$ Å and $\alpha' = 124°36'$. A correction based on normal modes calculated using this angle gives $r' = 1.487$ and $\alpha' = 125° 6'$. These results are to be compared with $r'' = 1.432$ Å and $\alpha'' = 119°32'$ for the ground electronic state from microwave studies. (Contractor's abstract)

ROTATIONAL STRUCTURE OF THE 3800Å ABSORPTION SYSTEM OF SO_2 (Abstract), by J. B. Coon, R. K. Russell, and B. L. Landrum. [1956] [1]p. [AF 18(600)-439] Unclassified

Presented at Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 11-15, 1956.

Published in Symposium on Molecular Structure and Spectroscopy. Abstracts, 1956, p. 18.

The geometry of the excited electronic state associated with the 3800Å absorption system of SO_2 vapor has been recently determined by a quantitative application of the Frank-Condon principle. The results reported are $r' = r'' + 0.060 = 1.492$Å, and $2\theta' = 2\theta'' + 5°4' = 124°36'$. These data yield the constants of the rotational structure, namely $2\Delta(A - \bar{B}) = 0.396$ cm^{-1} and $2\Delta\bar{B} = -0.071$ cm^{-1}. In order to check these results, and in order to remove the uncertainty as to the polarization of the bands of this system, the resolvable features of the rotational structure of the bands are being examined. Preliminary measurements yield $2\Delta(A - \bar{B}) = 0.438 \pm 0.03$ cm^{-1} and $2\Delta\bar{B} = -0.080 \pm 0.008$ cm^{-1} confirming the results based on the Frank-Condon principle. Although the polarization of these bands has not yet been determined with certainty, it is expected that this can be reported soon. (Contractor's abstract)

3700 Å BAND OF FORMALDEHYDE (Abstract), by C. M. Loyd and S. E. Hodges. [1956] [1]p. [AF 18(600)439] Unclassified

Presented at meeting of the Amer. Phys. Soc., Monterey, Calif., Dec. 27-29, 1956.

Published in Amer. Phys. Soc., Series II, v. 1: 393, Dec. 27, 1956.

The ground-state vibrational level from which the (3700 A)α band of formaldehyde arises has received much discussion in the literature: Recent temperature sensitivity measurements by Cohen and Reid give 1240 ± 50 cm^{-1} for the ground-state level of this band. This leads them to the conclusion that the band arises from one quantum of the in-plane bending mode, 1247.4 cm^{-1}. Robinson, on the other hand, interprets the band as arising from one quantum of the out-of-plane bending mode, 163.5 cm^{-1}. The present temperature sensitivity data support Robinson's interpretation, yielding 1160 ± 23 cm^{-1} for the ground-state level from a plot of ln ϵ vs 1/T that has a slope of 1.67. Measurements were made at eight points in the band on spectrograms taken at temperatures of 403, 439, 472 and 493°K and a path length of 6 meters. Formaldehyde pressures of 5 to 10 cm were used with 120 psi of nitrogen added to insure pressure broadening. (Contractor's abstract)

A HIGH RESOLUTION, LOW FIELD NUCLEAR MAGNETIC RESONANCE SPECTROMETER, by R. W. Mitchell and M. Eisner. Nov. 1956 [14]p. incl. diagrs. (AFOSR-TN-56-584) (AF 18(600)1300) AD 115008 Unclassified

Also published in Rev. Scient. Instruments, v. 28: 624-628, Aug. 1957.

A high resolution low field spectrometer is constructed to study relaxation time measurements of nuclear

magnetic resonance signals in pure liquids and liquid mixtures. For the resolution limited by the stability of the magnetic field, the best resolution was found for 43 gauss at about 80 microgauss and at 12 gauss at about 10 microgauss. At about 40 gauss, the output of the oscillator goes to a twin T bridge which feeds in turn to a two stage amplifier with 175 K. C.-I. F. transformers from which the synchronous detector receives its reference signal. This can be examined by the proper phase of the reference voltage. Some measurements and relaxation time measurements for C_2H_5OH-H_2O are given.

CONCENTRATION DEPENDENCE OF NUCLEAR SPIN-SPIN RELAXATION TIMES IN ETHANOL-WATER MIXTURES (Abstract), by R. W. Mitchell, W. L. Zingery, and M. Eisner. [1956] [1]p. [AF 18(600)1300) Unclassified

Presented at meeting of the Amer. Phys. Soc., Houston, Tex., Feb. 24-25, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 92, Feb. 24, 1956.

The nuclear spin-spin relaxation time T_2 was observed for hydrogen nuclei contained in mixtures of ethanol and water. Measurements were made at fields of 10 gauss with a resolution of 50 microgauss for 30 ml samples. This resolution was sufficient for the study of concentrations ranging from 0.01 to 1.0 mole fractions of ethanol. The relaxation time was obtained by analysis of the decay of the wiggle transients. The results indicate a broad minimum in T_2 occurring at about 0.25 mole fraction of ethanol. This minimum occurs at the same concentration at which other anomalies display peaks. Similar peaks are observed for viscosity, heat of mixing, and ultrasonic absorption at this concentration. (Contractor's abstract)

MEASUREMENT OF THE nmr RELAXATION TIME T_1 IN BINARY MIXTURES (Abstract), by A. F. Hildebrandt, W. L. Zingery, and M. Eisner. [1956] [1]p. [AF 18(600)1300] Unclassified

Presented at meeting of the Amer. Phys. Soc., Houston, Tex., Feb. 24-25, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 92, Feb. 24, 1956.

The longitudinal time T_1, of the different chemical groups of alcohol-water mixtures has been observed using a flow technique. It is observed that different groups in a fine structure pattern have different T_1, reflecting their different lattice environments. An estimate of the effects of the importance of interactions with neighboring groups in the same and different molecules can be made. The effects of chemical exchange are discussed. A SECOND-ORDER THEORY FOR THREE-DIMENSIONAL WINGS IN SUPERSONIC FLOW, by M. H. Clarkson. May 1, 1953, 64p. incl. illus. refs. (Rept. no. DRL-332) (AF 18(600)483) AD 18237 Unclassified

Also published in Quart. Jour. Mech. and Appl. Math., v. 7: 203-221, June 1954.

The problem is expressed mathematically as a non-linear partial differential equation in 3 independent variables with given boundary conditions. The equation is reduced to a sequence of linear equations by a series expansion (in powers of a wing-thickness parameter) of the dependent and one of the independent variables. These equations are solved by the use of the Riesz operator. The pressure distributions of several wing problems are obtained to the second order, and the shock surface is determined to the first order for the case of compressive flow. The first-order shock surface is also obtained for the expansion-region boundaries for the case of expansive flow. A discussion of the rectangular wing illustrates some of the complexities of wing problems.

TRANSFORM SOLUTIONS OF SINGULAR INTEGRAL EQUATIONS OCCURING IN AERODYNAMIC PROBLEMS. (1). APPLICATIONS, by H. J. Ettlinger, M. H. Clarkson, and C. E. Abraham. July 29, 1953, 42p. refs. (Rept. no. DRL-340) (AF 18(600)483) AD 19173 Unclassified

A 1-dimensional transform is defined which is related closely to certain singular integral equations of the Abel type that occur in wing problems in transonic and supersonic flow. The important properties of the transform which is based on the work of Holmgren, Riemann, and Riesz are developed, and the results are stated as theorems. The transforms of some important elementary functions are tabulated. An integral equation which formerly was solved by using the Hadamard concept of the "finite part" of a nonconvergent integral is interpreted in terms of the transform, and its solution is found with the aid of the tabulated transforms. This example illustrates a direct operational procedure for solving integral equations of this type.

THE HOLMGREN-RIESZ TRANSFORM AND ITS RELATION TO THE SOLUTION OF SUPERSONIC AERODYNAMIC BOUNDARY VALUE PROBLEMS, by H. J. Ettlinger and C . E. Abraham. Oct. 21, 1953, 39p. illus. refs. (Rept. no. DRL-347) (AF 18(600)483)
AD 22225 Unclassified

The 1-dimensional transform is extended to 3 dimensional and various types of conical regions. The transform is discussed with respect to identity and semigroup properties for the volume bounded by a 3-dimensional half-cone and a plane perpendicular to the cone axis. An expanded form of the transform is deduced for the same volume with the aid of Green's theorem. The transform is also defined for the volume bounded by a forecone, a horizontal plane, and a plane with a characteristic direction. Identity and limit properties are developed for functions defined by surface integrals which appear in the Green's theorem expansion of this transform. The results are applied to the Cauchy initial value problem and other boundary value problems in the theory of supersonic flow about 3-dimensional wings.

THE HOLMGREN-RIESZ TRANSFORM AND ITS RELATION TO THE SOLUTION OF SUPERSONIC AERODYNAMIC BOUNDARY VALUE PROBLEMS (CONTINUED), by H. J. Ettlinger and C. E. Abraham. Jan. 27, 1954, 60p. incl. illus. refs. (Rept. no. DRL-353) ([AF]OSR-TN-54-47) (AF 18(600)483) AD 27314
UNCLASSIFIED

The Holmgren-Riesz transform is further developed in 3 dimensions and is extended to apply in 4 or more dimensions. Solutions for the nonhomogeneous wave equation are obtained which satisfy linear boundary conditions of mixed type. It is pointed out that the transient supersonic flow equation for the 3-dimensional wing can be transformed to the wave equation in 4 dimensions.

SUPERSONIC SKIN FRICTION AND HEAT TRANSFER RESEARCH AT THE UNIVERSITY OF TEXAS, by R. C. McWherter. Mar. 15, 1954 [21]p. incl. illus. diagrs. tables, refs. [AFOSR-TN-54-64] (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)589 and Bureau of Ordnance under NOrd-9195))
Unclassified

Work done at the Defense Research Laboratory (DRL), Austin since 1947 is reviewed in a paper prepared for presentation at the 1954 Heat Transfer and Fluid Mechanics Institute, University of California, Berkeley. The early program was directed toward procuring experimental reliable data for turbulent skin friction on an insulated flat plate and culminated with a theoretical expression. A direct measuring skin friction balance was developed and is illustrated. Data obtained from the use of this device are compared with published direct measurements at Mach 2. Comparisons also are made of skin friction by direct measurement and boundary layer probe, and a figured compilation is given up to Mach 5 of experimental and theoretical work of several recent investigators in relation to the University of Texas results on insulated turbulent friction. An acceleration-insensitive model of the DRL local skin friction element was under test for use on a free flight missile. Research was being extended to consider broader aspects of supersonic skin friction with heat transfer. Existing wind tunnel circuits were being modified to allow ambient test section temperatures to approach stratosphere values (-67°F). A 6- x 6-in. blow-down type supersonic high temperature tunnel facility which was being calibrated is shown schematically as also is a heat transfer plate designed to eliminate the temperature gradient difficulty usually encountered.

THEORETICAL AND EXPERIMENTAL STUDIES OF BOUNDARY LAYER CHARACTERISTICS AT SUPERSONIC SPEEDS IN AIR INCLUDING INVESTIGATIONS

OF SKIN FRICTION, VELOCITY DISTRIBUTION AND HEAT TRANSFER, by J. L. Harkness, J. E. Weiler and others. Annual rept. Jan. 5, 1954, 27p. illus. diagrs. tables, refs. (Rept. No. DRL-352) (AF 18(600)589) AD 25306 Unclassified

A brief statement of the over-all study is first presented, and this is followed by a detailed discussion of the work completed. The bulk of the work has been concerned with the design and initial steps of construction of an additional high temperature circuit for the existing high Mach number test facility. A detailed description of this circuit is given, including a considerable discussion of the design problems and procedures. This is followed by a survey of present theories and experimental investigations carried out by other research organizations covering the problems concerned. This survey was made in order to avoid duplication of effort and also to aid in the initial design of test equipment. A discussion of an experimental study already under way in the existing tunnel is presented, and the value of this as a pilot tunnel to aid in the development of some of the test equipment is pointed out. The last section of this report indicates briefly the plans to be followed in the second year of the program. (Contractor's abstract)

THEORY, DESIGN, AND PERFORMANCE OF A 420-KW ELECTRICAL HEATER FOR AUTOMATIC CONTROL OF STAGNATION TEMPERATURE IN A BLOW-DOWN WIND TUNNEL, by W. H. Hartwig. June 1956, iv. incl. illus. diagrs. refs. (Rept. no. DRL 383) (AFOSR-TN-56-163) (AF 18(600)589) AD 86584 Unclassified

The design, theory, and performance are presented for a 420-kw electric heater with feedback control. The heater maintains a constant stagnation temperature in a 6- x 6-in. supersonic wind tunnel. The system, which is characterized by a high speed of response and low absolute error, uses ignition tubes to control current in a 3-phase, 440-v circuit. A 3°F maximum error, and a 1400°F design limit were achieved.

A DESIGN OF ELECTRICAL CONTROL HEATERS FOR OPERATION WITH A SUPERSONIC, BLOW-DOWN WIND TUNNEL, by R. A. Fetter, Jr. June 1956, 76p. incl. illus. diagrs. tables, refs. (DRL rept. no. 382) (AFOSR-TN-56-188) (AF 18(600)589) AD 87061 Unclassified

Two electric control heaters were designed which are used to maintain a constant stagnation air temperature in a 6- x 6-in., blow-down, supersonic wind tunnel. The heater maintains a supply of constant-temperature air to the nozzle stilling chamber. A large-capacity, gas-fired storage heater is installed upstream from the control heater. Air flowing through the circuit picks up heat in the storage heater, and additional heat is then added by the electric heater. Since the heated air is for heat-transfer studies, the electric heater must not only add an increment of temperature but must also control the air temperature at a constant value, even though the entering temperature is changing. Testing was conducted with M = 5.0 nozzles. Results indicated that the heaters are satisfactory for a blow-down wind tunnel where high constant-stagnation temperatures are required. The cost of the heaters is from one-half to one-third that of comparable wind-tunnel heaters. The simple design offers a minimum heat sink. High efficiency is sacrificed for a small amount of thermal insulation and few heat sinks.

A STORAGE-TYPE AIR HEATER FOR AN INTERMITTENT-FLOW SUPERSONIC WIND TUNNEL, by J. E. Weiler. Nov. 7, 1956, 1v. incl. illus. diagrs. tables. (Rept. no. DRL 393) (AFOSR-TN-56-572) (AF 18(600)589) AD 110394 Unclassified

A description is given of the development, design of components, and operation of a storage-type air heater adaptable to alternative use with a Mach number 2.0 nozzle or a Mach number 5.0 nozzle, each discharging into 6- x 6-in. test sections. These are four sections of 10-inch, heavy pipe filled ferrosilicon alloy spheres within an insulating lining. A hot mixture of natural gas combustion products and air heat the spheres to a desired level; then the wind tunnel supply air is heated to the same level as the spheres in the blowdown phase.

TEX. 02:007 - TEX. 03:003

Several units necessary to the operation are explained. Over a period of a year the performance of the unit has been satisfactory.

THEORETICAL AND EXPERIMENTAL STUDIES OF BOUNDARY LAYER CHARACTERISTICS AT SUPERSONIC SPEEDS IN AIR, INCLUDING INVESTIGATIONS OF SKIN FRICTION, VELOCITY DISTRIBUTION AND HEAT TRANSFER, by J. L. Harkness, J. E. Weiler, and W. H. Hartwig. Annual rept. Jan. 5, 1956, 28p. illus. diagrs. tables. (AF 18(600)589) Unclassified

The major portion of this report concerns the development, testing, and necessary revisions to the various components of the wind-tunnel circuit. These revisions and the results of the performance testing are presented in detail for the storage-type heater and the electrical-control heater. Instrumentation for the calibration testing of the flow produced in the nozzles is described, along with the performance of the pressure control system of the tunnel. Work has been resumed on the design and fabrication of the flat plate heat transfer model, and a brief description of this investigation is presented. It is noted that neither time nor manpower has been available for further theoretical work of significance. However, a seminar-type group has been established by the Defense Research Laboratory (DRL) in cooperation with the Department of Aeronautical Engineering which should benefit this phase of the investigation. An outline of this activity is included. Conferences held at DRL and at other laboratories are discussed, and a brief outline concerning plans for future work is also presented. EXPLORATORY EXPERIMENTS IN PRE-IGNITION AND FLAME SPECTRA IN ACETYLENE, by N. B. Humphreys, W. W. Robertson, and R. C. Anderson. June 1952, 9p. incl. illus. diagrs. (Technical rept. no. 3) (AF 33(038)21745) ATI-161755 Unclassified

This is a report of initial experiments and observations on emission and absorption spectra of flames in acetylene alone and of acetylene pre-heated just to the point of ignition. Flame spectra are continuous, but this might result entirely from the effect of the hot carbon particles present. The exploratory experiments indicate that spectra of acetylene excited past the ignition level can be observed by heating in the presence of helium or at low pressures without interference from carbon. Preliminary data show only continuous spectra for the excited acetylene, with no evidence of typical bands of radicals such as C_2. (Contractor's abstract)

EFFECTS OF CERTAIN ADDITIVES ON FLAME PROPAGATION IN ACETYLENE, by F. H. Coats, J. D. Frazee, and R. C. Anderson. June 1952, 15p. incl. diagrs. tables. refs. (Technical rept. no. 4) (AF 33(038)21745; continued by AF 18(600)430) ATI-161756 Unclassified

TEX. 04:001 - TEX. 04:003

Exploratory experiments are reported which were carried out on the influence of various additives on slow flame propagation in acetylene, particularly under conditions in which only small quantities (1% or so) of additive were used and effects of dilution minimized. Acetone, hydrogen, and water vapor were tested because they are commonly present in acetylene systems; nitrogen, because it is an example of a relatively inert diluent; methyl chloride and diethyl ether because they are sources of free radicals, and nitric oxide and sulfur dioxide because they are potential inhibitors of free radical chains and of carbon formation. Nitrogen was found to behave essentially as an inert diluent. Added hydrogen increased somewhat the ease of ignition and the speed of flame propagation, as did acetone and diethyl ether. Flame propagation was made more difficult by nitric oxide. Water, methyl chloride, and sulfur dioxide showed no appreciable effects. (Contractor's abstract)

CARBON FORMATION AND REACTION IN FLAMES IN ACETYLENE, by J. D. Frazee and R. C. Anderson. [1952] 12p. incl. diagrs. table, refs. (AF 18(600)430; continuation of AF 33(038)21745) Unclassified

In this study on flame propagation in the self-combustion of acetylene, an attempt has been made to obtain additional data on the mechanism involving the formation or reaction of C particles in these flames. Theories of other researchers are briefly treated, explaining C formation in flames, e.g., from C_2 radicals; from the pyrolysis of large molecules; from the pyrolysis of tiny droplets of liquid polymers. The mechanism suggested here differs from the earlier theories in that the essential steps involve reaction of large, unsaturated molecules, or free radicals, with H atoms or groups like C_2H, rather than the decomposition or simple dehydrogenation of such molecules. It is concluded that the results of this flame study are in agreement with earlier results in that they indicate a polymerization-dehydrogenation mechanism of C formation; however, they further indicate that a chain mechanism involving highly unsaturated hydrocarbon free radicals and H atoms is involved. It is pointed out that the nature, structure, and size of particles are controlled by the balance between simple combustion reactions leading to liquid polymers at lower temperatures, and dehydrogenation reactions leading to C formation at higher temperatures.

ELECTRON-IMPACT STUDIES ON PROPYNE, by F. H. Coats and R. C. Anderson. [1953] [8]p. incl. diagr. tables. (AF 18(600)430) Unclassified

Presented at the Southwestern-Southeastern Regional meeting of the Amer. Chem. Soc., New Orleans, La., Dec. 10, 1953.

A discussion of appearance and ionization potentials of organic ions and mass spectrometric methods of detecting reaction intermediates, introduces a report on the determination of the energy of bombarding electron beams required to form various ionic fragments of propyne and other acetylenic compounds. Ionization probability curves for the various ions and for reference ions were simultaneously determined spectroscopically. Use was made of an intermediate electrode in the electron gun to maintain a constant negative potential with respect to the filament to reduce curve uncertainty at very low ion currents. Typical curves of the propyne system are included. As preliminary mass scans of propyne showed appreciable but regularly decreasing peak heights for masses 40 through 36, determinations were made of the appearance potentials for ions of corresponding mass. A value of 10.3 v was obtained for the ionization potential of propyne. The appearance potentials of its C_3H_3, C_3H_2, C_3H, and C_3 ions are respectively 11.8, 14.0, 18.4, and 26 v; uncertainty for the C_3 value is ± 1.0 v, and for the remainder ± 0.1 v. Determinations of the order of dissociation of the C-H bonds of propyne under electron bombardment was made by comparison of the propyne dissociation appearance potentials with the corresponding values for dissociation of methane; the acetylenic H dissociates after the methyl group has been stripped of H atoms which is consistent with the high dissociation energy observed for the C-H bonds in acetylene. Appearance potentials are tabulated for various ions from acetylene, propyne, methane, and ethane.

PRE- IGNITION AND FLAME SPECTRA IN THE SELF-COMBUSTION OF ACETYLENE, by W. W. Robertson, N. B. Humphreys, and R. C. Anderson. [1953] [5]p. incl. diagr. (AF 18(600)430) Unclassified

Published in Jour. Chem. Phys., v. 21: 2093-2094, Nov. 1953.

No C_2 or CH bonds were observed in emission and absorption spectra in the visible and near-ultraviolet range of acetylene flames in the absence of oxygen, recorded photographically on a 3-meter grating spectrograph. The emission spectrum was obtained by flowing preheated acetylene down a heated vertical quartz tube 3.5 cm in diameter, discharging into a large flask. A turbulent flame was maintained for about 10 min, by adjustment of the flow rate, before carbon deposition affected high resolution. The observed emission spectrum was continuous, from about 3500 to 6000 Å, with a maximum at 5800 Å; no discrete bands or lines were observed. Absorption spectra were recorded using a heat absorption cell and a high intensity Hanovia xenon arc light-source. Pure acetylene showed continuous spectra from the ultraviolet into the visible range as cell temperature was raised from 375°C to the ignition temperature of 500°C, where combustion produced large quantities of

carbon and acetylenic polymers that completely scattered and absorbed light entering the cell. Samples of condensed combustion products also showed continuous absorption in the ultraviolet. Determination of absorption spectra at temperatures up to 1000°C by use of acetylene-helium mixtures also showed continuous spectra, with the limit extending to longer wave lengths as temperature ions increased. The continuous absorption at lower temperatures can be attributed to conjugated unsaturated condensation products whose concentrations increase with temperature; major participation of C_2 or CH radicals in the reaction mechanisms is not indicated.

CARBON FORMATION IN ACETYLENE FLAMES. CALCULATION OF FREE ENERGIES OF REACTION, by K. Hellwig and R. C. Anderson. May 1953, 20p. incl. tables, refs. (Technical rept. no. 5) (AF 18(600)430) AD 16157 Unclassified

Techniques for calculating the free energies of certain reactions were employed in determining the feasibility of mechanisms proposed to explain the spontaneous combustion of acetylene to C and H. Theoretical considerations indicated that combination reactions and dissociation of acetylene to form H and free radicals can be combined in a mechanism which will explain experimental results.

A MODIFIED TRANSITION STATE THEORY OF REACTION RATES, by F. A. Matsen. June 1953, 12p. diagrs. (Technical rept. no. 6) (AF 18(600)430) AD 30056 Unclassified

The specific reaction rate for chemical reactions is formulated in terms of the total transmission coefficient in the reaction coordinate and a modified transition state, which differs from the original transition state only in the treatment of the reaction coordinate. If the total transmission coefficient is factored into two partial transmission coefficients, the modified theory gives the transition state theory in both the classical and the quantum-mechanical-particle-in-a-box treatments. It is then shown that the momentum density in the virtual state over a symmetrical square barrier is that of a quantum-mechanical-particle-in-a-box at low momentum, and that of a classical system at high momentum. Finally the reaction rate transmission coefficient is calculated from the modified theory for an unsymmetric square barrier, and is shown to depend on the temperature, the activation energy, and the thermicity of the reaction. PRE-IGNITION ABSORPTION SPECTRA IN SELF-COMBUSTION OF ACETYLENE, by W. W. Robertson and R. C. Anderson. Aug. 1953, 10p. diagrs. (Technical rept. no. 7) (AF 18(600)430) AD 19347 Unclassified

Spectra were observed for various mixtures and conditions, including mixtures of 2 to 50% acetylene and temperature ranges from 500° to 1000°C. The spectra observed for the various mixtures were continua. Band spectra for C_2 and CH were not detectable even when He was the diluent and the acetylene was heated above the normal ignition temperature. The region of continuous absorption moved to longer wave lengths as the temperature increased. Plots are presented which show the results for acetylene at various temperatures, and the effects of substituting N for He as the diluent and of small additions of NO. The observed densities of the photographic plates were plotted so that the maximum density corresponded to the minimum adsorption. The adsorption decreased as the lower partial pressure of acetylene was reached. Data on the pressure variations accompanying these changes and the extent of adsorption are summarized graphically.

STUDIES OF CARBON FORMATION AND REACTION IN ACETYLENE, by J. D. Frazee and R. C. Anderson. Aug. 1953, 17p. incl. diagrs. tables. (Technical rept. no. 8) (AF 18(600)430) AD 19346 Unclassified

The electron microscope and extraction techniques were employed to obtain additional information on the C formed in the self-combustion of acetylene. The reactivity of the C with various hot gases was also tested. The greasy appearance of the C which formed in the later slow stage of flame propagation as contrasted to the dry, gray samples in the initial stage appeared to be the result of polymerization of untreated acetylene on hot particles produced in the flame propagation. The differences in particle sizes in the two regions and the reaction of C samples in a stream of hot acetylene suggested the formation of C in reactions of hot particles with acetylene. Tests indicated that vitreous C was formed in surface reactions on glass or porcelain, and that acetylene reacted with C more readily than on glass or porcelain. The general behavior of the flames was consistent with a mechanism involving the formation of large, highly saturated molecules which are pyrolyzed and dehydrogenated to form C nuclei.

R. C. Anderson. Mar. 1954, 9p. incl. diagrs. tables. (Technical rept. no. 9) ([AF]OSR-TN-54-111) (AF 18(600)430) AD 36514 Unclassified

Experiments were conducted to determine qualitatively the effects of a variety of chemical reagents on ignition, pressure changes, and flame velocities. Additional data are given for the effects of N, acetone, benzene, and halogenated compounds. The 1-bromopropyne compound increased the flame velocity significantly as contrasted to HBr, HCl, and Br_2, which interfered with flame propagation. The results of the first tests with acetylenic ethers are presented. Motion pictures were made of some flame tests.

SELF-COMBUSTION OF ACETYLENE. II. REACTIONS IN FLAME PROPAGATION, by E. A. Westbrook, K. Hellwig, and R. C. Anderson. May 1954 [24]p. incl. diagrs. tables, refs. (Technical rept. no. 11) ([AF]OSR-TN-54-112) (AF 18(600)430) AD 37356 Unclassified

Also published in Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y., Reinhold, 1955, p. 631-637.

Experimental results for the effects of certain additives on the flame velocity in the self-combustion of acetylene, and on UV absorption spectra, and data from mass-spectrographic analysis and from thermochemical calculations are reported. The significance of these and earlier results in connection with the mechanisms of reactions occurring in the flames is discussed. Thermal reactions can occur, but cannot account for many of the observations on flame propagation. Probable reactions involving free radicals and a chain mechanism are suggested. SELF-COMBUSTION OF ACETYLENE. I. PRE-IGNITION KINETICS, by W. W. Robertson, E. M. Magee and others. May 1954, 5p. diagrs. table. (Technical rept. no. 10) ([AF]OSR-TN-54-115) (AF 18(600)430) AD 40201 Unclassified

Also published in Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y., Reinhold, 1955, p. 628-631, 1954.

The thermal reactions of acetylene were studied at temperatures up to the ignition temperature on a straight-through flow system. Determinations were made by IR and mass spectrometric analysis of the gas product. Volume changes were determined from the intensity of IR absorption of added freon. The principal gaseous products were benzene, ethylene, CH_4, and H. Benzene increased exponentially with the temperature. Dilution with He raised the ignition temperature. NO had an inhibitory effect on the benzene and ethylene formation and raised the ignition temperature.

A FLOW REACTOR FOR KINETIC STUDIES, by J. R. Streetman and F. A. Matsen. May 1955 [10]p. incl. diagrs. table. (Technical note no. 18) ([AF]OSR-TN-55-125) (AF 18(600)430) AD 63363 Unclassified

A new flow reactor is described. It is designed to obtain kinetic data, i.e., specific reaction rate constants, reaction orders, and apparent activation energies, from a flow system. The reactor consists of a Vycor tube 214 cm long, having a bore of 1.3 cm. The tube is heated electrically, the temperature being recorded and controlled automatically. The flow of gases is measured by rotameters utilized individually and in combination. The reaction gases are analyzed continuously by an infrared spectrometer. Provision is made to permit dilution by helium, inhibition by nitric acid, and activation by ethylene oxide or oxygen. Using the reactor, it is proposed to study the self-combustion of acetylene and the kinetics of acetylene-oxygen reactions, particularly those having low concentrations of oxygen.

EXCESS KINETIC ENERGIES FOR IONS FORMED BY ELECTRON IMPACT FROM ACETYLENES, by F. H. Coats and R. C. Anderson. Apr. 1956 [6]p. incl. diagr. (Technical note no. 27) (AFOSR-TN-56-169) (AF 18(600)430) AD 86591
Unclassified

Attempts have been made by 2 methods to determine whether ions such as C_2H^+ from acetylene, CH_3^+ from propyne, and $C_2H_5^+$ from 1-butyne are formed with excess kinetic energy. Instrumental limitations proved to be such that the range of experimental error is rather large. The results indicate that the C_2H^+ from acetylene is formed with excess kinetic energy and the $C_2H_5^+$ from 1-butyne is not. The results for CH_3^+ are inconclusive. The value for the heat of formation of C_2H^+ obtained from the data on 1-butyne (112 kcal/mole) is indicated to be the better value. (Contractor's abstract)

CARBON FORMATION FROM ACETYLENE, by F. C. Stehling, J. D. Frazee, and R. C. Anderson. [May 1956] [33]p. incl. diagrs. tables, refs. (AFOSR-TN-56-201) [AF 18(600)430] AD 87514
Unclassified

Also published in Sixth Symposium (International) on Combustion, Yale U., New Haven, Conn. (Aug. 19-24, 1956), N. Y., Reinhold, 1957, p. 247-254.

The problem of C formation in combustion systems is studied through the processes by which large aggregate of atoms and molecules are built up under conditions such that the normal expectation is for degradation or fragmentation of molecules to occur. Particular attention is given to acetylene reactions and their importance in connection with general mechanisms of carbon formation. The three types of C found as products of flame propagation in acetylene in straight tubes are described and investigated. The studies on the actual conditions of particle formation in the thermal reaction of acetylene are compared with the results obtained from flame propagation. X-ray measurements are used to get additional information about the particle sizes.

A COOL FLAME PHENOMENON IN THE COMBUSTION OF ACETYLENE, by W. W. Robertson and F. A. Matsen. June 1956 [4]p. incl. diagrs. (Technical note no. 28) (AFOSR-TN-56-299) (AF 18(600)-430) AD 90011
Unclassified

Also published in Combustion and Flame, v. 1: 99-101, Mar. 1957.

The factors influencing the ignition temperature when adding small concentrations of oxygen to heated acetylene in a flow system were determined. Periodic pressure bursts were observed which seemed to indicate the presence of a "cool" flame. The "cool flame" was more pronounced at around 325°,

TEX. 04:029 - TEX. 04:033

merging into the ordinary flame at around 300° and 500°C. A temperature rise in the reactor and an increase in the glyoxal concentration in the reaction products accompanied the "cool flame." Apparently, a reactive intermediate was formed at both low temperature and oxygen concentration.

THERMODYNAMIC DATA FROM ELECTRON-IMPACT MEASUREMENTS ON ACETYLENE AND SUBSTITUTED ACETYLENES, by F. H. Coats and R. C. Anderson. Aug. 20, 1956 [5]p. incl. diagr. tables, refs. [Technical note no. 29] [AFOSR-TN-56-364] (AF 18(600)-430) AD 95450 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 1340-1344, Mar. 20, 1957.

Earlier measurements of electron-impact data for propyne and 2-butyne were extended to other substituted acetylenes: 1-butyne, diacetylene, 1-Br-1-propyne, 1-Cl-1-propyne and phenoxyacetylene. From these the heat of formation of C_2H was determined to be 112 kcal/mole. Bond energies for the C-H and C-C bonds in C_2H_2 and for certain bonds in the substituted acetylenes can then be evaluated. (Contractor's abstract)

ISOTOPE EXCHANGE STUDIES OF ACETYLENE REACTIONS, by F. H. Coats and R. C. Anderson. Oct. 1956, 29p. incl. diagrs. tables. (Technical note no. 31) (AFOSR-TN-56-491) (AF 18(600)430) AD 110305 Unclassified

The decomposition reactions of C_2H_2 with deuterium and deuteroacetylene with H_2 are studied in the early stages of the thermal polymerization and decomposition of C_2H_2. At low temperatures, CH_3D and CD_3H are slightly predominant in the respective C_2H_2 - deuterium and dideuteroacetylene -H systems, while at higher temperatures both systems exhibit a complex mixture of all possible isotopes. Both molecular and free-radical processes occurred during these reactions. The study of methane proves of interest in the question of how it is formed.

EFFECTS OF ADDITIVES ON PRESSURE CHANGES IN THERMAL REACTION OF ACETYLENE, by G. Morrow and R. C. Anderson. Oct. 1956 [18]p. incl. diagrs. table. (Technical note no. 32) (AFOSR-TN-56-493) (AF 18(600)430) AD 110307 Unclassified

Comparative studies have been made of the pressure changes occurring during thermal reaction of acetylene alone and in the presence of certain additives. These results show that the pressure effect is not a factor in the influence of benzene and propane on flame propagation in the decomposition of acetylene. It is an appreciable but not a controlling factor in the effect of ethylene oxide on flames in acetylene. Nitric oxide gave variable results and chloropropyne and octatriyne decomposed too readily themselves for reliable measurements to be made. The effects of other hydrocarbon types, such as cyclooctatetraene, anthracene, pyrene, etc., were also tested for later comparison with flame propagation data. (Contractor's abstract)

EXPLORATORY STUDIES OF THE ACETYLENE-ETHYLENE OXIDE COMBUSTION SYSTEMS, by R. Pratt, M. S. B. Munson, and R. C. Anderson. Oct. 1956 [7]p. incl. dtagrs. (Technical note no. 33) (AFOSR-TN-56-502) AD 110317 Unclassified

Since earlier experiments showed ethylene oxide to have a marked effect on flames in acetylene and since both these substances can give decomposition flames, the acetylene-ethylene oxide system offers interesting potentialities for study of a system in which flames may be possible in mixtures of any composition. Exploratory experiments have been made on flame propagation in tubes at 300° initial temperature and varying pressures. Attempts have been made to operate a burner at atmospheric pressure and in a lower temperature range, but so far these have not been successful. The results indicate interesting questions with regard to carbon formation, changes in luminosity,

rather pronounced pressure changes, and the nature of the reaction products in these flames. They also indicate that quantitative studies of flame properties are feasible. (Contractor's abstract)

EFFECTS OF ADDITIVES ON FLAME PROPAGATION IN ACETYLENE IV, by G. Morrow, M. S. B. Munson and others. Nov. 1956, 6p. incl. tables. (Technical note no. 34) (AFOSR-TN-56-598) (AF 18(600)430) AD 115025 Unclassified

The methods used earlier for testing the effects of additives on the velocities of decomposition flames in acetylene have been applied to a number of other compounds. These include certain ether-substitued and halogen-substituted acetylenes and certain types of hydrocarbons which are of potential interest because of the roles they might play as intermediates in carbon formation. Most of these had little effect. Phenoxy-acetylene and ferrocene were found to increase the flame velocity. Toluene and 3-ethoxyl-1, 1-bromo-1-propyne were rather striking in their inhibitory effects on flame propagation. (Contractor's abstract)

ACETYLENE AS AN INTERMEDIATE IN THE COMBUSTION OF PETROLEUM HYDROCARBONS, by R. C. Anderson. Jan. 1956, 21p. refs. (AF 18(600)-430) Unclassified

A review is presented of available information in the literature on formation and reaction of acetylene in combustion of hydrocarbons. Present data indicate that acetylene is not a direct intermediate in the chain reactions of hydrocarbon oxidation but can readily be formed in closely associated reactions of oxidation and thermal decomposition, particularly under any conditions where excess hydrocarbon may be present. The most likely reaction of the acetylene once formed seems to be dehydrogenation followed by combination or addition of O_2, though peroxide formation may also occur. These reactions may be a general source of the hydrocarbon flame bonds. It is clearly evident that they cause acetylene to be an important precursor - though not necessarily the sole one - of carbon formation in combustion processes. (Contractor's abstract, modified)

EFFECTS OF HIGH PRESSURE UPON THE NEAR ULTRAVIOLET ABSORPTION SPECTRA OF THE POLYACENES (Abstract), by W. W. Robertson. [1956] [1]p. (AF 18(600)430) Unclassified

Presented at Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 11-15, 1956.

Published in Symposium on Molecular Structure and Spectroscopy. Abstracts, 1956, p. 36.

The absorption spectra of naphthalene, anthracene, and napthacene in n-pentane have been recorded in the near ultraviolet at pressures up to 5500 bars. The wavelength of absorption increases linearly with the dielectric constant of the pressurized solvent,

$\lambda = \frac{\Delta\lambda}{\Delta K}(K-1) + \lambda_o$. $\frac{\Delta\lambda}{\Delta K}$ varies from 26 A for the

naphthalene $^1A_{1g}^- - {}^1B_{3u}^-$ transition to 235 A

for the naphthacene $^1A_{1g}^- - {}^1B_{2u}^+$ transition. Since $\Delta\lambda / \Delta K$ can be accurately measured, a practical method exists for distinguishing between transitions. Values of λ_o obtained by extrapolating to K = 1 are within a few angstroms of the measured values that are obtainable for the vapor state. $\frac{1}{\lambda_o}\frac{\Delta\lambda}{\Delta K}$ increases generally with the oscillator strength of the transition as is predicted by theory. However, no simple relation exists between slope and oscillator strength. (Contractor's abstract)

TOTAL CROSS SECTIONS OF CHLORINE, SODIUM, TITANIUM, AND BROMINE FOR FAST NEUTRONS, by H. R. Dvorak and R. N. Little, Jr. [1953] [5]p. incl. diagrs. refs. [AF 33(038)20681] Unclassified

Published in Phys. Rev., v. 90: 618-622, May 15, 1953.

Relatively new liquid scintillation counter methods were adapted to detect fast neutrons with a heretofore unattainable efficiency of about 19 percent. The geometry obtained was the so called "good" geometry, which was a half-angle at the counter of 2.7°. With the more efficient counter reasonable counting times could be obtained with the detector subtending a half-angle of only 2.7° from the target. The neutrons were obtained by using a modified Cockcroft-Walton linear accelerator of 100-kev bombarding energy. The neutron energy range was 2.15 to 2.82 mev. All the scatterers used were contained in almost identical glass "cells," and the effects of the glass cells were subtracted out by using an empty glass cell of the same type as a reference. The probable error, calculated statistically from the counting rates of the experiment, was 1.3 percent on total cross-section values. Actual reproducibility of each result was about 3 percent or better. A carbon cross-section curve was obtained as a check on this method, and agreement with previously reported values was excellent. The chlorine and sodium cross-sections were found to be about 3×10^{-24} cm^2, as determined indirectly by using carbon tetrachloride and sodium chloride. The titanium cross section was found to be about 4.1×10^{-24} cm^2 by using powdered titanium metal. The bromine cross section was found to be about 3.7×10^{-24} cm^2, by using a sample of liquid bromine. No large resonances were found in the energy region available. Data were also taken on the angular distribution of the number of neutrons with respect to the forward direction of the incident deuteron beam, and they were found to agree well with theory except in the region where experimentally necessary geometric conditions dictated a deviation. [GAMMA]-RAY SPECTRUM OF C^{15} AND γ-RAYS FROM PROTON BOMBARDMENT OF C^{14} (Abstract), by K. R. Spearman, E. L. Hudspeth, and I. L. Morgan. [1954] [1]p. [AF 33(038)20681] Unclassified

Presented at meeting of the Amer. Phys. Soc., Austin, Tex., Feb. 26-27, 1954.

Published in Phys. Rev., v. 94: 806-807, May 1, 1954.

The delayed γ radiation resulting from bombardment of C^{14} with 2-mev deuterons has been studied with a single crystal scintillation spectrometer. The 2.4-second activity is identical with the β decay of C^{15}. Pulse height analysis reveals a strong γ ray of energy approximately 5.3 mev (Phys. Rev., v. 85: 742, 1952), with evidence for very weak components of higher energies. A decay scheme for C^{15} will be proposed. We have also bombarded a target of $BaCO_3$ (18.6 percent enrichment in C^{14}) with protons and have observed γ-rays which apparently are formed by protons capture. A relatively strong γ-ray component of energy about 5 mev was observed, with energies up to approximately 10 mev also recorded but not well resolved in our present crystal. Evidence for resonances in a 44-kev target have been obtained in the bombarding region from 1 to 2 mev. (Contractor's abstract)

MODIFIED RELAXATION METHOD FOR EIGENVALUE PROBLEMS, by W. W. Clendenin. Dec. 22, 1955 [8]p. incl. table. [AFOSR-TN-55-313] [AF 33(038)20681] AD 151208 Unclassified

Also published in Jour. Math. and Phys., v. 36: 74-81, Apr. 1957.

This mathematical study describes a numeral method for solution of the 1-dimensional Schrödinger equation, of the form $d^2\psi/dx^2 + [\Lambda + U + (x)]\psi = 0$. The function U(x) is a potential energy defined over $a \leq x \leq b$ and Λ is an eigenvalue parameter. The boundary conditions are taken to be $\psi(a) = \psi(b) = 0$. For numerical solution, the interval ab may be divided into N equal subintervals of length $h = (b-a)/N$. To verify the accuracy and applicability of the method, it has been applied to examples with known answers. A table lists the eigenvalues obtained for particular forms of potential energy.

THE ANGULAR DISTRIBUTION OF THE PROTONS FROM THE $O^{16}(d, p)O^{17}$ REACTION AS A FUNCTION OF THE BOMBARDING ENERGY, by J. C. Grosskreutz. [Jan. 15, 1956] [20]p. incl. diagrs. tables. [AFOSR-TN-55-316] [AF 33(038)20681] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Abstract published in Phys. Rev., v. 99: 643, July 15, 1955.

Also published in Phys. Rev., v. 101: 706-709, Jan. 15, 1956.

The angular distribution of the protons from the reaction $O^{16}(d, p)O^{17}$ leaving O^{17} in its ground and first excited states has been measured as a function of the deuteron bombarding energy. Deuterons of energy 2.51, 2.26, 2.01, 1.76, 1.60, 1.35, and 1.05 mev were used to bombard thin ZnO targets. The resulting protons were detected at angles ranging from 5 to 160° with respect to the deuteron beam. Detection was accomplished with CsI(Tl) phosphors on 6291 photomultipliers mounted as a unit in the vacuum housing of the reaction chamber. The characteristic forward stripping maxima are obtained in both reactions plus considerable yield in the backward direction, especially near resonances in the reaction. The effect of a resonance at 1.7 mev is to flatten the distribution curves so that their stripping character is almost completely masked. Secondary maxima observed in the excited state distributions are interpreted as the result of nuclear interaction of the stripped proton with the residual nucleus. Coulomb effects are also observed as the deuteron energy is lowered. The stripping maxima are shifted to larger angles, and the valleys become less pronounced. Absolute differential cross sections for the reactions are also given. (Contractor's abstract, modified)

TEX. 05:011 - TEX. 05:014

A thin target of gaseous CO_2 enriched 14 percent in O^{18} has been bombarded with protons of energy 0.3 to 2.6 mev. The gas was contained in a cell of 2 cm depth, and the proton beam entered through a 0.05-mil Ni foil. Target thickness was estimated as 20 kev for 2.0 mev protons. A 1-½ in. x 1-½ in. NaI (Tl) crystal detector was used with a 20-channel analyzer. The excitation curve for ground-state transitions shows seven resonances, indicating levels in F^{19} tentatively evaluated as 8.49, 8.76, 9.65, 9.83, 10.04, 10.15, 10.22, 10.28, and 10.36 mev. The first two levels are also known from $O^{18}(p, \alpha)$; these are the least intense of the levels found in the present work. The excitation curve shows a sudden drop at the $O^{18}(p, n)$ threshold. A pulse-height analysis has been made of gamma radiation produced at a bombarding energy of 2.20 mev. It shows transitions to known excited states of F^{19}, in addition to ground-state transitions. (Contractor's abstract)

GAMMA RAYS FROM THE PROTON BOMBARDMENT OF Cu^{63} AND Cu^{65} (Abstract), by C. E. Weller and J. C. Grosskreutz. [1955] [2]p. [AF 33(038)20681] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 99: 655-656, July 15, 1955.

Gamma radiation from the bombardment of the separated isotopes Cu-63 and Cu-65 with 1.9-mev protons was observed by means of a NaI crystal and a 20-channel analyzer. From Cu-63 we detected 0.995-mev gamma rays, and from Cu-65 1.04- and 0.824-mev gamma rays, all presumably due to the inelastic scattering of the protons. The 0.995- and 1.04 mev radiations correspond to transitions from known excited states of Cu-63 and Cu-65, respectively. The 0.824-mev gamma ray we assign to either a new level in Cu-65 at 0.824 mev or to a transition from the 1.04 level to a level at 0.210 mev. Evidence for the latter level has been previously reported. We have as yet been unable to detect a 0.210-mev gamma ray. A continuous gamma-ray spectrum up to at least 10 mev was also observed, most probably due to proton capture. Thick target yield curves of the two 1-mev gamma rays will also be shown. The onset of the (p, n) reaction in Cu-65 is clearly evident just above 2.0 mev.

GAMMA RAYS FROM THE PROTON BOMBARDMENT OF SEPARATED COPPER ISOTOPES, by C. E. Weller and J. C. Grosskreutz. Feb. 14, 1956 [8]p. incl. diagrs. tables. [AFOSR-TN-56-77] [AF 33(038)20681] AD 81529 Unclassified

Also published in Phys. Rev., v. 102: 1149-1156, May 15, 1956.

The energy spectrum of γ rays obtained from the proton bombardment of separated Cu isotopes has been measured. It was found by coincidence measurements that the majority of these γ rays arise from the capture process when the bombarding energy is held below 2.2 mev. The thick target cross section for proton capture at 1.9 mev is found to be 0.1 millibarn. Above 2.2 mev, excitation of the 0.67-mev level in Cu^{63}, by either inelastic scattering or Coulomb excitation, is observed. Excited level schemes for both Zn^{64} and Zn^{66} have been obtained. The first 3 levels in Zn^{64} are found to be at 0.97, 2.27, and 3.04 mev. The scheme for Zn^{66} is essentially the same as that earlier proposed from the decay of Ga^{66}. (Contractor's abstract)

SOME REACTIONS LEADING TO N^{16}, (Abstract), by N. A. Bostrom, E. L. Hudspeth, and I. L. Morgan. [1956] [1]p. [AF 33(038)20681] Unclassified

Presented at meeting of the Amer. Phys. Soc., Houston, Tex., Feb. 24-24, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 94, Feb. 24, 1956.

Excitation curves for $O^{18}(d, \alpha)N^{16}$ and $N^{15}(d, p)N^{16}$ have been obtained with targets ~ 40 kev thick) respectively of $BaCO_3$ enriche to 9% in O^{18} and with gaseous targets of normal nitrogen. The preliminary excitation curve for O^{18} (d, α) shows a steep rise from 0.7 mev to a resonance maximum near 1.25 mev, with a second resonance at approximately 1.75 mev. The

$N^{15}(d, p)$ curve rises steeply between 1.0 and 1.2 mev and continues upward with smaller slope to $E_d = 2.0$ mev; some weak resonance structure is indicated. Both curves are being extended and further work will be done with thinner targets. Observation was made of $C^{14}(d, \gamma)N^{16}$, since N^{16} activity is presumed possible from this reaction. N^{16} activity was found but all of it was ascribed within the limits of observation to $O^{18}(d, \alpha)$; this latter reaction was found to be at least 400 times as probable as $C^{14}(d, \gamma)$ at $E_d = 1.3$ mev. The weak activity previously reported from $C^{14}(d, p)C^{15}$ below this deuteron energy is believed to be from bombardment of O^{18}. Proper allowance for this puts these data into agreement with other recently reported results. (Contractor's abstract)

COMPRESSORS FOR HIGH-SPEED WIND TUNNELS, by A. A. Fejer and J. Clark. Jan. 1956, 216p. incl. illus. diagrs. refs. (NATO AGARDograph rept. no. 14) [AF 18(600)1249] Unclassified

The compressor drive systems are considered for high-speed wind tunnels of the continuous type. This study contains information regarding the aerodynamic characteristics of wind tunnel circuits from which the compressor requirements can be established, presents a method to guide in the selection of the compressor type, and discusses compressor drives utilizing various types of prime movers. Some of the aerodynamic and mechanical considerations underlying the design and operation of wind tunnel drives are outlined, including a discussion of vibrational problems encountered in systems of this type.

AN EXPERIMENTAL STUDY OF ONE-DIMENSIONAL REFRACTION OF A RAREFACTION WAVE AT A CONTACT SURFACE, by I. J. Billington. June 1955, 1v. incl. illus. diagrs. tables, refs. (UTIA rept. no. 32) ([AF]OSR-TN-55-394) (AF 18(600)1185) AD 82221 Unclassified

An experimental investigation of the 1-dimensional interaction of a rarefaction wave and a contact surface in a shock tube is described. The rarefaction wave generated from the bursting of the shock tube diaphragm is utilized as the incident wave in the interaction with an air and helium or air and argon contact surface. The investigation shows that, as has been predicted in a previous theoretical treatment, a compression wave is reflected from the contact surface in the former case, and an expansion wave in the latter case. A rotating drum camera is used to measure the speed of the moving contact surface after the interaction and measurements of the flow properties in the regions formed by the interaction are made. A piezoelectric pressure gauge is used to measure pressure in these regions and a hot-wire anemometer is used to measure mass flow and stagnation temperature. The investigation shows that the initial rarefaction wave in the shock tube deviates considerably from the theoretically predicted wave. When this deviation is taken into account, however, the results of the rarefaction wave refraction show good agreement with the theory. Values are given for both gas combinations of contact surface speed measured from drum camera records. Piezoelectric pressure gauge results are given for the pressures behind the initial and final waves. Hot-wire anemometer results are listed for both stagnation temperature and mass flow for all the flow regions in the interaction.

HEAT TRANSFER IN SLIP FLOW, by R. L. Martino. Oct. 1955 [154]p. incl. diagrs. tables, refs. (UTIA rept. no. 35) ([AF]OSR-TN-55-443) (Sponsored jointly by Air Force Office of Scientific Research, under AF 18(600)1185 and Canadian Defence Research Board) AD 82234 Unclassified

The Rayleigh method has been applied to solve the energy equation for the temperature distribution for the case of a flat plate in laminar flow. The slip and temperature jump boundary conditions were used, as well as the conventional boundary conditions of gas dynamics. An analytical solution was derived for the case of arbitrary constant Prandtl number and for variable initial surface temperature. By a linear transformation between time and distance downstream from the leading edge, steady flow solutions have been derived. These solutions have been linked with the results of Chapman and Rubesin for the case of a constant surface temperature. The significant results of this study for a constant initial surface temperature are the following: (1) The results cannot be applied directly to explain the phenomena of the slip regime. No provision was made for free-molecule flow to exist at the leading edge. In order to extend the analysis, a leading edge condition must be included. (2) The recovery factor, while attaining the correct limit a great distance downstream from the leading edge, tends to the limit zero as the leading edge is approached. (3) As the leading edge is approached, the Nusselt and Stanton numbers become functions of both Mach number and initial wall temperature before approaching a common limit. A common limit also exists for conditions a great distance downstream. The general conclusion of this work is that while temperature jump and slip boundary conditions are sufficient to explain phenomena approaching slip flow from the continuum regime, they are insufficient to adequately describe the slip regime.

(AFOSR-TN-56-116) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1185 and Canadian Defence Research Board) AD 82512 Unclassified

The thermal equilibrium and heat loss relationships for small diameter heated cylinders placed normal to an airstream are discussed. Some experimental results are presented for the heat loss of a hot-wire in stationary gases. Procedures for the calibration of hot-wires and typical calibration curves are given. The design of an open-jet hot-wire calibration tunnel with a variable velocity and a low turbulence level is described. The sensitivity of a hot-wire to small fluctuations is considered and the limitations to frequency response imposed by the finite thermal lag of the wire are pointed out. Methods of overcoming the thermal lag effect by compensation and suppression are discussed. The use of hot-wire probes in non-steady shock-tube flows is considered. The typical response of a hot-wire to travelling shock and expansion waves in a shock tube is presented as an illustration of the method. Procedures for the reduction of shock tube results are outlined, and a correction for the effect of the finite impedance of the wire heating current source is developed. A simple circuit utilizing hot-wires to measure the speed of a travelling shock wave is shown. A discussion is included on the general considerations influencing the design of hot-wire probes and mounts.

INVESTIGATION OF THE TIME RESPONSE AND OUTGASSING EFFECTS OF PRESSURE PROBES IN FREE MOLECULE FLOW, by E. L. Harris. Oct. 1955 [28]p. incl. illus. diagrs. tables. (UTIA Technical note no. 6) (AFOSR-TN-56-117) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1185 and Canadian Defence Research Board) AD 82513 Unclassified

A study was made of the time response and outgassing effects of pressure probes in free molecule flow. A theoretical analysis was conducted to obtain expressions for the time constant of a pressure probe, and for the pressure difference resulting from outgassing between the gas in the gauge and the gas external to the gauge under steady conditions. The expression derived for the time constant was in terms of the physical dimensions of the gauge; that for the pressure difference was in terms of the physical dimensions and a factor q (the rate at which adsorbed gas was evolved from the interior surface of the gauge/unit area). For the range of geometries studied, it was shown that the pressure difference resulting from outgassing was proportional to the time constant, where the proportionality constant depended on q. The experimental results for the time constant and the outgassing pressure difference checked closely with theory. The outgassing rate depended on the pressure and temperature history; for practical gauges measuring pressures in the μ range, q may be reduced to a satisfactorily low value by subjecting the surface to a low pressure for a sufficient length of time. THE BOLTZMANN H-FUNCTION APPLIED TO THE SHOCK TRANSITION, by E. L. Harris and G. N. Patterson. May 1956 [32]p. incl. diagrs. tables. (UTIA rept. no. 40) (AFOSR-TN-56-336) [AF 18(600)-1185] AD 95212 Unclassified

Boltzmann's H-function is calculated for a Maxwellian distribution function and 2 nonisentropic cases. The variation of H through a shock front is given for M = 1.50 to 4.00. The results showed that the effect of heat conduction and viscosity on the distribution of H through the shock wave is to give a smoother transition than that obtained from the thermodynamic entropy.

THE CONVERGENCE OF AIRY SERIES, by W. J. Klimczak. Sept. 30, 1956, 8p. (AFOSR-TN-58-467) (AF 18(600)1397) AD 97086 Unclassified

An investigation was made of the domain of absolute convergence in the complex plane of series of the form $f(z) = \sum_{n=1}^{\infty} f_n A_n(z)$ where $A_n(z)$ are characteristic functions of the differential operator $\delta_z = d^2/dz^2 + z$. The investigation of the convergence of the series is based upon estimates of the asymptotic behavior for large values of n of the functions $A_n(z)$ and the corresponding characteristic values denoted by λ_n. Proof is given in terms of a theorem which states that if the series converges absolutely for any nonreal value of z, then it converges absolutely everywhere in the complex plane. The discussion is analogous to that of Hille (Duke Math. Jour., v. 5: 875-936, 1939) for Hermitian series.

TRI. 01:002

Trinity Coll., Hartford, Conn.

THE CONVERGENCE OF SERIES OF CHARACTERISTIC FUNCTIONS. I. AIRY AND LAGUERRE SERIES, by W. J. Klimczak. Oct. 30, 1956, 4p. (AFOSR-TN-56-531) (AF 18(600)1397) AD 110350 Unclassified

An investigation was made of the geometric character of the region of absolute convergence in the complex plane of series of the form $f(z) \sum_{n=1}^{\infty} c_n f_n(z\lambda_n)$, where

$f_n(z, \lambda_n)$ are characteristic functions of a linear second-order differential operator A_z. Hermitian, Laguerre, and Legendre differential operators are considered. Variations of these operators are studied and note is taken of the effect of these changes on $R(A_z)$, the region of absolute convergence of the series. The case of the Airy operator was studied in detail previously (item no. TRI. 01:001). If $a_n(z)$, $n = 1, 2, 3 \ldots$, denote the characteristic functions of the operator A_z corresponding to the characteristic values λ_n, $n = 1, 2, 3, \ldots$, then for any n and x real, $a_n(x)$ has no negative zeros and an infinite number of positive zeros. As $x \to \infty$, $a_n(x) \to 0$ and $a_n'(x) \to 0$. From these properties it was shown that the sequence of functions $\{a_n(x)\}$ is orthonormal on the interval $(-\infty, 0)$. The principal theorem established that if the series converges absolutely for any nonreal value of z, then it converges absolutely everywhere in the convex plane. In the Laguerre case, the determination of $R(L_z)$ for the series $1(Z) = \sum_{n=1}^{\infty} c_n 1_n^{(\alpha)}(z)$, where $L_z z^{1/2} 1_n^{(\alpha)}(z) = -\left[n + 1/2(\alpha + 1)\right] z^{1/2} 1_n^{(\alpha)}(z)$ must be based on some estimate of the asymptotic behavior of the functions $1_n^{(\alpha)} z$ for large values of n. From the estimates for $1_n^{(\alpha)}(z)$, $R(L_z)$ for the series was shown to be the interior of a parabola. (ASTIA abstract)

PART I. THE REACTIONS OF ALKOXYCHLOROALKANES WITH SOME METALS. PART II. THE PREPARATION AND PROPERTIES OF SOME ALPHA-FLUOROETHERS, by C. T. Mason. Technical rept. Sept. 1, 1953-Aug. 31, 1955. Oct. 1955, 34p. incl. tables, refs. (CF rept. no. 9; technical note no. 2) ([AF]OSR-TN-55-389) (AF 18(600)779) AD 79642 Unclassified

Part 1 was presented at Southeastern meeting of the Amer. Chem. Soc., Columbia, S. C., Nov. 3-5, 1955.

Part I. The action of various metals on alkoxychloralkanes is reported. Alkoxychloromethanes with Na give acceptable yields of the Wurtz product. With the 1-alkoxy-1-chloroethanes, however, Na yields the acetal and vinyl ether. Li does not react with the alkoxychloromethanes in the cold, but on heating, gives the formal. With 1-alkoxy-1-chloroethane, however, Li gives 26% of the Wurtz product. 1-Alkoxy-1-chloropropane gives acetal with both Li and Na. No evidence of a Li organometallic compound is found. Cu and alcoholized Fe powder gives no reaction when heated with the 1-alkoxy-1-chloromethanes or 1-chloroethanes. Reduced Fe powder with the former gives about 20% yield of the Wurtz product. Neither the 1-alkoxy-2-chloroethanes nor 1-alkoxy-1, 2, 2, 2-tetrachloroethane react with even the more active of the metals. In Part II various metal fluorides were examined as F-for-Cl exchange agents for $CCl_3CHClOR$. The efficiency of the exchange was found to descend in approximately the order: HgF_2, TlF, AgF, KF, Al_2F_6, and CrF_3. A series of compounds of the general formula CCl_3CHFOR and CH_2FOR (where R is Me, Et, Pr, Bu, and allyl) were prepared using HgF_2, and their physical and chemical properties were examined. All attempts to prepare CH_3CHFOR were unsuccessful, and led only to polymerization and decomposition. (Contractor's abstract)

MODELING OF HIGH SPEED IMPACT THROUGH THE USE OF PLASTICS, by M. E. Van Valkenburg. Feb. 1955 [24]p. incl. illus. diagrs. (Technical rept. no. 3) ([AF]OSR-TN-55-48) (AF 18(600)1217) AD 58379 Unclassified

The impact of high-speed plastic pellets on plastic targets has been studied for several plastic materials. Metal-to-metal impacts have also been studied using pellets of various shapes and with masses from 20 mg to 5 g. The experimental method for producing plastic pellets with velocities up to 6 km/ sec is similar to that used by Pugh, and was first reported in the literature by Allen, Rinehart, and White (Phenomena Associated with the Flight of Ultraspeed Particles, Jour. of Appl. Phys., v. 23: 123, 1952). This method and techniques for recording pellet velocity are described. Crater characteristics including (1) crater volume, (2) penetration (or crater depth), and (3) crater area at the target surface have been studied for a range of velocities. These results are compared with those from metal-to-metal impact using aluminum and steel pellets. Comparison is also made with experimental results of Eichelberger and Rostoker using jets [from steel liners]. The validity of several proposed empirical equations for penetration and crater volume is examined. (Contractor's abstract)

SOME CHARACTERISTICS OF CRATERS FROM HIGH-SPEED PELLETS IMPACTING INTO SEMI-INFINITE TARGETS, by M. E. Van Valkenburg, W. G. Clay and others. Sept. 1955, 15p. incl. diagrs. tables. (Technical rept. no. 2) ([AF]OSR-TN-55-287) (AF 18(600)1217) AD 72221 Unclassified

In this study, pellets of various shapes and materials were fired at speeds ranging from 1 to 4 mm/μsec (about 3000 to 13,000 ft/ sec) into various target materials. The following pellet-target combinations were used: (1) aluminum (24ST) into aluminum (61ST); (2) aluminum into lead; (3) aluminum (24ST) into wax (paraffin-petrolatum); (4) brass into brass; (5) brass into lead; (6) brass into magnesium; (7) epon 828 (thermosetting plastic) into wax (paraffin-petrolatum); (8) magnesium into lead; (9) magnesium into magnesium; (10) steel (SAE 1040) into steel (SAE 1040); (11) steel into zinc; and (12) zinc into zinc. Tabular data include pellet mass; pellet diameter; crater area (sq cm); crater volume (cu cm); and penetration depth (mm). The method for producing ultraspeed pellets is described, and the procedures for measuring pellet velocity, crater area, crater volume, and penetration depth are also considered.

IMPACT PHENOMENA AT HIGH SPEEDS, by M. E. Van Valkenburg, W. G. Clay, and J. H. Huth. Feb. 15, 1956, 34p. incl. illus. diagrs. tables, refs. (AFOSR-TN-[56-54]) (AF 18(600)1217) AD 81046 Unclassified

Also published in Jour. Appl. Phys., v. 27: 1123-1129, Oct 1956.

A study of high-speed, metal-to-metal impact characteristics in the velocity range 1-5 mm/μsec is described. Several experiments relating to the mechanisms of cratering, including the perforation of thin targets, are presented. For 1/8-in. diameter spherical pellets, it is found that the volume of the crater/ unit energy of the impacting pellet is essentially constant, and that the penetration is proportional to the velocity of the pellet. An attempt to model very high-speed impact by means of soft wax targets in which the sonic velocity is less than the impacting velocity is outlined. A speculative insight into meteoric speed impact may be gained by this means. (Contractor's abstract)

AN INVESTIGATION OF THE FEASIBILITY OF USING A SHORT SOLENOID AS AN ELECTROMAGNETIC ACCELERATOR, by M. M. Christensen, H. K. Okamoto, and W. S. Partridge. June 1956, 35p. incl. illus. diagrs. tables. (Technical rept. no. 4) (AFOSR-TN-56-214) (AF 18(600)1217) AD 87530 Unclassified

The investigation of the short solenoid as an electromagnetic gun utilized a system whereby the electrical energy in a bank of photo-flash capacitors was discharged into a solenoid. The pulse of electrical energy energized an accelerator coil, and the resultant magnetic field of the coil repelled a spherical Al pellet located initially within the solenoid. The problem was to observe the performance of the short solenoid when used to accelerate the pellet. First, the required initial position of the pellet within the solenoid was found to be forward of the center line of the solenoid. A second series of tests showed the correlation between the system efficiency and pellet velocity as the initial energy

or the initial voltage of the syetem was varied. Correlation of the reeults tndicated that the capacitance of the energy source should numerically equal the inductance of the solenoid to obtain the best system effticiency. The condttion for obtaining high pellet velocity depended upon the consideration of additional parameters as dampting factor and the frequency of osctllation of the network. High voltage and energy were required to perform the tests. The method of handling the large quantity of electrical energy as well as the method of obtaining the pellet velocity were important secondary probleme encountered tn the investigation. The solution to these problems were unique, since the high energy and voltage that were present with the aesoctated electromagnetic radtation made conventional methode tneffective, and tn some caees dangeroue. WAX MODELLING STUDIES OF HIGH-SPEED IMPACT, by W. G. Clay and W. S. Partridge. June 1956, 31p. incl. illue. dtagrs. tables, refs. (Technical rept. no. 5) (AFOSR-TN-56-257) (AF 18(600)1217) AD 88977 Unclaeetfted

An investigation of wax-to-wax tmpact te presented tn an attempt to "model" high-speed Impact of metal into metal. Wax te chosen as the modelling substance because of its comparatively low soutc velocity and the physical similarity of wax craters to craters formed at the impact of metal into metal. The sonic velocity in wax te determtned as a function of temperature; the work reported te made wtth the wax targete at a temperature of about 75°F, at whtch the sonic velocity tn wax te approximately 0.7 km/sec. A method of accelerating wax pellets by means of laboratory guns te given; also, use te made of the static charge on wax pellets tn some of the velocity measurements. The penetration of the tmpacting pellet te found to vary linearly wtth the cube root of the pellet mass and the pellet velocity to velocities tn excess of twice the sonic velocity in the wax target. The crater area varies directly as the pellet area and the velocity, both below and avove the sonic velocity, but there te a marked tncrease in the constant of proportionality above the sonic velocity. The volume of the crater per unit energy of the pellet te discussed, and it te found that in wax this characteristic te not tndependent of velocity. Valuee of volume per unit energy range from 1.5 to 4.0 x 10^{-8} cu m/joule between zero and 2 km/sec. Expertments are descrtbed whtch throw some light on the mechanisms of cratering. A large part of the crater volume te created by deformation of the target material and only a small part te due to ejection of target matertal. There te an apparent cavttation in the target material surrounding the crater, probably caused by a shock wave created by the impact. A comparison of features of wax craters with metal craters indicates validity of the wax model. (Contractor's abstract)

CIRCUIT ANALYSIS OF A SOLENOID-TYPE ELECTROMAGNETIC ACCELERATOR, by R. W. Walker and L. D. Harris. Aug. 1956, 46p. tncl. illus. diagrs. tables. (Technical rept. no. 7) (AFOSR-TN-56-385) (AF 18(600)1217) AD 96042 Unclassified

Paramsters of an experimental circuit were determined from current oscillograms. The prtmary ctrcuit was an underdamped resistance-tnductance-capacitance loop in whtch the condenser was discharged through a hollow coil that contained a conducting projectile. The current waveform was a damped sinusotd. The current produced a large magnetic flux with axial and radial components. The axial component induced a voltage tn the projectile. The current whtch results from thte voltage interacts with the radtal component of the flux to produce an accelerating force on the projectile. At the end of one-half cycle of prtmary current, the heat losses in the primary and secondary ctrcuits, the energy etored in the magnetic ftetd, and the kinetic energy in the projectile must balance the energy extracted from the prtmary ctrcuit during that period. The energy equation ts determined, and the energy terme are evaluated for one-half cycle. A straight line vartation of mutual tnductance with time te assumed. The current tn the projectile te evaluated by solving Kirchhoff's equation for voltage around the secondary circuit when (1) secondary resistance te neglected, (2) secondary tnductance te neglected, and (3) both are considered. The analysis tndicates that it te advantageous to tncrease the energy extracted during the first one-half cycle of prtmary current. Over-all effticiency can be tmproved by decreasing both the prtmary and secondary resietance. (ASTIA abstract)

THE INDUCTANCE COIL AS AN ENERGY RESERVOIR FOR AN ELECTROMAGNETIC ACCELERATOR, by C. R. Forbes and W. S. Partridge. Aug. 1956, 48p. incl. dtagrs. tables. (Technical rept. no. 6) (AFOSR-TN-56-386) (AF 18(600)1217) AD 96044 Unclassified

The power required to accelerate a pellet to very high velocities te enormous. It te not feasible, nor necessary, to deliver thte power from a continuous source. The extremely short time duration and small duty cycle allow the use of a system in whtch the energy te accumulated at a very slow rate and discharge at a very htgh rate. The feasibility of using the tnductance coil as an energy reservotr for such a system te discussed. Three systems are analyzed. The first system has the simplest circuit possible to transfer the energy from the ftetd of one coil to the field of another. The 2nd system te a modification of the first using the addition of a capacttor for tmproved performance. The

UTA. 02:001 - UTA. 02:004

3rd system employs a bank of capacitors as the energy reservoir, and serves as a standard for measuring the merit of the other 2 systems. The systems are evaluated from the standpoint of (1) energy storage and transfer, (2) power gain and supply, (3) timing, (4) switch requirements and (5) cost. It was concluded that it is not feasible to use the inductance coil as an energy reservoir for the systems considered. The problems created over-shadowed the mediocre performance obtained. The system using the capacitor bank as the energy reservotr is far supertor in both performance and simplicity. (Contractor's abstract)

KINETICS CF OXIDATION OF CARBON, by M. C. Chen, H. Eyrtng, and C. J. Christensen. Mar. 1, 1952, 14p. incl. diagrs. tables. (Technical rept. no. 1) (AF 33(038)20839) AD 23509 Unclassified

The oxidation rate of carbon films on a cylindrical ceramic base was studied. The results are summarized in ne following two equations:

$$\Delta t = 8.9 \times 10^{5} r_0^{-1.00} \frac{L}{D} \left(\frac{W}{C} - 1\right)^{-5.0},$$

$$\frac{dr}{dt} = 1.12 \times 10^{-7} r_0 \frac{D}{L} \left(\frac{W}{C} - 1\right)^{5.0},$$

where Δt is the time required for the hot resistance of the cylindrical resistor of length L, diameter D, and initial resistance r_0 to increase 10% as a result of oxidation of the carbon. The power dissipation in the resistor is W, and C is the maximum power input possible before appreciable oxidation takes place. The second equation refers to the rate of resistance increase. Theoretical discussion is presented of the 2 equations, and a comparison is made with experimental results.

THE SIGNIFICANCE OF ISOTOPIC REACTIONS IN RATE THEORY, by H. Eyring and F. W. Cagle, Jr. Mar. 15, 1952, 11p. tncl. diagrs. refs. (Technical rept. no. 3) (AF 33(038)20839) AD 23243 Unclasstfied

Also published in Jour. Phys. Chem., v. 56: 889-892, Sept. 1952.

The general theory of the tsotoptc effect on reaction rates is developed in terms of tlie absolute rate theory. The high temperature limtt of the separation factor $\left(m^{\ddagger}_{heavy}/m^{\ddagger}_{light}\right)^{1/2}$ is obtained and its significance and use discussed. The possibility of obtaining an α of less than unity is investigated and the rather physically unlikely condttions which would be necessary are stated. The electrolytic concentration of heavy water is considered since it provides a reaction with at least two mechanisms. An approximate separation factor is discussed for one mechanism and the unusual increase of separation factor with temperature, over a limited temperature range, is discussed. A very tentative activated complex is postulated for the hydrolysis of Al_4C_3 which explains the unusually high separation factor (ca 20) for the reaction with H_2O compared with D_2O. Four organic reactions involving isotopes for which separation factors have been observed tn light of a simplified model. Very good agreement between calculated and observed separation factors is obtained. (Contractor's abstract)

THE MECHANISM OF THE MERCURY-SENSITIZED PHOTOCHEMICAL OXIDATION OF PROPANE, by N. V. Fok, B. B. Bereslavsky and others, tr. by G. N. Larsen. June 15, 1952, 3p. diagrs. (Trans. of [Doklady Akademii Nauk SSSR, v. 67: 499-501, 1949]) (AF 33(038)20839) AD 16170 Unclassified

In this study conducted at the Institute of Chemical Physics, Academy of Science USSR, condensation products of an equimolar mixture of propane and oxygen were analyzed polarographically and chemically. The analyses indicated the presence of aldehydes and organic peroxides. Yields of these compounds were noted in relation to time of exposure in the zone of illumination, over a temperature range from room temperature to 300° C, at a pressure of 50 mm Hg. The data, presented graphically, indicate that: (1) at room temperature only one organic peroxide is the product of reaction; (2) as temperatures increase to

100°[C] aldehydes begin to appear, though in lesser amounts than the peroxides; and (3) at 300°[C] the yield of peroxides drops abruptly while that of the aldehydes continues to increase. Results thus show that peroxides are the initial intermediate products, while the aldehydes are the secondary intermediate products in the reaction studied.

EXPERIMENTAL DETERMINATION OF EQUILIBRIUM FREEZING TEMPERATURES, by D. Christensen, N. W. Ryan, and G. R. Hill. Oct. 15, 1952 [17]p. incl. diagrs. tables, refs. (Technical rept. no. 4) (AF 33-(038)20839) ATI-171900 Unclassified

In this study concerning the expansion of hot combustion gases through rocket nozzles, a method is being developed for determining the equilibrium "freezing" temperature by measurement. This measurement will eliminate the necessity of obtaining experimentally the rate constants, and will exclude the uncertainties associated with the assumptions and approximations made in the derivation of equations. Measurement of the "freezing" temperature requires that the composition and pressure be obtained as a function of temperature. These variables are determined at several points in the divergent section of the rocket nozzle, the "freezing" temperature being evaluated by interpolating between the points. It is pointed out that the equilibrium does not freeze at a particular temperature, but rather over a range of temperatures. A general description of the method to be applied and the equipment, e.g., nozzle, combustion chamber, feed system, thrust-measuring instrumentation, etc., is presented. In an appendix, an example of equilibrium "freezing" using 2NO and its dissociation products (N_2 and O_2) is given.

THE KINETICS OF COMBUSTION OF METHYL ALCOHOL, by W. H. Wiser and G. R. Hill. Dec. 15, 1952, 71p. incl. illus. diagrs. tables, refs. (Technical rept. no. 5) (AF [33](038)20839) AD 17800 Unclassified

The combustion kinetics of MeOH were studied in an effort to determine the effect of the OH upon the velocity of combustion and to improve the energy output of fuels in internal combustion engines. With specially designed combustion apparatus, the combustion limits of MeOH-air mixtures were established as 7.9 ± 0.2 and 25.0 ± 0.6% on the lean and rich ends, respectively. The combustion tube was 57.0 cm long between 2 (1.7 and 8.0 mm) orifices; the od was 3 cm. The observed velocities (U_o) of the flame in the combustion tube were from 29.4 to 91.5 cm/sec. The flame front areas (A_f) were calculated by the method of Coward and Hartwell (Jour. Chem. Soc. 1932, 2676-2684) with values taken from the contact prints. These A_f values were from 10.3 to 19.2 sq cm. The velocity of the unburned gas ahead of the flame front (U_g) was small; at most, it equalled 1.3% of the U_o value. The fundamental flame velocity U_f was calculated from the equation $U_f = (U_o - U_g)\frac{A_t}{A_f}$, where A_t is the cross-sectional area of the flame tube. The U_f values ranged from 11.7 to 44.7 cm/sec. The presence of a bubble tube on the combustion tube did not alter the U_o values. Natural gas was employed to check the combustion velocity upon the concentration of MeOH and O, runs were with one of the variables constant and the other varied over a wide range. Maximal velocities were observed with 10.0% MeOH and 18.0 and 18.9% O; the latter 2 maxima were the highest. The results are tabulated and compared with previous results. The effects and causes are discussed as well as theoretical considerations. (ASTIA abstract)

KINETICS OF OXIDATION OF CARBON [II], by M. C. Chen, C. J. Christensen, and H. Eyring. Dec. 15, 1952, 22p. incl. diagrs. tables. (Technical rept. no. 6) (AF [33](038)20839) AD 17873 Unclassified

The rate of C oxidation was evaluated in terms of the change in resistance of C films. The films were deposited from purified CH_4 gas at about 1000°C on a ceramic base. Flow rate of the oxidizing gas over the C resistor was measured by calibrated flowmeters. Values of resistance were determined as frequently as convenient for a period of 20 min. The resistance of the C films was determined from the equation $r_u = r_k \frac{P_u}{P_k}$. ($P_k$ is the voltage drop across the standard resistor, r_k, and P_u is the voltage drop across the C film resistor, r_u. The P_k employed to calculate r_u at a particular time is the average of P_u and P_k since both vary continuously.) When the reciprocal of the resistance of the C resistor was plotted against time, a straight line was obtained. The data may be expressed by the following equation $1/r_u = -mt + \text{constant}$. The slope of the straight line, m, was found graphically in each case. The resistance of the C resistor was measured from 350° to 500°C at 3 different O rates of flow. The effect of changing the % of O was determined when the temperature was kept constant. A determination was made with the O composition fixed at 1:1 ratio of O to N and varying temperatures. The slope and other related values are tabulated for the different rates of gas flow and temperatures; results are treated theoretically.

APPLICATION OF CONSISTENCY OF TYPE REACTIONS TO CHAIN DECOMPOSITIONS, by J. C. Giddings, F. W. Cagel, Jr. and others. July 15, 1953, 19p. incl. diagrs. tables, refs. (Technical rept. no. 8) (AF 33(038)20839) Unclassified

It is pointed out that there is no method available for studying and measuring directly the elementary processes that form the basis for all of the reactions found in fuels during combustion. Therefore, in this study, the concept of consistency of type reactions is introduced to reduce the over-all problem of solving the kinetic equations. An evaluation of the consistency of type reactions was made in terms of average deviation from the mean. Using 10 examples of direct bond rupture, it was found that the average deviation of ΔS, the activation entropy, is 1.7 EU. In 35 cases of H_2 abstraction reactions involving Me radicals, and a variety of other molecules, the average deviation was shown to be 1.4 EU. These small deviations justify application of the method. In applying the method, all reactions were written in terms of absolute reaction-rate theory, emphasizing the behavior of the potential energy surface. The results obtained show that: (1) κ (the transmission coefficient) = 0.1 for bond-rupture reactions in hydrocarbons; (2) the decomposition of acetaldehyde obeys Rice-Herzfeld kinetics very closely, showing that it is a chain reaction and has a true order of 3/2; (3) the activation entropies and transmission coefficients, respectively, found for various reactions are as follows:

$R' - R \rightarrow R' + R$	$\Delta S^{\ddagger} = -1.5$ EU	$\kappa = 0.1$
$R' + RH \rightarrow R'H + R$	$\Delta S^{\ddagger} -13.7$ EU	$\kappa = 1.0$
$RCH_2CH_2 \rightarrow R' + CH_2CH_2$	$\Delta S^{\ddagger} -1.5$ EU	$\kappa = 0.1$
$R' + R \rightarrow R' - R$	$\Delta S^{\ddagger} -1.0$ EU	$\kappa = 0.1$

It is pointed out that a system of equations has been formulated in which experimental work can be written easily in terms of the fundamental properties of the activated complex.

EQUILIBRIUM THEORY OF UNIMOLECULAR REACTIONS, by J. C. Giddings and H. Eyring. Mar. 1954. 5 [p. incl. diagr. refs. (Technical rept. no. 9) (AF 33(038)20839) Unclassified

Published in Jour. Chem. Phys., v. 22: 538-542, Mar. 1954.

This paper develops an equilibrium theory of unimolecular reactions, and shows how this theory is related to other theories, such as the Rice-Ramsperger-Kassel treatment. Unimolecular decomposition reactions and isomerization reactions are described in terms of statistical mechanics and quantum mechanics (potential energy surfaces). The nature of the transmission coefficient is discussed in detail. (Contractor's abstract)

A KINETIC COMPARISON OF THE COMBUSTION OF METHYL ALCOHOL AND METHANE, by W. H. Wiser and G. R. Hill. [1954] [6]p. incl. diagrs. tables, refs. (AF 33(038)20839) Unclassified

Published in Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y., Reinhold, 1955, p. 553-558.

Combustion tube determinations were made of the velocity of burning and combustion limits of methanol-air mixtures at a pressure of 65 cm Hg and an initial temperature of 24-27°C. Results show the combustion limits to be 7.9 ± 0.2% and 25.0 ± 0.6%. Calculations showed the fundamental flame velocity to vary from a minimum of 11.7 cm/sec at a methanol concentration of 20.0 mole % to a maximum of 44.7 cm/sec at 14.3 mole %, on the fuel-rich side of stoichiometric composition. Determinations under the same experimental conditions showed methane to have a maximum flame velocity of 36.3 cm/sec. Calculations of the relative heats of activation from experimental values showed that of methane to be 2163°K, and that of methanol 2023°K.

SECTION I. KINETICS OF THE STEAM-CARBON REACTION. SECTION II. A KINETIC THEORY FOR THE OXIDATION OF GRAPHITE, by J. S. Binford, Jr., G. D. Blyholder, and H. Eyring. Aug. 1955 [62]p. incl. diagrs. tables, refs. (Technical note no. 12) [AFOSR-TN-55-311] (AF 33(038)20839) Unclassified

Section I. A description is given of an apparatus for studying high-temperaiure (1500°C), low-pressure (1 to 100 μHg) heterogeneous processes in which one or more of the products is a gas. The H_2O-gas reaction has been studied in the 900°C to 1300°C iemperature range. This is the first kinetic study of this reaciion at high temperatures in which the oxidizing gases have been carefully preheated to the reaction temperature. A zero-order reaction with an activaiion energy of 60.3 kcal/mol is found in the 900°C to 1100°C range, changing to a first-order process by 1300°C, with a considerably lower value for the activation energy. Several possible mechanisms are discussed, including a surfaces rsarrangement of adsorption sites and predissociation of H_2O vapor. Section II. A considerable amount of data on the C-O_2 reaction has been collected from the literaiure, evaluaisd, and expressed in such a manner ihat comparison can be made. A theory is proposed which applies to the complete temperature range in which data have been obtained, 350° io 2000°C. In particular, the unusual maximum in the Arrhenius plot is explained on a theoretical basis, although the model proposed is not readily adapted to the known structural features of graphite. THE MECHANISM OF INHIBITORS FOR CHAIN REACTIONS, by A. T. Ree and K. Yang. Jan. 1, 1956, 11p. incl. diagrs. tables. (Technical note no. 16) (AFOSR-TN-56-61) (AF 33(038)20839) Unclassified AD 81053 Unclassified

In this study, the Rice-Herzfeld mechanism for the pyrolysis of hydrocarbons is assumed:

(1) $R \cdot CH_3 \rightarrow CH_3 + R$, (1') $CH_3 + Hc \rightleftharpoons CH_3H_c$, (2) $CH_3' + RCH_3 \rightarrow CH_4 + R_0'$, (3) $R' \rightarrow P + CH_3$, (4) $CH_3' + CH_3' \rightarrow C_2H_6$, (5) $CH_3' + B + CH_3' \rightarrow C_2H_6 + B$, where P indicates olefines, and R and R' are alkyl radicals. CH_3' indicates $CH_3 + CH_3H_c$. Assuming ths following equilibrium, (6) $CH_3 + 2NO \rightleftharpoons CH_3(NO)_2$ for the inhibition mechanism, the rate equation for the inhibited pyrolysis is derived as,

$$r = r_o \frac{1}{1 + \frac{K_2}{1 + K_1 Hc} NO^2},$$

where r and r_o indicate an over-all rate of inhibited decomposition and that of an uninhibited one, and K_1 and K_2 are the equilibrium constants for the reaction 1' and 6, respectively. Using this result, the inhibition curves for butane, pentane, hexane, heptane, octane, nonane, and decane are reproduced with good agreement with experiments. (Contractor's abstract)

THE KINETICS OF COMBUSTION OF METHYL CHLORIDE AND RELATED COMPOUNDS, by H. T. Henderson and G. R. Hill. June 30, 1955 [125]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 11) (AFOSR-TN-56-62) (AF 33(038)20839) AD 81054 Unclassified

A study of the combustion of methyl chloride, using the tubs method of Gerstein, Levine, and Wong, (Jour. Amer. Chem. Soc., v. 73: 518, 1951), is described. The results are analyzed and compared with data for related compounds. Flams-temperature curves have been calculated for comparison with the burning-velocity curves obtained. Soms of the more significant results are summarized as follows: (1) A comparison of maximum burning rates has been made for methyl chloride, methyl alcohol, and methane in air mixtures, the ratios found being 1:4.14:3.31. (2) The maximum burning velocity of methyl chloride has been compared with that for other chlorinated hydrocarbons, and a simple correlation has been found between the population of chlorine atoms in the fuel molecule and the burning velocity. From this correlation, a value of U_f (burning velocity) = 18.7 cm/sec was predicted for a stoichiometric mixture of ethyl chloride/air. (3) Burning velocities have been obtained for the systems methyl chloride/oxygen and methyl chloride/air. The order of burning-rate dependence on oxygen, methyl chloride, and total combustibles was determined by the use of argon and nitrogen inerts. Some of these curves revealed a rather anomolous maximum and minimum, indicating a change in the mechanism of combustion. (4) Limits of combustion of methyl chloride in air and in oxygen/inert-gas mixtures were determined. These were

compared with values obtained from the litsrature for methyl chloride and other chlorinated compounds. The population of chlorine in the molecula was found to be relaied in a regular manner to the calorific value of ths lower limit mixtures. (5) Relative activation energies havs been calculated for methyl chloride, methyl alcohol, and methane in air. The method of obtaining these is discussed. Though a complete mechanism for methyl chloride burning, has not been attempted, some of the unique features concerning it have been considered and explained. Evidencs has been cited showing the inhibitory roll of chlorine and iis compounds. Msthyl chloride dissociation has been calculated using as a basis the reaction

$$CH_3Cl \longrightarrow CH_3 + Cl.$$

An improvemsnt has been suggested in the svaluation of areas of flames in tubes to give larger values of burning velocity, especially for slow-burning systems. A study of burning velocity has bsen made as a function of iube diametsr, tubes bslow 2.4-cm inside diamster having a distinct cooling and slowing effect, while in those above 2.8-cm inside diameter the burning rate is independeni of diameier. The onsei of turbulence vs tube diameier has also been observed, being earlier for the larger tube diameters. (Contractor's abstract, modified)

MECHANISM OF INHIBITOR ACTION FOR CHAIN PROCESSES, by K. Yang, [A.] T. Ree, and H. Eyring. Mar. 10, 1956, 40p. incl. diagrs. tables, refs. (Technical note no. 18) (AFOSR-TN-56-I24) (AF 33-(038)20839) AD 82520 Unclassified

The Rice-Herzfeld mechanism for the pyrolysis of organic compounds is assumed: (I) $RCH_3 \rightarrow CH_3 + R$; (2) $CH_3 + R \cdot CH_3 \rightarrow CH_4 + R'$; (3) $R' \rightarrow CH_3$ + Produci (I); (4) $R \rightarrow CH_3$ + Product (2); (5) $CH_3 + CH_3 \rightarrow C_2H_6$; (6) $CH_3 + B + CH_3 \rightarrow C_2H_6 + B$. As the inhibition mechanism of an inhibitor for the chain process, the reactions, (i) $CH_3 + In \rightarrow CH_3In$; (j) $CH_3In \rightarrow$ Product (3); (2') $CH_3In + CH_3R \rightarrow CH_4 + R' + In$; (5') $CH_3 + CH_3In \rightarrow C_2H_6 + In$; (6') $CH_3 + B + CH_3In \rightarrow C_2H_6 + In + B$; (5") $CH_3In + CH_3In \rightarrow C_2H_6 + 2\,In$; (6") $CH_3In + CH_3In + B \rightarrow C_2H_6 + 2\,In + B$, are introduced. The symbols R' and R are alkyl or acyl radicals. The steady siaie treatment yields $[CH_3]_o = [CH_3] + b[CH_3In]$, and the overall rate of the inhibited reaciion, r, satisfies the following relationship:

$$\frac{r}{r_o} = \frac{I}{1 + \dfrac{{}_a b k_i}{k_j + k'_2 P_o}[In]},$$

where r_o ts the rate oi the uninhibited reaction, P_o the pressure of the decomposed organic compound, k the specific reaciion rates, and $[CH_3]_o$ and $[CH_3]$ the steady state concentrations of the CH_3 radicals for the uninhibited and inhibited reactions, rsspectively. The inhibition curvss for the thermal decompoeition of hydrocarbons, Et_2O, AcH, propaldehyde, and Me_2CO, are sxplained quantitatively and are in good agresment with experiment. The activation energies of reactions (j) and (2') are calculated from the proposed mechanism, and it is shown that inhibitors such as NO and propylene can suppress almost completely ths chain part of ths thermal decompositions of ths organic compounds studied. A STUDY OF THE THERMAL DECOMPOSITION OF METHANE, by F. W. Cagle, Jr. Mar. 31, 1956, 11p. refs. (Technical nots no. 19) (AFOSR-TN-56-177) (AF 33(038)20839) AD 86599 Unclassified

Also published in Jour. Chem. Phys., v. 25: 1300-1301, Dec. 1956.

A bibliography of ths literature on the homogeneous pyrolysis of CH_4 has been made. The known data are consistent with the following assumed mechanism:

	E
$CH_4 \xrightarrow{k_1} CH_3 + H$	101 kcal
$CH_3 + CH_4 \xrightarrow{k_2} C_2H_6 + H$	48
$H + CH_4 \xrightarrow{k_3} CH_3 + H_2$	7
$H + CH_3 + M \xrightarrow{k'_4} CH_4 + M$	0.

Th's mechanism assuming the usual steady state approximaiions gives:

$$-\frac{d[CH_4]}{di} = 2\left(\frac{k_1 k_2 k_3}{k'_4}\right)^{1/2} \cdot \frac{[CH_4]^{3/2}}{[M]^{1/2}}.$$

This leads to a calculated overall activaiion energy of 78 kcal in excsllent agreement with the measured value of 79 kcal. Further the expression agrees with the experimenially deiermined order of the reaction over the investigaied pressure range. A shori discussion of the nitric oxide inhibition data is included. UTA. 02:023 - UTA. 02:024

A description of an apparatus for studying heterogeneous gas-solid reactions in the one to 100 micron pressure and 600°C to 1300°C temperature range is presented. The data for the graphite-O_2 reaction in this range are presented. Below 800°C the surface reaction is zero order with an 80 kcal/mole activation energy. On samples thicker than 0.1 mm, the diffusion of O_2 into the pores in the graphite results in an observed half order reaction with a 42 kcal/mole activation energy. Above 1200°C the reaction is controlled by the frequency of O_2 collisions with the surface. Between 800°C and 1200°C a continuous transition region exists. An equation is derived which gives the reaction rate under conditions in which pore diffusion affects the observed reaction rate and the surface reaction varies with the pressure in a manner described by the Langmuir adsorption isotherm. A great deal of the literature on C oxidation deals with materials which have been carbonized but not graphitized. These materials are usually oxidized in first order reactions with an activation energy of 20 to 30 kcal/mole. A kinetic treatment is given which explains the maximum in the Arrhenian plot observed by many workers engaged in the oxidation of electrically heated, carbonized filaments. (Contractor's abstract)

OXIDATION STUDIES IN TOLUENE AS A CARRIER-GAS, by L. G. Tensmeyer, H. Eyring, and G. R. Hill. Sept. 1, 1956, 67p. incl. illus. diagrs. tables, refs. (Technical rept. no. 21) (AFOSR-TN-56-503) (AF 33(038)20839) AD 110318 Unclassified

The attempt was made to study the initiation reactions of hydrocarbon oxidation by utilizing a toluene carrier-gas technique. A vacuum system for toluene purification was described. A more complex vacuum system adequate for study of the oxidation processes was also described, with suggestions for refinement of equipment for future work. An infrared technique utilizing solid KBr was adapted for the study of combustion products. Chemical titrations were also used for total acids and total peroxides. The results showed that the toluene carrier-gas technique will not yield unquestionable data in oxidation systems. This is due partly to further reactions of the benzyl radical. Applied to the formaldehyde-oxygen reaction some of the radicals produced, apparently CHO and CHO_3, do not react quickly and quantitatively with toluene. The method yielded data from which the rate of the initiation reaction $HCHO + O_2$ could be calculated for the first time. The value of this constant, $5 \times 10^4 T^{1/2} e^{-39,000/RT}$, must be received with caution, because of further reactions of the benzyl radical. Benzyl hydroperoxide, benzyl alcohol, benzaldehyde, and bibenzyl were also found as products. The determination of the hydroperoxide in particular gives support to the hydroperoxidation theory of hydrocarbon autoxidation. Predominance of benzaldehyde over benzyl alcohol and benzyl hydroperoxide as temperature increased, was shown to reflect the decreasing stability of the benzyl peroxy radical in the range 400-550 C. AN X-RAY AND METALLOGRAPHIC STUDY OF LARGE GRAIN TITANIUM (Abstract), by F. J. Denise. [1955] [1]p. [AF 18(600)1319] Unclassified

Presented at meeting of the Virginia Acad. of Science, Charlottesville, May 11-14, 1955.

Published in Virginia Jour. Science, v. 6: 253-254, Sept. 1955.

Large single crystals of high temperature beta phase titanium can be prepared by a modification of the strain-anneal method, but recrystallization occurs on cooling. Etching revealed the titanium rod to consist of a great many crystalline fragments which were oriented with respect to one another. This was confirmed by x-ray back reflection methods. The results indicate strongly the existence of an orientation relationship between a low temperature hexagonal phase and a high temperature cubic phase. (Contractor's abstract)

THE PREPARATION AND STRANGE BEHAVIOR OF PSEUDO-MONOCRYSTALS OF ALPHA-TITANIUM (Abstract), by F. J. Denise and H. Leidheiser, Jr. [1956] [2]p. [AF 18(600)1319] Unclassified

Presented at meeting of Virginia Acad. of Science, Richmond, May 9-12, 1956.

Published in Virginia Jour. Science, v. 7: 265-266, Sept. 1956.

Commercially pure titanium rods, 1/2" in diameter and 2" long, were wrapped in foil and sealed in evacuated Vycor tubes. When such rods were cycled between 850° and 1200°C or between room temperature and 1200°C, large crystals of the beta-phase were formed at the high temperature. On cooling through the transition temperature at 880°C the high-temperature crystal recrystallized to a very highly oriented assembly of small crystals of the low-temperature, alpha phase. Since the orientation was so high and continued to the boundaries of the original high-temperature crystal the term "pseudomonocrystal" is warranted. Heating a pseudocrystal in an evacuated Vycor tube at 850°C for several days resulted in a great change in shape of the cross section, which change in shape was discontinuous at the boundary of another pseudocrystal. One type of commercial titanium became severely distorted when cycled between 860° and 1200°C. Metallographic and x-ray studies were made of the pseudocrystals. (Contractor's abstract)

PREPARATION OF CONJUGATED ALKADIENES, by R. C. Krug, T. F. Yen, and G. R. Tichelaar. Final technical rept. Sept. 1, 1953-Aug. 31, 1955. Sept. 1955, 23p. ([AF]OSR-TR-55-25) (AF 18(600)-690) AD 71632 Unclassified

In this chemical study, the preparation of conjugated alkadienes by means of the alkylation of unsaturated cyclic sulfones was not successful; however, some new and highly reactive halogenated sulfolenes have been prepared. The pyrolysis of a monosulfolene gave 2-bromomethyl-1, 3-butadiene, which may serve as a starting point for the synthesis of other compounds. A description is given of a new Diels-Alder reaction involving the conversion of a bromosulfolene into new polynuclear compounds possessing the hydrogenated chrysene system. It is pointed out that the reactivity of the α-hydrogen atoms in the sulfones has been proved.

PRESSURE DISTRIBUTION ABOUT TWO-DIMENSIONAL DIAMOND AIRFOILS AND A 180° WEDGE, by R. W. Truitt and F. W. Martin. June 1954, 25p. diagrs. (Rept. no AE641-1) ([AF]OSR-TN-54-149) (AF 18(600)641) AD 34600 Unclassified

The Schwarz-Christoffel mapping theorem was used to derive the pressure distribution about 2-dimensional diamond airfoils for the zero angle of attack condition. The theoretical (incompressible) pressures were compared with corresponding low-speed wind-tunnel tests, and the agreement was excellent except at the shoulder. The zero pressure coefficient was found to move toward the shoulder with increasing wedge angle. The effect of afterbody configuration is discussed in view of the experimental and theoretical results. A 180° wedge in a bounded or unbounded stream was found to be less sensitive to wall influence than small-angle wedges. Experimental low-speed results for the 180° wedge in an unbounded stream were found to be such that free-streamlines spring from the shoulder. The Sound-Space Theory was applied to the experimental results for the 180° wedge, and the local Mach number distribution was found to be symmetric about free stream Mach number one, but not constant. INVESTIGATION OF WEDGES IN TRANSONIC FLOW, by R. W. Truitt. Feb. 1954, 157p. incl. diagrs. refs. ([AF]OSR-TR-54-5) (AF 18(600)641) AD 32070 Unclassified

The present work is devoted to the thesis that a continuous (approximate) analytical solution can be obtained by a fundamentally new approach to transonic inviscid flow over simple wedges at zero angle of attack. The theoretical treatment is based on a new theoretical approach to compressible flow by deriving a local time- and space-unit transformation which is defined on the local speed of sound. It is shown that the incompressible inviscid solution for simple wedges may be employed in a new expression for compressible pressure coefficient to obtain a continuous solution from low subsonic to slightly supersonic flow. A detailed discussion of the structure and behavior of the compressible flow field about simple wedges is presented. This detailed discussion leads to the formulation of the transonic problem. Specifically, the theory is shown to be in fundamental agreement with experiment in the subcritical compressible range. Proof of the validity of the theory in the transonic range is given, an analysis being made to show that the theory satisfies the transonic similarity laws. A general analytical solution is then constructed whereby the constant ($p_{L/}p^*$) distribution may be calculated. This then establishes the approximate free-stream Mach number range in which the local Mach number distribution is constant. Using the general analytical method so developed, the pressure distribution is calculated for several specific wedge angles for a series of free-stream Mach numbers from low subsonic values to Mach numbers of greater than unity. The corresponding pressure drag coefficients are also presented in plots using the transonic similarity parameters. The present theoretical results are then compared with existing experimental and theoretical findings. In appendix A the "Sound-Space Theory" for 2-dimensional subsonic compressible flow is presented. A brief outline of the derivation of the transonic similarity parameters is given in appendix B. In appendix C, a method is derived for locating detached shock waves ahead of 2-dimensional wedges. Finally, a new expression for the pressure coefficient for 2-dimensional supersonic flow is derived in appendix D.

EFFECTS OF AFTERBODY CONFIGURATION ON THE PRESSURE DISTRIBUTION OVER THE NOSE OF TWO-DIMENSIONAL WEDGES, by R. W. Truitt and F. W. Martin. Mar. 3, 1954, 2p. incl. illus. [AF 18(600)641] Unclassified

Published in Jour. Aeronaut. Sciences, v. 21: 567-568, Aug. 1954.

Ths cases of (1) the symmetric diamond wedge, and (2) the single wedge wtth straight afterbody are considered at 0° angle of attack. A plot is pressnted of the theoretical prssure distrtbutions for these 2 cases for a wedge semiangle, θ, of 5°. Experimental results, obtained at low speed ($M_0 \approx 0.1$) for both afterbodies, were plotted and found to be in good agreement with the theoretical results. From thess results, it is seen that increasing the change of flow direction at the shoulder causes the front-wedge pressure distribution to become increastngly more negative. For given free-stream boundary conditions, the incompressible flow over the front wedge ts differsnt for the 2 afterbody configurations. It seems apparent, therefore, that any change in afterbody configuration should result in changes in the tncompresstble front-wedge pressure distrtbution.

INVESTIGATION OF PRESSURE DISTRIBUTION OF A 180° WEDGE (Abstract), by R. W. Truitt and J. C. Wtlltams, III. [1954] [1]p. [AF 18(600)641] Unclassifted

Presented at meeting of the Virginia Acad. of Science, Charlottesvtlle, May 5-8, 1954.

Published in Vtrginia Jour. Sctence, v. 5: 287, Sept. 1954.

A 180° wedge ts analyzed for incompressible flow in both bounded and unbounded streams by the Schwarz-Christoffel transformation. It is found that theoretically the boundartes (wing tunnel walls) do not appreciably affect the pressure distributton on the front face of the 180° wedge for tunnel-wedge ratios above 7. An expertmentally determtned pressure distribution on the front face of a 180° wedge in an unbounded stream at a free stream Mach number of 0.1 was corrected for compressibility by the Sound-Space Theory. The local Mach number on the front face of the 180° wedge was not constant in the transonic range as ts normally assumed for small angle wedges. For every subsonic free-stream Mach number in the range of 0.6 to 1.0 there ts a correspondtng supersonic free stream Mach number at which the local Mach number distribution is identical. Thts local Mach number distribution was converted to p_L / p^* values and checked against experimental work by Griffith at Princeton. (Contractor's abstract)

INVESTIGATION OF WEDGES AT SMALL ANGLE OF ATTACK IN TRANSONIC FLOW, by R. W. Truitt. Final rept. May 1955 [74]p. incl. diagrs. refs. (Rept. no. AE641-2) ([AF]OSR-TR-55-14) (AF 18-(600)641) AD 63145 Unclassified

The throat station concept of Tsien and Fejer, combined with the principle of stationarity of local Mach number, ts used to find the pressure dtstributton on the front face of a 2-dimensional wedge in the transonic speed range. The pressure dtstrtbution is deiermined by the von Kármán-Tsien method in the entire subcrttical range. The pressure distribution correspondtng to the throat station crttical Mach number establishes the locatton of the throat station to be near the wedge shoulder. The local Mach number distribution, corresponding to the throat station critical Mach number, remains constant with any further increase in the subsonic free-stream Mach number. Then, by the prtnctple of stationartty, the local Mach number distribution remains stationary in the supersonic range if the detached shock is normal. The method is applied to the theoretical incompressible pressure distribution of a simple 2-dtmenstonal wedge up to the throat station crttical Mach number. The constant p_L / p^* distribution, correspondtng to this Mach number, ts used tn the Maccoll-Codd method to determine the pressure drag coefftcient tn the transonic range. Under the assumption of small angle of attack, the present method is used to find the slope of the lift curve, the pressure drag owing to angle of attack and the front-wedge center-of-pressure in the transonic range. The results of the present method are presented tn transonic similarity form, and compared wtth existing theoretical and experimental results. In general, ths agreemsnt of the present method with other ftndings is good. (Contractor's abstract)

DETERMINATION OF THE TRANSONIC PRESSURE DRAG ON WEDGES BY THE THROAT STATION METHOD (Abstract), by R. W. Truitt [1955] [2]p. [AF 18(600)641] Unclassified

Presented at meeting of the Div. of Fluid Dynamics of ths Amsr. Phys. Soc., Old Point Comfort and Langley Aeronautical Lab., Va., Nov. 22-24, 1954.

Published tn Phys. Rev., v. 98: 1139-1140, May 15, 1955.

The throat station concept of Tsten and Fejsr, combined wtth the prtnctple of stationartty of the local Mach number, ts used to find the pressure drag on the front face of a two-dimensional wedge in the transonic speed range. The pressure dtstribu'ion ts dstermined by the von Kármán-Tsien method in the entire subcrttical range; the pressure dtstrtbution at the crttical Mach number establishes the location of the throat station at the wedge shoulder. The local Mach number

distribution, corresponding to the critical Mach number, remains constant with any further increase in the subsonic free-stream Mach number. Then, by the principle of stationarity, the local Mach number distribution remains stationary in the supersonic range if the detached shock is normal. The method is applied to the theoretical incompressible pressure distribution of a simple two-dimensional wedge up to the critical Mach number. The constant p_l/p distribution, corresponding to the critical Mach number, is used in the Maccoll-Codd method to determine the pressure drag coefficient in the transonic range ($-0.69 \leq \xi_0 \leq 1.1$). The results of the present method are presented in transonic similarity form and compared with existing theoretical and experimental results. The agreement of the present method with other findings is good.

TRANSONIC LIFT OVER THE FRONT SURFACE OF A TWO-DIMENSIONAL DIAMOND AIRFOIL, by R. W. Truitt. Dec. 6, 1954 [2]p. incl. illus. [AF 18(600)-641] AD 73149 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 22: 342-343, May 1955.

In this study, the throat station concept of Tsien and Fejer (A Method for Predicting the Transonic Flow over Airfoils and Similar Bodies from Data Obtained at Small Mach Numbers, GALCIT, Dec. 1944) combined with the Maccoll-Codd Method (Theoretical Investigations of the Flow Around Various Bodies in the Sonic Region of Velocities, Ministry of Supply, Armament Research Dept., Sept. 1945) are used to obtain the transonic chordwise lift distribution over the front surface of a symmetric diamond wedge at a small angle of attack. The present method is applied to the theoretical incompressible pressure distribution for the front surface of a symmetrical diamond ($\theta = 10°$) at 1° angle of attack. Results obtained indicate that: (1) The subsonic peak in the lift-curve slope arises primarily from the front wedge pressures. The subsonic reduced Mach number at the peak ($\xi = -0.983$) corresponds to the attainment of the Mach number freeze. (2) The curve of the lift-curve slope vs Mach number has a negative slope as long as the Mach number freeze persists. Excellent agreement with the theoretical value is obtained by the present calculated negative slope at $\xi_0 = 0$. (3) The change with Mach number of the pressure-drag coefficient owing to lift for a given angle of attack has the same type of variation as the curve of lift-slope vs Mach number. (4) By using the present method, the second or supersonic peak in the lift-slope curve can be anticipated for increasing Mach numbers above $Mo_{U.L.}$, the upper limit of the freeze for the wedge semiangle θ. Both the subsonic and supersonic peaks, therefore, result primarily from the flow over the front wedge.

TRANSONIC LIFT OVER THE FRONT SURFACE OF A SYMMETRIC DIAMOND WEDGE, by R. W. Truitt. [1956] 14p. incl. illus. (AF 18(600)641) Unclassified

Published in Proc. Fourth Midwestern Conference on Fluid Mechanics, Purdue U., Lafayette, Ind. (Sept. 8-9, 1955), Lafayette, Purdue U. Engineering Experiment Station (Research Series no. 128), [1956] p. 245-258.

The throat station concept, combined with the Maccoll-Codd method, is used to obtain the transonic chordwise lift distribution over the front surface of a symmetric diamond wedge at small angle of attack. The results given in transonic similarity form include the chordwise lift distribution, the variation of the lift-curve slope and the center-of-pressure position, in the reduced free-stream Mach number range ($-1.5 \leq \xi_0 \leq 0.983$). The present results are compared with existing experimental and theoretical findings. On the basis of the present results, it is found that the subsonic peak in the lift-slope curve is due primarily to the flow over the front-wedge. (Contractor's abstract)

ENERGY TRANSFER IN THE HIGH INTENSITY ARC. PART I. A STEADY STATE TREATMENT OF ENDOTHERMIC PROCESSES NEAR THE ANODE SURFACE, by M. A. Marquis, L. Mead and others.

VIT. 01:002

PART I. A STEADY STATE TREATMENT OF ENDOTHERMIC PROCESSES NEAR THE ANODE SURFACE, by M. A. Marquis, L. Mead and others. Apr. 16, 1956 [19]p. incl diagrs. tables. (AFOSR-TN-56-178) (AF 18(603)3) AD 87051 Unclassified

Conditions are defined for the steady-state or time-independent behavior of the high-intensity arc. The measured properties of the high-intensity arc agreed well with the requirements of steady-state behavior. The establishment and maintenance of an anode vapor phase independent of input power and time requires that a constant total amount of energy be expended per gram of anode material. The quantity of radiant energy originating from each gram of vaporized anode material should be independent of power input and time. Values of the 2 steady-state energy requirements are derived from the experimental data. A detailed energy distribution in terms of a single parameter is obtainable for a specified set of endothermic processes and a model anode. A series of values of the parameter fixes corresponding values of the percentage ionization of C atoms, the average excitation energy per neutral specie, and the average over-all temperature of the gas phase. Based on the calculated quantities, an energy distribution characterized by 15% ionization of C atoms appeared to be favored. (ASTIA abstract)

ENERGY TRANSFER IN THE HIGH INTENSITY ARC. PART II. QUALITATIVE THEORY OF THE ANODE SHEATH, by L. Mead, M. A. Marquis and others. [1956] [20]p. incl. diagrs. refs. (AFOSR-TN-56-179) (AF 19(603)3) AD 87052 Unclassified

A theory is described for the energy-transfer mechanism in a high-intensity arc. The phenomena of interest occur in a very thin region adjacent to the anode terminus of the discharge called the anode fall space (sheath). Modifications are proposed for Finkelnburg's theory (Jour. Appl. Phys., v. 20, no. 5, 1949) of the anode mechanism which involves a transfer of energy to the anode itself and to the vapor of the anode in the region of the fall space. A preliminary calculation is summarized of the potential distribution based on the modified theory. The modifications appeared adequate in explaining the superheating effect, the rise in anode potential, and the positive resistance characteristics in the high-intensity arc. A possible approach in overcoming the high-temperature barrier is the use of high-speed electronic measuring techniques. (ASTIA abstract)

GENERAL APPROXIMATION THEORY FOR COMPRESSIBLE LAMINAR AND TURBULENT BOUNDARY-LAYERS WITH RESPECTATION OF FLOW-EFFECTS NORMAL TO THE WALL ACROSS THE BOUNDARY-LAYER (INVESTIGATIONS ON AN IMPROVEMENT OF KNOWN APPROXIMATION-METHODS OF BOUNDARY-LAYER CALCULATION), by A. Walz. Final rept. Aug. 1, 1954-Nov. 30, 1955 [122]p. incl. diagrs. tables, refs. [AFOSR-TR-56-13] (AF 61(514)738-C)
AD 86312 Unclassified

An approximate solution of the general equations of Navier and Stokes is given in which the partial differential equations are transformed into an infinite system of ordinary differential equations by partial integrations in the y direction. By limiting the investigation to 2 dimensions, only 4 of the infinite number of equations are physically meaningful: the momentum- and energy-law equations in the x and y directions, averaged over the boundary-layer thickness. The analysis is further restricted to a study of 3 boundary-layer parameters: the boundary-layer thickness, the form parameter of the velocity-profile, and the pressure difference between the edge of the boundary layer and the wall. Practical boundary-layer calculations are conducted by an iterative procedure, and when the correction terms are relatively small, the first approximation is given by the result of usual approximation theories based on the Prandtl boundary-layer theory. The example of a supersonic flow with following shock wave and measured pressure difference between the edge of the boundary layer and the wall shows satisfactory agreement between the theoretical result for this pressure difference and experiment. The theory permits the treatment of the problem of reciprocal effects between the boundary layer and the pressure distribution of a flow-body section in a manner such that the pressure distribution determined from the first approximation of the pressure difference is the base of a repeated boundary-layer calculation.

WORK FUNCTION OF CADMIUM, by P. A. Anderson. [1955] [2]p. incl. diagr. [AFOSR-TN-54-266] [AF 18(600)699] Unclassified

Published in Phys. Rev., v. 98: 1739-1740, June 15, 1955.

The contact difference of potential Cd-Ba is measured by the electron beam and Kelvin methods. These measurements agree within the limits of reproducibility of either method alone and yield a work function value of 4.08 ± 0.02 ev for the work function of cadmium films deposited on tantalum. The barium surfaces, formed by redistillation following fractional distillation, show their characteristic constancy and reproducibility to ± 0.01 ev. Cadmium retains some gas after exhaustive multiple distillation. Measurements taken immediately after deposition of a Cd film and during its aging show: (1) that freshly deposited Cd films are generally contaminated with gas which distills with the metal; (2) that the adsorbed gas is removed progressively by getter clean-up with an attendant rise in work function totaling 0.10 ev in extreme cases; and (3) that the work function thus established is constant and reproducible to 0.03 ev or better. Comparison of these measurements with our earlier work on zinc leads to the conclusion that a cadmium surface in equilibrium with the residual gas of a well-gettered tube contains so little adsorbed gas that its final work function can probably be accepted as characteristic of the clean metal. WORK FUNCTION OF LEAD, by P. A. Anderson and A. L. Hunt. [1956] [2]p. incl. diagrs. [AF 18-(600)699] Unclassified

Published in Phys. Rev., v. 102: 367-368, Apr. 15, 1956.

The work functions of twelve lead surfaces have been determined by measurement of their contact differences of potential with respect to barium reference surfaces of known work function. The lead surfaces were prepared by subjecting Hilger's spectroscopic lead to intensive outgassing followed by fractional distillation, redistillation, and deposition on glass targets. The barium surfaces were prepared by a similar standardized technique which yields surfaces constant and reproducible to 0.01 ev. Measurement was by the electron beam method, and the time lapse between deposition and measurement of a fresh surface was five seconds. The contact difference of potential for Ba - Pb is found to be 1.48 ± 0.01 v. The work function of lead, referred to a Ba work function of 2.52 ev, is then 4.00 ± 0.02 ev. No drift of work function exceeding 0.01 ev was found on aging. Since the minimal time required for deposition of a monolayer of gas is large with respect to the metal deposition-measurement interval, it is concluded (1) that the film of gaseous contaminants adsorbed by a lead surface during equilibration is insufficiently dense to affect the work function, and (2) that the observed work function is probably characteristic of clean lead. AUTOMORPHISMS GENERATED BY A CLASS OF SUBNORMAL SUBGROUPS, by F. Haimo. Mar. 1953, 10p. (AF 18(600)419) Unclassified

Also published in Duke Math. Jour., v. 21: 349-354, June 1954.

The author shows that the well-known result "that every normal subgroup of a group gives rise to an Abelian group of automorphisms of the group" is implied by the following: that to each of a large class of subnormal subgroups of a group G is associated an ascending chain of groups of automorphisms, the first of which is nilpotent, the rest solvable, and the number of groups in this chain depends upon how much of the ascending central series of G lies in the subnormal subgroup.

INVESTIGATION OF ANALYTIC CONTINUED FRACTIONS AND GROUP THEORY, by F. Haimo, W. J. Thron, and R. A. Moore. Final rept. June 30, 1953, 6p. (AF 18(600)419) Unclassified

The investigators here summarize their accomplishments under the contract. W. J. Thron prepared a joint paper (with V. F. Cowling) on Zero Free Regions of Polynomials. Thron's investigations on the location of singular points of functions represented by continued fractions yielded partial results. R. A. Moore studied the oscillation and boundedness of solutions of a certain self-adjoint differential equation. Some results of Leighton and Hille were extended, and a number of equivalent systems of first-order equations were studied. F. Haimo obtained results on semi-direct group products, on group holomorphs, on fixed points of central automorphisms, on automorphisms generated by a class of subnormal subgroups, and on non-abelian complete groups.

SOME NON-ABELIAN EXTENSIONS OF COMPLETELY DIVISIBLE GROUPS, by F. Haimo. Technical note. [1954] 6p. (AF 18(600)419) AD 46165 Unclassified

Also published in Proc. Amer. Math. Soc., v. 5: 25-28, Feb. 1954.

It has been shown by Baer that those Abelian groups G which are direct summands of every including Abelian group are precisely those Abelian groups G for which nG = G for every positive integer n. The latter class of groups consists of the so-called complete or infinitely divisible Abelian groups. Examination of the proof of the equivalence of these two classes discloses essential difficulties in the way of extension to the non-Abelian case. Once "complete" is defined suitably for these latter groups, the following can be proved: Let H be a complete group interpolated into the ascending central series of a group G. Let K be a subgroup, maximal with respect to the property of meeting H or that portion of the ascending series of G below H. Then if N(K) is the normalizer of K in G, N(K) = H + K. This result seems to be the natural extension of half of the Baer theorem to the non-Abelian case.

UNIVALENT FUNCTIONS AND LINEAR DIFFERENTIAL EQUATIONS, by Z. Nehari. Technical rept. June 1953, 18p. (AF 18(600)568) AD 28473 Unclassified

Also published in Lectures on Functions of a Complex Variable, by W. Kaplon, ed. Ann Arbor, Michigan U. Press, 1955, p. 49-60.

Consideration is given to a connection which exists between univalent functions and linear differential equations of the second order. The theory of univalent functions in a domain D is said to be equivalent to the theory of the equation

(1) $u''(z) + p(z)u(z) = 0$, where $p(z) = 1/2 \{f(z), z\}$, $f(z) = \frac{u(z)}{v(z)}$, and u(z) and v(z) are 2 analytic functions defined in D, whose coefficient p(z) is regular in D and whose solutions do not vanish in D more than once. This equivalence provides a new approach to the investigation of univalent functions since the methods available for the study of the zeros of the solutions of (1) are very different from those generally used in the theory of univalent functions. The results are said to be independent of any particular normalization of the schlicht function, since the Schwarzian derivative is invariant with respect to a general linear transformation. Consideration is given to the proposition: if $\sigma(z)$ is regular and not zero on a connected set T in the domain of regularity of u(z), then the function v(z) defined by $u(z) = \sigma(z) v(z)$ has on T the same zeros as u(z), and it satisfies the differential equation

$$(\sigma^2 v')' + (p\sigma^2 + \sigma\sigma'')v = 0.$$

Theorems attendant to the analysis are presented. (ASTIA abstract)

POWER-TYPE ENDOMORPHISMS OF SOME CLASS 2 GROUPS, by F. Haimo. Technical note. July 1953, 15p. (AF 18(600)568) AD 46168 Unclassified

Also published in Pacific Jour. Math., v. 5: 201-213, June 1955.

Abelian groups possess a class of endomorphisms of the form $x \rightarrow x^n$ for each integer n. In general, however, non-Abelian groups do not possess such power endomorphisms. In an earlier note, it was possible to show for a nilpotent group G with a uniform bound on the size of the classes of conjugates that there exists an integer $n \geq 2$ for which the mapping $x \rightarrow x^n$ is an endomorphism of G into its center. Endomorphisms of some groups of class 2 which induce power endomorphisms on the factor-commutator groups are considered. In particular, it will be shown, under suitable uniform torsion conditions for the group of inner automorphisms, that such power-type endomorphisms form a ring-like structure. Let G be a group of class 2 for which Q the commutator subgroup, has an exponent. Then the relation $(xy, u) = (x, u)(y, u)$ shows that $x \rightarrow (x, u)$ is an endomorphism of G into Q for fixed $u \in G$. Let n be any integer such that $n(n-1)/$ is a multiple of the exponent of Q. Then the mapping $x \rightarrow x^n(x, u)$ is a trivial example of a power-type endomorphism. If G/Q has an exponent m, it will be shown that the number of distinct endomorphisms of the form $x \rightarrow x^j$, where x^j is in the center Z of G, divides m. In particular, if G/Q is an elementary p-group (an Abelian group with a prime p as its exponent), then a non-Abelian group G of class 2 has 1 or p distinct central power endomorphisms. NORMAL AUTOMORPHISMS AND THEIR FIXED POINTS, by F. Haimo. Technical note. Aug. 1953, 30p. (AF 18(600)568) AD 46164 Unclassified

Also published in Trans. Amer. Math. Soc., v. 78: 150-167, Jan. 1955.

The elements of the centralizer T of the group of inner automorphisms J of a group G (in the group A of automorphisms of G) are called the normal automorphisms of G. The center Z of G is the set of all elements of G which are fixed by each mapping from J. Likewise, let B be the set of fixed points held in common by the mappings from T. G/B is Abelian, and the elements of T which induce either the identity or

the involution on G/B form a subgroup W of T. An investigation of the ascendtng centrat sertes of W ts to be made. Just as the ascending centrat sertes $\{ Z_t \}$ is formed over $Z = Z_t$, so an ascending sertes is formed over B. Elements of G lying tn members of thts B-series turn out to be fixed points for high powers of normal automorphisms. For automorphisms which induce the identity on G/Z_n, it is shown that the common fixed points lie tn the centraltzer of Z_n tn G.

ON THE ZEROS OF SOLUTIONS OF SECOND-ORDER LINEAR DIFFERENTIAL EQUATIONS, by Z. Nehari. Technical note. Aug. 1953, 14p. (AF 18(600)568) AD 46033 Unclassified

Also published in Amer. Jour. Math., v. 76: 689-697, July 1954.

An analysis is made of the relation between the analytic function p(z) defined in a domain D of the complex plane and the location of the zeros of the solutions of the dtfferential equation $w''(z) + p(z)w(z) = 0$. Proofs are presented for the following theorems: (1) let p(z) be regular and let $|p(x + iy)| < x\epsilon(x)$ in the half strip $0 \leq x < \infty$, $-1 < y < 1$ $(z = x + ty)$, where $\epsilon(x) \to 0$ for $x \to \infty$; if, for sufficiently small positive η, $\int_0^\infty |xp[x \pm t(1-\eta)]\, dx < \infty$, then $w''(z) + p(z)w(z) = 0$ ts nonosctllatory tn any half strip $0 \leq x < \infty$, $-1 + \delta \leq y < 1 - \delta$, $(0 < \delta < 1)$; (2) if p(z) is regular tn the half strip $0 = x < \infty$, $-1 < y < 1$, and if $a'_1, a'_2, \ldots$ $(a_1 < a_2 < \ldots)$ are the abscissas of the zeros of any solution of $w''(z) + p(z)w(z) = 0$ in this half strtp, then the assumption $|p(x + iy)| < \frac{C}{x^\delta}$, $1 < \sigma < 2$, $0 \leq x < \infty$, $-1 < y < 1$ is incompatible with $a'_n = o(n^{2-\sigma})$; (3) tf p(z) ts regular tn $|z| < 1$ and $\int_0^{2\pi} |p(e^{i\theta})|\, d\theta < \infty$, then $w''(z) + p(z)w(z) = 0$ ts non-osctllatory in $|z| < 1$; and (4) if p(z) is regular in a domatn D bounded by an analyttc Jordan curve C, and $\int_C |p(z)dz| < \infty$, then $w''(z) + p(z)w(z) = 0$ ts nonos-cillatory tn D. THE DECOMPOSITION OF FOURIER SERIES, by I. I. Hirschman, Jr. Technical note. Dec. 1953, 31p. incl. refs. (AF 18(600)568; AD 59692 Unclassified

If $f(\theta) \epsilon L^{\alpha,p}$ if $\| f \|_{\alpha,p}$ is finite where $\| f(\theta) \|_{\alpha,p} = \left(\int_\pi^\pi |f(\theta)|^p |\theta|^{\alpha p} d\theta\right)^{1/p}$, $(1 \leq p < \infty)$, $\| f(\theta) \|_{\alpha,\infty} = \text{essential sup}_{|\theta| \leq \pi} |f(\theta)\, \| \theta |^\alpha$ $(p = \infty)$, and we set $L^p = L^{0,p}$, $\| f \|_p = \| f \|_{0,p}$. Note that if $-\frac{1}{p} < \alpha < 1 - \frac{1}{p}$ then $L^\infty \subset L^{\alpha,p} \subset L^1$.

Let $f(\theta) \epsilon L^1$ and let $f(\theta) \sim \sum_{\nu=-\infty}^{\infty} a_\nu e^{i\nu\theta}$ where $a_\nu = (2\pi)^{-1} \int_{-\pi}^{\pi} f(\theta) e^{-i\nu\theta}\, d\theta$. Then define

$$\Delta_n(\theta) = \begin{cases} \sum_{2^n-1}^{2^n-1} a_\nu e^{i\nu\theta} & n = 1, 2, \ldots \\ a_0 & n = 0 \\ \sum_{-2^{-n}+1}^{-2^{-n}+1} a_\nu e^{i\nu\theta} & n = -1, -2, \ldots . \end{cases}$$

The $\Delta_n(\theta)$'s are blocks from the Fourier series of $f(\theta)$. It has been shown by Littlewood and Paley that if $1 < p < \infty$ then

$$A' \| f \|_p^p \leq \int_{-\pi}^{\pi} \left[\sum_{n=-\infty}^{\infty} |\Delta_n(\theta)|^2 \right]^{p/2} d\theta \leq A'' \| f \|_p^p$$

where A' and A'' are positive constants depending only on p. The work of Babenko suggests that if $1 < p < \infty$, $-\frac{1}{p} < \alpha < 1 - \frac{1}{p}$ then

$$A' \| f \|_{\alpha,p} \leq \int_{-\pi}^{\pi} \left[\sum_{n=-\infty}^{\infty} |\Delta_n(\theta)|^2 \right]^{p/2} |\theta|^{\alpha p} d\theta \leq$$

$A'' \| f \|_{\alpha,p}$ where A' and A'' now depend on p and α.

The present investigation is devoted to proving this inequality, which must occupy a central role in any theory of Fourier series of functions $f \epsilon L^{\alpha,p}$. The proof of this last equation makes use of the complex variable methods of Littlewood and Paley and Zygmund. Application of this equation is made to the theory of fractional integration in $L^{\alpha,p}$. (Extracted from rept.)

AN INTEGRAL EQUATION ASSOCIATED WITH A FUNCTION-THEORETIC EXTREMAL PROBLEM, by Z. Nehari. June 1954 [30]p. [Repl. no. 10] [AFOSR-TN-54-332] (AF 18(600)568)
Unclassified

Presented at the International Congress of Mathematicians, Amsterdam (Holland), Sept. 1954.

Published in Jour. Analyse Math. (Jerusalem), v. 4: 29-48, 1954/55.

Let $L^2(D)$ be the family of functions, single-valued and regular in a finite domain D and square-integrable over the boundary C which consists of a finite number of rectifiable Jordan curves. The starting problem is to minimize $\int_C |f(z)|^2 ds$, $ds = |dz|$, for $f(z) \in L^2(D)$ under the condition that $\int_{C_1} |f(z)|^2 ds = 1$, where C_1 is an assigned subset of D consisting of a finite number of rectifiable Jordan arcs or curves. It is shown that $\int_C |g(z)|^2 ds \geq \lambda_1$ for any admissible g(z), where $\lambda_1 (> 0)$ is the lowest eigenvalue of the integral equation

$$f(\zeta) = \lambda \int_{C_1} K(z, \zeta) f(z) ds,$$

$K(z, \zeta)$ being the Szegö kernel function of $L^2(D)$; the equality can appear only if g(z) is a solution of the integral equation associated with $\lambda = \lambda_1$. On the other hand, the author proves the following result: Let ζ_ν ($\nu = 1, \ldots, n$) be any points in a subdomain D_1 bounded by C_1 of D; then

$$\lambda_1 \sum_{\nu,\mu=1}^{n} a_\nu \bar{a}_\mu K(\zeta_\mu, \zeta_\nu) \leq \sum_{\nu,\mu=1}^{n} a_\nu \bar{a}_\mu K_1(\zeta_\mu, \zeta_\nu)$$

($n = 1, 2, \ldots$), where $K_1(z, \zeta)$ is the kernel associated with D_1 and the a's are indeterminate variables; every inequality is sharp. Analogous problems for the Bergman kernel function are discussed. (Math. Rev. abstract)

A MAXIMUM PROBLEM IN HARMONIC ANALYSIS, by E. Hewitt and I. [I.] Hirschman, Jr. [1954] [13] p. refs. [AF 18(600)568] Unclassified

Published in Amer. Jour. Math., v. 76: 839-852, Oct. 1954.

Let G be a locally compact Abelian group, G^* its character group. Denote by f^* the Fourier transform of the (suitably restricted) function f on G. This paper deals with the cases of equality in the familiar majorisation $\|f^*\|_q \leq \|f\|_p$, where $1 < p < 2$, $1/p + 1/q = 1$, $f \in L_p(G)$ and the norms are the usual ones on the appropriate Lebesgue spaces constructed relative to Haar measures. An $f \in L_p(G)$ for which equality holds is termed maximal in $L_p(G)$. The case in which G is the compact circle group was discussed by Hardy and Littlewood (Math. Ann., v. 97: 159-209, 1926), who showed that, for any p satisfying $1 < p < 2$, the maximal functions in $L_p(G)$ are precisely the scalar multiples of the characters of G. The authors extend this result to arbitrary G, for which it is necessary to introduce the so-called sub-characters: these are the scalar multiples of functions on G, of the form $x \to (x, y)\varphi_A(x)$, where (x, y) is the value at x of the character $y \in G^*$, A is a compact and open subgroup of G, and φ_A is the characteristic function of A. Main theorem: For any p, $1 < p < 2$, the maximal functions in $L_p(G)$ are precisely the scalar multiples of sub-characters and the translates thereof. A preliminary step in the proof is the determination of cases of equality in Hölder's inequality, whilst the main stage invokes complex function theory and the maximum modulus principle in a manner reminiscent of recent proofs of the Riesz Convexity Theorem. Various examples are given: G compact; $G = R^n$; G the additive group of p-adic numbers; and G the direct product of denumerably many copies of the multiplicative group $\{-1, +1\}$. (Math. Rev. abstract)

[THE BASIC EQUATIONS OF ELASTICITY AND METHODS OF ATTACK] Ansätze zur Lösung der Elastischen Grundgleichungen, by K. F. Marguerre. Nov. 1954, 33p. incl. refs. (AF 18(600)568)
Unclassified

In recent days many special problems of 3-dimensional theory of elasticity have been solved (chiefly in the U. S. A.). The methods of attack, apparently varying greatly from author to author, can be shown to be closely related to one another; basically all the different solutions turn out to be built up by a set of potentials. In this study, the procedures of about 50 papers, together with an interesting new one, are discussed in such a way that their interrelations become clear. Elasticity-problems of 2 dimensions (plane and axial symmetry), and 3 dimensions as well as problems of the torsion type, are considered. An appendix gives the necessary rules of vector and tensor calculus. (Contractor's abstract)

A FAMILY OF BEST TWIN CONVERGENCE REGIONS FOR CONTINUED FRACTIONS, by V. Singh and W. J. Thron. June 1954, 11p. (Rept. no. 12) [AFOSR-TN-55-72] (AF 18(600)568) Unclassified

Also published in Proc. Amer. Math. Soc., v. 7: 277-282, Apr. 1956.

Combining methods of the theory of linear fractional transformations and their iteration with an application of Strettjes-Vitali theorem, it has been proved that the continued fraction $1 + K(c_n^2/1)$ converges if for all $n \geq 1$, $|c_{2n-1}| \leq p$ and $|c_{2n} + 1| \leq p$, where $0 < p < 1$. This result gives a set of best twin convergence regions and is an improvement of an earlier theorem by one of the authors (Duke Math. Jour. v. 10: 677-685, 1943) (Contractor's abstract)

WEIGHTED QUADRATIC NORMS AND LEGENDRE POLYNOMIALS, by I. I. Hirschman, Jr. Nov. 1954 [32]p. (Rept. no. 13) [AFOSR-TN-55-73] (AF 18-(600)568) Unclassified

Also published in Canad. Jour. Math., v. 7: 462-482, 1955.

Let $w_n(x) = (n + \frac{1}{2})^{\frac{1}{2}} P_n(x)$ be the normalized Legendre polynomials. If $f(x) \in L^1(-1, 1)$ and if $a_n = \int_{-1}^{1} w_n(x) f(x)\,dx$, then we write $f(x) \sim \sum_0^\infty a_n w_n(x)$. Let T be the linear transformation which carries f(x) into Tf(x) defined (formally by $Tf(x) \sim \sum_0^\infty a_n t_n w_n(x)$, and let $N_{\alpha,\beta}[f] = [\int_{-1}^{1} (1 + x)^\alpha (1 - x)^\beta [f(x)]^2 dx]^{\frac{1}{2}}$, where $-1 < \alpha, \beta < 1$. $N_{\alpha,\beta}$ will also be used to denote the space of functions f(x) for which $N_{\alpha,\beta}[f]$ is finite. The present paper gives a rather general sufficient condition for T to be a bounded linear transformation of $N_{\alpha,\beta}$ into itself if $-\frac{1}{2} < \alpha, \beta < \frac{1}{2}$. Specifically it is proved that if

$$(a.) \quad |t_n| \leq C \qquad n = 0, 1, \ldots,$$

$$(b.) \quad \sum_{2^n}^{2^{n+1}} |t_k - t_{k-1}| \leq C \qquad n = 0, 1, \ldots,$$

then

$$N_{\alpha,\beta}[Tf] \leq D(\alpha,\beta)\, C N_{\alpha,\beta}[f] \quad (-\tfrac{1}{2} < \alpha, \beta < \tfrac{1}{2}),$$

where $D(\alpha,\beta)$ depends only upon α and β. (Contractor's abstract)

A REGULAR SINGULAR FUNCTIONAL, by A. D. Martin. [May 1955] [16]p. [AFOSR-TN-55-84] (In cooperation with Institute for Advanced Study, Princeton, N. J.) [AF 18(600)568 and AF 18(600)1109] Unclassified

Published in Canad. Jour. Math., v. 8: 53-68, 1956.

Extremals exist for quadratic functionals of the type $\int_a^b [r(x)y'^2 + p(x)y^2]\,dx$, with $0 < a < b$, in which $x = 0$ is a singular point of the functional otherwise regular on a closed interval [0, b], if the functions r and p are continuous and positive. The Riccati equation $z' - \frac{z^2}{r(x)} + p(x) = 0$ then has continuous solutions, at least locally; it and its solutions are presumed to be

annihilated if r vanishes, although the functional is much less affected. In order to generalize the Riccati equation $z' - \frac{(z + q(x))^2}{r(x)} + p(x) = 0$, a consideration is made of the functional $J(y)\Big|_a^b = \int_a^b [r(x)y'^2 + 2q(x)yy' + p(x)y^2]\,dx$, a Lebesque integral. The functions r, p, and q are measurable functions defined on $(-\infty, \infty)$, with r and q bounded on bounded subinterval of $(-\infty, \infty)$ and p integrable Lebesgue on each bounded subinterval. A function y is held F_t-admissible on [a, b] if y is absolutely continuous on [a, b] and y'^2 is integrable Lebesgue thereon, and if y (a) = t. F_t [a, b] denotes the class of all functions y which are F_t-admissible on [a, b]. Principal attention is given to cases in which t = 0 or 1. Conjugate points are defined and the necessary conditions and sufficient conditions are established for existence of a minimum limit of $J(y)\Big|_a^b$ among functions F_t-admissible.

THE DECOMPOSITION OF WALSH AND FOURIER SERIES, by I. I. Hirschman, Jr. [1955] 65p. refs. (AF 18(600)568) Unclassified

Published in Mem. Amer. Math. Soc., No. 15, 1955, 65p.

Inequalities are generalized for Fourier series and Walsh expansions of Paley, Littlewood, Riesz, Marcinkiewicz, Babenko and others by introduction of a weighting factor in certain means. The Walsh functions $\psi(k, t)$ $(k = 0, 1 \cdots; 0 \leqq t \leqq 1)$ are defined by $\psi(k, t) = \varphi(n_1, t)\varphi(n_2, t) \cdots \varphi(n_r, t)$, where

$$\varphi(n, t) = \text{sign sin } (2^{n+1}\pi t)$$

and $k = 2^{n_1} + 2^{n_2} + \cdots + 2^{n_r}$ is the dyadic representation of n. If $f(t) \in L(0, 1)$, $c(o) = \int_0^1 f(t)dt = 0$, we have

$$f(t) \sim \sum_0^\infty c(k)\psi(k, t),\quad c(k) = \int_0^1 f(t)\psi(k, t)dt,$$

with the formal decompositions

$$f(t) = \sum_{n=0}^{\infty} fn(t),\quad fn(t) = \sum_{2^n}^{2^{n+1}-1} c(k)\psi(k, t),\quad c(k) = \sum_{n=1}^{\infty} c_n(k),\quad c_n(k) = \int_{2^{-n}}^{2^{-n+1}} f(t)\psi(k, t)dt.$$

Then if $w(\psi) = w_{\alpha, p}(\psi) = \left\{\int_0^1 t^{p\alpha} |\psi(t)|^p dt\right\}^{1/p}$ and $w(a) = w_{\alpha p}(a) = \left\{\sum_{k=0}^{\infty} (k+1)^{p\alpha} |a(k)|^p\right\}^{1/p}$ for functions $\psi(t)$ in (0, 1) or sequences a(k), respectively, it is shown that

(1) $A' \leqq w(F)/w(f) \leqq A''$, $A' \leqq w(C)/w(c) \leqq A''$

when $F(t)^2 = \sum_n |f_n(t)|^2$, $C(k)^2 = \sum_n |c_n(k)|^2$ and $1 < p < \infty$, $-1/p < \alpha < 1 - 1/p$. Further, if $S_m = S_m(t) = \sum_{k=0}^{m} c(k)\psi(k, t)$, $S_\mu = S_\mu(k) = \int_\mu^1 f(t)\psi(k, t)dt$, then $w(S_m) \leqq Aw(f)$ and $w(S_\mu) \leqq Aw(c)$. The case $\alpha = 1$ of the first inequality (1) is due to Paley (Proc. London Math. Soc., v. 34: 241-264, 1932). The results for Fourier series follow a similar pattern. If

$$f(\theta) \sim \sum_{-\infty}^{\infty} a_\nu e^{i\nu\theta}\quad (-\pi \leqq \theta < \pi),$$

we have the decomposition

$$f(\theta) \sim \sum_n \Delta_n(\theta),\quad \Delta_n(\theta) = \sum_{2^{n-1}}^{2^n - 1} a_\nu e^{i\nu\theta} \text{ or } \sum_{-2^{-n+1}}^{-2^{-n}+1} a_\nu e^{i\nu\theta}$$

according as $n > 0$ or $n < 0$. Instead of $w_{\alpha p}$ there is the analogous mean $||\psi(\theta)|| = ||\psi(\theta)||_{\alpha, p} = \left\{\int_0^{2\pi} |\psi(\theta)|^p |\theta|^{\alpha p} d\theta\right\}^{1/p}$, and the analogue of (1) is

(2) $A' \leqq ||F||/||f|| \leqq A''$

when $F(\theta)^2 = \sum_n |\Delta_n(\theta)|^2$. The case $\alpha = 0$ here is due to Littlewood and Paley [ibid., v. 42: 52-89, 1936]. This result is equivalent to (3) $\|T_\epsilon f\| \leqq A\|f\|$, where the transformation $T_\epsilon f$ is defined by $T_\epsilon f \sim \sum \epsilon_n \Delta_n(\theta)$, and ϵ_n is a sequence with values ± 1. The particular case $\epsilon_n = 1$ for $n > 0$, $\epsilon_n = -1$ for $n < 0$ gives $\|\tilde{f}\| \leqq A\|f\|$, where $\tilde{f}$ is the conjugate function of f. This result is due to Babenko (Dokl. Akad. Nauk SSSR, (NS), v. 62:157-160, 1948) and reduces to the theorem of M. Riesz (Math. Z., v. 27: 218-244, 1927) when $\alpha = 0$. The proof of (2) depends on the inequality

$$\int_{-\pi}^{\pi}\left[\int_0^1 |g'(re^{i\theta})|^2 |1 - re^{i\theta}|^{2\alpha}(1 - r)dr\right]^{p/2} d\theta \leqq A\|g(e^{i\theta})\|^p$$

for functions g(z) analytic in $|z| < 1$, a result which generalizes the case $\alpha = 0$ of Paley and Littlewood. This proof does not simplify when $p = 2$, and a special elementary proof is given for this. The inequality (3) is extended to transformation Λf defined by $\Lambda f(\theta) \sim \sum a_\nu \lambda_\nu e^{i\nu\theta}$ in which the sequence

WAS. 02:021 - WAS. 02:023

λ_ν is bounded and of bounded variation in ranges $(\pm 2^k, \pm 2^{k+1})$, the case $\alpha = 0$ being due to Marcinkiewicz (Studia Math., v. 8: 78-91, 1939). (Math. Rev. abstract)

QUADRATIC FUNCTIONALS WITH A SINGULAR END POINT, by W. Leighton and A. D. Martin. [1955] [30]p. [AF 18(600)568] Unclassified

Published in Trans. Amer. Math. Soc., v. 78: 98-128, Jan. 1955.

The authors consider the functional

$$J(y)\Big|_e^b = \int_e^b (ry'^2 - py^2)dx,$$

where $0 < e < b < d$, where $r(x)$ and $p(x)$ are continuous functions of x in $0 < x < d$, and the integral is an L-integral, in a further development of a previous paper by M. Morse and W. Leighton (Trans. Amer. Math. Soc., v. 40: 252-286, 1936) in which $p(x)$ was assumed to have a constant sign in a neighborhood of $x = 0$. This hypothesis is removed. A function $y(x)$ is said to be F-admissible in $[0, b]$ if 1) $y(x)$ is continuous in $(0, b]$ and $y(b) = 0$; 2) $y(x)$ is AC and y'^2 is L-integrable on each closed subinterval of $(0, b]$. In addition, if $y(x)$ is also bounded in $[0, b)$, or continuous in $[0, b]$ with $y(0) = 0$, then $y(x)$ is said to be F'-, or A-admissible, respectively. The authors seek necessary and sufficient conditions in order that $\liminf J(y)\Big|_x^b \geq 0$ as $x \to 0+$, for all $y(x)$ which are F-, or F'-, or A-admissible in $[0, b]$. Then $J(y)$ is said to possess a F-, or F'-, or A-minimum limit in $[0, b)$. The point $x = 0$ is, in general, a singular point. Here are some main results: I. If $[0, b)$ contains no focal point of the y-axis, then $J(y)$ possesses an F-minimum limit (variable end-point problem). II. If $[0, b)$ contains no conjugate point of $x = 0$ and $\int_x^b p(x)dx = 0(1)$ as $x \to 0+$, then $J(y)$ possesses an A-minimum limit (fixed end-point problem). (Math. Rev. abstract)

TWO PARAMETER MOMENT PROBLEMS, by A. Devinatz. Aug. 16, 1956 [18]p. refs. [AFOSR-TN-56-240] (AF 18(600)568) AD 88360 Unclassified

Also published in Duke Math. Jour., v. 24: 481-498, Dec. 1957.

According to Stieltjes, a necessary and sufficient condition that a sequence of constants $\{\mu(n), N = 0, 1 \ldots\}$ may be written as the integral $\mu(n) = \int_0^\infty x^n \, d\alpha(x)$, where the measure $d\alpha(x)$ is non-negative and bounded. Hamburger stated that a necessary and sufficient condition that there exists a non-negative bounded measure $d\alpha(x)$, such that $\mu(n) = \int_{-\infty}^\infty x^n \, d\alpha(x)$. It is shown that under an additional restriction the 2 parameter analogues of conditions for any finite set $\{\zeta_i\}$ of real numbers ((1) $\sum_{i=0}^n \sum_{j=0}^n \zeta_i \zeta_j \mu(i+j) \geq 0$ and $\sum_{i=0}^n \sum_{j=0}^n \zeta_i \zeta_j \mu(i+j+1) \geq 0$ and (2) $\sum_{i=0}^n \sum_{j=0}^n \zeta_i \zeta_j \mu(i \pm j) \geq 0$) are sufficient to give the 2 parameter analogues of the 2 integral equations, respectively. The additional restriction is put on amounts to demanding uniqueness for the measures which appear in these representations.

NONOSCILLATION AND DISCONJUGACY IN THE COMPLEX DOMAIN, by P. R. Beesack. [1956] [32]p. incl. refs. [AF 18(600)568] Unclassified

Published in Trans. Amer. Math. Soc., v. 81: 211-242, Jan. 1956.

The equation $w''(z) + p(z)w(z) = 0$, with $p(z)$ analytic in domain D, is called disconjugate on D if no solution $w \neq 0$ vanishes more than once in D, non-oscillatory on D if no solution vanishes infinitely often in D. Criteria for disconjugacy or non-oscillation are given: mostly they involve properties of $M(r) = \sup_{|z|=r} |p(z)|$, D being a disk $|z| < R$. Typical results: (A) Disconjugacy holds in $|z| < b \leq 1$ if $(1 - r^2)^2 M(r)$ is nonincreasing for $0 \leq r < b$ and if $y'' + M(r)y = 0$ has a solution which does not vanish for $-b < r < b$. (B) If $(1 - r^2)M(r) \leq n(n+1)$, where n is an odd positive integer, and if b is the least positive zero of $P_n'(r)$, then there is disconjugacy in $|z| < b$. (C) If $y'' + M(t)Y = 0$ has a solution with $y(0) = 0$ and $y(t) \neq 0$ for $0 < t < R$, then there is disconjugacy in $|z| < \frac{1}{2}R$. (E) If D lies in the half-strip $x \geq 0$, $|y| \geq 1$, and includes the real axis $x > 0$, if $|p(x+iy)| \leq \delta(x)$ where $\delta(x) > 0$ as $x \to +\infty$ and $\int_0^\infty x|p(x)|\,dx < \infty$, then there is non-oscillation in D. (A) includes as special cases several

results proved by Z. Nehari (Bull. Amer. Math. Soc., v. 55: 545-551, 1949) or announced by V. V. Pokornyi (Dokl. Akad. Nauk SSSR (N. S.), v. 79: 743-746, 1951). (C) and (D) were also announced by Pokornyi (E) and its method of proof are closely related to work of Z. Nehari (Amer. Jour. Math., v. 76: 689-697, 1954). Many other results are proved, some of them being extensions or refinements of known results. (Math Rev. abstract)

HARMONIC ANALYSIS AND ULTRASPHERICAL POLYNOMIALS, by I. I, Hirschman, Jr. July 1956, 24p. incl. refs. (Bound in Cornell U. Dept. of Math., Ithaca, N. Y. Final tech. rept. on the Symposium on Harmonic Analysis and Related Integral Transforms, Volume I; AF 18(603)12) [AF 18(600)568] Unclassified

The considerable analogy that exists between Fourier series and expansion in terms of the classical polynomials is shown to be applicable to the case of ultraspherical polynomials. The extent of this relationship is demonstrated by a consideration of the douhle convolution structure of the ultraspherical polynomials.

ANGULAR DISTRIBUTIONS OF PROTONS FROM $Na^{23}(d, p)Na^{24}$ and $Ti^{47, 48}(d, p)Ti^{48, 49}$, by M. M. Bretscher, J. O. Alderman and others. June 21, 1954 [7]p. incl. diagrs. table, refs. (Technical rept. no. 1) ([AF]OSR-TN-54-350) [Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)777 and Office of Naval Research under N6ori-11701] AD 57108 Unclassified

Also published in Phys. Rev., v. 96: 103-109, Oct. 1, 1954.

Sodium and titanium targets were bombarded with 10-mev deuterons, and angular distributions of protons from the stripping reaction were observed with arrays of nuclear emulsions. Absorbing foils in front of each emulsion were arranged so that the integrated flux of protons in a limited energy range could be determined. Distributions were found for each of the four most energetic proton groups from sodium, corresponding to Q values of 4.731 (ground state), 4.259, 4.167, and 3.390 mev. The data were compared with the Butler theory, and l_n values of 2, 2, 0, and 0, respectively, were necessary to fit theory to data. With Ti^{47} targets, l_n values of 3, 1 (and 3?), 1, and 1, respectively, were determined for proton groups corresponding to Q values of 8.14, 6.81, 5.83, and 4.83 mev. With Ti^{48} targets l_n values of 3, 1, 1, and either 1 or 2 were determined for proton groups corresponding to Q values of 5.81 (ground state), 4.46, 4.11, and 3.40 mev, respectively, From these data, parity and possible spin values for the various states of Na^{24}, Ti^{48}, and Ti^{49} are deduced. ANGULAR DISTRIBUTIONS IN (d, p) REACTIONS WITH Ti^{47} AND Ti^{48} (Abstract), by F. B. Shull and M. M. Bretscher. [1954] [1]p. incl. table. [AF 18(600)777] Unclassified

Presented at meeting of the Amer. Phys. Soc., Minneapolis, Minn., June 28-30, 1954.

Published in Bull. Amer. Phys. Soc., v. 29: 15, June 28, 1954.

Thin targets of TiO_2 (one with Ti^{47} enriched to 82 percent, another with Ti^{48} enriched to 99 percent) were bombarded with 10.2-mev deuterons. Proton angular distributions were determined by a photographic method. Aluminum foils in front of nuclear emulsion plates served as energy selectors, so that proton groups from various excited states could be studied separately. Comparison with Butler's theoretical curves establishes the angular momentum $l_n\hbar$ for the captured neutron, from which spin and parity of the final nuclear level may be determined. The results are tabulated:

WAS. 03:003 - WAS. 03:005

Reaction	Q value (mev)[a]	l_n	Final spin	Ftnal parity
$Ti^{47}(d, p)Ti^{48}$	8.14	3	0	even

ANGULAR DISTRIBUTIONS OF PROTONS FROM $Cr^{52, 53}(d, p)$-$Cr^{53, 54}$ (Abstract), by A. J. Elwyn and F. B. Shull. [1956] [t]p. [AF t8(600)777] Unclasstfted

Presented at meeting of the Amer. Phys. Soc., New Haven, Conn., June 21-23, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 281, June 21, 1956.

Thin targets of Cr_2O_3, one enriched with 90% Cr^{53} another enriched with 99% Cr^{52}, were bombarded by 10-mev deuterons. Protons corresponding to the formation of the final nucteus tn its ground and various of its excited states were detected by a double proportional counter telescope. Proton energi[illegible]ere selected by means of aluminum foils placed i[illegible]ont of the counter system. Q values were measured and angular distributions of the proton groups were obtatned. Compartson with Butler's theoretical curves establishes the angular momentum $l_n\hbar$ for the captured neutron from which the spin and parity of the ftnal nuclear state may be determtned. The tentative results are given in the following table:

	Q value	$l_n\hbar$	Final spin	Final parity
$Cr^{52}(d, p)Cr^{53}$	5.74	1	3/2	Odd
	5.17	1	1/2, 3/2	Odd
	4.77	3	5/2, 7/2	Odd
	3.43	1	1/2, 3/2	Odd
	7.55	1	0	Even
	6.69	1	0, 1, 2, 3	Even
	6.24	1	0, 1, 2, 3	Even
	4.88	1	0, 1, 2, 3	Even
	4.36	1	0, 1, 2, 3	Even

ELECTRON TRANSFER BETWEEN NAPHTHALENE NEGATIVE ION AND NAPHTHALENE, by R. L. Ward and S. I. Weissman. [1954] [1]p. [AF 18(600)1133] Unclassifted

Published in Jour. Amer. Chem. Soc., v. 76: 3612, July 5, 1954.

The electron-transfer reaction between naphthalene negative ton and naphthalene dissolved tn tetrahydrofuran was examined spectroscopically. When naphthalene was added to a dtlute solution of naphthalene negattve ton, the paramagnetic resonance spectrum of the latter was altered. Addition of a small amount of naphthalene broadened the tndividual hyperftne components. As larger amounts of naphthalene were added to hyperftne components merged into a stngle peak with broad latls exiendtng beyond the region encompassed by the origtnal hyperfine pattern. The ltne-broadening in the presence of naphthalene was ascrtbed to the transfer of electrons from naphthalene negative tons to naphthalene molecules. The method dtd not depend on some method of dtstingutshing reactants from products. The observations revealed directly the quantity of tnterest, the mean ltme during which a particular configuration perststs undisturbed. (C. A., 1955: 8706a)

PARAMAGNETIC RESONANCE ABSORPTION IN GLASS, by R. H. Sands. Mar. 2, 1955 [5]p. incl. diagrs. lable. (Technical repl. no. 1) ([AF]OSR-TN-55-61) (AF 18(600)1133) AD 99521(a) Unclassified

Also published in Phys. Rev., v. 99: 1222-1226, Aug. 15, 1955.

Paramagnetic resonance absorptions occurring with spectroscopic splitting factors of 4 and 6 were noted in all glass samples studied. These were apparently anisotropic g-values for a specific impurity, and the peaks recorded are interpreted as being the result of a distribution of Stark fields over all directions in the glass. Resonances were also recorded having g-values near 2. Nearly all of these showed hyperfine structures characteristic of the known paramagnetic additions in the glasses. The absorption line observed for cupric ions in lattice-modifying positions in a soda-lime-silica base glass has been quantitatively explained, and the parameters compared favorably with those resulting for copper tn the Tutton salts. Also published in Jour. Amer. Chem. Soc., v. 78: 116-120, Jan. 5, 1956.

The stoichiometry, optical absorption spectra, and electrical conductivity of the products of the reaction of metallic sodium with aromatic hydrocarbons tn tetrahydrofuran solution were studied. The results indicate that products contatning 1 mole of sodium/mole of hydrocarbon are formed, tn agreement with the conclustons arrived at by paramagnetic resonance absorption measurements. A relationship was found between the absorpiton spectra of reaction products and thetr parent hydrocarbons. The absorption spectra also were used as an analytical tool for the study of equilibria involving pairs of aromatic hydrocarbons and their corresponding negative tons. The results of these measurements give the following order of increasing electron affinities: benzene ≪ phenanthrene < naphthalene < anthracene, naphthacene. A mechanism is proposed for the reaction of a negative ion hydrocarbon free radical with various reactants, i. e., carbon dioxide, water. (Contractor's abstract)

OPTICAL AND PARAMAGNETIC RESONANCE SPECTRA OF SOME COORDINATION COMPOUNDS, by S. I. Weissman. [1956] [4]p. [Technical repl. no. 7] [AFOSR-TN-55-193] [AF 18(600)1133] Unclassified

Published in Recueil Trav. Chim. Pays-Bas, v. 75: 853-856, June 1956.

A brief description is given of some of the applications of optical and paramagnetic resonance spectroscopy to the study of coordination compounds. The study presented here concerns the chelate compounds of beryllium with dibenzoyl methane, benzoylacetone, and acetylacetone. In some respects, these compounds resemble aromatic hydrocarbons. As in the case of aromatic hydrocarbons, beryllium dibenzoylmethide and beryllium benzoyl acetonate are reduced by metallic sodium in tetrahydrofuran solutions, yielding negative

WAS. 04:005 - WAS. 04:008

ions. The acetylacetonate, however, is not reduced. Paramagnetic resonance measurements indicate that the first-formed compounds are paramagnetic, while those finally produced in the presence of excess sodium are diamagnetic. The optical spectra of the reduction products correspond quite well to a picture in which the singly-charged negative ion contains one electron in the lowest vacant orbital of the chelate, while the doubly-charged negative ion contains 2 electrons in this orbital. The paramagnetic resonance spectra of the singly-charged negative ions of the dibenzoyl methide and benzoyl acetonate are different from each other. The former exhibits a single absorption peak with some signs of a close hyperfine structure (probably from the protons in the molecule), while the latter possesses a spectrum of 4 peaks. These undoubtedly result from interaction with the beryllium nucleus. The separation between peaks corresponds to admixture of a few % of beryllium 2s atomic function in the molecular orbital of the unpaired electron. Apparently in the negative ion of the large dibenzoyl methide complex, the electron resides in the rings. In the smaller benzoyl acetonate, it may be found, infrequently, in the beryllium atom.

DOUBLE-FREQUENCY MAGNETIC RESONANCE IN A FREE RADICAL, by J. H. Burgess and R. E. Norberg. July 11, 1955 [1]p. incl. diagrs. (Technical rept. no. 2) ([AF]OSR-TN-55-267) (Sponsored jointly by [Air Force] Office of Scientific Research under 18(600)1133 and Office of Naval Research) AD 99521(b) Unclassified

Also published in Phys. Rev., v. 100: 752-753, Oct. 15, 1955.

In the course of double resonance experiments on hyperfine components resolvable in aqueous solutions of the free radical ion peroxylamine disulfonate, $ON(SO_3)_2^-$, an unusual distortion of the absorption line shape has been observed. This "bump" occurs at a position dependent both on the intensity of the saturating field and on the 2 applied frequencies. Experiment shows that the effective gyromagnetic ratio of the combined transition determines the direction of the position shift of the bump. Increasing the amplitude of the saturating field, increases both the magnitude of the shift of the bump and the enhancement of the detected transition. An analysis, based on the density matrix equation, leads to an expression for $\chi''(\omega_d)$, the imagtnary component of the susceptibility at the detecting frequency.

MEASUREMENT OF THE RATE OF AN ELECTRON EXCHANGE REACTION BY NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY, by C. R. Bruce, R. E. Norberg, and S. I. Weissman. Nov. 28, 1955 [2]p. incl. diagrs. (Technical rept. no. 5) ([AF]OSR-TN-55-472) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1133, Office of Naval Research, and Atomic Energy Commission) AD 86308(a) Unclassified

Also published in Jour. Chem. Phys., v. 24: 473-475, Feb. 1956.

The electron-exchange reaction between N, N, N', N'-tetramethyl-p-phenylenediamine and Wurster's blue was studied. The method is applicable to reactions in which $k > 3 \times 10^3$ l/mol/sec. This limitation occurs because 1 member of a pair of molecules between which 1 electron-exchange occurs must be paramagnetic. For $k = 3 \times 10^3$ l/mol/sec, contributions of thermal paramagnetic relaxation to the line breadth may become comparable with the exchange contribution.

ISOTROPIC HYPERFINE INTERACTIONS IN AROMATIC FREE RADICALS, by S. I. Weissman. Dec. 19, 1955 [2]p. (Technical rept. no. 11) ([AF]OSR-TN-55-473) (AF 18(600)1133) AD 123638 Unclassified

Also published in Jour. Chem. Phys., v. 25: 890-891, Nov. 1956.

It is shown by a procedure similar to one used by Abragam, Horowitz, and Pryce in their studies of hyperfine structure in paramagnetic ions and atoms that configurational admixture of the type $(\sigma_B)^2(\pi) + \lambda(\sigma_B)(\sigma_A)(\pi)$, the hyperfine interaction is $32\pi/3\sqrt{6}\,\mu_n\mu_e\,\sigma_B(r_n)\sigma_A(r_n)$ where μ_e and μ_n are

magnetic moments of the electron and the nucleus η, and $\sigma(r_\eta)$ is the magnitude of the orbital σ at the position of the nucleus. Since the hyperfine coupling is linear in λ only small admixtures of excited configurations are required to account for the proton hyperfine splittings observed in aromatic free radicals. HYPERFINE STRUCTURE IN THE PARAMAGNETIC RESONANCE OF VANADIUM IONS IN SOLUTION (Abstract), by G. E. Pake and R. H. Sands. [1955] [1]p. [AF 18(600)1133] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Berkeley, Dec. 28-30, 1954.

Published in Phys. Rev., v. 98: 266, Apr. 1, 1955.

Paramagnetic resonances of vanadium ions in aqueous, acetone, and ether solutions have been observed. Although attempts were made at preparing valence states V^{3+}, V^{4+}, and V^{5+} in accordance with the procedures of Freed, solutions corresponding in color to V^{3+} and to V^{4+} both gave the same hyperfine pattern of eight (21 + 1) lines of different individual widths. The hyperfine coupling constant corresponds to about 120 oersteds, with line spacings being progressively larger toward higher fields as expected in second order for a spectrum centered at 3200 oersteds. The coupling is slightly larger for aqueous than ether solutions, which is not unlikely for solvents forming different complexes with the vanadium ions if the electron promotion hypothesis of Abragam and Pryce for the unexpectedly large hyperfine couplings in such ions is valid. Asymmetric component line shapes for certain solvents and temperatures are interpreted as viscosity effects leading to incomplete averaging of an anisotropic spectroscopic splitting factor of the complexed ion.

NUCLEAR MAGNETIC RELAXATION TIMES IN POLYETHYLENE (Abstract), by I. J. Lowe, L. O. Bowen, and R. E. Norberg. [1955] [1]p. (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under [AF 18(600)1133]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago U., Ill., Nov. 25-26, 1955.

Published in Phys. Rev., v. 100: 1243, Nov. 15, 1955.

Direct measurements of T_1 and T_2 for the proton magnetic resonance in polyethylene have been made from observations of Bloch decays and spin echoes produced by microsecond pulses of 30 mc/sec radio-frequency power. Observations were made at temperatures between 240°K and 392°K using the same commercial stock material as Wilson and Pake. The results are in substantial agreement with the relaxation times postulated by Wilson and Pake and show the coexistence of several very distinct T_2's between 260°K and 295°K. The T_2 values measured ranged from 4 microseconds near 240°K to 0.1 second in a molten sample at 392°K. Over much of this temperature range T_1 was measured to be of the order of 0.1 second with T_2 becoming nearly equal to T_1 at 392°K. The short T_2 component visible on the Bloch decays grows progressively weaker as the temperature is raised, becoming nearly undetectable by 340°K. Near 280°K there is a weak "slow-beat" structure on the Bloch decays.

PARAMAGNETIC RESONANCE OF OCTACYANOTUNGSTATE (V), by S. I. Weissman and C. S. Garner. Feb. 6, 1956 [1]p. (Technical rept. no. 6) ([AF]OSR-TN-56-149) [In cooperation with California U., Los Angeles] (Sponsored jointly by Air Force Office of Scientific Research under AF 18-(600)1133 and Atomic Energy Commission under AT(11-1)34) AD 86308(b) Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 1072, Mar. 5, 1956.

The paramagnetic resonance of $K_3W(CN)_8 \cdot 0.55\ H_2O$ and the aqueous solutions are described. At room temperature a polycrystalline sample yields a single, almost symmetrical, resonance. The g value at peak center is 1.98; peak breadth between points of extreme slope is 30 oersteds. An approximately 0.01 M $W(CN)_8^{---}$ aqueous solution yields a symmetrical resonance of three lines, with the central intense peak at g = 1.972 and breadth between points of extreme slope of 9.3 oersteds; the two satellites are 7 ± 3% of central peak intensity and are separated by 52 oersteds. The central peak probably results from ions containing W^{184} which has zero spin and is 86% abundant, while the satellites are the hyperfine components associated with W^{183} which has a spin 1/2 and is 14% abundant. The sharp spectrum of the aqueous solution is briefly discussed, and an attempted measurement of the rate of electron exchange between $W(CN)_8^{---}$ and $W(CN)_8^{----}$ by observation of the spectrum of the former in the presence of the latter is described.

SPIN DENSITY IN NAPHTHALENE NEGATIVE ION,

WAS. 04:013 - WAS. 04:016

by T. R. Tuttle, Jr., R. L. Ward, and S. I. Weissman. July 1956 [1]p. incl. diagr. (Technical rept. no. 8) ([AF]OSR-TN-56-226) (AF 18(600)1133) AD 88035 Unclassified

Also published in Jour. Chem. Phys., v. 25: 189, July 1956.

The paramagnetic resonance absorption of naphthalene negative ion in dilute liquid solution consists of a complex pattern of hyperfine components. The salts of Li and K in solution in tetrahydrofuran, and of Na, K, and Rb in dimethoxyethane yielded almost identical spectra of 17 lines. The 17 hyperfine components resulted from the isotropic part of the interaction between the electronic magnetic moment and the moments of the 8 protons in naphthalene negative ion. Two spectra of both α-deutero- and β-deuteronaphthalene yielded a 15- and 16-line spectra, respectively. When the value at the nucleus in a H atom in its normal state is taken as the unit of spin, the spin densities of α- and β-H were 0.010 and 0.0035, respectively. The sum of the spin densities at the positions of all the H nuclei was 0.054.

C^{13} HYPERFINE SPLITTING IN NAPHTHALENE NEGATIVE ION, by T. R. Tuttle, Jr. and S. I. Weissman. July 1956 [1]p. (Technical rept. no. 9) ([AF]OSR-TN-56-227) (AF 18(600)1133) AD 88036 Unclassified

Also published in Jour. Chem. Phys., v. 25: 189-190, July 1956.

The isotropic hyperfine splitting of naphthalene negative ion containing C^{13} in the α position was measured. The sample contained 53 atom-% of C^{13} in this position. The C^{13} splitting was 7.1 oersteds; this corresponds to a spin density at the C nucleus of 0.056. The spin density at the nucleus for a C atom in the $2s(2p)^3$ configuration was estimated as 4.25. If in the 2σ orbitals involved the respective coefficients of carbon 2s and hydrogen 1s functions were c_1, h_1, and c_2, h_2, the observed C^{13} splitting resulted in $c_1c_2/h_1h_2 = 1.31$.

ELECTRON SPIN RESONANCE AND THE STRUCTURE OF FREE RADICALS, by S. I. Weissman, T. R. Tuttle, Jr., and E. de Boer. Aug. 1956 [4]p. incl. diagrs. refs. (Technical rept. no. 13) ([AF]OSR TN-56-443) (AF 18(600)1133) AD 96786 Unclassified

Also published in Jour. Phys. Chem., v. 61: 28-31, Jan. 1957.

In this study, it is pointed out that the hyperfine structure of the electron spin resonance of a polyatomic free radical yields information concerning the electronic

siructure of the radical. The hyperfine inieraction is conveniently separaied inio an isoiropic and a non-isoiropic pari. Only the former is observed in fluid solutions. From ii ihe value of the eleciron spin density ai ihe position of each magnetic nucleus in the molecule may be deduced. The spin density ai $\vec{r}_0$ is ihe expeciation value of $\sum_k \sigma_{zk}\,\delta(\vec{r}_k - \vec{r}_0)$, where σ_{zk} is the Pauli operaior for z componeni of spin of the k^{th} eleciron and r_k iis position. The nonisoiropic part is observable in deiail in diluie single crysiais and in ceriain average properties in rigid glassy solutions. It yields expeciaiion values of $\sum_k \frac{\sigma_{zk}(3\cos^2\theta_k - 1)}{|\vec{r}_k - \vec{r}_0|^3}$ θ_k is the angle beiween $r_k - r_0$ and the exiernal magnetic field. if the elecironic wave function of a free radicai is represenied by a single configuraiion consisting of filled orbitals and one singly occupied orbital, the spin densiiy ai each poini is proportional io the square of the ampliiude of the singly occupied orbiial ai thai poini. in planar aromatic free radicals the unpaired eleciron is usually placed in a π orbiial which yields zero spin density in ihe plane of ihe molecule; neverineless, experimenis reveal nonvanishing spin densities in the molecular plane for many aromatic free radicals. These are inierpreied ihrough admixiure of configuraiions coniaining unfilled σ orbiials. The coniribuiion of such an admixiure io spin density is linear in the ampliiude of ihe admixiure. The above consideraiions apply to ihe proion and C^{13} hyperfine spliiiings in negaiive ion hydrocarbons, iriarylmeihyls, and oiher free radicals. Several examples are discussed. LIGHT-INDUCED PARAMAGNETISM IN CHLOROPLASTS, by B. Commoner, J. J. Heise, and J. Townsend. Dec. 1956 [9]p. incl. diagrs. refs. (Technical repi. no. 1) ([AF]OSR-TN-56-410) (AF 18(600)1592) AD 96219 Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 42: 710-718, Oct. 1956.

Ii was observed thai ihe paramagnetic resonance absorption of suspensions of chloroplasis from iobacco (Nicotiana tabacum (variety Whiie Burley)) ai 35°C increased 3 io 6 times when the suspensions were illuminated. This response was rapid, readily reversible, and recurrent. A maximum was obiained about 20 sec afier onsei of illumination, and decay time in the dark was 50-60 sec with half-times being 8 and 32 sec, respectively. Ii was concluded thai unpaired elecirons associated with either or both an excited siaie of chlorophyll and oxidation-reduction inlermediaies, e.g., diphosphopyridine nucleotide, are ihe cause of the paramagnetic resonance absorption tn tlluminated chloroplasis. Experiments are underway which are designed io idenlify the substances in question, and io describe ihetr relaiionship to the process of photosynthesis.

THE EXCITED ELECTRONIC STATE OF THE 2600 Å TRANSITION IN BENZENE, by A. C. Albrecht and W. T. Simpson. [1953] [1]p. (AF 18(600)375) Unclassified

Published in Jour. Chem. Phys., v. 21: 940, May 1953.

Both molecular-orbttal and valence-bond approximations foi C_6H_6 indicate that ihe ftrst singlet exctted electronic siate is of the symmeiry spectes B_{2u}. Experiments were performed wtth para-disubstituted benzene derivattves, tncluding p-dimethoxybenzene. The results obtatned from the crystal spectrum confirmed the presence of the exctted electronic state tn the spectes B_{2u}. The presence of both "x" and "y" absorption tn the 2280 Å band was demonstrated.

SPECTRA OF SIMPLE AMIDES IN THE VACUUM ULTRAVIOLET, by H. D. Hunt and W. T. Simpson. [1953] [4]p. incl. diagrs. tables, refs. [AF 18-(600)375] Unclassified

Published in Jour. Amer. Chem. Soc., v. 75: 4540-4543, Sept. 20, 1953.

Absorption spectra from 2340 to 1500 Å for dimethylformamide and from 2000 to 1220 Å for formamide each show two broad absorption bands. The absorption maxima for the former are at 1974 and 1621 Å, for the latter at 1717 and 1345 Å. Approximate extinction coefficients for the maxima, Einstein absorption coefficients, etc., are given for the two bands of dimethylformamide. A Rydberg series leading to an ionization potential of 10.2 ev is found for formamide. An orbital energy diagram is presented which accounts for the observations. The longer wave length and shorter wave length bands are assigned as NV_1 and NV_2, respectively, the assignments are discussed, and the effect of hyperconjugation is considered. An improvement in the use of the Lyman source is described, involving the use of a Teflon capillary. (Contractor's abstract)

STRUCTURES AND Π-ELECTRON SPECTRA. II. THE TRANSFORMATION MATRIX, by C. W. Looney and W. T. Simpson. [1954] [8]p. incl. refs. [AF 18-(600)375] Unclassified

Published in Jour. Amer. Chem. Soc., v. 76: 6285-6292, Dec. 20, 1954.

A definite procedure is presented for the construction of a transformation matrix which relates π-electron spectra to structures. Arbitrariness in the transformation matrix which may exist even after the incorporation of symmetry is discussed. A method of removing the arbitrariness is shown, as applied to crystal violet and p-methoxy malachite green. (Contractor's abstract)

STRUCTURES AND Π-ELECTRON SPECTRA. III. TRIPHENYLMETHANE DYES, by C. W. Looney and W. T. Simpson. [1954] [8]p. incl. diagr. tables, refs. (AF 18(600)375) Unclassified

Published in Jour. Amer. Chem. Soc., v. 76: 6293-6300, Dec. 20, 1954.

The results of a spectroscopic investigation of crystal violet, p-methoxy malachite green, malachite green, p-nitro malachite green, and Michler's hydrol blue are presented. The positions, intensities and symmetry classifications of the visible and near ultraviolet bands are given. The observed transition energies and polarizations for crystal violet and methoxy malachite green were used in paper II as input data for a theoretical treatment using the methods of the structure representation. The observed intensities for crystal violet are here used similarly. Using only these input data the transition energies for malachite green, and the intensities for methoxy malachite green and malachite green are here calculated theoretically and compared with experiment. Electric moments of the structures are obtained. The transition energies and intensities of p-nitro malachite green and Michler's hydrol blue are also treated theoretically. Finally a set of relative basicities is deduced from the spectral data, spectroscopic resonance energies are obtained, and heats of carbinol formation predicted. (Contractor's abstract)

THE UNIT-CELL DIMENSIONS AND SPACE GROUP OF 1, 1'-DIETHYL-2, 2'-PYRIDOCYANINA IODINE, by J. D. Turner. [1955] [1]p. (AF 18(300)375) Unclassified

Published in Acta Crystallographica, v. 8: 119, Feb. 1955.

The crystals used in thts study were obtained from a sample prepared by the method of Brooker and Keyes (Jour. Amer. Chem. Soc., v. 57: 2488, 1935). Although most of the crystals were multiple twinned or poorly formed, a few suitable for single-crystal x-ray photographs were found. These were small needles, bounded on the stdes by prominent 110 and $1\bar{1}0$ and small 100 faces, and on the ends by 001 faces. The crystals are deep orange in color and under the polartzing nicroscope show distinct pleochroism, the color varytng from yellow to deep red, with the direction of maximum absorption in the 010 plane approximately -35° from the c axis. Oscillation, rotation, equt-inclination Weissenberg and precession photographs were taken, ustng Cu $K\alpha$ radiation. The cell dimensions were determined from the rotation and zero-level Weissenberg photographs, the camera radius of 57.074 mm having been determined by calibration with sodium chloride. The dimensions of the monoclinic unit cell were found to be: $a_o = 11.94 \pm 0.01$, $b_o = 10.66 \pm 0.02$, $c_o = 12.97 \pm 0.02$ Å, $\beta = 114.6 \pm 0.1°$. Systematic extinctions were found for hkl reflections with h + k odd and for h0l reflections with l odd. The space group must then be either Cc-C_s^4 or C2/c-C_{2h}^6.

The observed density of 1.557 g cm^{-3} agrees well with the density of 1.567 g cm^{-3} calculated on the basis of four formula units per unit cell.

POLARIZATION OF THE 1850 Å BAND OF AMIDES, by D. L. Peterson and W. T. Simpson. [1955] [2]p. tncl. diagr. (AF 18(600)375) Unclassified

Published in Jour. Amer. Chem. Soc., v. 77: 3929-3930, July 20, 1955.

A measurement of the transitional moment-vector dtrection for the ftrst N, V transition tn amtdes was obtatned on sublimated flakes of myristamide, in the region beiween 2300 and 1600 Å with ltght polarized along a and b crystallographic axes which are the prtncipal dtrections. X-ray precesston photographs were utilized in the orienlatton of samples. The optical denstty ratios observed along the principal dtrections over the long-wave-length (1/3 of the main band) were constant at $D_a/D_b = 14.62$; the resulting value for the ortentatton of the electric moment ts $\theta = \pm \arctan 0.262$, where θ is measured from the a axis. From the known crystal structure of myrtsta-mtde, the computed ortentations, tndicative of the amtde group ttself, were 9.1° and 26.7° from the line joining the N and O. These values do not agree with the recent data reported by Ward (Chem. Abstracts, v. 49: 7381a, 1955) whtch inferred that absorptton must be nearly along the C-N ltne of the amide group.

LOW RESOLUTION ELECTRONIC SPECTRUM OF CRYSTALLINE PARA-DIMETHOXYBENZENE WITH APPLICATION TO BENZENE, by A. C. Albrecht and W. T. Simpson. Aug. 1955 [6]p. incl. diagrs. table, refs. (AF 18(600)375) Unclassified

Published in Jour. Chem. Phys., v. 23: 1480-1495, Aug. 1955.

The spectrum of a thin (0.37 μ) crystal of para-dimethoxybenzene for light incident on the 001 plane and polarized along the a and b crystallographic axes is given. From this, approximate spectra are deter-mined for the two in-plane directions of the molecule. Absorptton at 2900 Å is polarized predominantly in a direction perpendicular to the line joining the substituents while absorption at 2350 Å is parallel to this line. The 2600 and 2000 Å absorptions tn benzene are related respectively to the 2900 and 2350 Å bands in

dimethoxybenzene and consequently the benzene bands are found to arise from transition to upper states of species B_{2u} and B_{1u} respectively. The relation to conventional orbital theory is briefly discussed. (Contractor's abstract)

RESONANCE FORCE THEORY OF CAROTENOID PIGMENTS, by W. T. Simpson. [1955] [5]p. incl. diagrs. refs. (AF 18(600)375) Unclassified

Published in Jour. Amer. Chem. Soc., v. 77: 6164-6168, Dec. 5, 1955.

A theory of the electronic spectra of carotenoid pigments is presented in which the double bonds are treated as quasi independent weakly interacting systems. The excited states are described as derived from an n-fold degenerate manifold, where n is the number of double bonds. The states split under a perturbation patterned after simple electrostatic resonance interaction. A number of experimentally observed phenomena are considered including the positions of energy levels, the ground state steric configuration, isomerization processes, intensities and intensity changes. MODIFICATION OF THE VECTOR MODEL TO INCLUDE A FIRST ORDER NON-ORTHOGONALITY CORRECTION, by W. T. Simpson. [Mar. 1956] 10p. refs. (AFOSR-TN-56-78) (AF 18(600)375) AD 81530 Unclassified

Also published in Jour. Chem. Phys., v. 25: 1124-1127, Dec. 1956.

When the vector model is used to describe chemical bonding, it appears that the orbitals participating in bond formation are required to be orthogonal. The success of the model on an empirical basis is puzzling because chemical binding will not occur without overlap. In this study the many-electron functions, consisting of products of appropriately overlapping ordinary atomic orbitals, are orthogonalized. The characteristic simple form of the model is then retained provided that the exchange integral is replaced by a corrected exchange integral called a bond integral. The success of the model becomes less puzzling because this integral is usually evaluated empirically. The nature of the bond integral is examined in the framework of the Heitler-London treatment of the H_2 molecule. (Contractor's abstract)

COUPLING STRENGTH FOR RESONANCE FORCE TRANSFER OF ELECTRONIC ENERGY IN VAN DER WAALS SOLIDS, by W. T. Simpson and D. L. Peterson. [1956] [19]p. incl. diagrs. refs. (AFOSR-TN-56-195) (AF 18(600)375) AD 87068 Unclassified

Also published in Jour. Chem. Phys., v. 26: 588-593, Mar. 1957.

The interpretation of the absorption spectrum of a molecular crystal requires a knowledge of the strength of resonance force electrostatic interaction between molecules in the crystal as compared to an energy parameter characterizing the molecular vibrational level pattern. Depending on the relative magnitudes of these energy terms the spectrum reflects absorption by the crystal as a whole or by independent, though oriented molecules. These 2 familiar cases are examined from both stationary state and time-dependent points of view with the object of defining the energy parameters. The resonance force interaction term is a theoretically derived quantity, the crystal electronic band width; the comparable vibrational energy term is shown to be the width of the total electronic band comprising all the vibronic transitions for an isolated molecule. Particular attention is given to the case in which these terms are nearly equal. (Contractor's abstract)

THEORETICAL ELECTRONIC SPECTRUM OF THE ALLYL SYSTEM, by H. D. Hunt, D. L. Peterson, and W. T. Simpson. [June 1956] [17]p. incl. diagrs. tables, refs. (AFOSR-TN-56-285) (AF 18-(600)375) AD 89495 Unclassified

Also published in Jour. Chem. Phys., v. 27: 20-23, July 1957.

Properties of π-electrons in allyl anion, cation, and radical are calculated by including interaction between anti-symmetrized products of molecular-orbital functions. Detailed results in the form of energies and orbital composition of π-electron state function for the anion as well as transition intensities and energies for all 3 molecules, including and excluding configurational interaction, are presented. The extent to which a valence-bond-type wave function resembles an obtained state function is investigated by the computation of overlaps between the 2 functions. The overlaps and energies of various valence-bond-type functions are presented, and suggest a relatively greater applicability of the valence-bond approach in the case of the neutral radical compared to that of the ions. CLASSIFICATION OF π-ELECTRON STATES, by W. T. Simpson. [1956] [6]p. incl. diagrs. refs. (AF 18-(600,375) Unclassified

Published in Jour. Amer. Chem. Soc., v. 78: 3585-3590, Aug. 5, 1956.

A classification of π-electron states is proposed in which two types are distinguished. The first type is described as involving resonance among normal structures. Empirical justification may be found in the spectra of dyes, radicals and aromatic hydrocarbons. The second is described as involving resonance among excited structures. States of this type are reached in transitions in the carotenoid pigments. The spectra of benzene, azulene and naphthalene are examined and the various states classified as belonging to one or the other of the two types under consideration (Contractor's abstract)

CALCULATION OF BOND EIGENFUNCTION MATRIX ELEMENTS WITH THE VECTOR MODEL, by W. T. Simpson. Dec. 1956 [2]p. (AF 18(600)375) Unclassified

Published in Jour. of Chem. Phys., v. 25: 1297-1298, Dec. 1956.

The vector model is generally considered not too well suited for abbreviated valence bond calculations in which not all of a set of interacting linearly independent canonical structures are used. But the model can be adapted to give matrix elements connecting bond eigenfunctions. This is demonstrated with a simple case in which the exchange degeneracy problem is considered for the π electrons in benzene whereby the Kekulé structures are used, but the Dewar structures are omitted.

HYDROGEN SORPTION AND THE PARAHYDROGEN CONVERSION ON EVAPORATED NICKEL FILMS, by J. H. Singleton. Mar. 18, 1957 [6]p. incl. diagrs. tables, refs. [Technical note no. 1] (AFOSR-TN-56-211) (AF 18(600)987) AD 87525 Unclassified

Also published in Jour. Phys. Chem., v. 60: 1606-1611, Dec. 1956.

The changes in electrical resistance of an evaporated Ni film, due to the adsorption and absorption of H, have been studied at -78°. Three processes have been distinguished. Initially, H is irreversibly adsorbed causing a drop in resistance. This is followed by reversible adsorption over a pressure range from 10^{-5} to at least 600 mm, causing an increase in resistance; this adsorbed H is responsible for the parahydrogen conversion. A third type of sorption occurs rapidly at room temperature and to an appreciable extent at -78°, decreasing the resistance of the film and poisoning the catalyst with respect to the parahydrogen conversion. The limitations involved in obtaining evaporated metal films of reproducible properties are discussed. (Contractor's abstract)

NUCLEAR ELECTRIC QUADRUPOLE INTERACTIONS OF B^{11} IN KERNITE (Abstract), by H. L. Blood and W. G. Proctor. [1954] [1]p. [AF 18(600)653] Unclassified

Presented at Meeting of the Amer. Phys. Soc., Seattle, Wash., July 7-10, 1954.

Published in Phys. Rev., v. 96: 861, Nov. 1, 1954.

Kernite, a monoclinic crystal of space group $P2/c$, has four molecules $Na_2B_4O_7 \cdot 4H_2O$ in a unit cell. Rotation of the crystal about the symmetry axis when perpendicular to a strong magnetic field H_0 reveals a pattern of 11 lines for the transitions between the magnetic energy levels of B^{11} ($I = 3/2$), strongly perturbed by the nuclear electric quadrupole interaction. Rotation about an axis perpendicular to the symmetry axis reveals a pattern of 21 lines, which, when related to the above, establish four non-equivalent sites for the boron nuclei in the unit cell. One rotation is sufficient to specify the electric field gradient tensor (except for signs) at a nuclear site if, as is the case for two of the sites, the transitions are such that second perturbation methods may be used in the analysis. In this way we have obtained a tentative value for the quadrupole coupling constant at one site to be 1250 kc. Rotation about a third axis is now in progress.

A NOTE ON THE STRUCTURE OF KERNITE, by H. L. Blood and W. G. Proctor. Mar. 1955, 4p. incl. tables. ([AF]OSR-TN-55-35) (AF 18(600)653) AD 58380 Unclassified

A study was made of the nuclear electric quadrupole interactions of B^{11} and Na^{23} in a single crystal of kernite, $Na_2B_4O_7 \cdot 4H_2O$, the low hydrate of the sodium biborates, using nuclear magnetic resonance techniques. Analysis of the frequency dependence of the various transitions involved upon crystal orientation in the magnetic field was carried out according to the theory of Volkoff (Canad. Jour. Phys., v. 31: 820, 1953). The analysis shows that there are 4 nonequivalent sites for B in the tetramolecular unit cell. Two of these sites have strong quadrupole interactions, and 2 have relatively weak interactions as shown by the magnitudes of the quadrupole coupling constants. Furthermore, there are 4 B atoms associated with each site, the positions of 2 being obtained from each other by inversion through the center of symmetry, and the positions of the remaining 2 being obtained from these by rotation about the 2-fold symmetry axis. Tabular data present for each site the absolute values of the largest quadrupole coupling constant and the eigenvalue of the electric field gradient tensor, the asymmetry parameter, and the orientation of the principle electric axis. It is pointed out that the present data conflict seriously with the kernite model proposed by Pertoles.

NUCLEAR ELECTRIC QUADRUPOLE INTERACTIONS OF Rb^{87} IN A RUBIDIUM TUTTON SALT (Abstract), by R. F. Kiddle and W. G. Proctor. [1955] [1]p. ([AF]OSR-TN-55-128) [AF 18(600)653] Unclassified

The splitting of the normal nuclear Zeeman spectrum of Rb^{87} by the interaction of the electric quadrupole moment with the electric field gradients in a single crystal of the monoclinic Tutton salt $Rb_2Mg(SO_4)_2 \cdot 6H_2O$ has been observed with a nuclear induction spectrometer. We find that there are two distinguishable sites in the bimolecular unit cell, as would be expected from the crystal symmetry (P2, a). Analysis with perturbation theory gives a quadrupole coupling constant of 3109 ± 50 kc/sec with an asymmetry parameter η equal to .48 ± .05 for both sites, although the orientations of the principal axes of the field gradient tensor are not identical. From the known value of the Rb^{87} quadruple moment (Q_{zz}) is calculated to be 4.3×10^4 statvolts/cm^2, indicating that the crystal bonding is primarily ionic in character. NUCLEAR QUADRUPOLE THERMAL RELAXATION IN SODIUM CHLORATE, by C. H. Chang. Aug. 1955 [31]p. incl. diagr. table, refs. ([AF OSR-TN-55-401]) (In cooperation with Smith Coll., Northampton, Mass.) (AF 18(600)653) AD 79857 Unclassified

The theory of nuclear quadrupole thermal relaxation in solids is applied to the Cl nucleus in the $NaClO_3$ crystal to determine: (1) theoretical values of the thermal relaxation time as a function of temperature; and (2) the possibility of externally exciting electric quadrupole transitions by the application of ultrasonic waves of appropriate frequency. The calculation of relaxation time is based on a simplified model in which the field-gradient tensor is assumed to have axial symmetry and to be correctly expressed by 2 terms in a Taylor expansion of the distance between the Cl nucleus and a single nucleus that is responsible for the electric field. A semiphenomenological theoretical calculation is made of the temperature dependence of the nuclear electric quadrupole thermal relaxation time. The energy density required in an ultrasonic wave for influencing the thermal relaxation time is of the order of 2×10^{-4} ergs/cu cm/kc over the natural bandwidth for the case of longitudinal waves at liquid-air temperature. At room temperature, the energy required would have to be about 20 times larger; another factor of 20 would be required at each temperature if the excitation is to be transverse rather than longitudinal waves. ULTRASONIC SATURATION OF NUCLEAR MAGNETIC ENERGY LEVELS, by W. G. Proctor and W. A. Robinson. Mar. 1, 1956 [3]p. (AFOSR-TN-56-101) (AF 18(600)653) AD 82014 Unclassified

Also published in Phys. Rev., v. 102: 1183-1184, May 15, 1956.

A change in the population of the nuclear magnetic energy levels of Na^{23} in a single crystal of NaCl was observed as a result of ultrasonic excitation. Tests were performed in a steady magnetic field of 4220 oersteds, and the nuclear magnetic resonance occurred at a frequency of 4.75 mc/sec. Thermal relaxation time was 8 sec at room temperature. A decrease in the $m = +3/2$, $m = -3/2$ population difference for a small range of ultrasonic frequencies centered exactly at twice the nuclear frequency. The difference of frequency values was 4 kc/sec for the population decrease, which was 1/2 of the maximum decrease.

ULTRASONIC EXCITATION OF NUCLEAR MAGNETIC ENERGY LEVELS OF Na^{23} IN NaCl, by W. G. Proctor and W. A. Robinson. [1956] iv. incl. diagrs. tables, refs. [AFOSR-TN-56-465] [AF 18(600)653] AD 97093 Unclassified

Also published in Phys. Rev., v. 104: 1344-1352, Dec. 1, 1956.

The nuclear magnetic levels of Na^{23} in a single crystal of NaCl placed in a strong magnetic field have been saturated by the pure quadrupole transition $\Delta m = 2$, caused by ultrasonic excitation. The observed transition rate has been compared with theoretical expressions to find that the electric field gradient generated at the nuclear site by the lattice distortion is very close to that expected from a simple classical model. Hence the

large covalent and anti-shielding factor required to explain the spin-lattice relaxation time on the basis of the theory of Van Kranendonk (Physica, v. 20: 781, 1954) is not found. Possible reasons for this discrepancy are discussed. (Contractor's abstract)

INFLUENCE OF ULTRASONIC ENERGY ON THE RELAXATION OF CHLORINE NUCLEI IN SODIUM CHLORATE, by W. G. Proctor and W. H. Tantilla. [1956] [7]p. incl. diagrs. tables, refs. [AF 18-(600)653] Unclassified

Published in Phys. Rev., v. 101: 1757-1763, Mar. 15, 1956.

An investigation of the direct and indirect thermal relaxation processes of Cl^{35} in a single crystal of $NaClO_3$ has been made by using pulsed techniques. The temperature dependence of the indirect process has been measured at four temperatures ranging between room temperature and liquid nitrogen temperature. The experimental results are in good agreement with the theoretical results of Chang. The direct process has been studied by introducing into the crystal ultrasonic energy at a frequency equal to the transition frequency between the two quadrupolar energy levels of the Cl^{35} nucleus. The agreement between the theoretical dependence of the direct-process relaxation time as a function of the energy density of the transition-frequency lattice vibration is poor. The experiment, as done, has the basic weakness that the calculated energy density of the introduced lattice vibrations is a function of the phonon relaxation time, T_p, a quantity only poorly known in the most favorable cases. A different method for making the same type of study independent of the phonon relaxation time is discussed. (Contractor's abstract)

ULTRASONIC EXCITATION IN $NaNO_3$ (Abstract), by R. T. Schumacher and W. A. Robinson. [1956] [1 .p. AF 18(600)653] Unclassified

Presented at meeting of the Amer. Phys. Soc., Eugene, Ore., June 21-23, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 254, June 21, 1956.

We have observed the effects of ultrasonic excitation of pure quadrupole transitions of Na^{23} nuclei in a single crystal of $NaNO_3$. Pound has shown that the m = 3/2 to m = 1/2 and m = -1/2 to m = -3/2 transitions are split from the center line by static electric field gradients split from the center line by static electric field gradients. It was observed in the experiment that the magnetic resonance absorption curve of the center line at ν_0 by cw techniques inducing $\Delta m = \pm 2$ transitions between m = 1/2 and m = -3/2 levels by means of an x-cut quartz transducer tuned to $2\nu_0 + \delta$, where δ is the splitting of the satellites from the center line. The strength of the center line absorption signal was observed to vary as a function of power to the transducer in a manner essentially in agreement with the theoretical predictions of m = 1/2, m = -1/2 population difference as a function of m = 1/2 ↔ m = -3/2 transition probability. The experiment also yields information about the phonon relaxation time in $NaNO_3$. Orientation dependence of the center line absorption signal at a single ultrasonic power level will be discussed.

NUCLEAR QUADRUPOLE INTERACTIONS IN TWO TUTTON SALTS, by R. F. Kiddle and W. G. Proctor. [1956] [5]p. incl. diagrs. table, refs. [AF 18(600)653] Unclassified

Published in Phys. Rev., v. 104: 932-936, Nov. 15, 1956.

This paper reports results of nuclear induction experiments on two isomorphic single crystals of Tutton' s salts, $Rb_2Mg(SO_4)_2 \cdot 6H_2O$ and $Cs_2Mg(SO_4)_2 \cdot 6H_2O$, belonging to crystal class $P2_1/a$. The splittings, due to nuclear electri. quadrupole interactions of the nuclear magnetic resonance spectra of Rb^{87} and Cs^{133} observed in these experiments are analyzed by using perturbation theory. Analysis of the data yields a quadrupole coupling constant for Rb^{87} of $|eQq/h| = 3141 \pm 35$ kc/sec, and the asymmetry of the field gradient at the nuclear site is $\eta = (\phi_{xx} - \phi_{yy})/\phi_{zz} = 0.47 \pm 0.01$. The principal axis of the field gradient is directed toward the nearest sulfate ion but no correlation of asymmetry and near neighbor locations is observed. Comparison of the magnitudes of the field gradient at the nuclear sites of Rb and Cs were obtained by comparing the observed line patterns for the symmetry axis rotations, using the known moments of Cs and Rb. The complexity of the Cs spectra precluded a more complete comparison of the electric field symmetry. (Contractor's abstract)

note no. 1) ([AF]OSR-TN-54-329) (AF 18(600)481) AD 53878 Unclassified

This work stems from the original discovery by Fink and Adler that the photocurrent from cuprous oxide photovoltaic cells is increased if the cells have been subjected to a sulfiding treatment so that the top layer of the oxide is converted to cuprous sulfide. A review of information available to date on cuprous oxide is presented, with an analysis and conclusions concerning the band structure of this material. Data from Hall effect and conductivity measurements are combined to yield a value of 2.0 ev for the width of the forbidden region, with acceptor levels at 0.3 ev above the top of the filled band. Sensitivity to method of preparation is discussed. In the expertmental portion, the methods of preparing and sulfiding the cuprous oxide cells are described. The experiments to study the effect of the sulfiding on the response of the cells are described and discussed. It is found that for over-all sulfiding, short sulfiding times yielding thin films of the sulfide give the greater improvement while thicker films may even cause a decrease in output. In further experiments using open mesh top contacts, it is found that the greatest improvement is obtained when there is sulfide only under the contact. It is concluded that the effect of the sulfiding treatment is to create a low resistance ohmic contact. This view is supported by experiments with a moving light probe. Further, various cells were made from isolated films of cuprous oxide by applying silver paint contacts, and studies on these indicate that the ordinary unsulfided contacts are rectifying while the sulfided contacts are nonrectifying. THE MAXIMUM EFFICIENCY OF SOLAR ENERGY CONVERSION BY QUANTUM PROCESSES, by D. Trivich and P. A. Flinn. [1954] 8p. [AF 18(600)481] Unclassified

A method is presented for the calculation of the maximum conversion efficiency of photovoltaic cells considered as converting solar energy into electrical by quantum processes. Mathematical expressions are developed for computing the total useful solar radiation absorbed by such a cell above a threshold frequency ν_0 and for the maximum efficiency for any given value of ν_0. The optimum threshold wavelength of solar radiation received at the earth's surface is found to be about 11,600A°; the efficiency for this choice of threshold is 40% or more. Possible increase in efficiency by use of multiple converters or by minimizing back diffusion is cited, and the calculation of the optimum threshold and efficiency is appended.

ON A PROBLEM OF MINIMAL SURFACE AND OF COMPRESSIBLE FLOW EQUATION WITH POLYGONAL BOUNDARY (I), by Y. W. Chen. Jan. 1954, 45p. ([AF]OSR-TN-54-10) (AF 18(600)437) AD 25396 Unclassified

Presented at meeting of the Amer. Math. Soc., New York, Apr. 23-24, 1954.

Abstract published in Bull. Amer. Math. Soc., v. 60: 338, July 1954.

The problem of a minimal surface in the compressible flow of a gas obeying Chaplygin's approximate adiabatic law is discussed as part of an investigation of a uniform stream disturbed by the presence of a polygonal profile. Solutions with convex polygonal profiles are obtained in the physical plane by a method of conformal mapping which generalizes the classical Schwarz-Christoffel formula.

DEGENERATE SOLUTIONS OF PARTIAL

DIFFERENTIAL EQUATIONS, by Y. W. Chen. June 30, 1954 [7]p. (AF 18(600)437) Unclassified

Published in Proc. Amer. Math. Soc., v. 6: 855-861, Dec. 1955.

The equation of motion of compressible fluids is of the form

$$(*)\quad L(u) = \sum_{i,j=1}^{n} a_{ij}(p_1, p_2, \cdots, p_n)\partial^2 u/\partial x_i \partial x_j = 0$$

$$\left(p_i = \frac{\partial u}{\partial x_i}\right).$$

A solution of (*), whose first partial derivatives satisfy n - s functional relations

$$p_\alpha = F^\alpha(p_1, \cdots, p_s) \quad (\alpha = s+1, s+2, \cdots, n)$$

among themselves is called a "s-tuple wave" (degenerate compressible flow). A necessary and sufficient condition for the existence of a degenerate solution u, of the type of an s-tuple wave, with nonvanishing determinant $|\partial^2 u/\partial x_k \partial x_l|$ is the following: the n - s + 1 functions F^α and G satisfy a system of C(n - 1, s - 1) differential equations of second order and degree s - 1, in the variables p_k,

$$(**)\quad (a_{lk} + 2a_{l\beta}\partial F^\beta/\partial p_k + a_{\alpha\beta}\partial F^\alpha/\partial p_l \partial F^\beta/\partial p_k) P_{lk}^{(m)} = 0$$

with

$$|x_\alpha \partial^2 F^\alpha/\partial p_l \partial p_k + \partial^2 G/\partial p_l \partial p_k| \neq 0.$$

The author introduces new independent variables $x_1', \cdots, x_n'$ and dependent variable $u'(x_1', \cdots, x_n')$ by the elementary contact transformation:

$$x_k' = p_k,\ x_\alpha' = x_\alpha,\ u' = u - p_k x_k,\ p_k' = -x_k,\ p_\alpha' = p_\alpha.$$

Hence one obtains:

$$G(x_1', x_2', \cdots, x_s') = u' - x_\alpha' F^\alpha(x_1', \cdots, x_r').$$

Each $P_{lk}^{(m)}$ is a homogeneous polynomial of degree s - 1 in the second derivatives of F^α and G with integer coefficients. In the case of double waves (s = 2) there are n - 1 equations and the same number of unknown functions $F^\alpha(p_1, p_2)$ and $G(p_1, p_2)$. Centered waves are those with G = 0. An interesting example is given by $L(u) = \Delta^2 u(x_1, x_2, x_3)$. The corresponding equation (**) is the differential equation of minimal surfaces. The solution of the initial-value problem for the functions $F^\alpha(p_1, p_2)$ (s = 2, problem I), which exists uniquely in a neighborhood of the initial curve Γ in the (p_1, p_2)-plane:

$$\Gamma: p_1 = s_1(\tau),\ p_2 = s_2(\tau)$$

gives a solution of the initial-value problem for the unknown function u(x) (in the neighborhood of an initial manifold M_{n-1} in the x-space, problem II). Conversely, one can find by simple means of differentiation and elimination from an unique solution u = U(x) of problem II the solution of problem I. The author discusses especially the case of constant coefficients a_{ij}, L(u) is totally and the initial manifold is "space like". (Math. Rev. abstract)

ON A BOUNDARY VALUE PROBLEM OF MINIMAL SURFACES (II), by Y. W. Chen. Jan. 1955, 28p. ([AF]OSR-TN-55-31) (AF 18(600)437) AD 53871 Unclassifted

Presented at meeting of the Amer. Math. Soc., Pittsburgh, Pa., Dec. 27-29, 1954.

A proof is presented of an existence theorem under very general assumptions on the boundary curves. The theorem is proved for any convex polygon, and the theorem is extended to boundary curves which consist of convex arcs with a finite number of protruding corners. The general case makes essential use of level lines of the harmonic function $-qx(w) + py(w) \pm z^*(w)$; $p+tq = e^{t\alpha}$, where α is arbitrary and $z^*(w)$ is the harmonic conjugate of z(w). Uniqueness is obtained for symmetrical profiles. The behavior of the discontinuity around the corners is studied. A different version of the results is formulated in terms of the conjugate minimal surfaces, and an elementary proof of the existence for a convex symmetrical profile is sketched. (ASTIA abstract)

DISCONTINUITY AND REPRESENTATIONS OF MINIMAL SURFACE SOLUTIONS, by Y. W. Chen. [1955] [24]p. refs. [AF 18(600)437] Unclassified

Published in Proc. Conference on Differential Equations, Maryland U., College Park (Mar. 17-19, 1955), 1956, p. 115-138.

Proof is given of the existence of a solution z(x, y) of the minimal surface equation

$$\left(\frac{z_x}{\sqrt{(1 + z_x^2 + z_y^2)}}\right)_x + \left(\frac{z_y}{\sqrt{(1 + z_x^2 + z_y^2)}}\right)_y = 0,$$

which is defined exterior to a closed convex curve C, such that (i) ∇z tends to a prescribed finite limit at infinity, and (ii) $\partial z/\partial n = 0$ on C in a generalized sense. The curve C is assumed to possess at most a finite number of protruding corners. A motivation for the problem can be found in the fact that solutions of the above equation can be viewed as local approximations

WAY. 02:006 - WES. 01:001

to "subsonic" solutions of the equations

$(\rho z_x)_x + (\rho z_y)_y = 0$,

$$\rho = [1 - \frac{\gamma - 1}{4}(z_x^2 + z_y^2)]^{1/(\gamma-1)} (\gamma > 1),$$

which describes the flow of an ideal compressible fluid. The problem is first solved in terms of uniformizing parametric coordinates (u, v) by means of an established variational procedure. The chief new difficulty is to show that the Jacobian $\partial(x, y)/\partial(u, v)$ does not vanish for this solution. This is done by a careful study of the behavior of the "Tchaplygin function"

$$\zeta = \frac{z_x - iz_y}{1 + \sqrt{(1 + z_x^2 + z_y^2)}}$$

which is an analytic function of u + iv for any solution, and is obviously bounded in magnitude. In the case that C is a convex polygon, the author shows that $\partial z/\partial n$ exists and vanishes at all points of C except at the vertices, where the solution surface necessarily contains a vertical segment. As a corollary of his method, the author shows that the corresponding problem, in which (ii) is replaced by (ii') $z = 0$ on C, admits no solution for any polygonal contour C. (Math. Rev. abstract, modified)

REFLECTION LAWS OF LINEAR DIFFERENTIAL EQUATIONS OF MIXED TYPE, by Y. W. Chen. Aug. 1956, 30p. (AFOSR-TN-56-399) (In cooperation with Calif. U., Berkeley) (AF 18(600)437) AD 96057
Unclassified

A study is made of a simple class of equations of the form $x^s u_{yy} + u_{xx} = 0$, with $s \neq 0$ and of the analytical extension of the solutions. The following theorem is proved: Let $u(x, y)$ be a given solution of class C_2 in a domain $0 < x < 1$, $a < y < b$ with continuous first and mixed 2nd derivatives on $x = 0$, and let $u(0, y) = T_0(y)$, $u_x(0, y) = T_1(y)$. Then (1) $T_0(y)$ and $T_1(y)$ uniquely determine the solution, and (2) when one of the $T_1(y)$ is zero, the other is necessarily an analytic function of y. In the latter case $u(x, y)$ can be extended to become an analytic function of 2 complex variables. The classical reflection principle for harmonic functions ($s = 0$) is generalized.

DISCONTINUITY OF SOLUTIONS OF QUASI-LINEAR DIFFERENTIAL EQUATIONS IN TWO VARIABLES, by Y. W. Chen. [Aug. 1956] [9] p. refs. [AF 18-(600)437]
Unclassified

Published in Commun. Pure and Appl. Math., v. 9: 373-381, Aug. 1956.

Published in Trans. Symposium on Partial Differential Equations, California U., Berkeley (June 20-July 1, 1955), N. Y., Interscience Publishers Inc., 1955, p. 75-83.

This paper consists of two parts. The first part is concerned with hyperbolic differential equations of the following form: $A(p_x, p_y)\, p_{xx} + B(p_x, p_y)\, p_{xy} + C(p_x, p_y)\, p_{yy} + k(p_x, p_y) y^{-1} p_y = 0$. A discontinuity of a second derivative of p propagates along the backward characteristics to a point P on the axis $y = 0$, and the question is how this continuity will be reflected from the axis into the interior of the domain along the forward characteristic issued from P. This paper demonstrates in a very simple manner both the quantitative and qualitative features of the non-linear behavior of the solution, without going into the details of the convergence procedure which is indicated. In the second part of this paper statement is made of an existence theorem for the equation of minimal surfaces, and an outline of the proof is given. The problem is to find a solution $z(x, y)$ of:

$$(1 + z_y^2) z_{xx} - 2z_x z_y z_{xy} + (1 + z_x^2) z_{yy} = 0$$

in the exterior of a convex curve C with a finite number of protruding corners, such that it has a preassigned normal direction at infinity and $\partial z/\partial n = 0$ on C. (Contractor's abstract, modified)

In this study AgBr sols were added to mixtures of NH_3-$Na_2S_2O_3$. The resulting solutions were colorless if the sols had not been exposed to light, but exhibited a yellow-brown color if they had been exposed to a 100-w bulb light source. The absorption spectra of the exposed solutions (photolytic Ag sols), determined with Bechman DU or Model B spectrophotometers, showed a broad peak near 410 mμ which changes shape and decreased in absorbancy over a 24-hr period. Test results indicated that the apparent absorption spectrum is produced by colloidal Ag, thus supporting the latent-image hypothesis. The hypothesis is further strengthened by the results of Van Kreveld and Jurriens (Physica, v. 4: 285, 1937) who measured the decrease in transmittance of a photographic emulsion on exposure.

INVESTIGATION OF PROPOSED HIGH-VOLTAGE BREAKDOWN MECHANISM, by A. I. Bennett, Jr. June 23, 1954, 6p. incl. diagrs. refs. (Repl. no. 71F159-R1) (AF 18(600)793) Unclassified

It is known that if a sufficiently high potential difference is impressed in a pair of electrodes immersed in a high vacuum (i.e., at a pressure < 10^{-6} mm Hg), a catastrophic reaction occurs, culminating in a high-current, low-voltage arc limited primarily by the power supply. Inasmuch as this phenomenon is usually a limiting factor in high-voltage devices employing vacuum tubes, attempts have been made to determine the nature of the mechanism involved in this breakdown. A mechanism of breakdown proposed some time ago by J. G. Trump and R. J. Van de Graaf (Jour. Appl. Phys., v. 18: 327, 1947) is reviewed in the light of recent data which indicate that the process may actually be adequate to explain this phenomenon. The Trump-Van de Graaf explanation envisions an electron, produced perhaps by field emission, leaving the cathode and striking the anode, where there is a finite probability that a positive ion or photon will be ejected. All of the positive ions, and a geometrically-determined fraction of the photons, will in turn impinge on the cathode, releasing some electrons by photoemission or by ion secondary emission. If the average number of such secondary electrons produced/primary electron is > 1, a cumulative process will occur, resulting in breakdown. A proposed experiment is described, by means of which it should be possible to obtain quantitative information about this mechanism. One of the major advantages of the experiment is that data are taken without actually causing breakdown, which if allowed to occur, would probably change the nature of the electrodes, making the results of subsequent experiments different. A disadvantage of the proposed experiment is that the photoelectron production is not measured under conditions of high-cathode gradient such as usually exists in actual high-voltage vacuum installations.

[INVESTIGATION OF PROPOSED HIGH-VOLTAGE BREAKDOWN MECHANISMS], by A. I. Bennett, Jr. Final rept. Dec. 1, 1954, 7p. incl. refs. (Rept. no. 71F159-R2) (AF 18(600)793) AD 51753 Unclassified

This study is concerned with high-voltage breakdown in a vacuum. In this brief review, the following are presented: (1) a description of the basic problem involved; (2) the experimental apparatus used; (3) the experimental and theoretical work performed, and (4) the present and proposed experimental program. It is concluded that the necessary apparatus is available for a series of experiments designed to throw light on the nature of the fundamental processes of high-voltage breakdown. It does not seem likely that an experimental program involving the actual production of successive breakdowns can yield much exact information on the initiation mechanism, since the discharge itself radically alters the properties of the surfaces involved. The absence of actual breakdown is an advantage offered by the present experimental program. It is pointed out that any research on breakdown initiation must include procedures for obtaining and preserving the cleanest possible surfaces. A bibliography of 41 references compiled from published literature, ranging in time from 1922 to 1954, is included.

CHARACTERIZATIONS OF FOURIER-STIELTJES TRANSFORMS, by W. F. Eberlein. Sept. 1, 1954, 5p. (Technical note no. 2) ([AF]OSR-TN-54-242) (AF 18(600)679) AD 44481 Unclassified

Also published in Duke Math. Jour., v. 22: 465-468, Sept. 1955.

A complex-valued function $\phi(x)$ on a locally compact Abelian group G with character group Γ is said to satisfy condition (B) if for some constant M

$$\left| \sum a_n \phi(x_n) \right| \leq M \sup_{\gamma \in \Gamma} \left| \sum a_n (x_n, \gamma) \right|$$

for all finite sets of complex numbers (a_n) and points (x_n) in G. The function ϕ is called a Fourier-Stieltjes transform (F-S) if there exists a bounded Radon measure μ on Γ such that

$$\phi(x) = \int_{\Gamma} (x, \gamma) d\mu(\gamma).$$

The main result is the following theorem: If ϕ is measurable and satisfies (B), there exists a unique Radon measure μ on Γ such that (F-S) holds nearly everywhere in x and $\| \mu \| \leq M_0$, where M_0 is the smallest value of M satisfying B. If ϕ is continuous, then (F-S) holds everywhere and $\| \mu \| = M_0$.

The author establishes a Parseval formula:

$$M(|\tilde{\mu}|^2) = \sum_{\gamma \in G^*} |\mu\{\gamma\}|^2,$$

where μ is a bounded Radon measure on the dual G^* of a locally compact Abelian group G, M denotes the mean value over G, and where $\tilde{\mu}$ is the Fourier transform of μ. The mean value used is that arising in the author's theory of weak almost periodic functions. The crux of the proof lies in showing that, with the mean value thus defined, one has $\mu\{0\} = M(|\tilde{\mu}|)$, a result easily established in the case of the real line owing to the special form of M there applicable. The formula is applied to give rapid proofs and extensions of some known results. (Math. Rev. abstract)

ON WEAK COMPACTNESS IN FUNCTIONAL ANALYSIS, by A. W. Wymore. June 17, 1955, 55p. refs. (Technical note no. 5) ([AF]OSR-TN-55-131) (AF 18(600)679) AD 69754 Unclassified

The theory of weak compactness in linear topological spaces is unified and developed from the point of view of the set of real-valued functions continuous on a compact Hausdorff space with the topology of pointwise convergence. In particular, the role played in the theory by the Lebesgue bounded convergence theorem is studied and generalizations resulting from this study are expounded. (Contractor's abstract)

THE SOLUTIONS OF THE DIFFERENTIAL EQUATION $v''' + \lambda^2 zv' + 3\mu\lambda^2 v = 0$, by R. E. Langer. Mar. 1, 1955 [29]p. (Rept. no. 1) ([AF]OSR-TN-55-70) (AF 18(600)1110) AD 71479 Unclassified

Also published in Duke Math. Jour., v. 22: 525-542, Dec. 1955.

The equation $v''' + \lambda^2 zv' + 3\mu\lambda^2 v = 0$, where μ is arbitrary and λ a complex parameter of large absolute value, has a double turning point at $z = 0$. The author derives asymptotic formulae for the solutions at this turning point. First, the principal solutions (1) $v_j(z)$ $(j = 0, 1, 2)$ are obtained as power series in z. Then for each integral index q a set (2) $v_{q,j}(z)$ of formal solutions in powers of $1/\lambda$ is established which represents actual solutions asymptotically in the sector $(q-1)\pi \leq \arg \zeta \leq q\pi$ $(\zeta = 1/3t\lambda z^{3/2})$ of the z-plane. Between the solutions of the set (1) and those of any set (2) there exist linear relations with coefficients that are independent of z. The main results of this paper consist in the determination of these relations. (Math. Rev. abstract)

THE SOLUTIONS OF A CLASS OF ORDINARY LINEAR DIFFERENTIAL EQUATIONS OF THE THIRD ORDER IN A REGION CONTAINING A MULTIPLE TURNING POINT, by R. E. Langer. May 17, 1955, 29p. (Rept. no. 2) ([AF]OSR-TN-55-143) (AF 18(600)1110) AD 71480 Unclassified

Also published in Duke Math. Jour., v. 23: 93-110, Mar. 1956.

Asymptotic forms of the solutions relative to the complex parameter λ whtch is unbounded in absolute value are determined for the equation

$$\frac{d^3w}{dz^3} + h_1(z,\lambda)\frac{d^2w}{dz^2} + \lambda^2 h_2(z,\lambda)\frac{dw}{dz} + h_3(z,\lambda)w = 0$$

in a region wtth a multiple turning point. The coefftcient functions $h_j(z,\lambda)$, $j = 1, 2, 3$, are expressible tn power sertes in $1/\lambda$ with coefftctents which are analytic functions of z. The forms of the solutions, as they depend asymptotically upon λ, are determined over a region of the complex z-plane which contains a potnt in which the critical coefficient $h_2(z,\infty)$ is zero.

ON THE CONSTRUCTION OF RELATED DIFFERENTIAL EQUATIONS, by R. E. Langer. Sept. 20, 1955, 28p. refs. (Rept. no. 3) ([AF]OSR-TN-55-350) (AF 18(600)1110) AD 75539 Unclassifted

Also published in Trans. Amer. Math. Soc., v. 81: 394-410, Mar. 1956.

A differenttal equation $L(u) = 0$ is said to be "related to" another equation $\mathcal{L}(u) = 0$, tf its solution forms are explicitly known and the coefficients of the 2 equations are the same to an arbttrarily prescribed degree. From the known solution forms of the one equation, the unknown ones for the other equation can be deduced by standard methods. This paper considers the case in

whtch $\mathcal{L}(u) = \frac{d^n u}{dz^n} + \lambda p_1(z,\lambda)\frac{d^{n-1}u}{dz^{n-1}} + \cdots + \lambda^n p_n(z,\lambda)u$,

with λ a large parameter, the regton of the variable z contatning a turning point at which $m < n$ of the roots of the auxtliary algebraic equation cotncide in accordance wtth a certain coincidence pattern. It shows how the related equation may be constructed when such a construction is known for a differential equation of the order m with the same coincidence pattern. This makes theory for lower order differential equations extensible to equations of higher order. (Contractor's abstract)

ON THE ASYMPTOTIC SOLUTIONS OF A CLASS OF ORDINARY DIFFERENTIAL EQUATIONS OF THE FOURTH ORDER, WITH SPECIAL REFERENCE TO AN EQUATION OF HYDRODYNAMICS, by R. E. Langer. Feb. 1, 1956, 72p. refs. (Rept. no. 4) (AFOSR-TN-56-50) (AF 18(600)1110) AD 81042 Unclassifted

Also published in Trans. Amer. Math. Soc., v. 84: 144-191, Jan. 1957.

This mathematical study is concerned with the differential equation $w^{iv} + \lambda^2[P(z,\lambda)w'' + Q(z,\lambda)w' + R(z,\lambda)w] = 0$, in which P, Q and R are power series in $1/\lambda$. The matter at issue is the forms of the solutions when $|\lambda|$ is large and the z-region in question contains a simple zero of $P(z,\infty)$ (a turning point). The limiting equation as $\lambda \to \infty$ in general has a regular singularity at the turning point. When the exponents do not differ by an integer, the differential equation is referred to as a regular type. A general theory of the solution forms to arbitrary powers of $1/\lambda$ is given. When the exponents differ by an integer, the equation is called irregular. There are several categories of irregular equations, and for these, with one exception, the theory is given. The Orr-Sommerfeld equation of hydrodynamics is of this type, and is irregular. The applttcation of the general theory to this equation is discussed. (Contractor's absiract)

The stereochemtstry of the radical-chain addition of hydrogen sulfide, thiophenol and thioacetic acid to

WIS. 03:003 - WIS. 03:005

1-chlorocyclohexene has been investigated. The additions give 1,2-disubstituted cyclohexanes and the configurational compositions of the 1:1 addition products were determined by selective solvolysis of the more reactive trans isomers. Under the conditions of the present experiments the addition of hydrogen sulfide to 1-chlorocyclohexene gives primarily cis-2-chlorocyclohexanethiol, together with small amounts of the trans isomer and a mixture of diastereo isomeric bis-2-chlorocyclohexyl sulfides. The addition of thiophenol similarly results in preponderant formation of cis-2-chlorocyclohexyl phenyl sulfide. The addition of thioacetic acid is less stereospecific than the other additions and gives a mixture of cis- and trans-2-chlorocyclohexyl thioacetates consisting of about 70% of the cis isomer. In each case the stereospecificity apparently depends upon the ratio of addendum of 1-chlorocyclohexene. (Contractor's abstract)

THE STEREOCHEMISTRY OF RADICAL ADDITIONS. II. THE RADICAL AND IONIC ADDITION OF HYDROGEN BROMIDE TO 1-BROMOCYCLOHEXENE AND 1-CHLOROCYCLOHEXENE, by H. L. Goering and L. L. Sims. Jan. 5, 1955, 18p. incl. diagr. refs. (Technical note no. 2) ([AF]OSR-TN-55-17) (AF 18-(600)1037) AD 52829 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 3465-3469, July 5, 1955.

Radical additions of hydrogen bromide to 1-bromo and 1-chlorocyclohexene in pentane give the corresponding cis-1,2-dihalocyclohexanes (trans-addition) containing less than 1% of the trans- isomers. In anhydrous ether radical additions could not be promoted by ultraviolet irradiation and from these reactions only the 1,1-dihalocyclohexanes (products of ionic addition) were isolated. Radical addition is promoted by ultraviolet light in a solvent consisting of 31 mol-% ether in pentane and in this solvent the addition appears to be as stereospecific (trans-addition) as it is in pentane. The radical addition of hydrogen bromide (initiated by benzoyl peroxide) was also investigated in a homogeneous equimolar mixture of hydrogen chloride and pentane and in this medium the addition is also as stereospecific as it is in pure pentane. Ionic additions of hydrogen bromide to 1-bromo and 1-chlorocyclohexene give 1,1 dibromocyclohexane and 1-bromo-1-chlorocyclohexane, respectively. (Contractor's abstract)

THE IODIDE ION-PROMOTED DEHALOGENATION OF CIS- AND TRANS-1,2-DIHALOCYCLOHEXANES, by H. L. Goering and H. H. Espy. Feb. 1954, 13p. incl. tables, refs. (Technical note no. 3) ([AF]OSR-TN-55-75) (AF 18(600)1037) AD 56868 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 5023-5026, Oct. 5, 1955.

The relative rates of iodide ion-promoted dehalogenations of cis- and trans-dihalocyclohexanes in methanol at 80° and 100°C have been determined. At both temperatures trans-1,2-dibromocyclohexane is debrominated about 11.5 times as fast as the cis-isomer and trans-1-bromo-2-chlorocyclohexane is dehalogenated at about the same rate as the cis-isomer. From (a) the relative rates of elimination, (b) the rate of the S_n2 reaction of iodide ion with cyclohexyl bromide and (c) numerous previous observations it is concluded that trans-1,2-dihalocyclohexanes undergo a concerted trans-dehalogenation (E_2 elimination), whereas the cis-isomers are converted to trans-1-halo-2-iodocyclohexanes, by a rate-limiting displacement reaction, prior to dehalogenation. THE SOLVOLYSIS AND BASE-CATALYZED DEHYDROHALOGENATION OF 1,1- AND 1,2-DIHALOCYCLOHEXANES, by H. L. Goering and H. H. Espy. Sept. 19, 1955, 26p. incl. diagrs. tables, refs. (Technical note no. 5) ([AF]OSR-TN-55-296) (AF 18-(600)1037) AD 73020 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 1454-1460, Apr. 5, 1956.

The relative rates of second-order dehydrohalogenation of 1,1- and cis- and trans-1,2-dihalocyclohexanes (dibromo-, dichloro-, and bromochloro-) and cyclohexyl bromide and chloride in "80%" ethanol containing 0.1 M sodium hydroxide have been determined. Under the conditions of the kinetic experiments, the reactions are second-order and E_2 elimination is not accompanied by S_N2 substitution. The solvolytic reactivities of a number of the compounds in "80%" ethanol were determined and show that under the conditions of the dehydrohalogenations, the E_2 reactions are essentially completely isolated from competing solvolysis except for the 1,1-dihalocyclohexanes. The order of reactivity for the E_2 dehydrohalogenation of the isomeric dihalides is: cis-1,2- $\gg$ 1,1- > trans-1,2-. Under the conditions of the present experiments, the 1,1- and cis-1,2-dihalocyclohexanes eliminate 1 molecule of hydrogen halide. The trans-1,2-dihalocyclohexanes give 2 molecules of hydrogen halide. The stoichiometry and relative reactivities indicate that a trans-elimination is involved. The relative reactivities, together with conformational considerations, provide information concerning the effects of α- and β-halogen atoms on the rate of dehydrohalogenation. THE BASE-PROMOTED DEHYDROHALOGENATION OF CIS- AND TRANS-2-CHLOROCYCLOALKYL ARYL SULFONES, by H. L. Goering, D. I. Relyea, and K. L. Howe. June 25, 1956, 20p. incl. tables, refs. [Technical note no. 6] (AFOSR-TN-56-279) (AF 18(600)1037) AD 89489 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 2502-2509, May 20, 1957.

The rates of second-order elimination of cis-(I), and trans-2-chlorocyclohexyl aryl sulfones (II), cis-(III) and trans-2-chlorocyclopentyl aryl sulfones (IV) and trans-2-tosyloxycyclohexyl phenyl sulfone in '80%' EtOH containing NaOH have been determined. For each of the 4 series of chlorocycloalkyl aryl sulfones (I-IV), electron withdrawing substituents in the aryl moiety increase the rate of reaction. For the phenyl sulfones, the following rate sequence is observed (relative rates at 0°): cis-2-chlorocyclohexyl (Ia; 810) > cis-2-chlorocyclopentyl (IIIa; 270) > trans-2-chlorocyclopentyl (IVa; 28) > trans-2-chlorocyclohexyl (IIa; 1) = trans-2-tosyloxycyclohexyl (I) > cyclohexyl chloride ($< 10^{-6}$). The trans-2-chlorosulfones (II and IV) undergo cis elimination, evidently by a two-step process involving abstraction of the C_1 hydrogen as a proton followed by conversion of the resulting anion to the elimination product. The first step is rate determining and irreversible under the present conditions (i.e., 80% EtOH containing 0.03 M NaOH. Presumably, the cis-chlorosulfones (I and III) undergo a concerted trans dehydrohalogenation. (Contractor's abstract)

EQUIPMENT FOR THE MEASUREMENT OF VERY SMALL X-RAY SCATTERING CROSS SECTIONS, by W. W. Beeman and R. H. Neynaber. [1954] 1 p. (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under [AF 18-(600),698]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, and May 1, 1954.

Published in Phys. Rev., v. 95: 617, July 15, 1954.

A rotating anode, water-cooled, x-ray tube, vacuum-scattering chamber, and proportional counter detector will be described. With slits furnishing an angular resolution of ±14 min, a copper anode, and 30 kv and 100 ma on the tube, over 10^9 effective (i.e., taking into account window absorption and counter efficiency) Cu Kα photons per second illuminate the scattering sample. Background counting rates, with the sample removed, are one-half count/sec. Absolute scattering cross sections are measured by calibrating the geometry at small angles with a gas scatterer. Under the above conditions of operation a two centimeter path of air at STP furnishes over 120 counts/sec. Angular measurements may be made from a lower limit determined by the slit resolution (about 1 degree scattering angle with the above slits) up to 110°. Possible applications include the measurement of scattering from gases, liquids and imperfect lattices away from Bragg angles. With a scattering sample of cold worked nickel and an iron anode the small-angle vacancy scattering first reported by Blin and Guinier has been verified. Counting rates are about 20 counts/sec. SMALL ANGLE X-RAY SCATTERING FROM COLD WORKED METALS (Abstract), by R. H. Neynaber, W. G. Brammer, and W. W. Beeman. Apr. 28, 1955 [1]p. [AF 18(600)698] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 99: 615, July 15, 1955.

The diffuse small angle scattering from cold worked metals is presumedly caused by the collection of lattice vacancies into small cavities. Some of the recent experimental results are difficult to explain on this model. We observe in annealed Ni, Cu, and Al foils sharp scattering peaks at 1° or 2° scattering angle (Fe K radiation). It is believed that these arise from two successive Bragg scatterings by adjacent and slightly tilted grains. The possibility that some or all of the diffuse scattering in cold worked foils is due to a similar mechanism is discussed. Foils cold worked at liquid air temperature show immediately the usual diffuse scattering. There is no evidence for the growth of cavities by the diffusion of vacancies as the foil is warmed. Below annealing temperatures the intensity of the diffuse scattering decreases and increases reversibly with increasing and decreasing foil temperature. This is understandable with double scattering (the Debye factor) but difficult with a cavity model. Arguing against double scattering is the failure to find scattering curves intermediate between the occasional sharp peaks from annealed samples and the continuous diffuse scattering from slightly cold worked samples.

SMALL ANGLE X-RAY SCATTERING FROM COLD-WORKED METALS (Abstract), by M. B. Webb and W. W. Beeman. [1956] 1 p. [AF 18(600)698] Unclassified

Presented at meeting of the Amer. Phys. Soc., Pittsburgh, Pa., Mar. 15-17, 1956.

WUR.01:001 - WUR.03:001

Published in Bull. Amer. Phys. Soc., v. 30: 138, Mar. 15, 1956.

Measurements have been made of the polartzation of the diffusely scattered x-ray tntenstty at small angles from cold-worked metals (Nt, Cu, Al). For small deformations the polartzation appears to be conststent wtth the double scatterng mechanism proposed by Neynaber et al. For larger deformation the polartzation d' appears and some other explanation of the smalt angle . atterng ts required. Two scatterings wtthin the same coherent domain gtve a beam tn the forward dtrection which, averaged over randomly ortented domains, ts unpolartzed. The posstbtlity that the small angle scatterng from heavtly deformed metals artses from the phystcal broadenings of these reflections is dtscussed. In cases where the double scattering mechanism of Neynaber ts applicable, the average tilt angle between adjacent subgrains can be calculated from the angular dependence of the scattering. The results are in general agreement with the measurements of Gay, Hirsch, and Kelly.

THEORETICAL RESEARCH ON THE THEORY OF SPHEROID FUNCTIONS, by H. L. Schmid, K. Krtckeberg, and E. Lamprecht. Ftnal rept. July 2, 1954, 66p. refs. (AF 61(514)443) AD 74981 Unclassifted

This report concerns three different but related questions tn the theory of spheroid functions. (1) The ftrst question ts the splitting up of etgenvalues of the spherotd dtfferential equation, t.e., the problem of calculating suitable asymptotic representations for the "splits" of etgenvalues (the dtfference of the components of a pair of etgenvalues). A method of J. Metxner is used for this calculation. The results are tabulated. (2) The second question concerns tntegral relations for spheroid functions, t.e., the existence of certain tntegral representations for products of spheroid functions, and the associated properties of the functions. Necessary condtttons for some of these relations are establtshed. (3) The third problem concerns perturbation calculations for three term recursions whtch artse in (2). The problem ts to determine a related etgenvalue so that the recurstons can be solved by not-identically-vanishing power series, under certain restrictions. This problem ts not completely solved.

FUNCTIONAL ANALYSIS AND SEMI-GROUPS, VOLUME XXXI, COLLOQUIUM SERIES, by E. Hille and R. S. Phillips. N. Y., Amer. Math. Soc., 1955, 1250p. (AF 18(600)469) Unclassified

This work is a systematic development of the modern theory of functional analysis, and the algebraic-topological structures on which the theory is based. It is an enlarged, expanded and slightly revised version of E. Hille's earlier work of the same title. This approach to functional analysis examines the properties of classes of functions (semi-groups of functions) and develops an associated theory of analysis incorporating modern algebraic and topological results. It has eventual application to problems of more classical analysis (which has been carried through for Cauchy's problem and the diffusion equation) as well as to other applications not amenable to conventional (classical) techniques.

SOME ASPECTS OF CAUCHY'S PROBLEM, by E. Hille. Nov. 1954, 9p. refs. (Rept. no. 2) ([AF]OSR-TN-54-295) (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)1127 and National Science Foundation) AD 47903 Unclassified

Presented in part at Symposium on Stochastic Processes at the International Congress of Mathematicians, Amsterdam (Holland), Sept. 2-4, 1954.

Also published in Proc. International Congress of Mathematicians, v. 3: 109-116, 1954.

The abstract Cauchy problem is formulated as follows: given a complex (B)-space X and a linear operator U with domain D[U] and range R[U] in X and given an element $y_0 \in X$, find a function $y(t) = y(t;y_0)$ such that:

(1) y(t) is strongly absolutely continuous and continuously differentiable in each finite subinterval of $[0,\infty)$ [or $(0,\infty)$];
(2) for each $t > 0$, $y(t) \in D[U]$ and $U[y(t)] = y'(t)$; and
(3) $\lim_{t \to 0_+} \| y(t;y_0) - y_0 \| = 0$.

Results are presented concerning uniqueness and relations to semigroup theory. A brief survey is given of applications to the diffusion equations in one dimension. Attention is called to the case in which the characteristic equation solutions, belonging to a subspace, which are entire functions in the parameter of order less than one. (ASTIA abstract)

Theorem 1 state the following: Let a triangular matrix U and a matrix $V \in M$ both belong to K. If $Z(t) = (z_{ij}(t))$,

YAL. 02:004 - YAL. 02:006

$t > 0$, belongs to M and satisfies(i) strong $\lim_{h\to 0}$ $h^{-1}(Z(t+h)-Z(t)) = Z(t)U$, (ii) $z_{ij}(t) \geq 0$, (iii) strong $\lim_{t \downarrow 0} Z(t) = 0$, (iv) $\lim\sup_{t\to\infty} t^{-1} \log \| Z(t)\| = w < \infty$, then the equation

strong $\lim_{h\to 0} h^{-1}(Q(t+h) - Q(t)) = Q(t)(U + V)$

admits a solution Q(t) satisfying the similar conditions as for Z(t), w being replaced by max (w, $\| V \|$). Theorem 2 says that Theorem 1 holds for $V = \beta B - BU$ with $\beta \geq 0$ if (1) $\lambda \| (\lambda I - U)^{-1} \| \leq K$ (with $1 \leq K < \infty$) for $R(\lambda) > 0$, (2) $\sup_j \sum_m b_{jm} u_{mk} < \infty$ ($k = 1, 2, \cdots$), and (3) $\| B \| < (1 + K)^{-1}$. OSCILLATION AND DISCONJUGACY FOR LINEAR DIFFERENTIAL EQUATIONS WITH ALMOST PERIODIC COEFFICIENTS, by L. Markus and R. A. Moore. Jan. 1956, 41p. refs. (AFOSR-TN-56-23) (AF 18(600)1127) AD 84489 Unclassified

Also published in Acta Math. v. 96: 99-123, Oct. 1956.

This study considers solutions of the differential equation

(1) $y'' + (-a + hp(x))y = 0$,

where p(x) is a real, almost-periodic function and (a, b) are real parameters. The theory of Hill's equation (where p(x) is periodic) is generalized but the Floquet theory is unavailable. The methods developed here are restricted to the case where equation (1) has disconjugate solutions. The domain D in the (a, b)-plane for which (1) has disconjugate solutions is found to be convex and closed. In the interior of D, the Riccati equation,

$$u' + u^2 - a + hp(x) = 0,$$

associated with (1) is shown to have exactly 2 almost-periodic solutions. From this, the analogue of the Floquet representation is obtained. Examples are given to show the limitations of the results. (Contractor's abstract)

ON A CLASS OF [illegible] FUNCTIONS, by E. Hille. [1956] 35 p. (AF 18(600)1127) Unclassified

Published in Rend. Sem. Matem. Univ. Padova, v. 25: 214-249, 1956.

It is the object of this mathematical study to estimate the characteristic values and the C-norms of the characteristic functions of L_2-norm 1 corresponding to a particular class of singular boundary value problems for linear second order differential equations. Section 1 contains introductory material concerning the study. In Section 2 a preliminary discussion is presented of the properties of the subdominant solutions of a differential equation $y'' + p(x)y = 0$ under different assumptions on p(x). The parameter λ is introduced in Section 3. The subdominant solutions at $+\infty$ and $-\infty$, normalized to have the value 1 in the limit, are shown to be entire functions of λ, and their growth properties are studied in some detail. Section 4 treats $D(\lambda)$ and its zeros $\{\lambda_n\}$, and that of the set $\{M_n\}$ is presented in Section 5. In Section 6 some extensions of the results are given. In concluding the study, some special cases are presented in Section 7 to verify the degree of accuracy of the general estimates.

[SOME REMARKS ON THE EQUATION OF HEAT] Quelques remarques sur l'equation de la chaleur, by E. Hille. [1956] [17] p. [AF 18(600)1127] Unclassified

Published in Rend. Matem. Appl., Roma, v. 15: 102-118, 1956.

Let C_ρ ($\rho \geq 0$) be the space of all continuous functions f(x) on $(-\infty, \infty)$ such that $f(x)\exp(-|x|^\rho)$ tends to finite limits as x tends to $\pm\infty$. C_ρ is a Banach space by the norm $\| f \|_\rho = \sup_x |f(x)| \exp(-|x|^\rho)$. An abstract Cauchy problem (PAC), in the author's sense (Jour. Analyse Math., v. 3: 81-196, 1954), for the equation

$$\partial u/\partial t = \partial^2 u/\partial x^2$$

is discussed in C_ρ, showing that the situations are entirely different according to the three cases, (1) $0 \leq \rho \leq 1$, 2) $1 < \rho \leq 2$, and 3) $2 < \rho$: 1) For every initial function $f \in C_\rho$, the classical solution

$$W(x, t, f) = \int_{-\infty}^{\infty} 2^{-1}(\pi t)^{-\frac{1}{2}} \exp(-s^2/4t) f(s + x)ds$$

gives a unique solution of PAC. 2) W(x, t, f) gives a unique solution of PAC if $W(x, t, f) \in C_\rho$ for every $t > 0$. However, there exists an $f \in C_\rho$ such that PAC does not admit a solution. (3) A positive increasing function f(x) with $\lim_{x\to\infty} \exp(-x_\rho) f(x) > 0$ does not give a solution which is positive increasing in $0 < t < c$, $c > 0$. In 3) there exists a solution $N(x, t) \not\equiv 0$ satisfying

$\lim_{t\to 0} \| N(x,t) \|_\rho = 0$, while such solutions do not exist in 1) and 2). (Math. Rev. abstract)

Also published in Phys. Rev., v. t0t: 977-983, Feb. t, 1956.

Abstract published in Bull. Amer. Phys. Soc., Sertes ff, v. 1: t36, Mar. t5, t956.

Room temperature measurements of the rate of colortng of NaCl crystals by x-rays at dtfferent depths below the trradtated surface and for dtfferent states of deformatton and heat treatment are reported. From the results it ts concluded that 2 mechantsms of colortng operate tn these crystals. The first, or "rapid-type" coloring, approaches a saturation density of F-centers of the order of 10^{17}/cc, and appears to result from the generatton of color centers from vacanctes already present tn the untrradtated crystal. The second, or "slow-type" coloring, takes place at a constant rate until F-centers in excess of 10^{18}/cc are formed. This type of colortng, whtch ts usually observed only near the trradtated surface, ts due to the generation of F-centers at dtslocation, and is responsible for the hardness and denstty changes produced by the x-rays. Raptd-type colortng is found to occur at essenttally the same rate in deformed crystals and tn carefully annealed crystals; recovery at low temperatures after deformation, however, decreases the colorabtltty. These results tndtcate that the prtnctpal effects of deformatton and heat treatment on colorabtltty may be related to the state of dtsperston of tmpurtties. (Contractor's abstract)

THE PINNING OF DISLOCATIONS BY X-IRRADIATION OF ALKALI HALIDE CRYSTALS, by R. B. Gordon and A. S. Nowtck. Dec. 1955 [50]p. tncl. dtagrs. tables, refs. (Technical note no. 3) ([AF]OSR-TN-55-479) (AF 18(600)850) AD 81431 Unclasstfted

Also published in Acta Metallurgica, v. 4: 514-527, Sept. 1956.

A study ts made of the effect of x-trradtation on the room temperature elastic modulus (s_{11}^{-1}) of NaCl crystals. The modulus ts observed to be unchanged by trradtation for well-annealed crystals, but may increase by as much as 7% when cold-worked crystals are trradtated. It ts demonstrated that the modulus change on trradiatton corresponds exactly to the eltmtnation of the modulus decrease owtng to osctllating dtslocation loops through the creatton of pinntng potnts along the dtslocattons. A quanttttative theory ts developed for the vartation of modulus wtth x-ray dose. This theory assumes that vacanctes, released wtthin the volume of the crystal through the action of the radtation, mtgrate to dtslocattons, and contrtbute to the formation of pinntng points. The theory appears to be tn good agreement wtth expertment, and makes posstble a calculation of the denstty of dtslocattons and the mean length of the free dtslocatton loops prtor to trradtation. CREATION OF A POTENTIAL DIFFERENCE ACROSS NaCl CRYSTALS BY DEFORMATION (Abstract), by D. B. Fischbach and A. S. Nowtck. [t955] [1]p. [AF t8(600)850] Unclasstfied

Presented at meettng of the Amer. Phys. Soc., Balttmore, Md., Mar. t7-t9, 1955.

Published in Phys. Rev., v. 98: t543, June 1, 1955.

A study has been made of the flow of current at room temperature through NaCl crystals deformed in

YAL. 03:005 - YAL. 04:002

compression. A sensitive vacuum tube electrometer is used to measure the potential drop across a 10-in. ohm resistor connected across the crystal. When the crystal is deformed inhomogeneously a transient potential drop difference is developed such that the side of the crystal which has the higher stress concentration becomes negative. If the load is left on, this potential decays to zero over a period of minutes in roughly a hyberbolic fashion. Removal of the load at any time drops the current flow to zero almost instantaneously. Reapplication of the same load produces a new transient current in the same direction as the original flow, but smaller in magnitude. The direction of the initial current flow is unaffected by externally applied fields as large as ±1000 volts/cm. A discussion of the possible interpretation of this effect is given.

ELASTIC MODULUS OF X-IRRADIATED ROCK SALT (Abstract), by R. B. Gordon and A. S. Nowick. [1955] [2]p. [AF 18(600)850] Unclassified

Presented at meeting of the Amer. Phys. Soc., Baltimore, Md., Mar. 17-19, 1955.

Published in Phys. Rev., v. 98: 1540-1541, June 1, 1955.

Measurements of the room temperature dynamic elastic modulus (Cu) of x-irradiated NaCl crystals have been made to an accuracy of better than 0.01 percent. It is found that the modulus is unchanged by irradiation for well-annealed crystals, but may increase by as much as 5 percent in cold worked crystals. This modulus change is a volume effect. It is closely related to the modulus decrease on cold working, which occurs as a result of the production of dislocation segments oscillating in phase with the stress. The modulus of a freshly deformed crystal increases with time because of the shortening of these segments. It is found that the x-irradiation of a deformed crystal raises the modulus by just the amount corresponding to the destruction of this dislocation contribution. The x-ray dosage required to saturate this modulus effect is very much smaller than that required to fully color the crystal. The irradiation time required to effect half the total modulus change is independent of the magnitude of the change. These results suggest that the radiation is to create new pinning points along a dislocation and that the rate at which a dislocation is attacked is independent of the density of dislocation lines.

QUENCH HARDENING OF PURE GOLD AS OBSERVED BY INTERNAL FRICTION METHODS, by A. E. Roswell and A. S. Nowick. Aug. 1956 [24]p. incl. diagrs. table, refs. (Technical note no. 4) (AFOSR-TN-56-360) (AF 18(600)850) AD 95446 Unclassified

Also published in Acta Metallurgica, v. 5: 228-235, Apr. 1957.

The effect of heat treatment of the dislocation damping was studied in high purity Au. A quench hardening effect was observed, analogous to that found by previous workers in Zn and Al. Measurements, made by means of a piezo-electric resonator of internal friction at a maximum strain amplitude of 1×10^{-7} gave values for $\phi_s \times 10^4$ of 30±5 for furnace-cooled samples, 8.5±1.0 for airquenched samples, and of 5.4 for one water-quenched sample. (The damping of the specimen is reported as ϕ_s, the phase angle of lag of strain behind stress when the specimen is vibrating alone.) A handling effect was found to be principally responsible for the large difference in damping between specimens given different initial heat treatments. The differences between airquenched and furnace-cooled specimens were observed to anneal out in the range 160° to 200°C; and there was no evidence for an agehardening effect prior to the resoftening. The phenomena are interpreted in terms of the pinning of dislocations by "attached vacancies" (i.e., vacancies which form an atmosphere about the partial dislocations in the metal), which are most probably in the form of clusters. The question of the origin of these attached vacancies is also discussed. (Contractor's abstract)

SARGENT DIAGRAM AND ft VALUES FOR ELECTRON CAPTURE TRANSITIONS (Abstract), by J. K. Major

and L. C. Biedenharn. Nov. 1954 [1]p. (Technical rept. no. 1) ([AF]OSR-TN-54-107) (AF 18(600)771) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 28-30, 1954.

Published in Phys. Rev., v. 94: 779, May 1, 1954.

Knowledge of the dtstntegration constant λ and the energy W of electron capture transitions ts useful tn calculating branching ratios and transformation probabilities and in tdentifying nuclear transttions. While λ may be computed from observed half-ltves and known decay schemes, W must be deduced tndtrectly, from closed decay cycles, mass differences from nuclear reaction or mass spectrometer measurements, posttron emisston between the same tnitial and final states, or end-points of inner bremsstrahlung accompanying electron capture. Earlier studtes have been extended to lighter nuclet wherever adequate tnformation on the half-life, branching ratios, and transttion energy was available, and a Sargent diagram constructed. Known allowed transttions fall considerably below the line proposed by Feather, but the scatter of the points does not permit differentiation of Sargent curves for dtfferent degrees of forbiddenness. Comparative half-ltves have also been calculated for capture transitions and will be compared to those for beta emitters. (Contractor's abstract)

INGOING WAVES IN FINAL STATE OF SCATTERING PROBLEMS, by G. Brett and H. A. Bethe. Nov. 7, 1953 [11]p. incl. dtagr. (Technical rept. no. 2) (In cooperation with Cornell U. Inst. of Nuclear Studies, Ithaca, N. Y.) ([AF]OSR-TN-54-108) (AF 18(600)771) AD 32232 Unclasstfied

Also published in Phys. Rev., v. 93: 888-890, Feb. 15, 1954.

A brief discussion is presented of scatterng by a central field as background for the problem where tt ts assumed that one deals with solutions of $\left(\frac{h}{i}\frac{\partial}{\partial t} + H_0\right)\phi_0 = 0$; H_0 ts the Hamiltonian of a scattering problem, and ϕ_0 is a wave packet. The problem is modifted by the introduction of a perturbing Hamiltonian H', and time-independent solutions are introduced by means of the relation $(H_0 - E_j)u_{j,s} = 0$, where s enumerates the continuum of posstbtlities for solutions at a fixed energy E_j. The function $u_{j,s}$ are normalized tn order to solve the perturbed equation to the first order in H'. A discusston is presented of the completeness of $u_{j,s}$, and an argument is advanced that the first-order solution tn H' may be used wtth the $u_{j,s}$ as etther ingotng or outgoing wave modifications of plane waves. The calculation tn terms of distorted plane waves with outgotng wave modifications ts not dtrectly interpretable in terms of a differential cross section. The solution tn H' gives the standard formula for the transttion probabtltty tn terms of squares of matrix elements; therefore, for the usually destred application to the calculatton of the flux of parttcles tn a gtven direction, the ingoing wave modification is indtcated.

ON THE VALIDITY OF THE BORN-OPPENHEIMER APPROXIMATION, by P. B. Daitch and S. Bludman. Apr. 23, 1954, 29p. (Technical rept. no. 4) ([AF]OSR-TN-54-110) (AF 18(600)771) AD 32234 Unclassified

Also published in Phys. Rev., v. 95: 823-830, Aug. 1, 1954.

Solutions of the Schroedinger equation for several stmple models tn which a light particle, mass m, is bound to a heavy particle, mass M, which tn turn ts bound to another heavy particle which may be fixed are considered as expanstons tn the parameter $1/\beta \equiv (m/M)^{1/2}$. A characteristic of such systems ts that when the light particle ts far from the heavy particle, it centers on the mean posttton of the heavy parttcle and when tt ts close to the heavy particle, tt centers on the heavy particle. The classtcal predtction that the change tn centering takes place when the motional frequenctes of the light and heavy particles are equal is born out tn quantum mechanics, except that here the transition takes place over an extended region as shown by the detailed tnvestigation of models. General arguments are presented which show how low and high momenta of the light particle contribute respectively to centering on the mean position and on the changing position of the heavy particle. The effect of the centertng on expectation values of quantities dependent on the denstty of the light particle at the heavy one is of the order of the ratio of an average radtus of the heavy particle motion to an average radtus of the light particle motion. Further corrections due to incomplete centertng are of the order $1/\beta$ times this ratio. In an appendtx, an estimate is made of the correction to the wave functton to order $1/\beta^2$ for the case of the two-lines-of-interaction model by application of perturbation theory.

LANDÉ-GOUDSMIT-FERMI-SEGRÈ FORMULAE, by G. Breit. [1954] 11p. incl. diagr. refs. ([AF]OSR-TN-54-153) [AF 18(600)771] Unclassified

The Landé-Goudsmit-Fermi-Segrè formulas have proved to be useful in the comparison of values of nuclear magnetic moments, as derived from molecular beam measurements, with those obtained from spectroscopic and atomic beam measurements of hyperfine structure. The derivation of these relations due to Fermi and Segrè depends on the validity of the JWKB approximation. In view of the limitations of the latter, another somewhat more general dertvattons ts presented. It makes use of formal extension of the space to negative values of the electron-nuclear distance and of viewpoints familiar in nuclear reaction theory. By means of relations established by Wigner for the energy dependence of his derivative function, it is shown that the formulas may be expected to have a wide range of validity. The phase of the WKB method is generalized into the phase of the reaction channel and the obvious regularity of the dependence of the WKB phase on energy is replaced by corresponding relations following from Wigner's work. ISOTOPE SHIFT IN THE X-RAY SPECTRA OF HEAVY ELEMENTS, by M. S. Wertheim and G. Igo. Dec. 1954 [16]p. tncl. diagrs. tables, refs. (Technical rept. no. 8) ([AF]OSR-TN-54-347) (AF 18(600)771) AD 51856
Unclassifted

Also published in Phys. Rev., v. 98: 1-5, Apr. t, 1955.

Isotope shifts in the x-ray levels resulting from the nuclear volume effect have been calculated for three different nuclear potentials by using first order perturbation theory with the relativistic wave functions in a Coulomb field. In order to correct for the error made tn using first order perturbation theory, the exact relativistic wave function was obtained for one of the potentials. The screening effects of the atomtc electrons are taken into account by compartng the value of the wave functton at the nuclear radius in a Fermt-Thomas field with that in a Coulomb field. An upper limit ts obtained on contributions to the tsotope shift owtng to the change in screening of the other atomic electrons when a K or L shelt electron ts removed or replaced. The results for isotope shift tn Mo and U are one-hatf and one-twentieth, respectively, of the expertmental resolution of Rogosa and Schwarz. (Contractor's abstract)

REDISTRIBUTION OF CLASSICAL AND QUANTUM DENSITIES, by G. Breit and P. B. Daitch. June 11, 1955, 14p. (Technical rept. no. 10) ([AF]OSR-TN-55-179) (AF 18(600)771) AD 69947 Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 41: 653-660, Sept. 1955.

ft is shown that if partticles tmpinge from right to left on a completely reflecting potential 1-dimensional potential barrier, the integral of the quantum mechanical density taken from the barrier interior tc 1 of the nodes of the wave function on the right of the barrier is equal to the integral of the classical particle density from the classical turning point to the same node of the wave function, provided that at the node the JWKB approximation applies. Similarly in the case of radial wave functions the integrals of particle densities, computed classically and quantum mechanically from the origin of coordinates to a node of the radical wave functton, are equal provided the JWKB approxtmatton applies at the node. An extenston of the relation to the case of 2 different quantum states is given. The bearing of the theorem on the success of the semt-classical treatment of Coulomb excitation is brought out, and the possibility of applttcations to problems in wave equattons of clasatcal physics is potnted out.

COMPARISON OF SEMI-CLASSICAL AND QUANTUM MECHANICAL COULOMB EXCITATION INTEGRALS FOR LARGE L, by R. L. Gluckstern, J. P. Lazarus, and G. Breit. July 29, 1955, 12p. (Technical rept. no. 11) ([AF]OSR-TN-55-256) (AF 18(600)771) AD 69684 Unclassified

Also published in Phys. Rev., v. 101: 175-177, Jan. 1, 1956.

Semiclassical and quantum mechanical integrals occurring in the theory of Coulomb excitation are compared in the limit of distant collisions which corresponds to setting the usual parameter $\eta = 0$. The integrals are expanded in powers of the energy of excitation, and are found to agree up to and including those of second order, provided the geometric mean of the initial and final energy is used in the semiclassical calculation. The results are generalized to include an arbitrary power law for the dependence of the interaction energy on radius. The agreement remains unchanged. (Contractor's abstract)

TRANSFORMATION OF RELATIVISTIC WAVE EQUATIONS, by B. Kursunoglu. Sept. 23, 1955, 21p. refs. (Technical rept. no. 11) ([AF]OSR-TN-55-339) (AF 18(600)771) AD 73467 Unclassified

Also published in Phys. Rev., v. 101: 1419-1424, Feb. 15, 1956.

A unitary transformation is found which achieves an exact separation of positive and negative energy states of a Dirac particle interacting with an external electromagnetic field. The $(v/c)^2$ approximation to the motion of a Dirac particle agrees with the Foldy and Wouthuysen result. The transformation is extended to quantized fields and to relativistic 2-body equations. The second order electromagnetic mass effects in the quantized Dirac equation appear, in the nonrelativistic limit, as the time derivatives of the electric terms of the nonrelativistic Hamiltonian without the radiative corrections. These mass effects in the nonrelativistic Hamiltonian are proportional to $(1/mc)^3$. Construction of unitary transformation operators for the ps-ps meson theory and for the Bethe-Salpeter equation are also discussed. (Contractor's abstract)

YAL. 04:0t4 - YAL. 04:0t7

Also published in Phys. Rev., v. t0t: t504-1507, Mar. 1, 1956.

In view of discrepancies in the literature regarding signs in formulas for the angular distribution of gamma rays emitted in Coulomb excitation this distribution is worked out for the special case of 0 → 2 transitions. The calculation is quantum mechanical, and neglects higher than first order effects in the Coulomb energy. The signs and forms obtained are confirmed by a semi-classical calculation. CONTRIBUTIONS OF OPTICAL METHODS TO NUCLEAR PHYSICS, by G. Breit. May 31, t956 [47]p. incl. illus. diagrs. tables, refs. (AFOSR-TN-56-274) (AF 18(600)77t) AD 89484 Unclassified

Also published in Jour. Opt. Soc. Amer., v. 47: 446-459, June 1957.

The developments in nuclear physics resulting from the application of optical methods to the study of nuclei are reviewed. The atom is presented as a type of laboratory with respect to the coupling of electron system to nuclear spin, the electron-nuclear volume and shape effect, the hyperfine structure of the H isotopes, distribution of nuclear magnetic, and isotopic shift and quadrupole moments. Related developments resulting from applications of atomic beams stimulated by early spectroscopic ideas are discussed.

FINE STRUCTURE OF THE GROUND STATES OF N^{t5} AND O^{t7}, by C. A. Pearse. Oct. 3t, t956 [35]p. incl. diagrs. tables, refs. (AFOSR-TN-56-535) (AF t8(600)77t) AD t t0354 Unclassified

Also published in Phys. Rev., v. t06: 545-553, May t, t957.

An attempt has been made to fit the experimental values of the groundstate splittings for N^{t5} and O^{t7} using the same nucleon-nucleon spin-orbit force for both cases. It is found that the spin-orbit force constants for the N^{15} case must be made about twice as large as those for the O^{t7} case. The magnitudes of the spin-orbit force parameters required to account satisfactorily for the N15 and O17 groundstate splittings have been found to be from 5 to t0 times larger than those necessary to obtain agreement between the calculated and the experimental values of the groundstate splitting in Li^7. The exchange-integral contributions to the splittings have been found to be from $\frac{1}{4}$ to $\frac{1}{2}$ of the direct integral contributions; therefore, the concept of a one-body spin-orbit force is not accurately applicable in the cases of the N^{15} and O^{t7} groundstate splittings. Gaussian error potentials and wave functions have been used. The wave-function range parameters have been adjusted by means of experimental Coulomb energies and examined by means of binding energies. Effects of excited configurations have not been included and no claim of an exhaustive consideration of all possible adjustments of wave function and potential parameters is made.

NOTE OF RELATIVISTIC CORRECTIONS TO p-p SCATTERING, by G. Brett. Nov. 30, t956, 22p. refs. (AFOSR-TN-56-565) (AF 18(600)771) AD t t0386 Unclassified

Also published in Phys. Rev., v. t06: 3t4-320, Apr. 15, t957.

Specific non-relativistic nuclear interaction effects are examined for the relation to relativistic corrections to Coulomb scattering. Improvement on the corrections is made in the first order of e^2 through a knowledge of wave functions in the presence of nuclear interactions. The spin-orbit interactions due to the action of the electric field are found to be affected by wave function distortion. Analysis is affected since the interaction changes the polarization of proton beams in scattering. Spin-orbit interactions are related to atomic spectra. The appendix proves the vanishing of first order tensor force effects on the polarization, which holds independently of the origin of the tensor force effects.

NUCLEON-NUCLEON SPIN-ORBIT FORCES IN N^{t5} AND O^{t7} (Abstract), by C. A. Pearse. [t956] [t]p. [AF t8(600)771] Unclassified

Presented at meeting of the Amer. Phys. Soc., New Haven, Conn., June 2t-23, t956.

Published in Bull. Amer. Phys. Soc., Series II, v. t: 303, June 2t, t956.

The spin-orbit splitting is given for Wigner, Majorana, and Heisenberg nucleon-nucleon potentials for a nucleon outside closed shells and for a "hole" in a closed shell. The spin-orbit forces are those derived from relativistic invariance by Brett. These expressions have been evaluated using Gaussian wave functions and potentials. The wave-function parameters are chosen by the alternative criteria: binding energy of last neutron, Coulomb energy of mirror nuclei, electron scattering and mu-mesonic atom experiments. The parameters a^W, a^M, and a^H are found to be about t0 for $p_{t/2} - p_{3/2}$ of N^{t5}

and about 20 for $d_{3/2}$ - $d_{5/2}$ of O^{17}. These values are compared with those of Breit and Stehn for $p_{3/2}$ - $p_{1/2}$ of Li^7. Effects of shape and range parameter uncertainties and perturbations are discussed. Exchange integral contributions are non-negligible; hence, the usual equivalent one-body spin-orbit force is inapplicable in these cases. (Contractor's abstract)

THE INFRARED SPECTRA AND STRUCTURE OF NaOH AND NaOD (PART I). THE RAMAN SPECTRA OF NaOH, LiOH, AND LiOH· H_2O (Part II). THE INFRARED SPECTRA OF KOH AND HYDRATED KOH (PART III), by W. R. Busing and B. A. Phillips. [Final rept.] Sept. 1954 [36]p. incl. diagrs. tables, refs. (Technical rept. no. 1) [AFOSR-TN-54-239] (AF 18-(600)859) AD 44632 Unclassified

Part I also published in Jour. Chem. Phys., v. 23: 933-936, May 1955.

The IR spectra of NaOH, NaOD, and the mixtures of these compounds were studied at room and liquid-air temperatures. The results at room temperature, taken together with the Raman spectrum of NaOH, were consistent with the x-ray structure and postulated H positions. At the liquid-air temperature, the spectrum of NaOD exhibited an unexpected complexity which could not be explained. The Raman frequencies of the hydroxide-streiching vibrations were measured for NaOH, LiOH, and LiOH· H_2O at room temperature. The results, taken together with the corresponding IR frequencies, were consistent with the x-ray structures of these compounds. The IR spectra of KOH and hydrated KOH were studied at room and liquid-air temperatures, but the interpretation of the results was incomplete.

COMPARISON OF THE INFRARED AND RAMAN SPECTRA OF SOME CRYSTALLINE HYDROXIDES, by B. A. Phillips and W. R. Busing. [Oct. 5, 1956] [1]p. incl. table, refs. [AF 18(600)859] Unclassified

Published in Jour. Phys. Chem., v. 61: 502-503, Apr. 1957.

A comparison is made of the infrared and Raman OH stretching frequencies in the following crystalline hydroxides:

Compound	Infrared[11-13]	Raman	Difference
	[Frequency (cm^{-1})]		
LiOH	3678	3664	14
LiOH· H_2O	3574	3563	11
NaOH	3637	3633	4
$Ca(OH)_2$	3644	3618	26

The observed spectra are consistent with the symmetries of these crystals in that one infrared active fundamental and one Raman active one have been observed in each case. Comparing the frequency differences, it is seen that the coupling of the hydroxide ion vibrations is greatest in $Ca(OH)_2$ and least in NaOH, and that the sign of the interaction force constant is the same for all of these compounds.

EFFECTS ON LIVING TISSUES BY PRIMARY COSMIC RAY PARTICLES, by J. A. G. Eugster, H. Waeffler, and W. Roost. Feb. 1956 [34]p. incl. tllus. dtagrs. refs. (AFOSR-TR-56-19) (AF 61(514)898) AD 87528
Unclasstfted

Flfty-five experiments were performed to determine the effects of cosmic rays on the living tissues of humans and animals by exposing specimens (1) at 11,000 ft (the Jungfraujoch station); (2) in the Simplon tunnel 8000 ft below the mountaintop (where control specimens were stored); (3) tn stratosphere balloons at Payerne; and (4) in sky hook and similar altitude balloons at 90,000 to 100,000 ft. Results, although not conclustve, indicated that cosmic radtation will not be a great hazard to the human body and will not hinder flight tn the upper atmosphere. The impairment of growth in the Simplon tunnel indicated that cosmic radiations act as a stimulant to growth.

Some generalities are presented on stellar scintillations and a method is dtscussed which provtdes a measure of the quality of seeing. The present investigation is concerned wtth tests by binoculars or small photographic cameras. The technique of stellar tmage trailing led to the important discovery that the disturbances causing poor seetng can be very high up in the atmosphere. Observations from the ground and tn the high altitude flights led to these preliminary conclusions: (1) that there ts very little systematic change tn vtsual seetng between the ground and about 7 km height; (2) that the sluggtsh scintillations wtth frequencies tnferior to 20/sec are caused mostly by atmospheric disturbances in the first 7 km of the atmosphere; and (3) that it wtll he necessary to ascend with instruments of much greater light gathertng power and much faster time resolution than the human eye to explore the quantitative aspects of the stellar sctntillation at great altitudes. The study of jet vapor tratls and the correlation of the observed phenomena wtth stellar scintillation data led to the discovery of very stable disturbances in air whtch were designated as Aertal Blobs or Aerial Mollusks.

OSR Control No. Index

OSR Control No. Index

The following is a list of all AFOSR reports to which control numbers were assigned and which were actually issued during this period. All omissions are deliberate; the absence of a number implies that the report assigned that number was never published.

Mathematical Subject Classification

Mathematical Subject Classification

ALGEBRA

Algebras:
- Associative algebras
  - CHI. 07:001
- Lie algebras
  - NYU. 06:003, 010-012
- Non-associative algebras
  - BUT. 01:001; CHI. 05:003

Combinatorial Analysis
- NBS. 09:015

Fields, Rings:
- Fields
  - OSU. 01:002
- Finite fields
  - COL. 03:006
- Rings
  - MIC. 02:001, 002

Groups and Generalizations:
- Abelian groups
  - WAS. 02:002
- Finite groups
  - IAS. 03:002; NBS. 09:009
- General
  - WAS. 01:002, 003; WAS. 02:003, 005, 016
- Group theoretic constructions, free groups, extensions
  - CHI. 08:002
- Matrix groups, representation, characters
  - NBS. 09:009
- Nilpotent and solvable groups
  - IAS. 03:001, 004, 005; WAS. 01:001
- Semigroups
  - STA. 01:005

Homological algebra:
- CHI. 08:001, 003; COU. 05:001-004; COU. 07:001-003, 005, 006; HAR. 07:033

Linear algebra:
- Eigenvalues and eigenvectors
  - NBS. 09:011, 018, 022, 025, 039; NCU. 03:001, 002; NCU. 04:015
- Forms and transformations
  - CAR. 04:002; STA. 01:004
- Inequalities for matrices
  - BCU. 02:001; NBS. 09:040
- Linear equations, matric inversion, determinants
  - IAS. 09:004; NBS. 09:037; NCU. 04:021
- Matrices
  - NBS. 09:034, 036, 041; NYU. 06:008; PRF. 02:003; STA. 01:005

Partial Order, Lattices:
- Boolean rings and algebras
  - NBS. 09:002

Polynomials:
- Algebraic equations, roots
  - NBS. 25:007; WAS. 01:004

FOUNDATIONS, THEORY OF SETS, LOGIC

Syntax, semantics, formal methods in general, recursive functions
- NHU. 01:001-003

GEOMETRY

Algebraic Geometry:
- General theory of varieties, surfaces
  - IAS. 05:012
- Group varieties, Abelian, equivalence theories
  - NOR. 02:001, 002
- Special varieties, curves, surfaces
  - MIN. 04:001

Convex Domains, Distance Geometries:
- Convex regions, Brunn-Minkowski theory
  - NBS. 09:012, 021; NBS. 10:001; STA. 01:004
- Distance geometries
  - NBS. 09:002
- Extremum properties and geometric inequalities
  - MDU. 09:005, 038, 051, 052; NBS. 09:032

Differential Geometry:
- Differential geometry in the large
  - JHU. 09:003; MDU. 09:045; PRI. 06:004

Geometries, Euclidean and Other:
- n-dimensional and hypercomplex geometries
  - STA. 01:007
- Non-Euclidean geometry
  - STA. 01:007
- Projective geometry
  - STA. 01:007
- Triangles, tetrahedra
  - NBS. 09:006

Manifolds, Connections:
- Riemannian geometry
  - MIT. 01:001, 002; MIT. 02:001

MATHEMATICAL ANALYSIS

Approximations and Expansions:
- PEN. 04:005
- Approximations and Expansions, general theory
  - COR. 05:004; HAR. 02:102; HAR. 04:001, 006, 007; NBS. 09:019
- Asymptotic approximations and expansions
  - BCU. 01:001, 002; CAL. 01:001-003; NBS. 09:043; NYU. 06:009; RIC. 01:002
- Degree of approximation, best approximation
  - HAR. 04:002, 010, 011, 014; NBS. 09:026; PEN. 04:004
- Interpolation: general theory
  - NBS. 09:003
- Orthogonal systems, expansions
  - WAS. 02:020

Calculus of Variations:
- Applications
  - MDU. 09:011; MIS. 01:004
- General theory
  - IAS. 05:004; WAS. 02:019, 021; WAY. 02:004, 007
- Theory in the large, topological methods
  - CAR. 04:012

Difference Equations, Functional Equations:
- Finite differences and difference equations
  - SCU. 01:001

Differential Equations: Ordinary
- MDU. 14:001
- Approximation of solutions
  - HAR. 01:001

Mathematical Subject Classification

MATHEMATICAL ANALYSIS (cont'd)

Asymptotic behavior of solutions
MIS. 01:005, 006, 008; WIS. 02:001, 002, 004
Boundary value problems, spectra, expansions in eigenfunctions
BCU. 01:003; MDU. 09:001; NYU. 06:004; NCU. 02:002, 003; PRI. 06:003; YAL. 02:005
Linear equations: other than second order
CAR. 04:007; NYU. 06:011, 013; WIS. 02:003
Linear equations: second order
CAR. 04:011; NYU. 06:019; WAS. 02:004
Periodicity, oscillations
IAS. 05:013; JHU. 07:001-004; WAS. 01:002; WAS. 02:015, 023; YAL. 02:004
Special types
JHU. 09:001; MIN. 02:003; MIS. 01:006; NYU. 06:001
Stability of solutions
NEB. 01:001-004
Systems of linear equations, matrix differential equations
IAS. 05:003; JHU. 09:002; NYU. 06:003, 010, 012; NCU. 02:001, 002

Differential Equations: Partial
DUK. 02:002; MDU. 14:001; MIN. 06:002
Analytic and algebraic theory of systems of equations
CAL. 02:005; CHI. 05:004; OKU. 01:001, 003; PRI. 06:005
Approximate methods
CAL. 02:003; HAM. 01:001; HAM. 02:001-004; NCU. 02:004; OKU. 01:002; NBS. 09:017
Classification, characteristics
NOT. 01:003
Eigenvalues, eigenfunctions
MDU. 09:015, 017, 020, 033, 038, 046, 047, 051-053; PRI. 06:003
Elliptic equations, boundary value problems
CAR. 04:003; DUK. 02:001, 002; MDU. 09:003, 011, 012, 019, 021, 024, 026, 037; NYU. 06:002, 005, 015; SCL. 01:001; WAY. 02:002
First order equations
CHI. 05:002
General theory
MIT. 10:057; NYU. 06:014; WAY. 02:003
Hyperbolic equations, Cauchy problem
CAL. 02:007; DUK. 02:002; MDU. 09:003, 007, 009, 013, 014, 016, 021, 024, 026, 028, 029, 035, 037, 042-044, 048-050; TEN. 01:002; WAY. 02:007
Mixed equations
CAL. 02:001, 004; CHI. 05:001; MDU. 09:021; WAY. 02:006
Parabolic equations
MDU. 09:003; MIN. 06:001, 003; YAL. 02:006

Functions of Complex Variables:
COR. 06:001, 002
Complex interpolation and approximation
HAR. 04:004, 009-011; NBS. 09:019, 026; RIC. 01:001
Conformal mapping, general
BRO. 01:001; CAR. 04:004, 009; HAR. 04:003, 005

Functions of Complex Variables: (cont'd)
Continued fractions
WAS. 01:002, 009, 017
Entire functions
BRO. 01:001; COR. 05:038, 052; RIC. 01:002
Functions of several complex variables
IAS. 05:006; NBS. 09:007
Generalizations
IAS. 04:001
Meromorphic functions
COR. 05:051; RIC. 01:002
Quasi-conformal functions
CAL. 02:002
Riemann surfaces and functions on them
HAR. 05:001
Singularities
CAR. 04:010
Univalent and p-valent functions
CAR. 04:013; WAS. 02:001, 008, 010
Zeros
COL. 03:005; HAR. 04:008, 012, 013; WAS. 01:004

Functions of Real Variables:
Calculus, mean-value theorems, inequalities
COR. 13:002; NBS. 09:031
Differentiation and tangents
STA. 01:002
One real variable
CIN. 03:005; MDU. 09:023; PEN. 04:003
Several variables
MIS. 01:002, 009

Harmonic Functions, Convex Functions:
COR. 06:001, 002; MDU. 14:001
Biharmonic and polyharmonic functions
MDU. 09:006, 032, 040, 041
Convex functions
CAL. 02:006
Generalized potentials, capacity
MDU. 09:030, 036
Harmonic forms and integrals
IAS. 05:007; IAS. 06:001-004
Harmonic functions, potential theory
COR. 05:001; KAN. 01:001-007; MDU. 09:006, 035, 040
Subharmonic functions
MDU. 09:018, 031, 045, 049

Integral and Integrodifferential Equations:
MIN. 06:002
Linear integral equations
CAR. 04:001; NYU. 06:017, 022; WAS. 02:012
Non-linear integral equations
MIN. 06:001
Singular integral equations
COR. 05:058; TEX. 01:002
Special integral equations
IOW. 01:003

Integral Transforms:
COR. 06:001, 002
Inversion formulas, self-reciprocal functions
COR. 05:030, 034, 053
Laplace and Fourier transforms
CLA. 02:001; CON. 01:001; COR. 05:002, 042; WIS. 01:001, 004
Other transforms, Hilbert, Mellin, Hankel
CHI. 06:004; COR. 05:019, 029

MATHEMATICAL ANALYSIS (cont'd)

Measure, Integration:
- Area, length
  - PRF. 01:001-006
- Measure theory
  - IAS. 05:008

Sequences, Series, Summability:
- Convergence and summability
  - CIN. 03:002-004, 006-008; COR. 05:031, 032, 043, 044, 046, 047
- Operations on series and sequences
  - CAL. 01:004; COR. 05:008, 033; WUR. 01:001; WUR. 03:001
- Power and factorial series
  - CIN. 03:001
- Special sequences and series, moments
  - COL. 03:003; PEN. 04:001, 002; TRI. 01:001, 002; WAS. 02:022; WUR. 01:001; WUR. 03:001
- Tauberian theorems
  - CIN. 03:009

Special Functions:
- Functions defined by definite integrals, differential and integral equations, infinite series
  - MIT. 10:072; NYU. 06:020
- Hypergeometric functions and generalizations
  - HAR. 02:003
- Legendre functions, spherical harmonics
  - WAS. 02:018; WUR. 02:001
- Polynomials as functions, orthogonal polynomials
  - WAS. 02:025

Trigonometric Series and Integrals:
- COR. 06:001, 002
- Convergence, summability
  - CHI. 06:007, 008
- Fourier integrals
  - COR. 05:016, 057; IAS. 07:002; NYU. 06:008
- Trigonometric polynomials, Fourier series
  - RUT. 01:001, 002; WAS. 02:006

NUMERICAL ANALYSIS

Computing Machines:
- Analogue computers
  - CIT. 01:003, 004
- Digital computers: coding and programming
  - IAS. 08:001; IAS. 09:002; NBS. 09:010, 027
- Digital computers: logic and design
  - IAS. 08:001; IAS. 09:001; MIC. 13:001
- Results of computation by machine
  - HAR. 01:001

Numerical Methods:
- PEN. 04:005
- Computation of special functions, series, integrals
  - HAR. 02:030
- Eigenvalues, eigenvectors, Rayleigh-Ritz method
  - MDU. 09:015, 033, 047; NBS. 09:033; NCU. 03:002
- Interpolation, smoothing, least squares, curve fitting, approximation of functions
  - NBS. 09:023
- Linear equations, determinants, matrices
  - NBS. 09:001, 020

Numerical Methods (cont'd)
- Linear inequalities, linear programming
  - NBS. 09:005, 008, 012-014, 020, 024, 035, 038
- Monte Carlo methods
  - HAR. 02:001; NBS. 18:001
- Numerical differentiation and integration, mechanical quadrature
  - MIT. 10:002; WIS. 01:002
- Partial differential equations
  - HAM. 01:001; HAM. 02:001-004; MDU. 09:015, 033; NCU. 02:004
- Roots of algebraic and transcendental equations
  - NBS. 25:007; NOT. 01:002
- Tables
  - MIT. 10:078

OTHER APPLICATIONS OF MATHEMATICS

Control Systems:
- PRI. 05:001
- Servomechanisms
  - PRI. 05:001-004
- Switching theory, relays
  - IAS. 09:005, 006

Economics, Management Science:
- Management science, operations research
  - MDU. 13:005; NBS. 09:038

Information and Communication Theory:
- Information theory
  - WAS. 02:024

Programming, Resource Allocation, Games:
- Games
  - IAS. 05:001; NBS. 09:014
- Linear and non-linear programming, scheduling
  - CAR. 04:008; IAS. 05:002; NBS. 09:024, 028-030, 038

PHYSICAL APPLICATIONS OF MATHEMATICS

Elasticity, Plasticity:
- CAR. 01:001
- Beams and rods
  - CIT. 01:004; CAR. 04:008; WAS. 02:011
- Foundations of mechanics of deformable solids
  - CAR. 04:006; WAS. 02:014
- Plane stress and strain
  - CAR. 04:005; MDU. 09:039
- Plates, shells, membranes
  - GIT. 02:001; IOW. 01:001, 002; MDU. 09:034
- Three-dimensional problems
  - MDU. 09:002; WAS. 02:014
- Torsion and bending
  - MDU. 09:004, 010, 025, 027
- Vibrations, structural dynamics
  - CIT. 01:001-003

Fluid Mechanics, Acoustics:
- Boundary layer theory
  - FRI. 02:001
- Compressible fluids: general theory
  - IAS. 09:003; SCI. 01:002; WAY. 02:001, 005

Mathematical Subject Classification

PHYSICAL APPLICATIONS OF MATHEMATICS (cont'd)

Compressible fluids: supersonic and hypersonic flow
IOW. 01:003; TEX. 01:001, 003-006
Compressible fluids: transonic flow
MDU. 09:008, 035
Free surface flows, water waves, jets, wakes
STA. 01:003
Incompressible fluids: general theory
BRO. 03:002; STA. 01:008
Incompressible fluids with special boundaries
MDU. 09:004
Shock waves
BRO. 03:001
Geophysics:
Meteorology
IAS. 08:001
Mechanics of Particles and Systems:
Foundations
LEH. 01:001, 002
Optics, Electromagnetic Theory, Circuits:
Diffraction, scattering
NYU. 06:021, 022
Electromagnetic theory
NYU. 06:017
Electron optics
NOT. 01:001
Technical applications
NYU. 06:007
Statistical Thermodynamics and Mechanics:
COR. 05:039, 045; IAS. 06:003
Gases
COR. 05:013, 017
Liquids
IAS. 06:003

PROBABILITY

MIN. 06:002
Applications
COR. 05:001
Distributions
COR. 05:014, 016, 018, 020, 048; MIN. 02:001; NCU. 05:001, 002
Elementary theory
COU. 06:015; NCU. 05:013
Limit theorems
COU. 06:010, 011, 017, 018; COR. 04:001; COR. 05:005, 009, 012, 024, 025, 041, 050 SYR. 01:014
Markov processes
COU. 06:001, 002, 004, 020; COR. 03:001; COR. 04:002, 003; COR. 05:023, 035, 055; SYR. 01:001-003, 005, 006, 010, 012, 013, 016
Special process, random walks
ILL. 06:001; MDU. 13:006; NCU. 05:020; SYR. 01:007, 008, 015
Stationary processes
COU. 06:005; PRI. 06:001
Stochastic processes: general theory
COU. 06:007-009, 012; COU. 07:007, 008; COR. 05:028, 040, 059; NCU. 05:014; SYR. 01:009

STATISTICS

Decision theory
COR. 05:018, 021; NCU. 04:002, 014, 028; NCU. 05:012, 015-018
Design and analysis of experiments
CHI. 01:002; COU. 05:014; NCU. 04:001, 004, 005, 007, 012, 018, 022, 023, 025, 026, 031; NCU. 05:007, 008, 019
Distributions of statistical functions
COU. 06:003; COR. 05:027; COR. 13:001, 004; NCU. 05:004, 014; SYR. 01:004
Elementary descriptive statistics
MIT. 10:065
Estimation theory (parametric case)
COU. 06:013; COR. 05:003, 018; MIS. 01:001, 007; NCU. 04:006, 009, 016, 019, 020, 029; NCU. 05:003, 013
Multistage decision procedures, sequential analysis
CHI. 01:003; COU. 06:021, 022; COR. 13:003, 005-012; NCU. 04:008, 010, 011, 013; NCU. 05:010, 011
Non-parametric methods and order statistics
COU. 06:019; COR. 05:022, 026; NCU. 04:027, 030; NCU. 05:009; SYR. 01:004
Testing of hypotheses (parametric case)
BOS. 01:001, 002; CHI. 01:001; COU. 06:006, 016; COR. 05:007, 037; NCU. 04:003, 017, 024, 032; NCU. 05:005, 006, 021

THEORY OF NUMBERS

Algebraic Numbers:
OSU. 01:002
Class fields
OSU. 01:001
Geometry of Numbers, Diophantine Approximation:
Geometry of numbers
COL. 03:008-010
Theory of Numbers: Analytic
Additive number theory, partitions
COR. 05:011
Analytic tools (zeta-function, L-functions, Dirichlet series)
COL. 03:004, 007; IAS. 07:001, 002
Theory of Numbers: General
Forms
COL. 03:001
Number-theoretical functions
COL. 03:002; IAS. 01:001

TOPOLOGICAL ALGEBRAIC STRUCTURES

Lie Groups and Algebras:
Lie algebras, Lie rings
EMO. 01:001; IAS. 03:003
Lie groups
IAS. 05:005
Representations
COR. 05:010

TOPOLOGICAL ALGEBRAIC STRUCTURES (cont'd)

Topological Groups:
- General
  - IAS. 05:009
- Semigroups and other generalizations
  - COR. 05:054; LSU. 01:001

Topological Vector Spaces, Functional Analysis:
- Applications of functional analysis; analysis of differential and integral operators
  - CHI. 06:003; COR. 05:049; NYU. 06:006, 013, 014; TEN. 01:001; YAL. 02:001, 002
- Banach spaces
  - CHI. 06:002, 006; NBS. 09:042; YAL. 02:002, 003
- Distributions
  - COR. 05:006, 054, 059
- Function spaces: general
  - NBS. 09:004; WIS. 01:005
- Groups and semi-groups of linear operators
  - SOC. 01:001; YAL. 01:001, 002
- Hilbert spaces
  - CHI. 06:005; COU. 07:004; PRI. 06:001, 002
- Linear operators
  - NYU. 06:018; PRI. 06:002; PRF. 02:001, 002; PUR. 02:001, STA. 01:001; SYR. 01:011
- Non-linear operators
  - IAS. 05:006
- Rings of operators, group algebras, abstract topological algebras and their representations
  - COR. 05:015, 036, 056

Topological Vector Spaces, Functional Analysis: (cont'd)
- Special function spaces
  - WAS. 02:007, 013; WIS. 01:003

TOPOLOGY

Topology: Algebraic
- Complexes and polyhedra
  - IAS. 09:005, 006
- Fixed point theorems
  - ILL. 04:001; ILL. 05:001-003; MUF. 01:001, 002, 004-006
- Homology and cohomology
  - STA. 01:006
- Transformations and special mappings
  - IAS. 02:001; IAS. 05:010

Topology: General
- Covering theorems
  - JHU. 08:001
- Fixed point properties
  - NBS. 09:016
- Metric and uniform spaces
  - MDU. 01:001; MIS. 01:003
- Topological dynamics
  - IAS. 02:002; PEN. 03:001, 002
- Topology of point sets, curves, continua
  - IAS. 05:011; MUF. 01:003
