Library of Congress Card No. 61-60038

This report has been released to the Office of Technical Services, U. S. Department of Commerce, Washington 25, D. C.

Qualified requestors may obtain copies of this report from the Armed Services Technical Information Agency, Arlington Hall Station, Arlington 12, Virginia.

FOREWORD

Any organization which has been granted the privilege of supporting basic research with public funds has a triple responsibility: to use those monies well and wisely, buying only the best; to observe, without unduly influencing, the progress and accomplishments of its investigators; and to strive to make the results of its research program freely available to the scientific community.

The Air Force Office of Scientific Research became an independent organization in August of 1955, and the principal agency through which the United States Air Force supported basic research outside its own laboratories. For some five years prior to this, the precursors of AFOSR—first in the Office of Air Research at Wright Field, then as a staff office in the Headquarters of the Air Research and Development Command in Baltimore, Maryland—had been supervising basic research contracts with universities and industry. These contracts formed the nucleus of the AFOSR program.

Since its beginning, AFOSR has encouraged, aided, and abetted its investigators in broadcasting the results of its studies. This they have done in diverse ways: in journal articles, in symposium papers, in books and monographs, and, when urgency could not brook the leisurely delays of scholarly publication, as "unpublished" research reports. Those reports, all too often regarded as ephemeral by their authors and by their recipients, produced in limited quantities, spurned until lately by standard abstracting services and even libraries, have all too recently been recognized, not just as transient clues to work in progress, but also as invaluable guides to work that has already been done. Despite the services of the Armed Services Technical Information Agency (ASTIA) and the Department of Commerce Office of Technical Services (OTS), discovery of such reports, particularly for the period spanned by this book, has not been easy. Nor, for that matter, are some of the journals in which our work has been published readily available in this country.

This book, then, brings together in one place, for the first time, abstracts of all publications produced during six years of research support by one agency, the Air Force Office of Scientific Research. It may be regarded, at the very least, as a report of our stewardship of some sixty million dollars of public monies. We hope it is more than that. We have supported the best of the scientists who sought our aid. These are the fruits of their labors. If this bibliography can provide clues to research that has already been done, if it can save precious laboratory time for doing new work rather than repeating old, it will amply repay the time and effort spent in its preparation.

KNOX MILLSAPS
Executive Director

PREFACE

Prolegomenon

"In science", wrote Lord Rayleigh in 1884, "by a fiction as remarkable as any in law, what has once been published is spoken of as known, and it is often forgotten that the rediscovery in the library may be a more difficult and uncertain process than the first discovery in the laboratory."*

A proper library, in those halcyon days, consisted of books and journals (preferably bound in calf), with a small clutch of pamphlets, feuilletons and the like relegated to the decent obscurity of some dark corner. What would Rayleigh have said, some sixty years later, of the invasion of such serene domains by a disorderly raggle-taggle of "documentary reports", pushing and crowding their elders from the shelves, defying regimentation, wearing neither uniforms nor badges of rank and, unfortunately, carrying too many messages from the front lines to be overlooked.

This book represents, in microcosm, such a library of the twentieth century—that curious melange of marks on variegated pieces of paper by which one of the basic drives of science, the urge and need to communicate, wells past and through the lags and lacunae of classic publication methods.

There are (at least) two sorts of library users: those who prefer to rummage through the stacks, and those who prefer first to paw through the card catalog. Many approaches to the problem of handling documentary reports have stopped, at least figuratively, with the card catalog, not even, in many cases, letting the customer use it but keeping it behind the reference desk. This bibliography attempts to provide the interested user access to the complete products of one agency over a six year period, appropriately indexed, to search as he will. This, in the Shavian dichotomy, is not a researching library, but a researchable library. Bonne chance!

Scope

This bibliography includes, within the limitations of the law of diminishing returns, abstracts of all technical notes, technical reports, journal articles, books, symposium proceedings, and monographs produced and published by scientists supported in whole or in part by the Air Force Office of Scientific Research during the period 1954 through 1956. It also includes all earlier reports supported by AFOSR or its anlage found during this search back through 1950.

The Air Force Office of Scientific Research supports fundamental research in the five major scientific disciplines: physics, chemistry, engineering sciences (subsuming mechanics and propulsion), life sciences (both biological and behavioral, but not medical), and mathematics. Thus, these abstracts are multi-disciplinary, their common link being their support by AFOSR.

Sources Searched

References, reports, and clues to the existence of reports were found by searching the indexes and report collection of the Air Force Office of Scientific Research Technical Library, and the collection of the ASTIA Document Center. Detailed searches were made of each contract file in the several AFOSR Directorates and Divisions.

* The quotation is borrowed from B. C. Vickery's "Classification and Indexing in Science", 2nd ed., Butterworths, London, 1959.

In addition, cover-to-cover searches were made of the following scientific journals for the specified time periods:

Acta Crystallographica	1953-1957
Acta Metallurgica	1953-1957
Aeronautical Engineering Review (Aero/Space Engineering)	1952-1958
American Journal of Mathematics	1954-1957
American Journal of Physics	1955-1957
Analytical Chemistry	1953-1957
Annals of Mathematical Statistics	1953-1958

Form of Entry and Arrangement

Inherent in the organization of this book is the concept of the reports within a contract as an unanalyzed monographic series. Reports are posted chronologically and/or alphabetically under contracts, these in turn under laboratories, and these under contractors. This does, in fact, provide a rough subject grouping, with the detailed subject index leading into clusters of like reports.

The abstracts are coded for possible future machine searching. A three letter mnemonic code designates the contractor; two digits are reserved for the contract; and three for the report within the contract. The lexicographer's trick of running page headings is used to indicate the scope of each page so that the searcher may home in on the proper area.

The form of entry is, in general, that being used for ASTIA catalog cards, i.e.: source of the document; title; personal author, if any; date; pagination; report number; contract number; and accession number.

Caveat Lector

The principal accession or control numbers, which indicate the location of the report in collections, are:

AD — ASTIA Document: available at ASTIA (Armed Services Technical Information Agency), Arlington Hall Station, Arlington 12, Virginia.

TIP — Technical Information Pilot: available at above address.

ATI — Air Technical Index: available at above address.

PB — Publication Board: for sale by the Office of Technical Services, Department of Commerce, Washington 25, D. C.

The fact that a report is abstracted in this book means that a copy of this report existed at the time the abstract was written; it should not be construed to imply that AFOSR necessarily has a copy available for distribution. Those seeking reports should do so from the cited agencies, not from AFOSR.

Indices

A detailed subject index, arranged alphabetically, has been provided. Because of the high percentage of mathematical papers included in this volume, a separate mathematical classification, made possible through the close cooperation of members of the Directorate of Mathematical Sciences, AFOSR, has been included. In addition to the subject indices, a contract index, an AFOSR control number index, and a personal author index are provided. A Code Guide, for identifying individual corporate entries, is included in three places.

Acknowledgements

Many people have made this book possible. The work has been fostered and encouraged by the previous Commanders of the Air Force Office of Scientific Research: Brigadier Generals H. F. Gregory and B. G. Holzman, and Colonel A. P. Gagge. Invaluable assistance has been given by AFOSR's own professional librarians, John Hetrick, Catherine Quinn and Eleanor Cipps. Alex Nagy, chief designer, and staff artist, Pat Shealy, of the Office of Aerospace Research drew the chapter end-plates (with the usual disclaimer about resemblances to persons living or dead being purely coincidental). And, perhaps most important of all, has been the cheerful and willing cooperation of the scientific staff of the Air Force Office of Scientific Research, both in locating the reports and in indexing them.

The bibliographic team has worked under the guidance and leadership of Dr. Clement R. Brown, Section Head of the Bibliography Section, Science and Technology Division, Library of Congress. The chief workers have been G. Vernon Hooker, Mabel H. Duffner, Aaron S. Dann, and Doris C. Yates; only their enthusiasm and untiring energy have carried them through a long task, made doubly arduous by the difficult pick-and-shovel chore of unearthing reports, and the intellectual skills required in developing new subject headings in advanced scientific areas.

Many other members of the professional and clerical staff of the Bibliography Section have participated in this effort. A special note of gratitude is due to those who have aided in abstracting and subject indexing, especially Jack R. Gibson, Thomas C. Goodwin, Vincent G. Waldron, Joseph W. Enke, and Bruce M. Blankenhorn. Recognition is also due for the invaluable work in the preparation of this manuscript done by Mrs. Marion S. Carr, assisted by Miss Mary Evelyn Briscoe, Mrs. Patricia Gravatt, Mrs. Loretta L. Franklin, Mrs. Beatrice T. Treese, and Mrs. Virginia Sims.

This bibliographic effort has been supported and supervised by the Information Sciences Division, Directorate of Mathematical Sciences, AFOSR, as part of a continuing research program to study and devise new and better ways of handling scientific and technical information.

THE ABSOLUTE THERMAL DECOMPOSITION RATES OF SOLIDS. PART I. THE HOT-PLATE PYROLYSIS OF AMMONIUM CHLORIDE AND THE HOT-WIRE PYROLYSIS OF POLYMETHYLMETHACRYLATE (PLEXIGLAS 1A), by R. D. Schuttz and A. O. Dekker. Nov. 1954 [15]p. incl. illus. diagrs. (Rept. no. TN-2) ([AF]OSR-TN-54-127) (AF 18(600)1026) AD 48403 Unclassified

Also published in Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y. Reinhold, 1955, p. 260-267.

Two new techniques are described for the direct measurement of linear decomposition rates of solids by pressing specimens of the solid against a hot surface maintained at constant temperature. Preliminary results on the thermal decomposition of pressed tablets of ammonium chloride at 300° - 600°C and the pyrolysis of polymethylmethacrylate (Plexiglas 1A) at 450° - 500°C are interpreted in terms of absolute reaction rate theory. These new methods may yield information useful in interpreting burning rates of solid propellants. (Contractor's abstract)

THE LINEAR VAPORIZATION RATE OF SOLID AMMONIUM CHLORIDE, by K. Bills, M. Therneau and others. July 1955 [8]p. incl. diagrs. (Rept. no. TN-10) ([AF]OSR-TN-55-117) (AF 18(600)1026) AD 67747 Unclassifted

The linear vaporization rate of compressed strands of ammonium chloride has been measured by an improved version of the hot-plate pyrolysis technique of Schultz and Dekker. ("The Absolute Thermal Decomposition Rates of Solids, Part 1," in Fifth International Combustion Symposium, Pittsburgh, 1954, Reinhold, 1955). Between 393°K and 807°K in vacuum the rate data correspond to the Arrhenius equation $B = 1.2 \times 10^2 \exp(-13,500/RT)$ $cmsec^{-1}$. At atmospheric ambient pressure, rates corresponding to this equation are obtained only above the 629°K temperature at which the equilibrium decomposition pressure of NH_4Cl is exactly 1 atmosphere. Below 629°K at atmospheric ambient pressure, the vaporization rate is limited by diffusion of NH_3 and HCl vapor away from the decomposition interface. (Contractor's abstract)

THE ABSOLUTE THERMAL DECOMPOSITION RATES OF SOLIDS. PART III. THE VACUUM SUBLIMATION RATES OF IONIC CRYSTALS, by R. D. Schultz and A. O. Dekker. July 1955 [33]p. incl. illus. tables, refs. (Rept. no. TN-7) ([AF]OSR-TN-55-138) (AF 18(600)1026) AD 67864 Unclassifted

The linear vacuum rates of sublimation of NaCl, NaBr, NaI, KCl, KBr, KI, RbCl, RbBr, CsCl, CsBr, CsI, BeO, MgO, CaO, CdO, NiO, SrO, BaO, ZrO_2, and ThO_2 have been estimated by use of absolute reaction rate theory. For those compounds which do not decompose during vaporization, reasonable agreement is obtained with rates measured directly, as in the case of KCl, or with rates derived from vapor pressure data by means of Knudsen's equation with the accommodation coefficient [α] assumed to be unity. The calculation from first principles of the activation enthalpy of sublimation is possible, at present, only for the alkali metal halides. An absolute rate treatment, very similar to that used for sublimation, is given for the linear rate of advance of the $CaO:CaCO_3$ interface during the decomposition of $CaCO_3$ crystal. THE ABSOLUTE THERMAL DECOMPOSITION RATES OF SOLIDS. PART IV. TRANSITION-STATE THEORY OF THE LINEAR RATES OF EXCHANGE AND DECOMPOSITTON OF CRYSTALLINE AMMONIUM CHLORIDE, by R. D. Schuttz and A. O. Dekker. July t955, t3p. (Rept. no. TN-8) ([AF]OSR-TN-55-t4t) (AF t8(600) 1026) AD 67749 Unctassifted

The equilibrtum rate of exchange of crystalline NH_4Ct with gaseous NH_3 and HCt is formutated according to the Laidler-Glasstone-Eyring treatment of the absolute rates of surface reactions ("The Absotute Rates of Surface Reactions", in Catalysis, P. H. Emmet, ed., v. t, pt. t: 195-243, Reinhold Publishing Co., N. Y., t954). This formutation is shown to be essentialty equivalent to that previously given for the maximum absotute rate of decomposition of crystalline NH_4Cl. The equivalence resutts from the use of the same modet for the activated comptex for each reaction, and provides support for the concept that the rate-controtling step tn the thermal dissociates of crystalline NH_4Ct is the desorption of gas motecules from a physicatly absorbed NH_3-HCt comptex. TRANSITTON-STATE TttEORY OF THE LINEAR RATE OF DECOMPOSITTON OF AMMONIUM PERCHLORATE, by R. D. Schultz and A. O. Dekker. July 1955, 3tp. diagrs. refs. (Rept. no. TN-9) ([AF]OSR-TN-55-t42) (AF t8(600)1026) AD 67748 Unctassified

Also published in the Sixth Symposium (International) on Combustion, Yate U., New Haven, Conn. (Aug. t9-24, t956), N. Y. Reinhold, t957, p. 6t8-626.

The experimental data of Bircumshaw and Newman (Proc. Roy. Soc. (London), v. 227A: tt5-t32, 228-24t, 1954) are anatyzed in terms of a linear rate of progression of the interface between residue and undecomposed crystal. Linear decomposition rates corresponding to given temperatures are derived directly from the maximum rate portions of the sigmoid curves of product pressure vs time. A proposat is made that tn the temperature range of 220° to 280°C, the decompositton interface travels exclusively through the disordered materiat between the mosaic blocks of the crystat and does not penetrate the interior of the blocks. Absotute rate treatments tn the manner of Laidler, Glasstone, and Eyrtng ("The Absotute Rates of Surface Reactions" in Catalysis, P. H. Emmet, ed., v. 1, pt. 1: 195-243, Reinhold Publishing Co., N. Y., 1954) are presented for each of the 2 crystal forms (orthorhombtc and cubic). These treatments are similar to those proposed for the sublimation of tonic solids and the vaporization of solid NH_4Cl, respectively. (Contractor's abstract)

BALLISTIC PROPERTIES OF FOUR EXPERIMENTAL SOLID PROPELLANTS FOR COMBUSTION STABILITY STUDIES, by C. O. Brown, L. Green, Jr., and D. M. Meehan. Mar. 23, 1955 [13]p. incl. diagrs. table. (Repl. no. TN-4) ([AF]OSR-TN-55-90(a)) (AF 18 (600)1048) AD 72530 Unclassified

The severity of the irregularities in chamber pressure attending unstable burning in solid-propellant rocket motors is known to be dependent in some fashion on the propellant composition and the configuration of grain and chamber. The objective of the present research is to investigate the effect of these variables. In the present study the specific impulse of the propellant is varied but not the general type of propellant system. For this purpose it was considered best to employ a propellant system using ammonium perchlorate as an oxidizer, and an organic resin as fuel. Then by varying the weight fraction of oxidizer in the mixture, the specific impulse of the propellant can be varied over a considerable range without changing the nature of the oxidizer. The experimental propellants are described and the calculated propellant properties are compared. (ASTIA abstract)

AN EXPERIMENTAL STUDY OF COMBUSTION INSTABILITY IN SOLID-PROPELLANT ROCKET MOTORS, by L. Green, Jr., M. Lipow, and K. L. Nail. July 1955, iv. incl. illus. diagrs. tables, refs. (Repl. no. TN-11) ([AF]OSR-TN-55-233) (AF 18(600)1048) AD 68446 Unclassified

The results obtained during the first 12-month period of an experimental investigation of unstable burning of solid-propellant charges are presented and briefly discussed. A comparison of four experimental, composite propellant formulations tested in internal-burning, tubular charges indicates that the tendency toward irregular reaction increases as the energy content of the propellant is raised, as long as the propellant burning rate is held constant. However, the highest-energy formulation showed a smooth reaction, owing to a lower burning rate than was desired, or, ultimately, to the coarse oxidizer grind employed in that formulation. The results suggest that a nominal rate of energy release (the product of burning rate, density, and heat of explosion) may possibly afford a measure by which the relative stability of various formulations may be estimated. STEADY-STATE PROPERTIES OF A SIMPLIFIED MODEL OF SOLID-PROPELLANT BURNING, by L. Green, Jr. Sept. 1955 [18]p. incl. diagrs. (Repl. no. TN-12) ([AF]OSR-TN-55-334) (AF 18 (600)1048) AD 77424; PB 140356 Unclassified

A model of solid-propellant burning is postulated, in which the complex chemical-reaction and heat-conduction problem in the gas phase is replaced by a simplified boundary condition which assumes convective heat transfer to the surface from a parallel flow of gas at flame temperature. The effective heat-transfer coefficient is assumed to be an inverse function of propellant burning rate, which in turn is assumed to be an Arrhenius function of the surface temperature. The model permits calculation of steady-state surface temperatures, burning rates, and temperature gradients which show the proper qualitative dependence upon the propellant and gas-flow parameters, and which, for the assumed values of these parameters, appear to be of the proper order of magnitude. PRESSURE-MEASURING INSTRUMENTATION FOR COMBUSTION STABILITY STUDIES, by L. Green, Jr. Dec. 1955 [42]p. incl. illus. diagrs. refs. (Repl. no. TN-14) ([AF]OSR-TN-55-474) AD 81081 Unclassified

A description is given of the operation of the 2 pressure-measuring instrumentation systems employed in investigating solid propellant combustion stability. One of the systems utilizes a low-frequency response to record the mean chamber pressure, while the other uses a high-frequency response to detect fluctuations around this mean value. The limitations of the low-frequency-response system are fairly well defined, but the limitations of the high-frequency-response system have not been determined accurately. This dual system is considered to be advancement over conventional pressure-measuring instruments; recommendations are made, however, for the use of further improved pressure-sensing elements and a tape recording system, as well as refined methods of determining the dynamic response of the pickups.

NONSTEADY BEHAVIOR OF A SIMPLIFIED MODEL OF SOLID-PROPELLANT BURNING, by L. Green, Jr. Nov. 1955 [21]p. incl. diagrs. (Repl. no. TN-15) ([AF]OSR-TN-55-473) (AF 18(600)1048) AD 81082 Unclassified

An analysis is presented of the nonsteady behavior of a previously proposed thermal model of solid-propellant burning (item no. AER. 02:005) in an effort to solve the

AER. 02:008 - AER. 02:011

problem of pertodic deflagration. The assumption ts made that a small time inlerval is required for completion of the phase change of the propellant malter from the solid to the gaseous stale tn a thin zone (burning surface). The results tndicate thal when the simplifted lransfer coefftctent, assumed to govern heat flow to lhe surface, fluctuates al high frequenctes, conditions can exist under which a coupling between the heat-transfer fluctuation and the decomposition reaction can cause large amplitude osctllations of the surface lemperalure; consequently, signiftcant deviations appear tn the mean effective burning rate from tts nominal steady-stale value. The predicled dependence of the model behavior upon the propellant and the operating condition paramelers appears to be tn qualitative agreemenl with the known behavior of actual propellants.

AER. 02:008

Aerojet-General Corp., Azusa, Calif.

STUDIES ON THE REACTION STABILITY OF SOLID PROPELLANT CHARGES, by L. Green, Jr. Ftnal repl. Apr. 1, 1954-Jan. 31, 1956. Mar. 9, 1956, 1v. incl. tllus. diagrs. tables, refs. (Rept. no. 1077) (AFOSR-TR-56-10) (AF 18(600)1048) AD 86012 Unclassifted

Research was conducted to acquire a clearer understandtng of the phenomenon of resonant burning tn solid-propellant rocket motors. An analysis of the effecl of transverse velocity fluctuations upon the rale of heat transfer from a gas to a solid, wtth fluid tnjection at lhe wall, indicated that the effect ls small when the flow conditions are lamtnar; the effect may be signiftcant when turbulent conditions prevail. An analysis of a simplifted thermal model of solid-propellant burning indicated that small fluctuations in heat-transfer rate can cause signiflcant vartations tn propellant burning rate. Tests of one propellant at 170°F in 4 different charges sbowed that charge conftguratton influences reaction stability. A comparison of 4 experimental composite propellant formulations with nominally constant burning rates tested at 170°F in internal-burning tubular charges indicated that the tendency toward irregular reaction increases as the energy content of the propellant ts increased, as long as the propellant burning rate is constant. Tests of the rod-in-sheil charge were made with the aid of 2 high-frequency-response pickups tn order to detect phase or amplitude differences tn the pressure-time traces; results tndicated that the observed oscillations corresponded to stationary wave patterns.

AER. 02:009

CHARGE-CONFIGURATION EFFECTS IN SOLID-PROPELLANT COMBUSTION, by L. Green, Jr. [Apr. 1956] 1v. incl. illus. diagrs. tables, refs. [AF 18(600)1048] Unclassifted

Static tests of a high-energy, composite solid propellant al 170°F tn four different types of charge tndicated a strong influence of charge conftguration upon the stability of the propellanl reaction, as manifested by the regularity of the mean chamber pressure vs time history. The relative tendency of short, internal-burning charges with annular and cylindrical cavities to exhibtt "resonant" burning was found to be in disagreement with the behavior predicted by Cheng's analysis of the "sonant" burning phenomenon. The several lypes of charge also exhibtled different average burning rale vs average chamber pressure characterlstics. Qualilative observations suggest that the relative reaction stabtlity of different solid propellant charge conftgurations may be delermined by viscosily effects, rather than tn the mechanisms postulaled ln Cheng's ldeal-fluid analysis. Tests of rod-in-shell charges, using two pressure ptckups in an effort to observe phase differences tn the pressure-time traces oblained, tndicaled that the observed osctllations probably corresponded to stationary wave patterns. Aerojet-General Corp., Azusa, Calif.

SOME PROPERTIES OF A SIMPLIFIED MODEL OF SOLID-PROPELLANT BURNING, by L. Green, Jr. [1956] [46]p. Incl. illus. diagrs. refs. [AF 18 (600)1048] Unclassified

Published as Amer. Rocket Soc. preprint no. 339-56, Nov. 1956.

A thermal model of solid-propellant burning is postulated, in which the complex chemical-reaction and heat-conduction problem in the gas phase is replaced by a simplified boundary condition which assumes convective heat transfer to the surface from a parallel flow of gas at flame temperature. The effective heat-transfer coefficient is assumed to be an inverse function of propellant burning rate, which in turn is assumed to be an Arrhenius function of the surface temperature. This model permits calculation of steady-state propellant temperatures, burning rates, and temperature gradients which show the proper qualitative dependence upon the propellant and gas-flow parameters and which, for the assumed values of these parameters, appear to be of the proper order of magnitude. The non-steady behavior of the model is analyzed. It is indicated that, when the simplified transfer coefficient assumed to govern heat flow to the surface fluctuates at high frequencies, conditions can exist under which a coupling between the heat-transfer fluctuation and the decomposition reaction can cause large-amplitude oscillations of the surface temperature, and, consequently significant deviations in the burning rate from its nominal steady-state value. The predicted dependence of the model behavior upon the propellant and operating-condition parameters appears to be in qualitative agreement with the known behavior of actual propellants. A VERSATILE, 1000-CURIE, COBALT-60 GAMMA-RAY SOURCE, by E. Hermats and G. Moe. July 1956 [35]p. incl. diagrs. tables. (Rept. no. TN-16) (AFOSR-TN-56-339) (AF 18(600)1216) AD 95215 Unclassified

A description is presented of the design and installation of a 1000-c Co^{60} source for conducting γ radiation studies. The installation consists of a movable source

AER. 05:002 - ANS. 0t:002

shielded by earth, concrete, and otl. The Co^{60} ts divided into 5 capsules of 200 c each, which may be moved individually or in selecied grouptngs from storage at the bottom of a 2t-fi concrete-lined shaft. This is accomplished by making the capsule a part of a sprocket-and-chain assembly which ts driven by an electric motor. When the capsule reaches the operating position, 8 ft below the ground level, tt actuates a switch which stops the motor drive. The calculated dose rate of this source ts approximately 14,000 r/hr at 1 ft, 300 r/hr on the roof tnside the fence. Personnel safety ts provided by interlocks, alarms, a remole area monitoring system, safety steps in operating procedure and the weartng of pocket dosimeters. The tnitial loadtng and the routine starting, trradiation and shuttingdown procedures are detailed for the Co^{60} source. Brief descriptive data are furnished in table form for 15 other Co^{60} irradiation sources as reported in the literature. The γ ray source described here was consiructed for a study of the possibility of producing higher-energy propellanls based on recombination of free radicals. Published observations had lead to calculations which indicated that if a slurry of 90 wt-% NH_3 in liquid H were irradialed until 50% decomposed to N + 3H, the resultant system would have a specific impulse of 600 lb-sec/lb. RESEARCH ON ULTRA-ENERGY FUELS FOR ROCKET PROPULSION, by L. Baum, H. Graff and others. Final rept. July t, 1954-June 30, 1956. July 31, 1956 [47]p. incl. diagrs. tables, refs. (Rept. no. 1149) (AFOSR-TN-56-346) (AF 18(600)1216) AD 95432 Unclassified

Research was underiaken lo determine the applicability of free radicals and atoms as high-energy subsiances. A theoretical consideration of tne relation of energy to thrust indicated that high specific impulse in rockets can best be achieved by using low-molecular-wetght gases, e.g., H or He, as working fluids. A method was conceived for using free radicals as a means of heating liquid H to the operating temperature. Methods of preparing and siabilizing free radicals are discussed, and the results of some experimental studies are given. A study of the stabtlization of the tmine radical indicated that the blue material reported to be NH ts probably electronically excited HN_3, and that the association of the blue material with NH is unitkely. Measurement by means of a new described microcalorimeter, indicated that irradtation of azomethane at -t96°C resulted in about t% decomposition, giving methyl radicals which may be stable at thal temperature. Several olher systems were explored using photolysis at liquid-N temperature. No decomposition products were observed for samples of acetone, nitrogen dioxide, cyanic acid, and chlorine. For diazomethane, a strongly exothermic reaction was noted. For ketene, little noncondensable material was observed, and ketene and diketene were found tn the product. Proposed work includes use of a 1000-c Co^{60} γ-ray source, described elsewhere, for trradiation al low temperatures. In this connection, it was estimated that by trradiation at 400-c of solid NH_3 about $t0^3$ radical pairs/γ-ray are produced. (ASTIA abstract tn part)

THE DESIGN OF A MULTICHANNEL TRANSISTORIZED FM/FM TELEMETERING SYSTEM WITH A COSMIC RAY DIRECTION CHANNEL, by R. C. Elton (Maryland U. Dept. of Physics). May t956 [62]p. incl. illus. diagrs. refs. (Md. U. Physics Dept. technical rept. no. 38) [AF 49(638)55] Unclassified

The design of a multichannel transistorized FM/FM telemetering system suitable for use in upper atmosphere experimenls is descrtbed. The system consists of four subcarrier aduio osctllaiors whose signals are combined to form the composite signal used to frequency modulate the radio frequency transmitter; plus a geiger tube and its associated circuitry consisting of a + 900 vdc supply, a scale-of-t6 stage, and a preamplifier. A transistorized version of the familiar Colpttis oscillaior is used to generate the subcarrier audio signals, which are frequency modulated by the information delected. A discussion of the exiensive temperature tesis on the audio oscillaiors and the resulting stabilization ts included. Also two basic methods of frequency modulating the subcarrier audio oscillators have been analyzed. A transistorized inductive kick method of generating the + 900 vdc necessary for the geiger tube from 15 vdc is discussed including regulation characierlstics; the scale-of-16 stage used is composed of cascaded scale-of-two stages and is also transistortzed. Due to the relatively low input impedance of the geiger tube, it was necessary to incorporate a preamplifier between these two stages. This amplifier consists of a buffer siage followed by an emitter follower stage. A hrief outline of transistor ctrcuit principles has been included to assist the reader in understanding the discussion of the transistor circuits involved tn the system. (Author's abstract)

STUDY OF BASIC MECHANISM OF DIFFUSION OF METALS INTO CERAMIC MATERIALS, by R. C. Turnbull. Technical rept. no. 1 for period Jan. 10, 1953 - Jan. 11, 1954. 7p. diagrs. (Rept. AU no. 1) ([AF]OSR-TR-54-9) (AF 18(600)591) AD 29788 Unclassified

Three techniques are discussed for evaluating the concentration changes of radioactive tracers in a diffusion experiment: (1) assays of slices removed from the specimen; (2) measurement of the change of radioactivity at the surface; and (3) photographic means. In this experimental study, samples of optically clear periclase were prepared by splitting large single crystals along crystal planes into specimens 1 cm on a side and .5 cm high. The sides of the specimens were covered with a strippable organic coating. The radioactive metal was condensed on the crystal face. The diffusion coefficients were determined for Fe, Co, and Ni in MgO at different temperatures. The activation energy was obtained by plotting the log of the diffusion coefficient against the reciprocal of the absolute temperature.

ON SEVERAL EXTENSIONS OF THE TAYLOR-GOLDSTEIN THEORY OF DIFFUSION BY DISCONTINUOUS MOVEMENT, by I. Michelson. [1953] [50]p. (AF 18(600)476) Unclassified

This contribution is a development of the work of Taylor and Goldstein in which mathematical models were considered representing diffusion by discontinuous movements. The meritorious features employed by them and those used by the author are discussed. Appropriate mathematical techniques for the analysis of each type of problem considered are indicated. The structure of solutions of the several equations derived is discussed in terms of "dispersion" of progressive waves which are regarded as fundamental elements of all propagation processes. DISCUSSION AND EXTENSION OF GOLDSTEIN'S MATHEMATICAL MODEL REPRESENTING DIFFUSION WITH HYPERBOLIC PARTIAL DIFFERENTIAL EQUATION [PART I], by I. Michelson. Technical rept. Jan. 11, 1954, 58p. (Rept. no. AR-1; rept. no. 193) ([AF]OSR-TN-54-53) (AF 18(600)476) AD 27865 Unclassified

The random walk problem examined by S. Goldstein is given an orientation convenient for comparison with well understood problems, and also for extension to the case in which diffusion is not assumed isotopic. The relationship of the several processes so considered, with the corresponding cases of continuous movements, is explored to determine the necessary modifications required in Fick's Law. The proper formulation of a complete mathematical problem is next considered, and further consequences of the use of hyperbolic equations are pointed out. General properties of solutions are discussed and the detailed analytic procedure given for giving representations of solutions in one case of interest. (Contractor's abstract)

THE CONNECTION BETWEEN THE SMOLUCHOWSKI EQUATION AND THE KRAMERS-CHANDRASEKHAR EQUATION, by R. W. Davies. [1954] [2]p. [AF 18(600)476] Unclassified

Published in Phys. Rev., v. 93: 1169-1170, Mar. 15, 1954.

It is known that the probability density, W(x, v;t), in phase space, of a particle describing Brownian motion is governed by the differential equation

$$W_t + vW_x = \{[\beta v - K(x)]W\}_v + (kT\beta/m)W_{vv},$$

where K (x) is an external force, T is the temperature, m is the mass and k is Boltzmann's constant. From this equation one readily obtains by integration $\rho_t + (\rho\bar{v})_x = 0$, and $(\rho\bar{v})_t + (\rho\langle v^2\rangle)_x + \beta\rho\bar{v} = K(x)\rho$, where $\rho(x,t) = \int_{-\infty}^{+\infty} W(x,v;t)dv$ and $\rho\langle v^2\rangle = \int_{-\infty}^{+\infty} v^2 W dv$. Eliminating $\rho\bar{v}$ from the foregoing two equations we obtain

$$\frac{1}{\beta}\rho_{tt} + \rho_t + \left(\frac{K(x)\rho}{\beta}\right)_x = \left(\frac{\rho\langle v^2\rangle}{\beta}\right)_{xx}$$

On the other hand, it has been stated in the literature that for times $t \gg \beta^{-1}$, the probability density ρ is governed by the Smoluchowski equation

$$\rho_t + \left(\frac{K(x)\rho}{\beta}\right)_x = \frac{kT}{m\beta}\rho_{xx}.$$

The author discusses the sense in which solutions of equation (4) may be considered as the limiting forms of the solutions of (3); and shows, in particular, that in order to obtain equation (4) in the limit $\beta \to \infty$, we must let $\langle v^2\rangle$ and K (x) also approach infinity in such a way that $\lim_{\beta\to\infty}(\langle v^2\rangle/\beta) = kT/6\pi a\eta$, $\lim_{\beta\to\infty} K(x)/\beta = U(x)$, where U (x) is the "drift" velocity, η is the absolute viscosity of the liquid surrounding the particles and a is the particle radius. ON DIFFUSION MODELS LEADING TO HYPERBOLIC PARTIAL DIFFERENTIAL EQUATIONS, PART II, by R. W. Davies and T. B. Smith. [1954] [17]p. (Bound with its Rept. no. 201; AD 32814 as Part II of AFOSR-TN-54-62) (AF 18(600)476) AD 32814(b) Unclassified

Refined diffusion equations are derived from various 1-dimensional random-walk models. Consideration is given to the random-walk models of R. Furth (Z. Physik., v. II: 244-256, 1920) and G. I. Taylor (Proc. London Math. Soc., v. 20: 196-212, 1921-22). Goldstein's model (Quart. J. Mech. Appl. Math., v. 4: 129-156, 1951) is extended so that the presistence probability is not isotropic, and several diffusion equations are derived from this model. A more complicated model is treated by using essentially the same probabilistic technique as Goldstein, Furth, and Taylor. In the first model particle velocities may exist, but particle accelerations do not exist. In the second model the particle accelerations may exist, but the rate of change of acceleration does not exist. (ASTIA abstract)

A SOLUTION OF A HYPERBOLIC DIFFUSION EQUATION FOR WHICH PROBABILITY IS CONSERVED, PART III, by R. J. Diamond and R. W. Davies. [1954] [20]p. (Bound with its Rept. no. 201; AD 32814 as Part III of AFOSR-TN-54-62) (AF 18(600)476) AD 32814(c) Unclassified

Two derivations are presented of the diffusion equation $\rho_{tt} + \beta\rho_t = c^2(\rho_x + \rho_{xx} + \rho_{yy} + \rho_{zz})$ where t is time, and x, y, and z are the 3 rectangular coordinates of physical space. One derivation is based on physical reasoning, and the other is based on probability considerations. An initial-value solution for the equation is obtained in the 3 sets $r<ct$, $r>ct$, and along the characteristic cone $r^2 = c^2t^2$. The solution for $r>ct$ is zero so that any modification of it alters the initial values. The solution for $r<ct$ can be multiplied by any constant N without changing its value at $t = 0$, so that the initial conditions are found on the characteristic surface.

ON THE CONNECTION BETWEEN SMOLUCHOWSKI'S EQUATION AND THE KRAMERS-CHANDRASEKHAR EQUATION, PART IV, by R. W. Davies. [1954] [4]p. (Bound with its Rept. no. 201; AD 32814 as Part IV of AFOSR-TN-54-62) (AF 18(600)476) AD 32814(d) Unclassified

Also published in Phys. Rev., v. 93: 1169-1171, Mar. 15, 1954.

Consideration is given to the equations $W_t + vW_x = \left[(\beta v - k(x))W \right]_v + \left(\frac{kT\beta}{m} \right) W_{vv}$ and $\rho_t + \left[K(x) \rho / \beta \right]_x = (kT/m\beta)\rho_{xx}$. The first equation is satisfied by W(x, v;t), the probability density for a Brownian particle in the phase space x, v where it is assumed that the Brownian motion is a simple Markov process in phase space. The second equation is satisfied by the probability density $\rho(x,t) = \int_{-\infty}^{\infty} W(x, v;t)dv$, where it is assumed that the Brownian motion is a simple Markov process in the configuration space x. The first equation when transformed into a diffusion equation in configuration space is shown to differ from the second equation by the term $(1/\beta)\rho_{tt}$. Solutions of these 2 equations are discussed. (ASTIA abstract)

FUNDAMENTAL ROCKET RESEARCH, by E. B. Zwick, G. R. Morgan, and H. H. Cover. Summary rept. for period July 1, 1954-July 1, 1956. Aug. 10, 1956, 1v. incl. illus. diagrs. tables. (Rept. no. AMF/TD-QA-104) [AFOSR-TR-56-55] (AF 18(600)1192) AD 110375 Declassified

The results of a combined analytical and experimental investigation into combustion phenomena in liquid propellant rocket motors are presented. The first of two analyses presented treats the rocket motor as a homogeneous reactor in which maintenance of combustion is provided by violent mixing and heating of the incoming propellants with the combustion products within the motor; the second deals with a recirculating reactor in which heating of the incoming propellants is obtained by a large-scale recirculation of exhaust products within the combustion chamber. Reaction times predicted from the analysis of the recirculating reactor were verified experimentally in a reaction chamber with simulated recirculation. The analysis of homogeneous reactor indicates that a rocket motor, with violent mixing in which chemical processes are rate-controlling, has a minimum characteristic length which varies inversely with p^{n-1}, where p is the chamber pressure and n is the order of reaction. The analysis is shown to agree generally with experimental data from ethylene oxide gas generators. The analysis of the recirculating reactor indicates that a rocket motor in which stable combustion is maintained by mixing and heating of the injected propellants with recirculated exhaust products has a minimum chamber stay time for steady operation. This minimum stay time depends on the fraction recirculated and for a given fraction recirculated varies inversely with p^{n-1}. Reaction times determined experimentally from a reaction chamber with simulated recirculation are in good agreement with reaction times predicted from chemical kinetic theory. Difficulties in procedure limited the range of experimental data. The applicability of chemical kinetic theory to the investigation of combustion processes in liquid propellant rocket motors is deemed justified. (Contractor's abstract)

ON THE DEVELOPMENT OF RATIONAL SCALING PROCEDURES FOR LIQUID-FUEL ROCKET ENGINES, by S. S. Penner. Sept. 19, 1956, 27p. (Rept. no. AMF/TD TR-101; technical note no. 1) (AFOSR-TN-56-383) (AF 18(603)107) AD 95819 Unclassified

Also published in Jet Propulsion, v. 27: 156-161, Feb. 1957.

A critical summary is presented of recent theoretical studies concerning similarity analysis and the scaling of liquid-fuel rocket engines. The similarity parameters for the steady aerothermochemistry of motor operation are defined. The discussion of a general formulation of scaling procedures is restricted to a fixed bipropellant mixture which is injected at the same temperature in both model and large-scale experiments. The special features of the bipropellant operation are emphasized. The Penner-Tsien scaling rule of fixed chamber pressure is developed, with the analysis illustrated by an example of a simplified combustion process. A discussion of the occurrence of high-frequency oscillations follows. The method of engine scaling as presented by Crocco (Scaling of the Liquid-fuel Rocket Engines, paper presented at the 2nd AGARD Combustion Colloquium, December 1955) is developed. This method considers design restrictions arising if similarity is maintained with respect

AMF. 02:002 - ANT. 01:001

to the cooling system, low-frequency oscillations, and nozzle design. It includes the rule for a fixed Mach number and the invartant Damköhler ftrst similarity group. A rational experimental program for the study of scaling procedures is suggested with spectal considerations to be given to diagnostic modeling, expertments concerning effects of pressure on operation, and effects of tnjection velocity and droplet size on motor performance.

ON GENERALIZED SCALING PROCEDURES FOR LIQUID ROCKET ENGINES, by S. S. Penner and A. E. Fuhs. Oct. 10, 1956 [23]p. incl. tables. (Rept. no. AMF/TD TR-104; technical note no. 2) (AFOSR-TN-56-510) (AF 18(600)107) AD 110325 Unclassifted

Also published in Combustion and Flame, v. 1: 229-240, June 1957.

The scaling procedures of Penner and Tsien, of Crocco and of Barrere have been generalized by using the assumption that the mean drop size is proportional to the product of powers of the Weber number and the Reynolds number, together with the hypothesis that the total conversion time vartes as a power (usually the second) of the drop diameter. The results obtained for the steady aerothermochemtstry and for unstable motor operation (low-frequency and high-frequency osctllations) are shown to reduce to previously pubitshed rules when suitable simplifying assumptions are made. MATtIEMATICAL REVIEWS, ed. by J. V. Wehausen and S. tt. Gould. 1949-1958. (AF t8(600)132 and AF 49(638)239) Unclassifted

Unavailability of the German comprehensive reviewing and abstracting servtce for mathematics during World War tI caused the American Mathematical Society to start tts own abstracting service. This effort was supported in part by the Office of Naval Research (1946-t949) and then by the Air Force Research and Development Command (1949-1958) under what eventually became the Mathematical Sciences Directorate of the Air Force Office of Scientific Research. A yearly rate of over 5,000 abstracts has been maintained, amounting to 1t volumes each year. Mathematical Reviews is the only comprehensive English language mathematical ahstracting service. It covers all fields of mathematics from topology and advanced algebra to mathematical physics and mechanics. tt obtains and abstracts all the major and most of the minor mathematicat pubtications in the worttd, and deliberately stresses papers written tn Russian and tess accessible languages by providing more comprehensive reviews of these papers. Mathematical Reviews at the present time uses over 750 reviewers who are the recognized authorities in their respective fields to provide useful, authoritative and complete reviews. These reviewers and the elected offtcers of the Soctety carry out their duties as a service to sctence and for the prestige involved.

COMPARISON OF PINCH-CALIPER AND X-RAY MEASUREMENTS OF SKIN PLUS SUBCUTANEOUS FAT, by S. M. Garn. July 27, 1956 [1]p. lncl. diagr. (AFOSR-TN-56-133) (AF 18(600)1566) AD 86009 Unclassifted

Also published in Sctence, v. 124: 178-179, July 27, t956.

The thtckness of the fat-plus-skin layer, at the level of the lowest rtb at the midaxillary line, was determined by both roentgenogramnetrtc- and sprtng-loaded ptnch-caliper measurements. Ptnch calipers, exerting a force of 300 g over a 30 sq mm area, were used to measure a double "fatfold", while measurements of the single-thickness shadow were made on standardized teleoroentgenograms. For 65 young men aged 2t to 22 yr, the medtan pinch-caliper value and roentgenogram-metric measurement were 12.0 and 9.3 mm, respec-ttvely. The actual pinch-caliper values were 65% of the true double thickness (t8.6 mm). Percentage compression appeared to be constant over the full range of pinch-caliper values obtained.

COMPARISON OF PINCH-CALIPER AND TELEOROENTGENOGRAMMETRIC MEASUREMENTS OF SUBCUTANEOUS FAT, by S. M. Garn and E. L. Gorman. Dec. 1956 [7]p. incl. diagrs. tables, refs. [AFOSR-TN-56-185] (AF 18(600)1566) AD 115069 Unclassified

Also published in Human Biol., v. 28: 407-413, Dec. 1956.

Roentgenogrammetric and pinch-caliper measurements of the fat-plus-skin thickness at the lower thoracic region at the midaxillary line were compared. For 65 young adult males (age 21 and 22 yr), the correlation between the 2 sets of measurements was 0.88. The 2 distributions were of comparable form and degree of skewness, but the "double skinfolds" averaged 70% of their calculated true value, indicating 30% reduction due to tissue compression under a total force of 300 g.

EXPERIMENTAL VALIDATION OF ROENTGENOGRAMMETRICALLY-DETERMINED SOFT TISSUE VOLUMES (Abstract), by S. M. Garn and E. L. Gorman. Apr. 1956 [1]p. (AF 18(600)1566) Unclassifted

Presented at Twenty-fifth annual meeting of the Amer. Assoc. of Physical Anthropologists, Chicago, Ill., Apr. 6-8, 1956.

Published in Amer. Jour. Phys. Anthropology, (New Ser.), v. 14: 374-375, June 1956.

The present study is concerned with validation using a water displacement technique. The basic apparatus consists of a vertically mounted 33-inch length of 12-inch air conditioning ducting, fitted with a reinforced bottom and equipped with a water inlet, drain, and a glass water-level gauge. Water at body temperature is pumped from a constant-temperature reservoir. In practice, the actual displacement of a 33-cm length of thigh is determined and this measured volume compared to the volume obtained by planimetry from a standardized A-P roentgenogram of the left thigh area. The relationship between the gross thigh volumes and the computed volumes is fully rectilinear, and when fully corrected, deviations of less than ± 200 cm^3 in 5000 cm^3 may be expected. Measured volumes range from 2900 to 6315 cm^3 for subjects weighing 61 to 109 kg respectively. On this basis, the muscle volumes bear a close relationship to the amounts of these tissues present. Further validation of the muscle mass is now in process, using creatine-creatinine conversion as a biological index of the functioning muscle mass. (Contractor's abstract)

ANALYSIS OF COMBUSTOR PERFORMANCE BASED ON SIMPLIFIED CHEMICAL KINETICS, by E. Mayer. Mar. 1956, 1v. incl. diagrs. table. (Technical note no. 4555-1) (AFOSR-TN-56-40) (AF 18(600)1560) AD 80552 Unclassified

An analysis is presented of the performance of a piloted can-type burner as a representative model of combustors with mass addition and heat evolution governed by a reaction-rate law. The analysis starts with a statement of the aerothermodynamic equations in a form suited for the treatment of ducted compressible flow with mass addition and internal heat generation. These equations possess simple solutions for a burner model operating at constant temperature and constant velocity. The model considered leads to elementary expressions for burner performance in terms of through-put [mass flow rate at burner exit/mass flow rate at burner entrance], order of the reaction, and a suitably defined velocity parameter. These simple analytical results permit the treatment of certain composite combustors, such as a can-type burner and a constant-area duct (tailpipe) in series combination, without excessive mathematical complications. The results also suggest an analytic approach to the treatment of mixing delay effects such as the can-type burner containing completely mixed and completely unmixed streams in parallel.

CALCULATION OF REACTION RATE PARAMETERS FROM FLAME SPEED DATA ON LAMINAR FLAMES, I, by E. Mayer and H. Carus. July 1956 [22]p. incl. diagrs. tables, refs. (Technical note no. 4555-2) (AFOSR-TN-56-286) (AF 18(600)1560) AD 89496 Unclassified

In the analysis of many technical combustion problems the rate controlling step is assumed to be given by a phenomenological reaction rate law of the Arrhenius type:

$$\frac{d\rho_{Fu}}{dt} = -B'\rho_{Fu}^{m}\,\rho_{ou}^{n}\,e^{-E/RT}$$

The Arrhenius parameters B', E, m, n may be determined by comparison of experimental flame speed with calculated data based on the assumed form of the reaction rate law. A numerical procedure is described for the calculation of laminar flame speeds based on the Arrhenius law. This procedure is practicable for temperature-dependent gas properties and general values of m and n. The procedure is applied to the determination of E and B' for propane-air mixtures treated as a second-order reaction with m = n = 1. This is done by matching 2 points of the experimentally observed flame-speed vs mixture ratio curve to corresponding calculated flame-speeds. Plausible agreement

is obtained with calculated results based on Semenov's approximate flame-speed formula for m = n = 1. Dedetailed study shows that agreement between experimental and calculated flame-speeds based on the Arrhenius law cannot be obtained for an extended range of mixture ratios if the overall second-order reaction is first order with respect to each reactant species. Further study with nonintegral m and n is planned in an attempt to improve the agreement between observed and calculated dependence of flame-speed on mixture ratio. (Contractor's abstract)

ANALYSIS OF LAMINAR FLAME PROPAGATION LIMITS DUE TO THERMAL LOSS, by E. Mayer. Sept. 1956 [29]p. incl. diagrs. table, refs. (Technical note no. 4555-3) (AFOSR-TN-56-478) (AF 18(600)1560) AD 97362 Unclassified

The effect of thermal loss on laminar flame propagation is investigated on the basis of simplified (Semenov) relations in thermal flame theory. With heat loss from the flame front to the cold wall of a cylindrical burner assumed proportional to flame thickness, it is found that flame propagation limits, governed by the heat loss, occur at finite combustible mixture strengths and finite low pressure. The limiting heat loss in the cylindrical burner is interpreted as representing conditions observed in quenching experiments. Under quenching conditions, the relations between actual and adiabatic flame parameters (T_f = flame temperature, S_u = flame velocity, δ = flame thickness) are found to be, in a high approximation,

$$T_f = \frac{T_f^a}{1 + \left(\frac{E}{RT_f^a} + 4\right)^{-1}} \qquad S_u = e^{-1/2} S_u^a \qquad \delta = e^{1/2} \delta^a$$

where the superscript a refers to adiabatic values. The theory also predicts the existence of a limiting Peclet number based on flame speed. Preliminary comparison of the theory with experimental data indicates the applicability of the thermal loss theory to quenching and to related limiting flame propagation data. THE CURRENT STATUS OF RESEARCH ON TURBULENT COMBUSTION IN PREMIXED GASES, by R. R. John. Nov. 1956, 15p. incl. refs. (Technical rept. no. 4555-1) (AFOSR-TR-56-59) (AF 18(600)1560) AD 115004 Unclassified

A review is presented of the current status of research on turbulent combustion in premixed gases. It is indicated that there is a spectrum of different possible mechanisms which govern the effect of turbulence on the reaction zone. The different mechanisms are identified with the wrinkled laminar flame, the zone of extended reaction, and the zone of instantaneous mixing. The major emphasis of the review is directed towards a discussion of the zone of extended reaction. It is suggested that the differences between the various mechanisms of turbulent combustion preclude the possibility of obtaining a simple quantitative theory of turbulent flame propagation in premixed gases. ANALYSIS OF A CAN-TYPE RAMJET BURNER, by E. Mayer. Jan. 20, 1956, 3p. [AF 18(600)1560] Unclassified

The performance of an idealized can-type ramjet burner is investigated analytically under conditions of rapid mixing, when a chemical reaction rate law is the rate controlling step in the combustion process. The analysis of the burner under these conditions is greatly simplified by the assumption of instantaneous mixing and heat exchange of the injected pre-mixed combustible gas with the main flow at the zone of injection. COORDINATION OF COPPER (II) IN COPPER 8-HYDROXYQUINOLINOLATE DIHYDRATE, by R. [F.] Kruh and C. W. Dwiggins, Jr. [1955] [3]p. (Bound with its AFOSR-TR-57-5; AD 115070 as Appendix 9) (AF 18(600)960) Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 806, Feb. 5, 1955.

The crystal structure of copper 8-hydroxyquinolinolate dihydrate, $Cu(C_9H_6ON)_2 \cdot 2H_2O$, has been determined as part of a study of the stereochemistry of copper (II). It has been found that this copper salt is isomorphous with the corresponding zinc salt whose structure has been determined by other authors. This finding raises the interesting question as to whether the anhydrous copper and zinc salts are also isomorphous. Hsu and Ballar have found tetrahedral coordination of the metal in the zinc salt of 8-hydroxyquinoline-5-sulfonic acid, and it is reasonable to assume the same arrangement in the 8-hydroxyquinolinolate. Now since copper (II) shows such a strong tendency to square planar coordination it would be extremely unusual if the isomorphism were found to persist in the anhydrous salts. The actual arrangement in the anhydrous copper salt remains to be investigated, but the supposition is strong

that copper's coordination is not tetrahedral, but rather square planar. The ubiquitous square planar coordination of copper (II) is found in the dihydrate. (Contractor's abstract)

THE EFFECT OF THE SELF-MAGNETIC FIELD UPON THE CHARACTERISTICS OF A POSITIVE COLUMN WITH AXIAL SYMMETRY, by M. Hoyaux and P. Gans. [1954] 25p. incl. diagrs. tables. (Rept. no. EOARDC-TN-54-1) [AFOSR-TN-54-306] (AF 61 (514)630-C) AD 66705 Unclassified

The motion of the charge carriers in the positive column of a discharge in a gas is investigated, taking into account the forces resulting from the self-magnetic field of the arc. An integral equation for the radial distribution of ionization density is set up and solved numerically. The solution depends upon a parameter A which is introduced into the theory, and which is essentially a measure of the effect of the magnetic field. The equation has been solved for various values of this parameter, and suitable methods of interpolation developed. An analysis of the form of the equations involved has enabled a nomograph to be plotted which permits the determination of the value A and of the electron temperature T for given values of the discharge parameters: the arc current I, the gas pressure p, the radius R of the arc, and the effective permeability σ (sigma) of the plasma. From this nomograph and some auxiliary curves, a family of

ATE. 01:002 - ATE. 01:005

curves has been plotted enabling the value of the arc drop in potential E to be evaluated in practical cases. (Contractor's abstract)

PROBE MEASUREMENTS IN A MAGNETIC PROTON SOURCE, by M. Hoyaux and P. Gans. [1955] 1v. tncl. diagrs. tables. (Rept. no. EOARDC-TN-55-2) (AF 61(514)630-C) AD 66707 Unclassified

Probe measurements have been carried out on a hydrogen discharge with the geometry of a magnetic proton source in an attempt to verify a theory established previously. In the course of these, tt has been found that the discharge current varies with probe penetration. It decreases extremely raptdly after a certain degree of penetration has been attained. This phenomenon appears to be peculiar to hydrogen. It was not observed in our previous experiments with mercury vapor and other gases. No explanation has yet been found for this effect. It occurs not only with a probe but also with a glass rod in the form of a spatula and appears to be independent of the orientation of the plane of the spatula with respect to the axis of the discharge. The results of the probe measurements show good agreement with the theory for the outer parts of the dtscharge. As far as the core ts concerned, no ftrm conclusions can be drawn. If the values of the electron concentration are corrected for the variations tn discharge current, reasonable agreement ts obtained for this region also, but it ts not clear to what extent the correction is justifiable and the agreement may be fortuitous. EQUATIONS OF SIMILITUDE IN A MERCURY-VAPOR ARC AT VERY LOW PRESSURES, by M. Hoyaux and P. Gans. [1955] [20]p. tncl. diagrs. (Rept. no. EOARDC-TN-55-5) [AFOSR-TN-56-230] (AF 61(514) 630-C) AD 83091 Unclassifted

Measurements were made with a plasmograph to check the validity of the followtng equations of simlitude, which hold for the case of a mercury-arc rectifier operating at moderate current densities, for the case of fluorescent tubes: (t) pR = function (T), (2) R^2N/I = function (T), and (3) ER = function (T), where p ts the gas pressure, R ts the wall radius, I ts the discharge current, E ls the axial electrtc ftetd tn the positive column, N ts the axial electron density, and T ts the electron temperature. The measurements showed a radtal distrtbution of electron density simtlar to a zero-order Bessel function. The second equation appeared to be satisfted, but the scatter of measured values was large. The third equation was not satisfted, since values of ER for a given value of T were about 50% higher than for a rectifier. Two possible explanations are offered for this result: (1) in a fluorescent tube situated in a relatively cold environment, the mercury vapor pressure is such that the mean free path of the charge carriers is larger than the tube diameter and consequently the Schottky theory of ambipolar diffusion ts not valid; and (2) the presence of argon in the tube may influence the discharge characteristics of the gas.

EXPERIMENTAL STUDY OF THE "HASH" IN A FLUORESCENT TUBE I, by M. Hoyaux and P. Gans. [1956] [24]p. tncl. diagrs. (Rept. no. EOARDC-TN-55-7) (AFOSR-TN-56-231) (AF 61(514)630-C) AD 88040 Unclassified

Experimental study was made of the phenomenon of "hash" in fluorescent tubes, by means of the high resolution plasmograph. The phenomena observed are extremely complex and have not as yet permitted very definite conclusions tobe drawn. The physical phenomena associated with the "hash" are located tn the vicinity of the anode. A more or less periodic variation of the anode fall tn potential ts observed which comprises a relatively slow rise (about 10 in 300μsec) followed by a very sharp fall; the rate of which is beyond the limits of resolution of the plasmograph (2μ sec). Attempts to observe the variation of the plasma parameters (electron, temperature, charge density, etc...) durtng the course of a cycle of "hash" have not led to any definite conclusions. One would expect a correlation between the duration of a period of "hash" and the electron temperature, but the experimental results are not sufftciently definite for this to be asserted with certainty. The development of a means of synchronizing the plasmograph upon the hash itself ts apparently required to obtain more satisfactory experimental results. (Contractor's abstract)

A STUDY OF THE HASH IN FLUORESCENT TUBES BY MEANS OF AN AUTO-SYNCHRONIZED PLASMOGRAPH, by M. Hoyaux and P. Gans. [t956] tv. tncl. diagrs. (Rept. no. EOARDC-TN-55-9) [AFOSR-TN-56-347] (AF 6t(514)630-C) AD 95433 Unclassifled

The small perturbation theory prevtously developed (Rev. gen. elec., v. 60: 279, 195t) described satisfactortly the vartations in the electron density and the electron temperature except for nonexplanation of the phenomenon which triggers off the cycle. Also, the theory accounted for variation in space potential only durtng the first two-thirds of each oscillation. Further analysis lead to the conclusion that the vartation tn space potential during the latter part of each oscillation can be explained by considertng the anode to behave essentially ltke a Langmuir probe tnmersed tn a plasma. Measurements of the distribution of potential along the whole length of the positive column showed the possible extstence of bursts of positive tons propagated from anode to cathode at t500m/sec, in agreement with suggestions of Yosimoto. A sertes of confirmatory experiments with an alternating discharge gave results tn agreement with those from the direct current discharge. (Contractor's abstract, modified)

INVESTIGATION OF THE CONDITIONS IN THE PLASMA IN MERCURY-VAPOR ARC DISCHARGES AND OSCILLATING ELECTRON ION SOURCES, by M. Hoyaux and P. Gans. [1955] tv. tnct. diagrs. refs. (Rept. no. EOARDC-TR-54) [AFOSR-TR-56-23] (AF 6t(5t4)630-C) AD 88353 Unclassifled

Theoretical and experimental study of the behavior of mercury-vapor arc discharges (a) at high current intensities and (b) at very low pressures, and (c) of thetr dynamic behavior tn fluorescent-type tubes. Anatytical results for case (a) tndicate that the so-called Gvosdover effect of etectron scattertng by the Coulomb mtcroftetd of the positive tons, acting tn conjunction with the self-magnetic ftetd, accounts more satisfactortty than other proposed hypotheses for experimentalty observed deviations from a set of taws due to Hoyaux; for case (b), the admixture of argon used in fluorescent-type tubes to facitlitate striking, simitarty accounts for deviations (observed tn such a tube) from a Hoyaux-Gans law. Tests for case (c) are conducted using an especially designed ptasmograph, white an espectally constructed autosynchronization plasmograph system ts used to tnvestigate the hash occurring tn hot-catnode tubes. [THEORETICAL AND EXPERIMENTAL CONTRIBUTION TO THE STUDY OF SPONTANEOUS OSCILLATIONS IN MERCURY VAPOR HOT CATHODE TUBES] Contribution theorique et experimentale a t'etude des osctltations spontanees dans tes tubes a vapeur de mercure a cathode chaude, by P. Gans and M. Hoyaux. [t956] 28p. tnct. diagrs. refs. (AF 6t (5t4)630-C) Unclassifled

By means of a ptasmograph, study was made of spontaneous osctllation occurrtng tn the anodic region of a mercury vapor hot cathode tube. The mechanism of oscillation occurs tn three phases: (t) a breakdown in the anode sheath; (2) a burst of tonization (which later falls off) in accord with the laws of small variations about a stable equtlibrium; (3) increase tn the anodic drop in accord with Langmuir's theory. Then the decrease of tension reaches a sufficient point, and a breakdown takes place again and the cycle recommences. The experimental results were in excellent accord with the theory. (In French)

DEFLAGRATION OF AMMONIUM PERCHLORATE, by R. Friedman, R. G. Nugent and others. May 1956 [21]p. incl. illus. diagrs. (AFOSR-TN-56-205) (AF 18(600)1502) AD 87519 Unclassified

Also published in Sixth Symposium (International) on Combustion, Yale U., New Haven, Con.. (Aug. 19-24, 1956), N. Y. Reinhold, 1957, p. 612-618.

Deflagration rates and product-gas temperatures were measured for near-adiabatic decomposition of NH_4ClO_4, both in the pure form and with added catalysts. These experiments were performed under N pressurization. Deflagration limits of about 45 to 300 atm at 21°C were obtained for the perchlorate pressed from as-received powder with varied particle size. Perchlorate pressed from a 74- to 105-μ sieved fraction gave deflagration rates that agreed with the results of Adams et al for 110 to 160 atm, but had a lower limit of 90 atm. Deflagration rates for pellets made from a -53μ sieve fraction were similar to those for the as-received material above 110 atm, but the material failed to burn at or below 100 atm. Deflagration rate of NH_4ClO_4 below 150 atm increased with increasing pressure and ambient temperature, and decreasing particle size from which the pellets are pressed. At higher pressures, an upper pressure limit existed which was only slightly dependent on particle size but could be raised by preheating. In all cases, the presence of catalysts eliminated the upper pressure limit or at least shifted it above 340 atm. The greatest increase in deflagration rate was produced by Cu chromite. The possible significance of the results with regard to the reaction mechanism are discussed.

FUNDAMENTAL WAVE FUNCTIONS IN AN UNBOUNDED MAGNETOHYDRODYNAMIC FIELD. I. GENERAL THEORY, by A. Baños, Jr. Oct. 1, 1954, rev. Dec. 10, 1954 [9]p. refs. (Technical note no. 1) ([AF]OSR-TN-54-281) (AF 18(600)1041) AD 84264
Unclassified

Also published in Phys. Rev., v. 97: 1435-1443, Mar. 15, 1955.

This is the first two papers dealing with a systematic study of the lineartzed, unbounded medium problems in magnetohydrodynamics of incompressible and compressible fluids. Part I deals with the fundamental equations which are set up quite generalty for an tdeal, homogeneous and isotropic, conducting fluid devoid of viscosiiy and expansive friction, subject only to the tnitial assumption that the externally applied fteld of magnetic tnduction be constant and uniform. The energy and momentum balance in a magnetohydrodynamic fietd is verified with the aid of the exact fundamental equations and the conservation laws of energy and momentum, for a rigid votume fixed in the (stationary) observer's inertial frame of reference, are disptayed in differential and tn tntegral form. By successive eliminations, there is obtained a singte partial differential equation in the particte vetocity from which the unwanted second-order terms are merely dropped in a linearized smatt amplitude theory, a process which is fully justified by considering the special case of infinite conductivity, zero disptacement current, and incompressible fluids. Also, assuming that a particular solution of the linearized magnetohydrodynamic wave equation has been obtained, tt is shown how to compute quite generatty, from the linearized Maxwellian set, the accompanying electromagnetic fteld vectors expressed in terms of the assumed velocity fteld. These computations are carried out for plane homogeneous waves and for time-harmonic cylindrical waves. The actual determination of particular wave functions appropriate for incompressible and compressible fluids, together with the computation of the corresponding wave numbers, is reserved for the sequel to this paper, Part II. MAGNETOHYDRODYNAMIC WAVES IN INCOMPRESSIBLE AND COMPRESSIBLE FLUIDS, by A. Baños, Jr. [1955] [42]p. incl. diagrs. (Technical note no. 2) ([AF]OSR-TN-55-66) (AF 18(600)1041) AD 89540
Unclassified

Also published in Proc. Royal Soc. (London), v. 233A: 350-366, 1955.

The application of the general theory of magnetohydrodynamics to the determination of the modes of propagation and to the computation of the corresponding propagation constants is considered. It is shown that an tncompressibte fluid sustains 2 types of modes: one type devoid of pressure fluctuations (vetocity modes), and the other accompanied by pressure oscillations (pressure modes). In the case of cylindrical waves in an incompressible fluid, there are 2 distinct pressure modes, one of which, however, is highly attenuated and therefore of little physical interest. It is found that a compressible fluid also sustains the same class of velocity modes (devoid of pressure fluctuations and hence independent of the velocity of sound tn the medium) as an incompressible fluid. In addition, a compressible fluid is shown to propagate 2 distinct pressure modes which, under appropriate limiting conditions peculiar to each type, behave, respectivety, as a modified sound wave and as a modified magnetohydrodynamic wave. For every mode discussed here, there are presented the limiting forms of the propagation constant in 3 cases of physical interest: infinite conductivity, slightly attenuated modes, and weak magnetohydrodynamic coupling which arises when the externally applied fietd is vanishingly small. NORMAL MODES CHARACTERIZING MAGNETOELASTIC PLANE WAVES, by A. Baños, Jr. [Dec. 1955] [6]p. incl. diagrs. (Technical note no. 3) (AFOSR-TN-56-16) (AF 18(600)1041) AD 120480
Unclassified

Also published in Phys. Rev., v. 104: 300-305, Oct. 15, 1956.

The general theory of magnetohydrodynamic waves tn an tdeal conducting fluid embedded in a uniform fteld of magnetic tnduction, and the application of the theory to the systematic analysis of the various modes of propagation in tncompressibte and compressible fluids have been presented by Baños tn 2 earlier papers (Phys. Rev., v. 97: 1435, 1955; Proc. Royal Soc. (London), v. 233A: 350-367, 1955). The techniques developed there have now been extended to the study of homogeneous plane waves in an unbounded conducting solid. It is found that, in the presence of a uniform static magnetic field, the elastic medium sustains 5 distinct modes of propagation as already pointed out by Knopoff. The first 2 modes are pure shear waves, one of which is a slightly attenuated shear mode with phase velocity modified anisotropically by magnetoelastic coupling; the companion shear mode is highly attenuated and exhibits a propagation constant which is essentially that of an electromagnetic wave of the same frequency. The remaining 3 modes are shear-compression waves of which one mode exhibits a phase velocity intermediate between the phase velocity of shear and compressional waves; the second mode has a phase velocity exceeding that of compressional waves; and the third shear-compression mode is again highly attenuated with the propagation characteristics of an

electromagnetic wave. (Contractor's abstract)

MAGNETOHYDRODYNAMIC WAVES IN COMPRESSIBLE FLUIDS WITH FINITE VISCOSITY AND HEAT CONDUCTIVITY, by A. Baños, Jr. June 1956, 26p. (Technical note no. 4) (AFOSR-TN-56-320) (AF 18(600)1041) AD 94856 Unclassified

Presented at the Internat'l. Symposium on Electromagnetic Problems in Cosmical Physics, Royal Inst. of Tech., Stockholm (Sweden), Aug. 27-31, 1956, under the auspices of the Internat'l. Astronomical Union.

Also published in Proc. I.U.P.A.P., Stockholm (Sweden), Aug. 26, 1956.

The general theory of magnetohydrodynamic waves in an ideal conducting fluid embedded in a uniform field of magnetic induction, and the application of the theory to the systematic analysis of the various modes of propagation in incompressible and compressible fluids were treated in 2 earlier papers. In the present paper first the conservation laws are established of momentum and energy for a (macroscopic) compressible fluid with finite viscosity and finite thermal and electrical conductivities, which is embedded in a uniform field of magnetic induction, and then is derived quite generally the exact (nonlinearized) equation governing the distribution of temperature in such a fluid. Next, using the linearized magnetohydrodynamic wave equation in the fluid velocity, combined with the resulting heat diffusion equation and with the equation of state of the fluid, and applying the mathematical techniques developed earlier, there is obtained a higher order partial differential equation in the fluid temperature from which ensue all the temperature modes. In particular, the behavior of the plane homogeneous waves is examined in detail, and it is shown that a compressible fluid with the indicated properties sustain altogether 6 different modes, 2 of which are pure shear modes, devoid of density, pressure, and hence temperature fluctuations (v-modes), while the remaining 4 are shear-compression waves accompanied necessarily by density, pressure, and temperature fluctuations (p-modes). The 2 shear modes, which are isothermal, comprise a slightly attenuated Alfvén wave, and a highly attenuated viscous mode, sometimes referred to as a vorticity mode. The 4 shear-compression modes have in general very complex properties, but in the low frequency and low heat conductivity case they are easily identified as: (1) a modified (adiabatic) sound wave slightly attenuated; (2) a slightly attenuated modified Alfvén p-wave; (3) a highly attenuated viscous wave; and (4) a highly attenuated thermal wave governed in the main by the thermal properties of the medium. THERMOMAGNETIC EFFECTS IN InSb (Abstract), by R. K. Willardson and A. C. Beer. Nov. 1955, 1p. (AFOSR-TN-55-425) (AF 18(600)1547) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Due to the unusually high electron mobility in InSb, large galvanomagnetic effects have been observed. If temperature gradients exist across the specimen, one may expect correspondingly large thermomagnetic effects. Investigation of these phenomena is generally complicated by the fact that ordinary measurements are done under adiabatic conditions so that careful attention must be given to transverse gradients and the resulting additional second-order effects, since the region of interest encompasses values of $\mu H >> 1$. However, by choosing boundary conditions such that transverse electric fields and temperature gradients are eliminated, both measurement and calculations are simplified. Under these conditions, it has been found that the contribution of the electrons to the thermoelectric power of intrinsic InSb at room temperature decreases significantly as the magnetic field is increased. Data were taken over a range of magnetic field strengths sufficient to change the thermoelectric power from -240 to $+75 \mu V/C$. Results are analyzed in terms of the electron and hole mobilities and the position of the Fermi level. (Contractor's abstract)

PROTEIN STRUCTURE AND AGING CROSSLINKING IN GELATIN. 1. FORMALDEHYDE-INDUCED, by H. L. Gottlieb. Nov. 1954, 16p. incl. tables. (Technical note no. 1) ([AF]OSR-TN-54-304) (AF 18(600)-1010) AD 52015 Unclassified

Crosslinks in protein aceous materials could be of numerous chemical types. In order to study the chemical characteristics of crosslinked native proteins some chemical properties of experimentally induced crosslinks were investigated. Purified pigskin gelatin has been treated with chemical reagents to induce crosslinks and the treated gelatin analyzed to describe the probable crosslinking mechanisms. Polypeptide degradation by enzymatic and ionic methods was done in order to obtain different types of hydrolytic liberation of individual amino acids. The products of degradation were subjected to paper strip chromatographic analysis by the master overlay dimensional technique. Qualitative and quantitative differences in the selective rates of liberation of certain individual amino acids indicated the locations and types of crosslinks induced by the reactions of chemical reagents in pigskin gelatin. IN VITRO CHOLESTEROL DEPOSITION ON HOG AORTA TISSUE, by J. Bjorksten and H. Gottlieb. [1954] [3]p. (AF 18(600)1010) Unclassified

Published in Finska Kemistsamfundets Medd., v. 63: 74-77, 1954.

The precipitation of cholesterol (I) from suspensions on membranes treated with $CrSO_4$ and $Pb(OAc)_2$ was studied. I was precipitated from carboxymethylcellulose (II) suspension on 5% $CrSO_4$-treated filter paper, cotton cloth, glass cloth, and hog aorta. II was precipitated by all salts listed in the previous work (Proc. Soc. Exper. Biol. Med., v. 81: 350, 1952) except $HgCl_2$. The degree of I deposition is inversely related to the amount of rinsing after salt treatment. Hog aorta tissue after 24-hr treatment in $CrSO_4$ and $Pb(OAc)_2$ and rinsing showed I deposition from II and beef synovial fluid suspensions of I. There was no precipitation from the suspension media methylcellulose 1%, arrowroot starch 4%, chondroitin sulfate 4%, human saliva, or hog blood serum. A proposed mechanism is that whenever a material contains a colloid precipitant available at its surface in sufficient concentration to cause precipitation of the suspending colloid, the colloid will be precipitated and carry with it any suspended material. THE OCCURRENCE OF ARTERIOSCLEROSIS IN THE AORTA OF SWINE, by H. Gottlieb and J. J. Lalich. [1954] [3]p. incl. illus. table. [AF 18(600)1010] Unclassified

Published in Amer. Jour. Path., v. 30: 851-855, July-Aug. 1954.

Fresh aortas were examined from more than 2000 swine which varied in age from 4 mo to more than 3 yr. The incidence of arteriosclerotic plaques was found to increase with age. Firm white or pale yellow intimal plaques of 1 to 10 mm in size were encountered principally in the descending arch and the thoracic aorta. Such plaques accounted for almost all of the lesions observed, and they were composed of fibrous connective tissue. Sclerosis of the abdominal aorta is more rare. In two of these instances when such lesions were encountered, calcium precipitate was observed in the media. (Contractor's summary)

MORPHOGENESIS OF ATHEROSCLEROSIS IN SWINE AORTAS (Abstract), by H. L. Gottlieb. Nov. 1, 1954 [1]p. [AF 18(600)1010] Unclassified

Presented at Eight annual meeting of the Amer. Soc. for the Study of Arteriosclerosis, Chicago, Ill., Oct. 31-Nov. 1, 1954.

Abstract published in Circulation, v. 10: 598, Oct. 1954.

Recent examination of several thousand random swine aortas has revealed marked incidence of intimal lesions morphologically similar to minimal atherosclerotic lesions in humans. Histologic studies of the lesions in swine have been made of serial sections of embedded and frozen specimens and by means of the endothelial surface staining technic. The intimal structure of the swine aorta is very similar to the human aorta. A thin layer of connective tissues cells separates the endothelial lining from the medial. As the chronologic age of the animal advances a gradual diffuse thickening of the subendothelial connective tissue layer was observable. The gross lesions can be classified into two classic types: fibrotic and calcified. The fibrotic lesions can further be differentiated by the presence and absence of stainable lipid materials. A morphologic development of gross fibrotic lipid-containing lesions will be presented from the first discernible stages of appearance in the intima of lipid-like materials. (Contractor's abstract)

A POSSIBLE MOLECULAR BASIS FOR AGING, by J. Bjorksten and H. Gottlieb. [Mar. 1, 1956] [9]p. incl. tables. [Technical note no. 2] [AFOSR-TN-56-100] [AF 18(600)1010] Unclassified

A laboratory method for proving the existence of cross-linkages in proteins and for measuring the extent of cross-linking with gelatin, based on the amount of free amino acids liberated, is described. In this study on aging, it is pointed out that proteolytic enzymes attack protein molecules at certain points. It is assumed that if enough molecules of cross-linking agents block all these attack points on 2 adjacent, cross-linked protein molecules, then the protein molecules are immobilized. When this occurs, these protein molecules are withdrawn from metabolism. As a result, with increasing age, an increasing amount of the protein is thus made inert, tending to clog the cells, interferring first slightly, then considerably with the normal function of the cells.

SEQUENTIAL TESTS OF RANDOMNESS, by G. E. Noether. Dec. 1953 [28]p. incl. tables, refs. ([AF]OSR-TN-54-65) (AF 18(600)778) AD 49990 Unclassified

This report describes and discusses sequential tests of randomness with respect to alternatives of the following three types:

Linear trend: $F(x_1, \ldots, x_n) = \prod_{i=1}^{n} F(x_i + i\theta)$,

Cyclical change: $(F(x_1, \ldots, x_n) = \prod_{i=1}^{n} F(x_i + \theta_i)$

where the θ_i fottuws some regular or irregular cyclical movement,

Stochastic relationship: $X_i = \delta X_{i-1} + U_i$. (Contractor's abstract)

SEQUENTIAL TESTS OF RANDOMNESS. Final research rept. [1954] 3p. (AF 18(600)778) Unclassified

A sequence of random variables $X_1, X_2, \ldots$ is chosen. $F(x_1, x_2, \ldots, x_n)$ denotes the joint cumulative distribution function of $X_1, X_2, \ldots, X_n$. The hypothesis of randomness states that $F(x_1, x_2, \ldots, x_n) = F(x_1)F(x_2) \ldots F(x_n)$ with $F(x)$ the individual cumulative distribution function. The investigation is made of sequential tests of the hypothesis of randomness H_0 with the following alternatives considered (a) linear trend; (b) cyclical changes; (c) stochastic relationship; and (d) changes in variance.

"CLASSICAL" NUCLEAR PHYSICS IN THE USSR, by F. Ajzenberg[-Selove]. [1956] 1v. tncl. diagrs. refs. (Sponsored jointly by Air Force Offtce of Scientific Research under [AF 18(600)997] and [Atomic Energy Commission]) Unclassifted

Also published in Nuovo Ctmento, Ser. 10, v. 4: 2-30, Supplement no. 1, 1956.

A summary ts given of Soviet work conducted tn "classtcal" nuclear physics from about 1953-1955. Subjects considered include: (1) α-, β-, γ-spectroscopy; (2) induced nuclear reactions; (3) masses, btnding energies, and abundances; and (4) theories of nuclear structure. The résumés of the Soviet research undertaken have been obtained tn or prepared from Physics Abstracts, Brookhaven Selected Reading List, and Soviet journals tn physics. They indicate that β- and γ-spectroscopic studies appear to be of greatest tnterest to Soviet phystcists. Also, it ts apparent, that a large part of thetr research efforts have been fccussed on the measurement of cross sections and tn the determination of the behavior of heavy nuclet, in particular that of Th, U, and the transuranic elements. In addition, much work has been devoted to the theories of nuclear structure, e.g., the shell model, and on β-decay theories. It is pointed out that a large number of papers in Soviet scientific literature detail, in professionally-competent reviews, Western scientific and technical progress tn basic nuclear physics. A bibliography of the 124 Soviet references ts tncluded for use with the textual matertal presented.

NEUTRONS FROM THE PROTON BOMBARDMENT OF P^{31}, by A. G. Rubin, G. D. Johnson, and J. B. Reynolds. Aug. 30, 1956 [7]p. incl. diagrs. table. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)997 and Atomic Energy Commission) Unclassified

Also published in Phys. Rev., v. 104: 1444-1445, Dec. 1, 1956.

The reaction $P^{31}(p, n)S^{31}$ has been studied at E_p = 17.2 mev. The energy spectrum of the neutrons was determined by means of proton recoil measurements in nuclear emulsions. The mass excess, M — A, of S^{31} was calculated to be -10.04 ± 0.20 mev. Excited states of S^{31} have been located at 1.15 ± 0.15, 2.28 ± 0.20, 3.35 ± 0.20, 4.51 ± 0.15, 5.94 ± 0.30, and 6.41 ± 0.20 mev. (Contractor's abstract)

APPLICABILITY OF THE LANGEVIN EQUATION TO IRREVERSIBLE PROCESSES (Abstract), by A. Siegel. [Feb. 1956] 1p. (AF 18(603)29) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 220-221, Apr. 26, 1956.

Onsager and Machlup have proposed the Langevin equation, $R\alpha + s\alpha = \varepsilon(t)$, as a general equation of motion for a fluctuating thermodynamic variable. In an idealized treatment, the fluctuating force $\varepsilon(t)$ is considered uncorrelated with itself from one instant to another, and Gaussianly distributed. $\alpha(t)$ then has a determinate part $\alpha(o) \cdot \exp(-t \cdot s/R)$, and a stochastic part $\alpha_s(t)$. In reality, of course, $\varepsilon(t)$ consists of discrete elementary processes. Under certain circumstances the main details of the idealized $\alpha_s(t)$ may show up only within intervals shorter than the time between elementary processes. The stochastic description is then largely fictitious. A limit to its applicability may be sought in the simple physical situation of the Brownian motion: α = velocity of the colloid particle. Using results of elementary kinetic theory, and assuming Stokes friction, the Langevin description is found to be applicable if $mL/M\rho << \sqrt{k/s}\alpha$; m, M are masses of molecule of the medium and colloid particle; L, mean free path of a molecule in the medium; ρ, radius of the colloid particle; k is Boltzmann's constant. STOCHASTIC ANALYSIS OF A VARIABLE SUBJECT TO A QUANTUM FORCE SPECTRUM (Abstract), by H. Goldring and A. Siegel. [Dec. 1956] 1p. (AF 18(603) 29) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 203, Apr. 25, 1957.

The problem has been solved of the diffusion of a variable f subject to the Langevin-type equation $\dot{f} + \gamma f = a(t)$, where the random force a(t) has the spectral density $\hbar\omega/[\exp(\hbar\omega/kT)-1]$, i.e., Nyquist's quantum form of the noise spectrum. Assuming Gaussian distribution for a(t), we get the conditional probability $P[f(t)|f(t_0)]$ by calculating the correlation function of f: $\langle f(t_0)f(t_0+t)\rangle / \langle f(t_0)^2\rangle$. Verification of the validity of the assumed spectrum could in principle be obtained with these results through direct analysis of

notse curves tn time. (Work is nowtn progress toward a simitar analysis of diffusion of collodial particles). The extremely slow fall-off with frequency of the quantum notse spectrum, even at quite tow temperatures, still presents an obstacle to experimental verification, tn that extremely fine time resolution of the measured curves would be required. RHENIUM SULFIDES AS LIQUID-PHASE HYDROGENATION CATALYSTS. [I] A COMPARISON WITH MOLYBDENUM SULFIDE AND COBALT POLYSULFIDE, by H. S. Broadbent, L. H. Slaugh, and N. L. Jarvis. Mar. 20, 1954 [5]p. tnct. tables, refs. [AF 18(600)1164] Unctassified

Published in Jour. Amer. Chem. Soc., v. 76: 1519-t523, Mar. 20, 1954.

Rhenium heptasulfide and rhenium disulfide hydrogenation catalysts were prepared and examined for catalytic activity loward a variety of substrates tn comparison with the wett-known molybdenum sulfide and cobalt potysulfide catalysts. In these experiments rhenium heptasulfide was most active, rhenium disulfide tess so, and molybdenum and cobatt sulftdes much less so. Some advantages enjoyed by the rhenium heptasulfide hydrogenation catalyst are as fottows: Consistent and easy reproductbtlity, activity maintained tndeftnitety by simple storage In a closed bottle, stability to hydrogenative decomposition al high temperatures, extreme resistance to "potsoning", tnsolubility tn strong, non-oxidiztng actds, and ability to saturate multipte bond system without accompanying hydrogenolysis of carbon-sulfur bonds. Its chief disadvantages are tts relatively high cost, due tn considerable part to the lack established demand for rhenium compounds, and the fact that tt ts not as active toward most non-sulfur containing compounds as some nicket, platinum and paltadium catalysts. (Contractor's abstract)

RHENIUM HEPTASELENIDE AS A HYDROGENATION CATALYST, by C. W. Whittle. May 1, 1956, 98p. Incl. diagrs. tabtes, refs. (AFOSR-TN-56-243) (AF 18(600) 1164) AD 88363 Unclassified

The catalytic activity of Re compounds was studied, especially the activity of Re_2Se_7 which is closely related to Re_2S_7. The compound Re_2Se_7 was prepared and its catalytic activity established; the method yielding the most active catalyst was determined. The catalyst was tried with a variety of substrates, and the ease of reducing different functionat groups and structural features was compared. In general, Re_2Se_7 was slightly less active than Re_2S_7 for most reductions, but it was superior to CoS_x or MoS_3. A comparison was made of the reduction of nitro groups, and acetylenic and otefinic linkages with Raney Ni, Adam's catalyst, Re_2S, Re_2Se_7, and Co and Mo sulfides.

RHENIUM AND ITS COMPOUNDS AS HYDROGENATION CATALYSTS. III. RHENIUM HEPTOXIDE, by H. S. Broadbent, G. C. Shaw and others. Aug. 11, 1958, 27p. tnct. tabtes, refs. (AFOSR-TN-56-602) (AF 18 (600)t164) AD 115030 Unclassified

Presented tn part at 131st meeting of Amer. Chem. Soc., Miami, Fla., Apr. 11, 1957.

The catalysis of liquid phase hydrogenations by rhenium "blacks", obtained from the reduction of rhenium heptoxide, ts reported. A comparison of these calalysts with commonly used taboratory catalysts ts made. It ts found that these "blacks" are the most effective catalysts for the hydrogenation of carboxylic acids to alcohols. This conversion takes ptace with a variety of actds at 150°-250° (usually 160°)/ca 200 atm tn a few hours. Good yields of alcohol are attained with occasional ester by-products. The actd ts usually reduced. The rhenium "btacks" effecl the hydrogenation of amides quite well. Many common organic functions reductble through Pl or Nt catalysts are affected only moderatety by these catalysts. A comparison ts made of the catalysl's role tn several reactions.

SOME ALGEBRAIC PROPERTIES OF ASYMPTOTIC POWER SERIES, by T. E. Hull. June 1955, 9p. (UBCAR rept. no. 1) ([AF]OSR-TN-55-264) (AF 18 (600) 1517) AD 75157 Unclassified

Also published in Canad. Jour. Math., v. 8: 220-224, 1956.

A series $c_0 + c_1x + c_2x^2 + \ldots + c_nx^n + \ldots$ is called an S-series whenever (i) c_n, x are real; (ii) $c_0 \geq 0$; and (iii) there exists a function f(x) such that

$$|f(x) - c_0 - c_1x - \ldots - c_{n-1}x^{n-1}| \leq |c_nx^n|, \quad x > 0,$$

n = 0, 1, 2, ... Condition (iii) means that the series is the asymptotic expansion of the function f(x), and that the remainder after n terms, with respect to f(x), is numerically less than the (n + 1)th term. It is shown that the S-series form a semiring, and that the ring of all power series, or all asymptotic series, is generated from this semiring when one adjoins all differences to the semiring. These results enable one to define a partial ordering on the ring of power series. (Contractor's abstract)

ON A REPRESENTATION FOR ASYMPTOTIC SUMS, by T. E. Hull. July 1955, 14p. (UBCAR rept. no. 2) ([AF]OSR-TN-55-265) (AF 18(600)1517) AD 75156 Unclassified

The problem considered here is that of assigning a function of the form

$$\int_0^\infty e^{-xt}\, dc(t)$$

to each series

$$c_0 + c_1x + c_2x^2 + \ldots + c_nx^n + \ldots.$$

It turns out that the function can be chosen in a unique way so that it has 2 important properties. First, it is a natural sum of the series in that the series is its asymptotic expansion. Second, the collection of all such sums is isomorphic to the collection of all series with respect to addition while a subring of the sums is isomorphic to the corresponding subring of the series with respect to both addition and multiplication. Use is made of some of what is known about the problem of moments. The results are a generalization of results obtained earlier by Stieltjes and Borel and are, in a certain sense, best. The results enable one to define a norm over the space of power series in a natural way. (Contractor's abstract)

EXTREME VALUE PROPERTIES OF HERMITIAN MATRICES, by M. Marcus and B. N. Moyls. Aug. 1956, 36p. refs. (AFOSR-TN-56-341) (AF 18(603)83) AD 95217 Unclassified

Extreme values are determined which minimize or maximize $f(x_1, \ldots, x_k) = F((Ax_1, x_1), \ldots, (Ax_k, x_k))$, where $x_1, \ldots, x_k$ is an orthonormal set in an n-dimensional unitary space V_n and A is a Hermitian transformation on V_n to itself; $F(a_1, \ldots, a_k) = F(a)$ is a real symmetric function of the indicated variables, $1 \leq k \leq n$. Extreme values are obtained for the case $F(a_1, \ldots, a_k) = \prod_{j=1}^{k} a_j$, $1 \leq k \leq n$, without assuming that F(a) is either monotone increasing or decreasing in each a_j for values of a_j in the field of A or that A is nonnegative Hermitian. The maximum value of $g(x_1, \ldots, x_k) = F((U_1A_1 \ldots U_mA_mx_1, x_1), \ldots, (U_1A_1 \ldots U_mA_mx_k, x_k))$ is determined as x and U vary over sets of k orthonormal vectors and sets of m unitary transformations respectively, were $A_1, \ldots, A_m$ are arbitrary linear transformations and $U_1, \ldots, U_m$ are unitary transformations. All transformations are on V_n to V_n. The analysis utilizes the properties of the compound of a transformation. The classical Minkowski determinant inequality is extended to all of the coefficients in the characteristic polynominal.

ACOUSTIC STREAMING RESULTING FROM LOCALIZED VIBRATORY EXCITATION OF A MEMBRANE (Abstract), by F. J. Jackson and W. L. Nyborg. [1956] [1]p. (Sponsored jointly by National Institutes of Health and [Air Force Office of Scientific Research under AF 18(603)54]) Unclassified

Presented at joint meeting of Acoust. Soc. of Amer. and International Congress on Acoustics, Cambridge, Mass., June 17-23, 1956.

Published in Jour. Acoust. Soc. Amer., v. 28: 796, July 1956.

If a membrane bounding a liquid is caused to vibrate in a localized region, the fluid adjacent to it will be set into steady vortex motion. One simple way to realize this situation is to bring a vibrating metal tip of circular cross section into contact from below with a membrane which supports a small body of liquid. A characteristic (axially symmetric) vortex motion then takes place near the tip in the liquid above, as may be seen by observation with a microscope and by use of indicating particles. Particularly high accelerations and velocities exist in a ring near the tip periphery. Streaming phenomena of this kind have now been observed under a variety of situations, at frequencies varying from 100 to 40,000 cps. Because of the associated convection and viscous stress such streaming is an important secondary cause of sonic irradiation effects. (Contractor's abstract)

A classical transformation method in the theory of linear partial-differential equations, the cascade method of Laplace, is used to construct families of hypothetical gas laws which contain arbitrarily many parameters and for which general integrals of the flow equations can be given. For simplicity in the presentation, only supersonic flows are considered. The formulas have exact counterparts in the case of subsonic flow, and these can be obtained by the introduction of complex characteristic variables.

ASPECT RATIO INFLUENCE AT HIGH SUBSONIC SPEEDS, by G. F. Anderson. July 1954 [21]p. incl. diagrs. (Technical note no. WT-13) ([AF]OSR-TN-54-232) (AF 18(600)664) AD 49365 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 23: 874-878, Sept. 1956.

The finite wing is considered to be composed of an infinite wing less the portions of the infinite wing which lie outside the span of the finite wing. This permits a comparison to be made of the velocities induced by thickness at corresponding points on the finite wing and infinite wing. The difference in these induced velocities on the finite wing is averaged over the span and applied as a correction to the free stream velocity. If the free stream velocity of the finite wing is corrected so that both the finite wing and the infinite wing have the same static to total pressure ratio at corresponding points in the chord-wise direction, then the force per unit span can be compared. The results of this theory are compared to some available data.

STREAM FUNCTIONS AND TRANSONIC SIMILARITY IN THREE-DIMENSIONAL FLOW, by P. F. Maeder and A. D. Wood. Oct. 1954 [50]p. incl. diagr. (Technical repl. no. WT-14) ([AF]OSR-TN-54-339) (AF 18(600)664) AD 63079 Unclassified

It is shown that the introduction of stream functions for a general three-dimensional flow is sufficient to satisfy the equation of continuity. The two-dimensional and axisymmetric stream functions are shown to be special cases of this more general approach. The differential equation which these functions must satisfy is then deduced for the special case of steady, compressible, potential flow about slender bodies at small angles of attack, assuming a perfect gas, and an isentropic, isoenergetic process, and retaining certain second order terms. This differential equation is then transformed, and an expression which relates properties on the real and transformed surfaces is developed, which is then simplified for the two special cases of two-dimensional and axisymmetric flows. If the higher order term in the differential equation is neglected, then, by proper choice of one of the constants of the transformation, the well-known similarity laws, and a new, more general law, for linearized compressible subsonic flows are obtained. If the higher order term of the differential equation is not neglected, similarity between bodies in transonic flows is established for the special cases of two-dimensional and axisymmetric flows. EXPERIMENTAL INVESTIGATION OF SUBSONIC WALL INTERFERENCE IN RECTANGULAR SLOTTED TEST SECTIONS, by P. F. Maeder, G. F. Anderson, and J. B. Carroll. Jan. 1955 [31]p. incl. illus. diagrs. (Technical note no. WT-16) ([AF]OSR-TN-55-68) (AF 18(600)664) AD 64221 Unclassified

The force coefficients of 2 wing models of different size, but geometrically similar, were measured in the same slotted-wall test section. It is concluded from the experimental study that: (1) if the drag coefficients at zero angle of attack are the same for the 2 wings at the same Mach number, no buoyancy or blockage interference is present; and (2) if the theoretically evaluated angle of attack and streamline curvature correction is applied to the angle of incidence, the 2 wings should show the same corrected angle of attack to produce the same lift coefficient. The data showed that the blockage and buoyancy influence on the model in the slotted-wall test section were negligible. The theoretical angle of attack and streamline curvature correction were correct in every sense, but the magnitude of the total

correction was too small. Evidence gathered through examination of the data indicated that the error in magnitude of the total theoretical correction, was most likely contained in the evaluation of the streamline curvature correction. (Contractor's abstract)

SOME ASPECTS OF THE BEHAVIOR OF PERFORATED TRANSONIC WIND-TUNNEL WALLS, by P. F. Maeder. Sept. 1954, 20p. diagrs. (Technical rept. no. WT-15) ([AF]OSR-TN-55-116) (AF 18(600)664) AD 68442 Unclassified

Presented at Sixth meeting of the NATO-AGARD Wind-Tunnel Panel, Paris (France), Nov. 2-6, 1954.

Also published in AGARD Memorandum Papers presented at the Sixth meeting of the Wind Tunnel and Model Testing Panel, Nov. 1954, p. tt8-246.

tt is shown that, for flow past a walt containing a single transverse slot, the mean outflow vetocity and the pressure difference between the plenum chamber and the main flow are related linearly. The analysis is extended to the case of a wall containing an infinite number of infinitely small slots, and a linear relationship is again found to exist. The ratio of open to total surface necessary for zero interference on a two-dimensional doublet is shown to be independent of Mach number. The sinular behavior of such a slotted walt and a perforated walt (a result which has been verified by experiment) is utilized in the anatysis for a funnel with two finite perforated walls. The theory is devetoped for compressible flow with the aid of Goethert's rute, and the pressure distributions along the wall and centerline are deternined. The flow is atso determined for the condition at which the tunnel is choked by air entering through the perforated watts. (Contractor's abstract)

SOME RESULTS OF LINEARIZED TRANSONIC FLOW ABOUT SLENDER AIRFOILS AND BODIES OF REVOLUTION, by P. F. Maeder and H. U. Thommen. Aug. 8, 1955, 2p. incl. diagrs. (AF 18(600)664) Unclassified

Published in Jour. Aeronaut. Sciences, v. 23: 187-188, Feb. 1956.

Recently Oswatitsch (Flow Around Bodies of Revolution at Mach Number One, paper presented at Brooklyn Polytechnic Institute's Conference on High-Speed Aeronautics, Jan. 20-22, t955) determined the flow about a half-body of revolution at the speed of sound by assuming part of the nonlinear term, the derivative of u in x-direction, constant, and thus linearizing the transonic equation without omitting the damping or interference term altogether. He further assumed that no disturbances shall travel upstream of the nose of the body. The result obtained in this special case agreed surprisingly well with experiments. It has been shown that the first assumption is much closer to the actual behavior of the fluid at all speeds than had been originalty supposed, and that the second assumption need not have been made at all. Certain implications of this theory are discussed. It is pointed out that all solutions of slender-body and airfoil theory, as well as wing-body combinations, which have been obtained by applying the equations of linearized subsonic or supersonic flow can be incorporated in this more generat treatment, which also yields results throughout the transonic regime. From this theory, the wett-known transonic sinularity laws follow explicitly. Some theoretical results are presented for the symmetrical airfoil and the body of revotution at zero angle of attack, and a comparison of the theory is made with experiment.

BOUNDARY-LAYER EFFECT ON LOCAL MACH NUMBER MEASUREMENTS ON A CIRCULAR ARC HALF PROFILE, by J. B. Carroll and G. F. Anderson. Oct. 31, 1955 [2]p. incl. diagrs. (AF 18(600)-664) AD 100759 Unclassified

BRO. 04:012 - BRO. 05:002

Also published in Jour. Aeronaut. Sciences, v. 23: 604-605, June 1956.

The results of an experimental investigation, conducted at the Aerodynamics Research Laboratory, Brown University, involving the case of a body (model) mounted on the wall of the wind tunnel are presented. It is seen that the boundary layer, starting its growth upstream of the model, is of appreciable thickness by the time it passes over the model. The assumption of a thin boundary layer, therefore, cannot be made, and pressure gradients must be accounted for in the local Mach number calculation. A scale drawing is given of the model, and the apparent Mach number distributions over the profile are plotted for several Mach numbers ranging from 0.80 to 0.90. For free-stream Mach numbers of 0.83 and above, there seems to exist a supersonic region about the point of maximum thickness of the profile. The data also indicates no presence of a shock wave up to a free-stream Mach number of 0.86. On the other hand, however, the results of static- and stagnation-pressure measurements taken in a vertical plane at the maximum thickness of the profile are also plotted, and these indicate that at a free-stream Mach number of 0.85 the flow is still subsonic. It is seen that at a free-stream Mach number of 0.85 an error of 6% is made in the maximum Mach number calculation if the pressure gradients are neglected. Plots are also made of the Mach number field in the region of the maximum thickness for Mach numbers of 0.85, 0.86, and 0.87, showing the progressive nature of the supersonic region.

MEASUREMENT OF THE VISCOSITY OF FIVE GASES AT ELEVATED PRESSURES BY THE OSCILLATING-DISK METHOD, by J. Kestin and K. Pilarczyk. Aug. 5, 1953 [ ]p. incl. diagrs. table, refs. (Paper no. 53-A-67) AF 18(600)891. Unclassified

Presented at annual meeting of the Amer. Soc. of Mech. Engineers, Heat Transfer Div., New York, Nov. 29-Dec. 3, 1953.

Published in Trans. Amer. Soc. Mech. Engineers, v. 76: 987, 1954.

The paper describes the measurement of the influence of pressure on the viscosity of five commercially pure gases: air, nitrogen, hydrogen, argon, and helium, in a range up to about 70 atm (1000 psi) at room temperature (20° or 21° C). The viscosity was measured by observing the period of oscillation and the logarithmic decrement of an optically ground-quartz disk of 70-mm diam suspended on a thin rhodium-platinum wire between two fixed optically ground-quartz plates with a separation of 1 mm and performing torsional oscillations. The data were evaluated on the basis of Macwood's equations, but the instrument proved capable of a higher accuracy of measurement than the 1% inherent in the theory. The scatter of the experimental data did not exceed 0.1% and repeatability was of the same order of accuracy. In view of the mathematical difficulties no attempt is made to improve the theory of the instrument, but it is shown that the motion of the disk is nonlinear and that the relation between the period of oscillation and the logarithmic decrement is not that which would be expected on the assumption of simple damped harmonic motion. SLOW OSCILLATIONS OF AN INFINITE PLATE AND AN INFINITE DISK IN A VISCOUS FLUID, by J. Kestin and I. N. Persen. June 1954, 101p. incl. diagrs., tables, refs. (Technical rept. no. 1; rept. no. AF-891/1) ([AF]OSR-TN-54-151) (AF 18(600)891) AD 37677 Unclassified

It is shown that both physical problems correspond to an identical mathematical problem if the axial velocity component in the fluid is neglected in the case of the disk. This problem is solved rigorously and in closed terms by Laplace transforms. Exact solutions are given for the general case when the body oscillates between two fixed plates as well as for the limiting case of infinite spacing. The motion of the body is described in detail, and it is shown that it does not correspond to that predicted by the classical linearized theory; in particular the strong influence of fluid density is demonstrated. Simplified solutions for small values of viscosity and density indicate (1) that the body moves with an apparent increase in its mass or moment of inertia; and (2) that its damping corresponds to a linear velocity distribution in the fluid over the depth of penetration of a viscous wave for very large spacings. Equations suitable for viscometry viscometry are deduced and compared with published experimental data. It is shown that it is possible to determine viscosity by measuring the period or loga-

rithmic decrement alone, and that the principle can be used for the determination of viscosity and density simultaneously.

THREE PAPERS ON THE THEORY OF THE OSCILLATING CUP VISCOMETER, by E. G. Shvidkovskii, A. M. Butov, and L. S. Priss, tr. by J. Kestin. Oct. 1954, 40p. incl. diagrs. tables. (Rept. no. AF-891/4) ([AF]OSR-TN-54-315) (AF 18(600)891) AD 48560 Unclassified

The present is an abbreviated translation of three papers dealing with the theory of oscillating cup viscometers. The references in question are: E. G. Shvidkovskii, Uchenye Zapiski MGU (Moscow University), v. 74: 135-144, 1944; A. M. Butov, L. S. Priss, and E. G. Shvidkovskii, Zhur. Tekh. Fiz., v. 21: 1319-1324, 1951; and L. S. Priss, Zhur. Tekh. Fiz., v. 21: 1050-1061, 1952. So far the oscillating cup viscometer has been used mainly in connection with liquids and in particular in connection with molten metals. At the present time there seems to be a great need to develop alternative methods of measuring the viscosity of gases, particularly at high pressures and temperatures. A critical review of existing methods reveals that, apart from capillary transpiration methods, those based on the oscillatory motion of a body offer certain advantages which should be explored. It has been shown in previous reports in this series that the theory of the oscillating disk viscometer presents considerable difficulties particularly in the matter of the edge correction. Consequently it is thought that methods based on the oscillations of a container filled with the gas should also be explored. (Contractor's abstract)

SMALL OSCILLATIONS OF BODIES OF REVOLUTION IN A VISCOUS FLUID, by J. Kestin and L. N. Persen. Oct. 1954, 59p. incl. diagrs. tables, refs. (Technical rept. no. 2; rept. no. AF-891/2) ([AF]OSR-TN-54-326) (AF 18(600)891) AD 48559 Unclassified

Solutions are presented of the Navier-Stokes equations for oscillating bodies under the assumption that the body performs small oscillations in a viscous fluid under the influence of an elastic restoring force or couple. The particular cases studied include an infinite cylinder, a sphere, and a pile of disks. All of the problems are solved by the Laplace transform method, and the cases analyzed, as well as those previously discussed, are summarized in one general equation. In all cases of practical importance, the motion consists of a damped harmonic oscillation and a transient term whose importance is confined to the first few initial beats. The motion becomes isochronous with a logarithmic decrement. (ASTIA abstract)

THE INFLUENCE OF EDGES ON SHEARING STRESSES IN VISCOUS LAMINAR FLOW, by J. Kestin and L. N. Persen. June 1955, 57p. incl. diagrs. tables, and refs. (Technical rept. no. 3) ([AF]OSR-TN-55-195) (AF 18(600)891) AD 63134 Unclassified

A study is made of the influence exerted by the existence of thin edges on slow laminar flow patterns. The following cases are solved: (a) an infinitely thin strip sliding within an elliptic cylinder; (b) an infinitely thin disk rotating within an ellipsoid of revolution; (c) a semi-infinite infinitely thin plate sliding between 2 parallel fixed plates; (d) an infinitely thin disk of finite radius rotating between 2 parallel fixed plates (approximate); and (e) an infinitely thin disk of finite radius rotating in an infinite fluid. It is found that the velocity gradient for the 2-dimensional cases and the gradient of angular velocity for the axially symmetrical cases have singularities at an edge (increasing to infinity like $1/\sqrt{x}$, where x is the distance from the edge). The "edge effect", i.e., the ratio of the viscous force or of the viscous moment to that which would act on the same body on the assumption that the body forms part of one of infinite extent, varies from close to 1.0 to 1.6 depending on the actual geometrical arrangement. It increases with increasing separation between the moving and fixed walls. In steady motion, this ratio is independent of the properties of the fluid. (Contractor's abstract)

CORRECTIONS FOR THE OSCILLATING DISK VISCOMETER, by J. Kestin and H.-E. Wang. Dec. 1955, 65p. incl. diagrs. tables, refs. (Technical rept. no. 5) ([AF]OSR-TN-55-467) (AF 18(600)891) AD 82740 Unclassified

Presented at annual meeting of the Amer. Soc. Mech. Engineers, New York, Nov. 25-30, 1956.

Also published in Jour. Appl. Mech., v. 24. 197-206, June 1957.

An exact theory, based on work by Kestin and Persen is given of the finite- and of the infinite-spacing arrangement of the oscillating disk viscometer. The equations allow for the effects of wire damping, unequal spacing, side drag, drag on the rod carrying the mirror, and the main viscous drag on the flat faces; the edge effect, however, is excluded. An empirical method is given for obtaining the edge correction as a correction factor C applied to the ideal

BRO. 05:007 - BRO. 05:009

viscous moment M so that the actual moment is given by $M_f = CM_{xx}$. The analysis shows that, for a given arrangement, C is a function of the radius R_0 expressed in terms of the boundary-layer thickness δ so that $C = (\delta/R_0)$. Experiments by Kestin and Pilarczyk (Trans. Amer. Soc. Mech. Engineers, v. 76: 987, 1954) with a finite-spacing viscometer show good agreement with theory in that points for several gases trace the relation $C(\delta/R_0)$ with a minimum of scatter and with the predicted behavior at 2 extremes.

THE VISCOSITY OF FIVE GASES: A RE-EVALUATION, by J. Kestin and H.-E. Wang. Mar. 1956, 23p. incl. diagrs. table, refs. (Technical rept. no. AF-891/6) (AFOSR-TN-56-98) (AF 18(600)891) AD 82011 Unclassified

Presented at annual meeting of the Amer. Soc. Mech. Engineers, New York, Nov. 25-30, 1956.

Also published in Trans. Amer. Soc. Mech. Engineers, v. 80: 11-17, Jan. 1958.

This study contains a re-evaluation of the experimental results for the pressure dependence of viscosity obtained by Pilarczyk and described by Kestin and Pilarczyk. The re-evaluation is based on an improved theory of the oscillating disk viscometer described by Kestin and Wang (see item no. BRO. 05:006). The results for air, N_2, A, He, and H_2 are given in graphical and tabular form, as well as in the form of empirical equations. The range covered is 1 to 70 atm at 25°C. The results constitute a relative measurement which is based on Gibson and Michels' data for N_2. Very good agreement with previously published data for N_2, air, and H_2 has been reported. In the case of He, no comparative data could be found and in the case of A there is good agreement with the data published by Michels and others, but the difference in absolute values is somewhat higher than the preceding 3 gases. The agreement as to rate of change with pressure is excellent. It is believed that the data now reported contain an uncertainty of no more than 0.2% for N_2, air, H_2, and He and of not more than 0.6% for A with respect to N_2. (Contractor's abstract)

SLOW OSCILLATIONS OF BODIES OF REVOLUTION IN A VISCOUS FLUID, by J. Kestin and I. N. Persen. July 1956 [10p. refs. (AFOSR TN-56-372)] (AF 18 (600)891) AD 95808 Unclassified

Also published in Proc. Ninth International Congress of Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956), v. 3: 326-338, 1957.

The paper concerns itself, first, with small oscillations performed by an infinite plate moving in its own plane and an infinite circular disk performing torsional oscillations under the influence of an elastic force or couple. It is shown that both physical problems correspond to an identical mathematical problem if the axial velocity component in the fluid is neglected in the case of the disk. The mathematical problem is solved rigorously and in closed terms by the use of the Laplace transform, and the solution includes the initial transient of the motion. Exact solutions are given for an oscillation between 2 fixed plates as well as for the limiting case of infinite spacing. The motion of the body is described in detail and it is shown that the damping force or couple is not proportional to the velocity. The damping term depends both on the viscosity and on the density of the surrounding fluid. The motion performed by the body consists of a damped harmonic oscillation superimposed on a drifting zero position. For small values of viscosity and density simplified solutions are obtained. These lead to the conclusion that the body moves with an apparent increase in its mass or moment of inertia and that its damping corresponds to a linear distribution of velocity over the spacing, and to a linear velocity distribution over the boundary layer in the case of infinite spacing. Relations are deduced which for a given system must be satisfied by the period of the motion and the logarithmic decrement of damping independently of the properties of the fluid. The same methods of analysis are then applied to spheres and infinite cylinders oscillating either in free space, or in concentric fixed spheres or cylinders. Cylinders and spheres filled with a fluid and piles of disks are also considered. In all cases the motion exhibits the same features as in the simple case discussed in detail at the beginning. ON THE MEASUREMENT OF THE VISCOSITY OF STEAM BY THE OBSERVATION OF SMALL OSCILLATIONS, by J. Kestin and J. R. Moszynski. May 1956, 50p. incl. diagrs. table, refs. (Rept. no. SPR-1) (AF 18(600)891) Unclassified

Presented at Fifth International Conference on Steam Properties, London (England), July 10-12, 1956.

Measurements of the viscosity of steam were made up to 300 atm and 500°C with the aid of oscillating systems. A general outline is presented of the principle of the method and of the theoretical results available for the evaluation of the measurements. It is shown that complete and exact equations can be obtained for the oscillatory motion of rotationally symmetrical, smooth bodies, e.g., spheres, so that absolute determinations can be made with them. In the case of the more common disks, no exact theory is in existence, the difficulty arising from edge effects, and only relative measurements can be performed.

Since, however, the damping suffered by a sphere under given conditions is much less than that for a disk, it is necessary to achieve a compromise between measuring accuracy and the desirability of making absolute measurements. For these reasons, both relative measurements with disks and absolute spot checks with a sphere are envisaged. A detailed description is given of the instrument designed to carry out the measurements. It consists of a high-pressure bomb made of stainless steel, sealed with the aid of tie bolts made of Inconel X, and provided with a synthetic sapphire Bridgman-type window. The oscillating system is enclosed in the bomb and carries a reflecting mirror. The bomb is mounted on a sapphire ball bearing and is enclosed in an automatically-controlled heater surrounded by a manually-controlled radiation shield. The bomb is filled with water under a moderate vacuum, and steam is raised inside it. The oscillation is started by rotating the bomb on its bearing, and is observed by a telescope which is trained on a precision back-lighted scale through the mirror which oscillates with the suspension system. Temperatures are measured with the aid of calibrated thermocouples, and pressures are measured with a set of precision Bourdon gauges. Time is measured with the aid of an electronic counter actuated by a suitable time-base signal through a photoelectrically operated thyraton trigger which, in turn, operates the gates of the counter. THEORY OF THE OSCILLATING CUP VISCOMETER, by G. F. Newell, J. Kestin, and D. A. Beckwith. May 1956, 109p. incl. diagrs. table, refs. (Technical repl. no. 7; repl. no. AF-891/7) (AFOSR-TN-56-210) (AF 18(600)1548) AD 87524 Unclassified

Also published in Zelt. Angew. Math. Phys., v. 8: 433-465, Nov. 25, 1957. (Title varies)

The complete theory of the oscillating cup viscometer is given. The viscometer consists of a cylindrical cup of finite height and is filled with fluid whose viscosity is to be measured. The cup is suspended axially by an elastic wire and performs torsional oscillations. The oscillation is assumed to be slow so that the linearized Navier-Stokes equations are used. An exact solution which includes the effect of the sharp corners is given and then modified so that it can be used for the evaluation of experimental results. The limitations on design which are due to the limitations on easily measurable decrements are described. (Contractor's abstract)

SUPERSONIC WIND TUNNEL LOSSES, by A. W. McCoy, R. B. Dowdell, and P. F. Maeder. Dec. 1949, 153p. incl. illus. diagrs. tables. (Technical rept. no. WT-1) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N7onr-35805 and Air Materiel Command, Wright-Patterson Air Force Base, Ohio under W33-038-ac-22027] ATI-136970 Unclassified

The object of this report is to furnish design information regarding the pressure losses and boundary layer corrections for supersonic wind tunnel in the Mach number range $1.5 < M_T < 5.0$. A distinction had to be made between the tunnel with conventional subsonic diffusers only, and the tunnel with various types of supersonic-subsonic diffusers. As may be expected, the operating losses are reduced greatly by the use of a supersonic-subsonic diffuser, while a corresponding reduction of the starting losses, employing new wind tunnel starting methods, will depend on further investigations which are briefly discussed in this report. For example, at a test section Mach number $M_T = 3.5$ and a Reynolds number of 10^7, the operating pressure ratio can be reduced from 6.25 to 2.55 by the use of a supersonic-subsonic diffuser. The different types of diffusers discussed are the shock free diffusers (merely a reversed nozzle) and the diffusers with one and two oblique compression shocks. The calculations show that the diffuser with one oblique shock is superior to the shock free diffuser in the range $1.5 < M_T < 3.9$ at $Re = 10^7$ because of the large friction losses occurring in the latter. The results are presented in graphical and tabular form in terms of general wind tunnel parameters. For a test section Reynolds number of 10^7, we obtain, for example, an aerodynamic energy ratio of 4 for $M_T = 3$ if a supersonic diffuser is used and only $M = 1.9$ if a conventional diffuser with no supersonic contraction is employed. NOTE ON DEBLOCKED TRANSONIC TEST SECTIONS, by P. F. Maeder. May 5, 1950. 4 l. p. incl. diagrs.

tables. (Technical rept. no. WT-4) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N7onr-35805) ATI-78072 Declassified

Theoretical calculations were made to form the basis for experimental investigations of the blocking effects, encountered in wind tunnel testing in the transonic range of flow, and their elimination. The tunnel wall was assumed to have slots in the flow direction, to compensate for the blocking effects of the closed portions. A method was then developed to determine the size of the openings in the case of a rectangular model section containing either wings of finite or infinite span, or bodies of revolution. The pressure distribution at the walls was also computed. The results seem very satisfactory, and justify an experimental investigation to find the influence of the boundary layer and the behavior of the model section outside the range of validity of the linearized theory. INVESTIGATION OF TUNNEL BOUNDARY INTERFERENCE ON TWO DIMENSIONAL AIRFOILS NEAR THE SPEED OF SOUND, by T. F. Maeder. Apr. 1951, 117p. incl. diagrs. refs. (Technical rept. no. WT-6) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N7onr-35805) U68721; ATI-105885 Declassified

This report describes the theoretical and experimental investigations of the blockage effects encountered in testing two-dimensional wings in wind tunnels close to the speed of sound. The experimental investigation showed that blockage corrections, according to the semi-experimental method described in this report, could be applied to test results obtained in a closed model section if the local supersonic region is not too large. As a working rule, it has been found that the supersonic region should not exceed in height one quarter of the tunnel height if such corrections are to be applied with any degree of accuracy. The results of the experimental investigation, carried out to determine the deblocking effects of slotted walls are summarized as follows: (1) so long as the local supersonic region is not too large, i.e., about the same condition as holds true for applicability of corrections, the wall configuration calculated (presented in a previous rept., see item no. BRO. 07:003) yield test results with no wall interference; (2) as the local supersonic region becomes larger, the slots will have to be wider to deblock the rear portion of the airfoil; and (3) the effects of variation of slot width on the front portion of the airfoil are small. INVESTIGATION OF LOSSES IN WIND TUNNEL TEST SECTIONS FITTED WITH SLOTTED WALLS, by D. Adamson and J. B. Carroll. Sept. 1952, 1v. incl. diagrs. table. (Technical rept. no. WT-8) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-35805) ATI-171229; U68722 Declassified

A detailed description is presented of tests made to determine the losses in wind tunnel test sections fitted with slotted walls. The tests illustrate 2 important results: (1) the increased range of Mach numbers obtainable with slotted walls in the transonic range; and (2) the increased working section losses associated with the use of slotted test section walls. For smaller tunnels, these increased losses may present no serious consequences. However, their use in larger tunnels may necessitate a prohibitively large power requirement. From previous work it was determined that the slot width is an important parameter of the deblocking ability of a slotted wall; therefore, since the larger losses are associated with the larger slots, some compromises may have to be made in choosing

the particular wall conftguration to be used. (Contractor's abstract, modified)

THE INFLUENCE OF DEFINED SMALL AMOUNTS OF IMPURITIES ON THE RECRYSTALLIZATION OF ALUMINUM, by K. Detert and K. Lücke. Mar. 1, 1956 [32]p. incl. itlus. diagrs. tables. (Rept. no. AF-1495/1) (AFOSR-TN-56-103) (AF 18(600)1495) AD 82016 Unclassifled

The influence of small additions (0.008 to 0.14%) of Fe, Cu, Si, Mg, and Ag upon the recrystallization of high purity Al after rolling of 40% and 90% has been investigated with the help of the x-ray method described by Nölting and Lücke. In atl cases, recrystallization is delayed by the impurities. The effect of Fe is the largest, additions of the order of 1/100% increases the recrystallization temperature by 210°C and decreases the rate of recrystallization by a factor up to 10^{11}. For Cu, Si, and Mg, values of the order of 150°C and 10^{7} were obtained. The effect of Ag ts very much smaller. The activation energy seems to decrease with tncreasing amount of tmpurity. It can be shown that the effect ts caused by the foreign atoms in solid solution and not by those in precipitations, due to direct tnteraction between the boundaries and the foretgn atoms rather than a difference between the deformed states of the pure and tmpure metal. The rates of nucteation and growth are diminished by the impurities; for small additions, both are affected nearty by the same factor. (Contractor's abstract)

A QUANTITATIVE THEORY OF GRAIN-BOUNDARY MOVEMENT AND RECRYSTALLIZATION IN METALS IN THE PRESENCE OF IMPURITIES, by K. Lücke and K. Detert. Apr. 15, 1956 [29]p. tnct. diagrs. tabtes, refs. (Rept. no. AF-1495/2) (AFOSR-TN-56-164) (AF 18(600)1495) AD 36585 Unctassifted

Also published in Acta Metalturgica, v. 5: 628-637, Nov. 1957.

The experimental facts concerning the tnfluence of small amounts of impurities upon recrystallization are briefly reviewed and a quantitative atomistic theory of these phenomena has been developed. In this theory it ts assumed that interaction forces exist between the foreign atoms tn solid sotution and the boundary, tncreasing the concentration of foretgn atoms in the boundary. At high concentrations (or tow temperatures), the moving boundaries are hetd back by the foreign atoms and the speed of the boundary ts controlled by the speed of the foretgn atoms diffusing behind the boundary. At tow concentrations (or high temperatures), the boundary cannot be hetd by the foretgn atoms; breakaway occurs and the boundary moves much faster. Betow the critical concentration for which breakaway just occurs, the recrystallization temperature drops much faster with decreasing concentration than it does above this concentration. The quantitative formulation of these ideas teads to expressions for the ahsolute rate of boundary nigration, its temperature dependence, the activation energy of recrystallization, and etc. They agree very well with the experimental results so far available. The fact that the influence of a foreign etement upon the rate of recrystallization increases with increasing difference in atomic radius between the solute and the basic metal shows the interaction between boundary and foreign atoms is largely of elastic nature. Further experiments to check the theory more thoroughly are outlined.

Published In Proc. International Conference on Dislocations and Mechanical Properties of Crystals, Lake Placid, N. Y. (Sept. 6-8, 1956), N. Y., John Wtley & Sons, Inc., 1957, p. 425-427.

A general survey ls presented of the damping of dislocation motion ln metals presumably due to dislocations ln different frequency ranges, as well as that shown to be due to dislocations tn experiments on the effects of plastic deformation, orientation, and tmpurities tn metals. Various theories concerning the dampmg phenomena are considered tncludmg the pinned dislocation model developed by the authors. This model ls based on restrictions to dislocation motion effected by nodes of the dislocation network and by tmpurities. Dertved mathematical expressions are applied to the available experimental data with regard to strain-amplitude dependent damping and to residual damping at low strain amplitudes.

THE COMBUSTION CALORIMETRY OF ORGANO-FLUORINE COMPOUNDS. THE HEAT OF FORMATION OF FLUOROBENZENE, by W. D. Good, D. W. Scott and others. [1954] [13]p. tncl. diagr. tables. [CSO-630-55-47] Unclassified

A method ls described for the determination of the heats of combustion and formation of nongaseous fluorocarbons. A method of comparative measurements ls used to minimize experimental uncertainties and the magnitude of the Washburn corrections. Two types of experiments are performed: (t) a sample of the liquid compound, contained tn a sealed Vycor ampoule ts burned in a Pt-lined rotating combustion bomb containing approximately t0 ml of water; (2) benzoic actd and auxiltary hydrocarbon otl are burned tn the same bomb containing about t0 ml HF (aqueous) and a dummy Vycor ampoule. The relative amounts of reactants are adjusted so that the energy release and products (mainly CO_2 and llF (aqueous)) tn the 2 experiments are essentially tdentical. Thermochemical corrections are applied for the small amount oi Vycor which ls dissolved by llF (aqueous). A procedure ts given for the chenucal analysis of the bomb products. Application of the method to C_6H_5F ts describe', and the heat of the reaction $C_6H_5F(l) + 7\ O_2(g) + 58\ H_2O(l) = 6\ CO_2(g) + HF \cdot 60\ H_2O(l)$ ls given. The standard heat of formation of C_6H_5F ln the liquid state at 25° from graphite, ll (g) and F (g) is also given. It is believed that the results obtained are more accurate than old literature values. (Contractor's abstract)

FLUOROBENZENE: THERMODYNAMIC PROPERTIES IN THE SOLID, LIQUID AND VAPOR STATES; A REVISED VIBRATIONAL ASSIGNMENT, by D. W. Scott, J. P. McCullough and others. May 2, 1956, 29p. incl. diagr. tables, refs. (Contribution no. 58) (AFOSR-TN-56-170) (CSO-630-55-47 and CSO-680-57-4) AD 86592 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 5457-5463, Nov. 5, 1956.

Studies were made of fluorobenzene by low-temperature calorimetry, comparative ebulliometry, flow-calorimetry, and combustion calorimetry to obtain values of the standard entropy, heat capacity, and heat of formation of the vapor. A revised vibrational assignment, consistent with the calorimetric values of vapor heat capacity, was made and used with other molecular structure data to compute values of thermodynamic functions at selected temperatures between 0° and 1500°K. Values of the heat, free energy, and logarithm of the equilibrium constant of formation were computed for the same selected temperatures. The experimental studies yielded the following information: Values of the heat capacity for the solid [t4° to 225°K], the liquid [C_{satd} = 39.496 - 0.t3777 T + 5.7tt3 x t0^{-4} T^2 - 5.3644 x t0^{-7} T^3 cal deg^{-t} mol^{-1} (230° to 350°K)] and the vapor [C°_p = 6.581 + 0.1t589 T - 6.t22 x 10^{-5} T^2 cal deg^{-t} mol^{-t} (343° to 500°K)]; the heat of fusion [2702.0 cal mot^{-1}] at the triple point [230.94 ± 0.05°K]; the entropy of the liquid at 298.t6°K [S_{satd} = 49.22 cal deg^{-1} mol^{-t}]; the heat of vaporization [Δ Hv = t0689 - 3.850 T - t.448 x t0^{-2} T^2 cal mol^{-1} (3t8° to 382°K)]; the second virial coefficient in the equation of state, PV = RT(t + B/V, [B = 2t2 - 158.6 exp (750/T) cc mot^{-t} (3t8° to 500°K)]; the vapor pressure [$\log_{t0}$p (mm) = 6.95208 - 1248.083/(t + 22t.827), (39° to t20°)]; and the standard heat of formation of liquid fluorobenzene at 298.16°K [-34.7_5 kcal mot^{-1}]. PHOTOGRAPHIC STUDIES OF TURBULENT FLAME STRUCTURE, by J. Grumer, J. M. Singer and others. Sept. 16, 1955 [25]p. incl. illus. diagrs. table, refs. (Technical rept. no. 1190) ([AF]OSR-TN-55-332) (CSO-630-55-29) AD 84391 Unclassified

The concept that the turbulent flame brush is composed of a fluctuating, wrinkled, essentially continuous, laminar combustion wave is mainly supported in the literature by very short duration schlieren, shadow, and smoke photographs of the brush. This concept has been the basis of published theories of turbulent burning velocity, flame-generated turbulence and stability of turbulent flames. Previously reported tests of these theories appear inconclusive. New experiments, bearing on schlieren photography, reveal the technique to be ambiguous at best in revealing the structure of the turbulent brush. Observed density gradients were found to have apparent velocities greater than the turbulence intensity, laminar burning velocity and cold approach flow; to change with turning of the schlieren knife-edge; to be different for turbulent flames piloted by a laminar hydrogen-air flame and those piloted by heating the port electrically; and to be present in the absence of turbulent flame, provided that a pilot and a turbulent air stream were on. It is concluded from these and other observations that schlieren photography (and very likely shadow and smoke photography) as previously employed does not prove the existence of a wrinkled laminar wave in the brush. In addition, direct photographs of a 10,000-Reynolds number turbulent brush, at 1 and 2 msec exposure time, are evaluated as being nonsupporting and contradictory to both the wrinkled, fluctuating laminar wave and continuous reaction zone concepts of turbulent burning, but compatible with one of discontinuous flamelets.

SCHLIEREN AND DIRECT PHOTOGRAPHIC STUDIES OF THE TURBULENT FLAME STRUCTURE, by J. Grumer. June t956 [2]p. (CSO-630-55-29) Unclassified

Published in Jet Propulsion, v. 26: 48t-482, June t956.

The concept that the turbulent flame brush is composed of a fluctuating, wrinkled, essentialty continuous, laminar combustion wave is questioned. New experiments, bearing on schlieren photography, reveal the technique to be ambiguous at best in revealing the structure of the turbulent flame brush. Smoke photography, though not as extensively studied as schlieren, is also questioned as a technique for elucidating the structure of the turbulent flame brush because of con-

celvable uncertainties arising from the interaction of lncident light and the amount and particle sizing of the smoke, temperature and delay time for vanishing the smoke, plckup of radiant heat, and possible chemical reaction between smoke and flame. These observations point to tlie conclusion that schlieren photography (and very likely shadow and smoke photography) as previously employed does not prove the existence of a wrinkled laminar wave tn the brush. Latest experlments lndicate that the brush is made of discontinuous flamelets of varying intensity, most of which are inclined nearly parallel to the flow.

TURBULENT BURNING VELOCITIES OF NATURAL GAS-AIR FLAMES WITH PIPE-FLOW TURBULENCE, by J. K. Richmond, J. M. Singer and others. Apr. 30, 1956 [28]p. incl. diagrs. refs. (Technical rept. no. 1205) (AFOSR-TN-56-238) (CSO-680-56-16) AD 88358 Unclassifted

<u>Also published in</u> Sixth Symposium (International) on Combustion, Yale U., New Haven, Conn. (Aug. 19-24, 1956), N. Y., Reinhold, 1957, p. 303-311.

tn order to test existing theorles of turbulent burning velocity and to search for flame-generated turbulence, measurements were made of burning velocity as a function of height in Bunsen flames. Flames of stoichiometric mixtures of Pittsburgh natural gas and air were studied at 10,000, 25,000, 50,000 and 100,000 Reynolds number of approach flow, with a 1-1/4 inch burner tube. Several lmprovements in technique are presented. Flame luminosity measurements were made with a newly developed flame radiation photometer in the region of λ = 4315A. Corrections were made of the flame-cylindrical curvature to find the true radial dtstrioution of light. The direction and magnitude of approach flow at each point were measured with a Pitot tube; velocities were extrapolated systematically to the mean flame position. The turbulence intensity in the flame was determined with an electronic probe. Burning velocity values were computed by the angle and frustum methods, and correlated with the flame turbulence data. For the flames of tte = 50,000 and 100,000, the formula $S_T = S_L + v'$ fits the experimental data well, where S_L is the laminar burning velocity and v' the approach flow turbulence. For the flames of lower Re, the values of burning velocity are larger than indicated by thts formula, and tentative explanations are given. The indications are that flame-generated turbulence is quite small. (Contractor's abstract)

VIBRATIONS OF COMPOSITE SYSTEMS, by R. H. MacNeal. Oct. 1954, 302p. incl. dtagrs. tables, refs. (Technical rept. no. 4) ([AF]OSR-TN-55-120) (AF 18(600)669) AD 63118 Unclassified

This study is concerned exclusively with the vibrations of linear, conservative mechanical systems and their electrical equivalents. The concepts of "normal mode" and of "impedance" are brought together and interrelated in a number of ways. It is shown, for example, that normal modes can be used to compute "impedances", and that impedance measurements, in turn, can be utilized to obtain normal modes. The mathematics used in this analysis of vibration is presented in the language of matrix algebra. With the exception of matrix theory, no "advanced" mathematical concepts are employed. The solution is given for several examples relating to the vibrations of a conventional airplane, and a comparison is made with analog computer results.

A STUDY OF THE EFFECTS OF DAMPING ON NORMAL MODES OF ELECTRICAL AND MECHANICAL SYSTEMS, by S. F. Crumb. Jan. 1955, 158p. incl. diagrs. tables, refs. (Technical rept. no. 2) ([AF]OSR-TN-55-121) (AF 18(600)669) AD 58338 Unclassified

A general investigation is presented of some of the properties of free and forced vibrations in linear, nonconservative systems. Particular emphasis is placed upon the problems which arise in normal mode studies made on the electric analog computer at the California Institute of Technology. In Part I the major problems are defined, and limitations of the study are discussed. Part II contains a review of the basic theory of normal modes. In Part III, modifications of normal mode concepts, as applied to damped systems, are examined. "Small damping" criteria are discussed, and a set of theorems of small damping is presented. In Part IV, a series of normal mode analog circuits for damped systems are developed. Part V is a study of uniform damping, generalizing and extending some of the work of Rayleigh, Bode, and Guillemin. It is shown that for any type of uniform damping, all of the basic normal mode concepts are preserved. In Part VI, the theory of mode separation in uniformly damped systems is considered. Criteria for determining mode frequencies and mode parameters are developed. A multiple drive method of exciting normal modes is proposed. In Part VII, some of the methods of Part VI are extended to nonuniformly damped systems. Equivalent orthogonal systems are proposed to approximate the behavior of systems with moderately nonuniform damping. A quantitative measure of nonuniformity is presented. In Part VIII, numerical examples and experimental results in support of the theory are presented. Concluding remarks are made in Part IX. (Contractor's abstract)

GENERAL METHODS OF SYNTHESIS FOR ELECTRICAL-MECHANICAL ANALOGIES OF AIRCRAFT STRUCTURES, by G. D. McCann and R. H. MacNeal. Oct. 1954, 130p. incl. illus. diagrs. refs. (Technical rept. no. 1) ([AF]OSR-TN-55-124) (AF 18(600)669) AD 58331 Unclassified

A general treatment is presented of the methods of analysis which have been developed successfully for the vibration studies of airframes together with the corresponding electrical circuit analogies that must be programmed into the electric analog computer. This computer type is distinguished from electronic differential analyzers in that passive circuit elements consisting of decade resistors, capacitors, inductors, and multiwinding, multitap transformers are utilized directly, as well as amplifiers and other electronic devices. The passive electrical elements are used to represent analogous passive elements of the physical system under study when a 1:1 physical analogy can be developed between electric circuit theory and physical system; thus, both currents and voltages in the computer take on physical significance, whereas in electronic differential analyzer techniques only voltages are used to represent voltages. In other cases, where amplifiers are employed, the passive elements are utilized to simulate transfer functions, reducing the number of electronic amplifiers that would be required if only electronic differential analyzers were used.

A STUDY OF THE ACCURACY OF LUMPED PARAMETER AND ANALOG COMPUTER REPRESENTATIONS OF CANTILEVERED BEAMS UNDER CONDITIONS OF STATIC STRESS AND DYNAMIC VIBRATIONS, by G. D. McCann and H. S. Braham. Apr. 1955, 154p. incl. diagrs. tables. (Technical rept. no. 3) ([AF]OSR-TN-55-148) (AF 18(600)669) AD 63173 Unclassified

The cantilevered beam in simple bending is a basic element of airframes as analyzed for stress, dynamic vibration, and aero-elastic analysis. The accuracy with which this element can be represented by lumped parameter approximations, and on the direct analogy electric analog computer, has been studied in detail. Concerning static loading, finite difference analogies with both full and half cell end termination and the Russell analog were investigated. Exact solutions, calculated lumped parameter, and analog computer solutions were obtained for comparison. It was found that for the wide range of beam conditions studied, the

computer parasitic errors in recording deflections and slopes lie within a maximum of 2.6% with the error 1% or less for most cases. Considering the effects of finite difference lumping alone, it was found that half cell termination gives greater accuracy for beams having variation in the (EI) properties that do not exceed the second power of distance along the beam, while the full cell termination analog gives better accuracy for higher rates of taper. Four finite difference cells are required for the uniform beam to reduce the slope and deflection errors to 3% and 8 cells for 1%. For the extreme fourth power taper, 4 cells produce a 10% error and 16 cells are required to reduce the error to 1%. The Russell analog is exact if loading is applied only at the ends of cell divisions. Concerning dynamic vibrations, 3 types of analogies were considered; the finite difference analog with both full and half cell end terminations, the modified Russell analog, which is the finite difference analogy with mass lumped at the center of the cells (half cell termination only was used), and the Russell analog. Exact, calculated lumped parameter and analog computer solutions were obtained for the first 15 free vibration mode frequencies and shapes. Shears and moments were also measured on the computer and compared with exact values. The analog with mass lumped at the cell division points and half cell termination was found to be the most accurate of the finite difference analogies. The Russell analog was found to provide considerably better accuracy in all cases except for the higher modes of the beam with large taper. It was found that the transformer parasitic parameters are the only significant factors affecting the accuracy of the computer for structures of this type. The effect of these can be calculated reliably and optimum computer constants chosen for each case. Thus, for complex problems requiring the representation of a large number of modes, the computer set up can be so designed as to ensure that the important modes are represented to the greatest accuracy or to about 1%. DIFFRACTION OF A TRAPPED WAVE BY A SEMI-INFINITE METALLIC SHEET, by C. G. Weill. May 31, 1956, 21p. incl. diagrs. (Technical rept. no. 7) (AFOSR-TN-56-477) (AF 18(600)1113) AD 97361 Unclassified

A mathematical analysis is given of reflection and transmission coefficients for the trapped modes, the radiating power, and the far field pattern of a trapped wave in a grounded dielectric slab of permittivity ϵ and thickness a; and in the half space over the slab, a dielectric of permittivity 1. The case of a single incoming mode is considered, propagation from $z = +\infty$ and diffracted by a semi-infinite metallic sheet of zero thickness. The scattered field component of the total field is analyzed by means of Green functions and Wiener-Hopf techniques. Determination of the characteristic parameters of a simple obstacle embedded in a dielectric slab indicates the transmission and reflection coefficients in general to be complex, showing the characteristic mode phase-shift previously described. Application of such radiating obstacles can be made to dielectric line antennas, acting in this case like arrays.

DIELECTRIC PROPERTIES OF A LATTICE OF ANISOTROPIC PARTICLES, by Z. A. Kaprielian. Jan. 1956 [9]p. (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research under AF 18(600)1113]) Unclassified

Published in Jour. Appl. Phys., v. 27: 24-32, Jan. 1956.

The constitutive dielectric parameters for uniform space arrays of generalized structural geometry composed of similarly oriented elements of completely generalized material and shape are derived. The theoretical procedure employed in evaluating these parameters is analogous to the classical method applied to the study of the dielectric properties of nonpolar media and assumes that the disturbing action of each particle on a uniform static field can be allowed for, if each particle is replaced by a set of dipoles. Consequently, the results are applicable to microwave frequencies only if the cross-sectional dimensions and interelemental spacings remain small compared to the wavelength. The general result is particularized for the case in which the elements are spherical objects with a tensor permeability and scalar dielectric constant. The results have several applications to the design of artificial dielectrics and some of these are given. (Contractor's abstract)

THE GROWTH OF SINGLE CRYSTALS OF ZINC OF PREFERRED ORIENTATION, by T. Vreeland, Jr., D. S. Wood, and D. S. Clark. Feb. 1955, 31p. incl. illus. diagrs. (Technical note no. 1) ([AF]OSR-TN-55-65) (AF 18(600)490) AD 61826 Unclassified

The results of an experimental investigation concerning the production of zinc single crystals of a specific orientation are presented. A technique developed for the production of crystals in the form of rods with the basal plane of the zinc crystal perpendicular to the rod axis is described. This technique yields crystals of the desired orientation containing a relatively small amount of substructure.

THE BASAL SLIP IN ZINC UNDER STATIC AND DYNAMIC LOADING, by T. Vreeland, Jr., D. S. Wood, and D. S. Clark. Apr. 1956, 45p. incl. illus. diagrs. table. (Technical note no. 2) (AFOSR-TN-56-158) (AF 18(600)490) AD 86318 Unclassified

Also published in Jour. Mech. and Phys. of Solids, v. 6: 111-126, 1958.

This report presents the results of an investigation of static and dynamic shear behavior of two purities of zinc single crystals. All the crystals tested were in the form of cylindrical rods with the [0001] crystallographic direction parallel to the rod axis. The static tests were performed by applying simple transverse shear loading in one of the slip directions to one end of the crystals with the other end of the crystals rigidly clamped. The static shear stress vs shear strain relations are obtained from these tests. The dynamic tests were conducted by suddenly stopping (within a period of about 25×10^{-6} sec) one end of the crystals which were moving in the slip direction at various velocities. The resulting waves of plastic shear deformation which propagate from the stopped ends of the crystals toward the free ends are analyzed. The analysis is based upon the assumption that elastic strains may be neglected in comparison with the plastic strains. The use of the results of this analysis in conjunction with measurements of the permanent lateral deflections of the crystals resulting from the dynamic tests leads to the determination of dynamic shear stress vs shear strain relations. The results of this study show that the stress required to produce a given permanent basal shear strain in single crystals of zinc is considerably greater under the dynamic conditions employed than under static conditions. This stress decreases with increasing temperature (Contractor's abstract)

TRANSONIC FLOW PAST SIMPLE BODIES, by J. D. Cole, G. E. Solomon, and W. W. Willmarth. [1953] 1v. incl. illus. diagrs. refs. (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)383 and National Advisory Committee for Aeronautics under NAw-6154) Unclassified

Published in Jour. Aeronaut. Sciences, v. 20: 627-634, Sept. 1953.

The results of some experiments on transonic flow past two simple shapes, namely a cone-cylinder and a double-wedge airfoil, are presented. The main aim of these experiments is to bring out some of the general features of transonic flow, especially over the whole transonic range of Mach numbers. Special studies were made on the finite cone at zero angle of incidence, and the symmetric double-wedge airfoil at very small angles of attack. The experiments were carried out in the 4-in. by 10-in. transonic tunnel at GALCIT. Details of the experiments and their results are described and discussed.

NOTE ON NONSTATIONARY SLENDER-BODY THEORY, by J. D. Cole. July 14, 1953, 1p. [AF 18(600)383] Unclassified

Published in Jour. Aeronaut. Sciences, v. 20: 798-799, Nov. 1953.

A body of revolution performing arbitrary motion along its axis can be represented within linearized (acoustic) theory by a distribution of sources that vary in time along the axis of flight. Frankl (Effect of the Acceleration of Elongated Bodies of Revolution upon the Resistance in Compressible Flow, NACA Tech. memo. no. 1230, 1949; Translation from Prikladnaîa Mathematika i Mekhanika, v. 10, (no. 4): 1946) has shown that for very slender bodies, the instantaneous source strength is equal to the velocity times the rate of change of cross-sectional area along the body. In this study, an asymptotic expansion of the potential near the axis is given, and the results are presented for the special case of a cone decelerating uniformly from supersonic to sonic velocity.

ACCELERATION OF SLENDER BODIES OF REVOLUTION THROUGH SONIC VELOCITY, by J. D. Cole. Jan. 1954, 12p. illus. ([AF]OSR-TN-54-55) (AF 18(600)383) AD 47836 Unclassified

Presented at meeting of the Amer. Phys. Soc., Albuquerque, N. M., Sept. 3, 1953.

Also published in Jour. Appl. Phys., v. 26: 322-327, Mar. 1955.

The linearized theory of slender bodies in arbitrary motion at zero angle of attack has been worked out. The results have been applied to a smooth body accelerating uniformly through sonic velocity. The results of linearized theory can be used to estimate the non-linear or transonic effects. For an accelerating body the parameter $\sqrt{bl/c^2}$ is important, where $2b$ = acceleration, $2l$ = length of body, c = sound speed at infinity. For sufficiently high $\sqrt{bl/c^2}$ transonic effects can be neglected. Using linearized theory to estimate the ratio of non-linear terms in the differ-

CIT. 05:004 - CIT. 05:007

ential equation gives

$$\lambda = \frac{\text{non-linear terms}}{\text{significant linear terms}} = \frac{3}{4}(\gamma + 1)\,\frac{\delta^2}{\frac{bl}{c^2}}\,\text{Log}\,\frac{2}{\delta^2}\,\frac{c^2}{bl} - \frac{9}{4}$$

where δ = thickness ratio of body. The result above is evaluated at the maximum thickness of a symmetric parabolic arc body at the instant it passes through sonic velocity. For $\lambda < 1$ transonic effects can be neglected while for $\lambda > 1$ they begin to dominate. For practical applications the result shows that there is a possibility of a sufficiently long and slender missile accelerating fast enough to avoid transonic effects (e.g., 50 ft long, 5% thick, 3 g acceleration). For conventional aircraft and all sorts of wings, transonic effects will dominate. An interesting side result is that when the acceleration is sufficiently large so that transonic effects do not matter the drag coefficient near sonic speed is independent of the acceleration ($C_D = 3\delta^2$ for parabolic arc body). THE LIFT OF THIN AIRFOILS AT HIGH-SUBSONIC SPEEDS, by W. W. Willmarth. June 1954, 1v. incl. illus. diagrs. refs. ([AF]OSR-TN-54-168) (AF 18(600)383) AD 47210 Unclassified

Experimental results are presented for the lift characteristics of thin, 2-dimensional airfoils at high-subsonic speeds and small angles of attack. Symmetrical airfoils with different locations of maximum thickness were investigated using a surface pressure probe technique which should find use in other applications. The flow fields over each airfoil are discussed, and the quantitative results for the lift and location of the center of lift are compared with theory whenever possible. The effects of flow separation caused by boundary-layer shock-wave interaction are noted and discussed. In particular, the possibility of the forced oscillation of control surfaces resulting from boundary layer separation is mentioned. (Contractor's abstract)

TRANSONIC LIMITS OF LINEARIZED THEORY, by J. D. Cole. May 1954, 11p. diagrs. ([AF]OSR-TN-54-228) (AF 18(600)383) AD 47835 Unclassified

The range of validity of linearized theory in terms of an estimation of nonlinear effects in the transonic range is computed on the basis of linearized slender-body theory. The method is applied to a slender body of revolution in steady flight and accelerating through sonic speed, and to slender lifting wings in steady flight. The results provide regions of breakdown of the linearized theory. An approximate method of accounting for the nonlinearity in steady flight at sonic speeds is indicated for the body of revolution. EXPANSION PROCEDURES AND SIMILARITY LAWS FOR TRANSONIC FLOW. PART I. SLENDER BODIES AT ZERO INCIDENCE, by J. D. Cole and A. F. Messiter. Jan. 1956, 39p. ([AF]OSR-TN-56-1) (AF 18(600)383) AD 90890 Unclassified

Also published in Zeit. Angew. Math. Phys., v. 8: 1-25, Jan. 25, 1957.

The transonic approximation for flow over a slender body of revolution is discussed by means of a mathematical expansion procedure. The expansion is carried out in terms of a decreasing sequence of functions of the thickness ratio, and a similarity parameter relating the Mach number and thickness ratio is introduced. The first few terms of the expansions of the velocities near the axis are obtained, and similarity laws are derived for the pressure coefficient and drag coefficient of a body at zero incidence. By means of another expansion, an approximate "area rule" is obtained for a body of noncircular cross section. (Contractor's abstract)

SIMILARITY SOLUTION FOR TRANSONIC FLOW PAST A CONE, by Y.-C. Shen. Mar. 1956, 45p. incl. diagrs. tables. ([AF]OSR-TN-56-121) (AF 18(600)383) AD 82517 Unclassified

By applying a transonic expansion procedure to a conical flow field, a system of approximate transonic equations, boundary conditions, and shock relations is derived. A similarity law for the pressure coefficient on the surface of slender cones is established. The surface pressure is computed by solving the approximate equations. By use of similarity, the second order differential equations of the first 2 steps of the approximation scheme are reduced to first order equations. The solution of the first step is carried out numerically in great detail for different transonic parameters; the procedure for solving the latter is explained in the Appendix. The results are compared with the exact solution, and a highly satisfactory agreement is reached. (Contractor's abstract)

FLEXURE VIBRATION OF UNIFORM BEAMS SIMPLY SUPPORTED AT EQUAL INTERVALS - NORMAL MODES AND FREQUENCIES, by C.-M. Cheng. July 1955 [13]p. incl. diagrs. [Rept. no. 3; GALCIT rept. no. 86] ([AF[OSR-TN-55-235) [AF 18(600) 1142] AD 101501 Unclassified

The normal modes and frequencies of flexural vibrations of uniform beams simply supported at equal intervals are determined. The number of supports is arbitrary. A simple formula is given for computing the frequency of each normal mode. The mode shape is shown to be expressible in terms of elementary functions in a closed form. The frequency spectra are of special interest. For example, for an infinitely long beam on an infinite number of supports, the frequency parameter, $\beta = (\rho/D)^{1/4} l\, \omega^{1/2}$, will assume every value in the intervals $[n\pi, (n + 1/2)\pi]$, (n = 1, 2, 3 ...); whereas there exists no frequency in the intervals $[0, \pi]$, $[(n + 1/2)\pi, n\pi]$, (n = 1, 2, 3...). For a finite beam of M intervals (M+1 supports), there are M frequencies in each of the ranges $[n\pi, (n + 1/2)\pi]$, and none elsewbere. (Contractor's abstract)

THE FLUTTER OF SIMPLY SUPPORTED RECTANGULAR PLATES IN A SUPERSONIC FLOW, by J. G. Eisley. July 1955 [53]p. incl. diagrs. tables, refs. (Rept. no. 1; GALCIT rept. no. 86) ([AF]OSR-TN-55-236) (AF 18(600)1142) AD 70404 Unclassified

The problem of flutter of a simply supported rectangular plate placed in a supersonic airstream is studied. Only small deflections of the plate are considered so that linear plate theory may be used. The flutter mode is described by a series expansion in terms of the normal modes of oscillation of the plate in a vacuum. Linearized aerodynamic theory is used. Additional simplification is introduced in 2 forms. In 1 case, the strip assumption is introduced, and in another the quasisteady approximation is made. The exact solution is carried out, and the result is compared with the 2 approximate results. Numerical calculations were made to determine the flutter boundaries for plates of varying aspect ratio using strip theory aerodynamics. These calculations were made for $M = \sqrt{2}$ and M = 2 over a range of values of the reduced frequency. For M = 2 the flutter mode was described by considering 2 or 3 normal modes. For $M = \sqrt{2}$ only 2 normal modes were considered. (Contractor's summary)

THE FLUTTER OF A BUCKLED PLATE IN A SUPERSONIC FLOW, by Y. C. Fung. July 1955 [31]p. incl. diagrs. (Rept. no. 2; GALCIT rept. no. 86) ([AF]OSR-TN-55-237) (AF 18(600)1142) AD 70403 Unclassified

The flutter of a thin elastic plate in a "2-dimensional" supersonic flow is considered. The edges of the plate are hinged to supports that are perfectly rigid and fixed in space. A sufficiently large compressive load is assumed to act in the plane of the plate, so that the plate would buckle if it were free from all tractions normal to the surface of the plate. The solution is based on Galerkin's method, and under the assumption of small reduced frequency and linearized aerodynamic theory. Nonlinearity in the problem is caused by the dependence of the compressive load in the plane of the plate on the lateral deflection. Both the linear, small amplitude flutter about equilibrium positions and the nonlinear, finite amplitude flutter are considered. Certain theoretical difficulties and unsolved problems are discussed. (Contractor's summary)

THE FLUTTER OF A TWO-DIMENSIONAL BUCKLED PLATE WITH CLAMPED EDGES IN A SUPERSONIC FLOW, by J. G. Eisley. July 1956 [40]p. incl. diagrs. tables. (Rept. no. 4; GALCIT rept. no. 86) ([AF]OSR-TN-56-296) (AF 18(600)1142) AD 90008 Unclassified

The flutter of a 2-dimensional buckled panel with clamped edges is studied both theoretically and experimentally. In the first part, the flutter mode is described by a series expansion of functions which satisfy the boundary conditions for clamped edges. Quasi-steady linearized aerodynamics is used. Large deflections of the plate are considered. Numerical calculations have been made for only the first 2 terms of the series expansion. An experimental program designed to study the nature of panel flutter is described. The results of the experiments are used to check the validity of the assumptions used in the theoretical study and to shed some light on the process of panel flutter for use in future studies. METHOD OF CALCULATING FREE STREAM TEMPERATURE AND AMOUNT OF CONDENSATION FROM WEDGE TESTS; REMARKS ON THE PRESSURE COEFFICIENT IN HYPERSONIC TUNNELS, by R. [D.] Buhler, P. Jackson, and H. T. Nagamatsu. Apr. 10, 1951, 63p. incl. diagrs. Appendix. (Memorandum no. 3) [Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19] ATI-104880 Unclassified

A study is presented of shock waves with complete evaporation and of the use of the shock results for the determination of free stream temperature and amount of air condensed. This is followed by remarks on sound velocity, pressure change produced by weak waves, and the Mach number as similarity parameter. It is concluded that from the results presented the free stream temperature and the amount of condensed phase present in the flow in a hypersonic tunnel could apparently be calculated to at least fair accuracy from experiments involving fairly strong oblique shock waves. Good (but not excessive) accuracy is required to these wave-angle, static-pressure and flow-deflection measurements. If the stagnation temperature in the free stream can also be measured, then the evaluation of these experimental data requires no assumptions or knowledge of vapor pressure or surface tension of the condensed phase.

CONDENSATION OF NITROGEN IN A HYPERSONIC NOZZLE, by H. T. Nagamatsu and W. W. Willmarth. Jan. 15, 1952, 77p. incl. illus. diagrs. Appendixes A-C. (Memorandum no. 6) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) ATI-152346 Unclassified

A small stainless two-dimensional source-flow nozzle supplied with bottled nitrogen was used for the condensation investigation. It was found that the nitrogen supersaturates approximately 15°K or 1.2 Mach numbers when expanded from stagnation conditions of 70°F and pressures of 8.21 and 10.15 atm. A numerical method for solving the equations of motion with the aid of the experimental data allows the computation of the fluid temperature during the condensation process. The addition of small amounts of carbon dioxide reduced the degree of supersaturation obtainable with bottled nitrogen.

CIT. 07:005

EFFECTS OF IMPURITIES ON THE SUPERSATURATION OF NITROGEN IN A HYPERSONIC NOZZLE, by P. D. Arthur and H. T. Nagamatsu. Mar. 1, 1952, 32p. incl. illus. diagrs. table. (Memorandum no. 7) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) ATI-143891 Unclassified

An investigation is reported which was conducted to determine the effects of impurities on the supersaturation of commercial bottled nitrogen in a hypersonic nozzle. A description is given of the equipment used in the experiment, and the procedure is explained. For the conditions of the experiment commercially pure nitrogen, expanded from room temperature, was found to supersaturate by approximately 18°K or 1.2 Mach number. The degree of supersaturation of the nitrogen was decreased by the addition of impurities. Argon and oxygen were found to be much less effective in decreasing the supersaturation. During the collapse of the supersaturated state, the static pressure gradually increased above the isentropic value because of

the heat release from the condensing gas. There was no evidence of condensation shock with nitrogen. The impact pressure was only slightly changed from the isentropic value by the presence of condensation in the flow. After the collapse of the supersaturated state, the flow in the nozzle appeared to be that of an equilibrium flow of saturated vapor with either liquid or solid nitrogen, depending on the temperature.

THE EFFECTS OF AIR CONDENSATION ON PROPERTIES OF FLOW AND THEIR MEASUREMENT IN HYPERSONIC WIND TUNNELS, by J. Grey and H. T. Nagamatsu. June 15, 1952, 112p. incl. illus. diagrs. tables. Appendixes A-C. (Memorandum no. 8) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) ATI-155630 Unclassified

Some of the fundamental problems encountered in the measurement of flow properties in condensing air were investigated experimentally in the GALCIT hypersonic wind tunnel. The saturated-expansion theory of flow in a condensing fluid, as developed by Buhler, was corroborated and some of the unknown properties of the theory were clarified by analysis of the wind-tunnel tests. Several experimental techniques for the measurement of two-phase fluid properties were developed and the results were used to supply additional information concerning the nature of phenomena such as supersaturation, and normal and oblique shock waves. No definite conclusions could be reached with regard to future application of condensed-air wind-tunnel data on the basis of these tests, but the subject of similarity parameters comparable to the Mach number in flow of a perfect gas is discussed at some length. (ATI abstract)

EFFECT OF DENSITY FLUCTUATIONS ON THE TURBULENT SKIN FRICTION ON A FLAT PLATE AT HIGH SUPERSONIC SPEEDS, by T.-Y. Li and H. T. Nagamatsu. Nov. 1, 1952, 34p. incl. diagrs. (Memorandum no. 11) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) ATI-174166 Unclassified

A method is proposed for estimating the effects of density fluctuations on the turbulent skin friction on a flat plate at high supersonic speeds. This method consists of the following steps: (1) with some suitable assumptions relative to the order of magnitude of the correlation functions involving the density fluctuations, a system of differential equations is obtained which for Prandtl number (Pr) = 1 yields a mean energy integral satisfying the conventional boundary conditions; (2) by extending von Kármán's similarity considerations and Prandtl's mixing length concepts to the compressible flow regime, a derivation is made of an approximate turbulent friction equation which can be integrated

to determine the approximate velocity profile in the turbulent boundary layer over a flat plate; and (3) the formulae in closed form for the turbulent skin friction are finally obtained on the basis of our approximate velocity profile relations.

A NOTE ON THE REMOVAL AND METHOD OF MEASURING CARBON DIOXIDE IN A HYPERSONIC WIND TUNNEL, by R. D. Wallace and H. T. Nagamatsu. Nov. 15, 1952, 5p. (Memorandum no. 12) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19)
ATI-174164 Unclassified

A technique is described for the removal of carbon dioxide and the accurate determination of its concentration in the air of a hypersonic wind tunnel. The technique requires that the airflow be metered through a barium hydroxide solution for complete absorption of the carbon dioxide. The resulting alkaline solution is then titrated to the neutral point with a strong acid, the amount of acid used indicating the amount of carbon dioxide present. A sketch of the apparatus utilized is presented. It is considered necessary to measure small amounts of carbon dioxide to a high degree of accuracy in wind tunnels since this contaminant is apparently a nucleant which promotes a condensation phenomenon.

CONDENSATION OF AIR COMPONENTS IN HYPERSONIC WIND TUNNELS — THEORETICAL CALCULATIONS AND COMPARISON WITH EXPERIMENT, by R. D. Buhler and H. T. Nagamatsu. Dec. 1, 1952, 149p. incl. diagrs. tables. (Memorandum no. 13) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19)
ATI-187041 Unclassified

The effect of condensation on the flow in hypersonic wind tunnels is bracketed by equilibrium-saturated expansion and by instantaneous condensation. By calculation of shock waves with evaporation, direct comparison of theoretical and measured pressures is made possible. Satisfactory agreement between saturated expansion theory and experiment is obtained after the collapse of the supersaturated state. The droplet-growth theory (for free molecule regime) is re-examined and a good approximate solution is obtained for the nonsteady case (i.e., rapidly changing vapor properties). Limits of validity of the quasisteady theory are defined, and an upper limiting (zero growth) drop size is given for expanding flow. A simplified method is presented for calculating the pressure-time history of the collapse of the supersaturated state in nozzles. From this, the most effective nucleus sizes for given total mass of impurities are calculated. Thus, the earliest possible collapse in a nozzle resulting from impurities is estimated theoretically for low impurity concentrations. The agreement of the predicted trend with experimental results in nitrogen appears to justify the assumed mechanism of the collapse, which is reputedly caused by condensation on existing foreign nuclei formed upstream of the collapse. EXPERIMENTAL HEAT TRANSFER AT HYPERSONIC MACH NUMBER, by R. D. DeLauer and H. T. Nagamatsu. Apr. 15, 1953 [76]p. incl. illus. tables, refs. (Memorandum no. 14) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 10238 Unclassified

Heat-transfer coefficients were determined for the laminar boundary layer on a cooled flat plate at a nominal M = 5.8. A 6.2 ratio of wall temperature to free stream temperature existed in the 5- x 5-in. hypersonic wind tunnel under stagnation temperature conditions ranging from 200° to 285°F with a maximum Re of 2.1×10^6. A flat-plate temperature recovery factor of 0.858 ± 0.004 was determined. The laminar recovery factor was independent of the Reynolds number up to the beginning of transition; the range of Mach number independence of the temperature recovery factor extended to M = 5.8. The heat-transfer coefficients obtained with a negative chordwise temperature gradient were up to 60% higher than coefficients resulting from a constant-temperature surface. A value of 0.285 ± 10% was obtained for the nondimensional heat-transfer parameter $Nu/(Re^{1/2}Pr^{1/3})$ of an isothermal plate; this value agreed with the results of a skin friction investigation at the same Mach number. The investigation showed: (1) the possibility of forcing transition at $Re = 1.2 \times 10^6$ by a shock-wave boundary-layer interaction; (2) lowering of the temperature recovery factor by the condensation without changing the heat-transfer coefficients; and (3) stability of the boundary layer which separated from the plate surface when the transition point was subjected to an adverse pressure gradient.

BOUNDARY LAYER TEMPERATURE RECOVERY FACTOR ON A CONE AT NOMINAL MACH NUMBER SIX, by D. S. Mackay and H. T. Nagamatsu. June 15, 1953, 26p. incl. illus. (Memorandum no. 15) (Spon-

sored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 15345 Unclassified

The investigation was conducted on two 20° cone models about 3 in. long at free stream M = 5.6 to 5.9. One was composed of a ceramic core with a thin (0.010 to 0.015 in.) steel surface, and the second was a hollow copper shell of 0.005-in. thickness. One- and 2-phase (condensation) flow conditions were investigated. Temperature recovery factors were determined from the data obtained in tests with 1-phase air flows. The ratios of the temperatures recovered on the cone surface to the respective stagnation temperatures were computed from data obtained in the 2-phase air-flow investigations and were compared with these ratios for the 1-phase air flows. The local temperature recovery factors for the laminar boundary layer were 0.844 ± 0.008 for Re = 2.1×10^4 to 5.4×10^5. The recovery factor was independent of the Reynolds number. The independence of the recovery factor on the Mach number was substantiated up to M = 5.9 by comparison with previous results for lower Mach number. The ratios of the temperatures recovered on the cone to the stagnation temperatures were the same for 1- and 2-phase air flows. The square root of the Prandtl number at the mean of the temperatures of the cone surface was less than 1% lower than the mean of the experimental temperature recovery factors. The experimental results were considered to verify theoretical solutions.

DIRECT MEASUREMENT OF LAMINAR SKIN FRICTION AT HYPERSONIC SPEEDS, by M. Elmer and H. T. Nagamatsu. July 1, 1953, 113p. incl. illus. tables, refs. (Memorandum no. 16) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 15346 Unclassified

Experimental techniques for the study of boundary-layer characteristics at hypersonic speeds and high stagnation temperatures were developed and applied to the behavior of the laminar boundary layer at M = 5.8. Transition could not be forced at Re = 2×10^6, and the side-wall turbulent boundary layer did not contaminate the flat-plate laminar boundary layer to produce transition in a region bounded by the usual contamination angles. Observations of the leading edge with a schlieren system indicated that the shock wave and boundary layer are separated at M = 5.8 by an appreciable distance wherever the boundary-layer equations hold. Local laminar skin-friction measurements indicated that existing theories overestimate the magnitude of the local viscous sheer force at these Mach and Reynolds numbers. A theory describing the properties of the laminar boundary layer in a 2-phase fluid with condensation in the free stream was developed which predicts that (1) skin friction remains unchanged in the presence of moderate condensation for a specified nozzle geometry and stagnation temperature, and (2) heat transfer for a given wall temperature is affected by the presence of condensation which produces major changes in the adiabatic wall temperature. HYPERSONIC VISCOUS FLOW OVER AN INCLINED WEDGE, by L. Lees. July 29, 1953 [3]p. (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under [AF 33(038)250] and DA-04-495-ord-19) Unclassified

Published in Jour. Aeronaut. Sciences, v. 20: 794-796, Nov. 1953.

Results of hypersonic viscous flow over the compression side of a wedge at a large angle of attack are discussed. It is pointed out that although the flight Mach number is high, the inviscid flow Mach number is reduced considerably across the leading-edge shock, and the interaction effects are much smaller than for a flat plate at the same local Reynolds number and Mach number ahead of the body. Regions of "strong" and "weak" interactions are defined. Preliminary experimental results regarding the expansion side of a wedge at a large angle of attack are presented. These results show that the pressure rise across the trailing-edge shock is communicated upstream and causes separation of the laminar boundary-layer almost from the leading edge.

INFLUENCE OF THE LEADING-EDGE SHOCK WAVE ON THE LAMINAR BOUNDARY LAYER AT HYPERSONIC SPEEDS, by L. Lees. July 15, 1954, 26p. incl. illus. (Technical rept. no. 1) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 40933 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 23: 594-600; 612, June 1956.

In order to bring out the importance of the leading-edge region at hypersonic speeds the influence of the leading-edge shock wave on the laminar boundary layer is investigated in two simple cases of steady flow over a semi-infinite insulated flat plate: (1) sharp leading edge; (2) blunt leading edge, as approximated by a normal shock wave. The streamlines that enter the boundary layer over a large region of the plate surface have previously crossed the shock wave very near the leading-edge, where the shock is strong and highly curved. Consequently, the temperature at the outer edge of the boundary layer is appreciably higher than free stream temperature, and the vorticity there is not zero. The effects of this shock wave "heating" and vorticity on the boundary layer are shown to be much larger than the usual "errors" made in the boundary-layer theory, and an estimate of these effects can therefore be obtained within the framework of that theory. The numerical magnitude of the shock wave influence is found to be appreciable. For the case of the blunt leading-edge the slope of the curve of induced pressures plotted against the hypersonic interaction parameter closely approaches the experimental data of Hammitt and Bogdonoff obtained in helium at large values of this parameter. These approximate results show that the influence of the leading-edge region at hypersonic speeds requires careful theoretical and experimental study. (Contractor's summary)

TRANSITION STUDIES AND SKIN FRICTION MEASUREMENTS ON AN INSULATED FLAT PLATE AT A HYPERSONIC MACH NUMBER, by R. H. Korkegi. July 15, 1954, 91p. incl. illus. tables, refs. (Memorandum no. 17) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 48454 Unclassified

Tests were made in the 5- x 5-in. hypersonic wind tunnel at a nominal M = 5.8. The results of phosphorescent lacquer technique measurements for transition detection agreed well with total-head rake measurements along the plate surface and pitot boundary-layer surveys. The boundary was laminar for Re $\leq 5 \times 10^6$. Transverse contamination because of the turbulent boundary layer on the tunnel sidewall originated far downstream of the leading edge at Re = 1.5 to 2×10^6, and spread at a uniform angle of 5-1/2° as compared with 9-1/2° in low-speed flow. The effect of 2-dimensional and local disturbances was investigated by the technique of air injection into the boundary layer. Despite the onset of transition at Reynolds numbers down to 10^6, a fully developed turbulent boundary layer was not obtained at Reynolds numbers much below 2×10^{-6} regardless of the amount of air injected. Direct skin-friction measurements were made by the floating-element technique incorporating a null system using chain loading for Re = 10^6 to 4×10^6 (based on distance from leading edge). Without artificial tripping, the boundary layer was laminar over the complete range. With air injection, turbulent shear occurred only for Re = 2×10^6. The turbulent skin-friction coefficient was approximately 0.40 of that for incompressible flow for a constant value of the Reynolds number which is based on the momentum thickness, and 0.46 for an effective Reynolds number between 5 and 6×10^6. (ASTIA abstract)

HYPERSONIC SHOCK TUBE, by Y. A. Yoler. July 19, 1954, 168p. incl. illus. refs. (Memorandum no. 18) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 46521 Unclassified

Theoretical and experimental studies were made of the feasibility of using a shock tube for quantitative investigations of hypersonic flow phenomena at temperatures simulating free-flight conditions. Discussions are given of methods of producing high Mach numbers, limitations on the test section Mach number, methods of generating strong shock waves, flows with variable specific heats and dissociation, and types of problems amenable to study with the hypersonic shock tube. The experimental investigations to date have dealt with pressure studies using piezoelectric gages and schlieren studies of the flow.

BASE PRESSURE AND STATIC PRESSURE FOR A CONE-CYLINDER AT A NOMINAL MACH NUMBER OF 5.8, by W. D. Harkins. July 20, 1954, 28p. incl. illus. diagrs. tables, refs. (Memorandum no. 19) [AFOSR-TN-54-271] (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 42331 Unclassified

The scope of this investigation was: (1) to determine interference data from both 1- and 2-phase flow for

evaluating base pressure results; (2) to study the effect of Reynolds number on base pressure; and (3) to compare experimental and theoretical static-pressure distribution. Pronounced viscous effects in hypersonic flow demonstrated the increased nonlinearity of such flow problems. Based on tests in the 5- x 5-in. hypersonic wind tunnel, the following conclusions are drawn: the critical length of the sting required to prevent feed-up in the boundary layer is about 7 in. for d/h = 0.3125; the effect of varying effective sting diameter is not a monotonic variation at M = 5.8; base pressure increases monotonically for the Reynolds number range tested; and the effect of viscosity is great enough to change the effective shape of the body in the vicinity of the shoulder.

CIT. 07:021

IMPACT PRESSURE AND TOTAL TEMPERATURE INTERPRETATION AT HYPERSONIC MACH NUMBER, by J. C. Graves and N. R. Quiel. July 26, 1954, 60p. incl. illus. diagrs. refs. (Memorandum no. 20) ([AF]OSR-TN-54-272) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 42330 Unclassified

Results are presented of an experimental investigation of impact-pressure and total-temperature interpretation at a nominal Mach number of 5.6. The data indicate that the Rayleigh equation, which assumes non-viscous flow, requires correction at low free-stream Reynolds numbers. These viscous effects are detected at Reynolds numbers (based on impact-probe diameter) as high as 3000, and they continue to increase with decreasing Reynolds numbers. At the low pressure limit of the facilities used in this investigation, the maximum viscous correction is 2.5 per cent for a Reynolds number of 425. The calibration curves for the recovery factor of a total-temperature probe are given, plus an analysis of suitable parameters with which to present this information. For the limited range of total-temperatures of 200° to 260°F, and a nominal Mach number of 5.6, single calibration curves are shown using either the free-stream Reynolds number, or the Nusselt number of the flow inside the probe (based on thermocouple wire diameter) as parameters. LAMINAR BOUNDARY LAYERS ON SLENDER BODIES OF REVOLUTION IN AXIAL FLOW, by R. M. Mark. July 30, 1954, 101p. incl. illus. refs. (Memorandum no. 21) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 44929 Unclassified

An exact similar solution of the modified boundary layer equations was obtained for the axial incompressible flow past paraboloids of revolution, and an approximate method was developed for determining the local skin friction on arbitrary slender bodies of revolution in this type of flow. The approximate and exact results agreed satisfactorily for paraboloids and circular cylinders. The existence of energy integrals of the modified equations and their similarity was established. The results from an approximate method of analyzing slender insulated bodies showed that compressibility counterbalances the rise in local skin friction due to curvature at high Reynolds numbers, and increases this friction at low Reynolds numbers. Velocity profiles on a slender ogive-cylinder were obtained experimentally at M = 5.8 and at different Reynolds numbers. The results indicate a curvature effect when compared with flat plate results.

California Inst. of Tech. Guggenheim Aeronautical Lab., Pasadena.

SIMILAR SOLUTIONS OF COMPRESSIBLE BOUNDARY LAYER EQUATIONS, by T.-Y. Li and H. T. Nagamatsu. Sept. 10, 1954, 16p illus. tables, refs. (Memorandum no. 22) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 46821 Unclassified

In this investigation, it is disclosed that the partial differential equations for the compressible laminar boundary layer can be transformed into a system of ordinary differential equations by a direct procedure. This new procedure yields explicitly a differential equation for the free stream velocity distribution, u_1, which allows similar solutions. On integrating this differential equation, the special forms of u_1 are found, and these results are correlated with Stewartson's results. As an example of the similar solutions, the hypersonic viscous flow over a flat plate is discussed. From the analysis of the numerical solutions, obtained on the Reeves Electronic Analogue Computer, the characteristics of the laminar boundary layer flow with pressure gradient and heat transfer are discussed. It is shown (1) that on a heated surface, the local velocity inside the boundary layer can exceed the free stream value when a certain favorable pressure gradient exists; (2) that the variation of C_{h1}/C_{f1} for various surface temperatures with different free stream pressure gradients can be accurately predicted; and (3) that the effects of heat transfer on the laminar separation phenomenon can be quantitatively studied. (Contractor's abstract)

A STUDY OF PIEZOELECTRIC ELEMENTS FOR THE MEASUREMENT OF TRANSIENT FORCES, by Y. A. Yoler and H. T. Nagamatsu. Feb. 1, 1955, 27p. illus. tables. (Memorandum no. 23) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 62149 Unclassified

A survey of the suitability of various piezoelectric crystals for the measurement of transient forces is made. This is done by comparing the "figure of merit", which is proportional to the static charge produced by a unit stress for crystals which are otherwise satisfactory with respect to effect of temperature, humidity, brittleness, natural frequency, etc. The equations determining the output and the "response time" of a pickup are presented. The advantages of stacking the crystals in parallel to increase the "figure of merit" are shown. The application of piezoelectric elements to measure normal forces, shear forces, and volume expansion forces is discussed. The advantages of recently developed ceramic elements over natural crystals for the measurement of normal forces and volume expansion are shown. To measure shear forces, natural crystals must be used. Tables showing the properties of various crystals for measuring normal forces and shear forces are presented. (Contractor's abstract)

AN EXPERIMENTAL INVESTIGATION OF PRESSURE GRADIENTS DUE TO TEMPERATURE GRADIENTS IN SMALL DIAMETER TUBES, by W. M. Howard. June 10, 1955 [16] p. incl. illus. (Memorandum no. 27) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19) AD 67096 Unclassified

Results of an experimental investigation of pressure gradients due to axial temperature gradients in small diameter tubes are presented. The tests, which covered the region of Knudsen numbers (based on tube inside radius) of 0.01 to 6, indicate good correlation with theory. It is of value to note that this correlation

was obtained by using T equal to the temperature difference between the hot and cold ends of the tubes and T_{ave} equal to the average of these two temperatures. In contrast, theory would dictate obtaining the temperature variation along the length of the tube and applying the formulas to small incremental T's, then summing to get the total effect. Therefore, for normal laboratory conditions where pressure gradient corrections are to be computed, it is sufficient to record only the temperatures at the hot and cold ends rather than having to obtain a number of temperature readings along the tube. In order to apply pressure corrections easily and rapidly, a system of correction curves is given. To simplify the procedure, the tube cold end temperature was assumed to be 80°F, and the correction curves drawn accordingly. However, for different laboratory conditions a similar system of curves could be drawn and used. (Contractor's abstract)

CIT. 07:029

RAYLEIGH'S PROBLEM AT LOW MACH NUMBER ACCORDING TO THE KINETIC THEORY OF GASES, by H.-T. Yang and L. Lees. July 15, 1955, 88p. incl. illus. tables, refs. (Technical rept. no. 2) (Sponsored jointly by Army Ordnance and [Air Force] Office of Scientific Research under DA-04-495-ord-19)
AD 67093 Unclassified

Rayleigh's problem of an infinite flat plate set into uniform motion impulsively in its own plane is studied by using Grad's equations and boundary conditions developed from the kinetic theory of gases. For a heat insulated plate and a small impulsive velocity (low Mach number), only tangential shear stress and velocity and energy (heat) flow parallel to the plate are generated, while the pressure, density, and temperature of the gas remain unchanged. Moreover, no normal velocity, normal stress, or normal energy flow is developed. Near the start of the motion the flow behaves like a "free-molecule flow", and all physical quantities are analytic functions of the flow parameters and time. The results obtained for "large time", however, add to the growing lack of confidence in the Burnett-type series expansions in powers of mean free path. Although such expansions are obtained here, they are poorly convergent and inappropriate to the problem. To replace these unsatisfactory solutions, approximate closed-form solutions valid for all values of the time are developed, which agree with the free-molecule values for small time and the classical Rayleigh solution for large time. This technique may be useful in studying more general flow problems within the framework of the kinetic theory of gases. (Contractor's summary)

CIT.08:001 - CIT.08:003

The theoretical considerations of an intense spherical blast wave analysis are shown to be applicable to the shock wave generated by a blunt nose of finite radius on an unyawed slender body. Constant energy conditions were used to develop equations which described the shape of the bow shock wave (not too close to the nose) for a body of revolution and for a planar body. The comparison of theoretical results with those of experiments on a flat plate with a blunt leading edge at $M_\infty = 13$ in helium indicated that the wave shape is predicted very accurately by this analysis. A consideration of energy and drag showed that at hypersonic speeds the inviscid surface pressures generated by blunt noses are larger than those produced by boundary layer growth on a flat surface over a distance of order 1 from the nose, where 1 is the influence length. At $M_\infty = 15$ the viscous interaction effects are important for $Re < 10^3$, but somewhere in the range $1500 < Re < 2000$ the inviscid effects must spread rapidly over the plate surface. For $Re > 3000$ the inviscid pressure is dominant and determines the boundary layer development, skin friction, and heat transfer over the forward portion of the body.

A SIMPLE LAMINAR BOUNDARY LAYER WITH SECONDARY FLOW, by H. G. Loos. June 1953 [13]p. incl. diagrs. (Technical rept. no. 1) (AF 18(600)178) AD 12626 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 22: 35-40, Jan. 1955.

An exact calculation was made of the incompressible laminar boundary layer developed on a flat plate by a flow having streamlines which are parabolic in shape and parallel to the plane of the plate. The free stream was rotational with a constant vorticity directed normal to the plate. The solution, when the angle between the free-flow direction and the x-axis at the leading edge is zero, coincides with that of Mager and Hansen (NACA Technical note no. 2658) for small turning angles, and also remains valid for large angles. The cross flow does not separate because it transports fluid with high energy to the critical regions. Because of the variation of the total pressure from one streamline to another in the free stream, the total pressure within the boundary layer at a given point can exceed that of the corresponding free stream. (ASTIA abstract)

LAMINAR BOUNDARY LAYER PROBLEMS ASSOCIATED WITH FLOW THROUGH TURBOMACHINES, by A. Mager. June 1953 [113]p. incl. diagrs. refs. (Technical rept. no. 2) (AF 18(600)178) AD 13547 Unclassified

An analysis is presented of 3-dimensional boundary-layer flows of interest in the design of turbomachinery. A set of zero- and first-order equations were developed by assuming small lateral-pressure gradients and applying a perturbation procedure to the steady, laminar boundary-layer equations of motion. The zero-order equations are the 2-dimensional equations for flow over a flat plate. The first-order equations retain the characteristic Blasius similarity for a family of external flows expressible by $U^* = Bx^m z^l$ and $W^* = Ax^n z^r$, where U^* and W^* are the perturbation velocities, x and z the coordinates, and A and B the arbitrary constants. Boundary-layer velocity distributions were numerically determined for several types of external flows. The first part of the report deals with boundary-layer flows over plane surfaces; the second considers flows over surfaces with sharply varying lateral curvature. To obtain solutions, the equations were expanded in terms of the product of the local surface curvature and the boundary-layer thickness to obtain solutions for the curved surfaces. The effects of compressibility and rotation of the surface on the flows over a plane surface were quantitatively evaluated. The results qualitatively agreed with data from more exact solutions.

ANALYSIS OF SECONDARY FLOW IN THE STATOR OF AN AXIAL TURBOMACHINE, by H. G. Loos. Sept. 1953, 44p. diagrs. refs. (Technical rept. no. 3) (AF 18(600)178) AD 20614 Unclassified

A technique is developed to calculate the circulation along the blades and the gapwise average upwash behind the blades of a stator cascade in a nonlinear flow caused by wall boundary layers. The method takes into account both the self-transport of the secondary vorticity, and the influence of the excessive turning of the flow in the wall boundary layer on the generation of the secondary vorticity. The secondary flow with the given vorticity field is approximated by channel and lifting-line methods. In the former, the solution is obtained by extending the cascade blades downstream as rigid surfaces in the trailing edge direction. The velocity field in the Trefftz plane is determined through the boundary conditions at imaginary walls. The results of the 2 methods for the gapwise average upwash distribution downstream of the cascade are similar in the main part of the channel. The losses directly or indirectly attributed to the secondary flows are calculated to be about 5% of the energy input of the next moving blade row.

PROPAGATION OF STALL IN A COMPRESSOR BLADE ROW, by F. E. Marble. Jan. 1954, 32p. illus. (Technical rept. no. 4) ([AF]OSR-TN-54-69) (AF 18(600)I78) AD 29759 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 22: 541-554, Aug. 1955.

The experimental observations of Iura and Rannie (Am. Soc. Mech. Eng., Paper no. 53-SA-69, 1953) are used as a primary basis for a simple model of the propagation of stall in compressors. This model characterizes the stall process in an airfoil cascade by a static pressure loss across the cascade which increases discontinuously at the stall angle. The turning angle is assumed to be affected in only a minor way. The analysis for a 2-dimensional approximation of a stationary or of a rotating blade row which is free of adjacent blade-row interference reveals the extent of the stall region, the stall-propagation speed, and the pressure loss associated with stalled operation together with its effect on performance. The effect of stall propagation upon the performance of a single stage axial compressor is illustrated, and the mechanism of entering the stall-propagation regime is discussed. The essential points of the results are considered to be in agreement with the experimental evidence, and such discrepancies between theory and experiment as with regard to the propagation speed cannot be interpreted as an inadequacy of the model until either a more detailed experimental investigation is undertaken or the results are extended to situations more nearly approximating those on which the observations were made. THICK LAMINAR BOUNDARY LAYER UNDER SUDDEN LATERAL PERTURBATION, by A. Mager. Apr. 1954 [22]p. incl. diagrs. (Technical rept. no. 5) (AF 18(600)178) AD 33652 Unclassified

The crosswise flow in a 3-dimensional boundary layer is treated; in its outer part the boundary layer is assumed essentially nonviscous, but next to the wall viscosity must be considered. These 2 boundary layer regions are joined, providing an approximate but rapid solution for the crosswise velocity profile. This technique is useful in treating 3-dimensional boundary layer problems which have 2 characteristic lengths, such as a layer which has time to thicken in the usual fashion, but then is suddenly laterally perturbed at a certain fixed distance away from the leading edge. A comparison is given, where possible, with velocity distributions obtained by more conventional procedures. (ASTIA abstract)

COMPRESSIBILITY EFFECTS ON SECONDARY FLOW, by H. G. Loos. [Nov. 4, 1954] 5p. incl. illus. [AF 18(600)I78] Unclassified

Published in Jour. Aeronaut. Sciences, v. 23: 76-80, Jan. 1956.

The method of W. R. Hawthorne for the calculation of the secondary vorticity is generalized for compressible flow. It is shown that in the linearized theory (small vorticity) the influence of compressibility upon the secondary vorticity is due to: (1) the entropy gradient in the approaching flow; and (2) the compression of the fluid during the turning of the flow. The analysis is applied to the secondary vorticity which generates in a cascade or bend if the approaching flow has a boundary layer with a Prandtl number equal to unity, and has been developed along an insulated wall. For a cascade with a passage cross section which increases linearly with the turning angle and at the exit is 1.4 times the entrance cross-section area, the compressibility correction, to be applied upon the secondary vorticity, amounts to 24 per cent for a cascade entrance Mach number of 0.8. The problem of determination of the secondary flow downstream of the cascade, which is associated with a given secondary vorticity, is the same for compressible and incompressible flow.

THREE-DIMENSIONAL LAMINAR BOUNDARY LAYER WITH SMALL CROSSFLOW, by A. Mager. [1954] 18p. illus. diagrs. refs. (AF 18(600)178) Unclassified

Published in Jour. Aeronaut. Sciences, v. 21: 835-845, Dec. 1954.

The analysis of three-dimensional, steady flow laminar boundary layer with small crossflow has indicated that many important problems in this class can be solved with relatively little effort, thus affording a greater understanding of real fluid flow. Although the accurate determination of the separation point is certainly beyond the scope of small perturbation analysis (and also beyond the standard boundary layer theory), the factors which affect the separation of three-dimensional boundary layers are clearly pointed out. Among these factors, the crosswise variation of flow is indicated as important in affecting the separation. In particular, the examples show the strong tendency toward the separation as a result of crosswise variation of crossflow, both on a cylindrical shell and in a simulated s-shaped duct. Similarly, the sharp, laterally varying, concave curvature of the sur-

A THEORY OF NON-STEADY STALL FLOW ARCUND AN AIRFOIL WITH APPLICATION TO ROTATING STALL IN COMPRESSOR BLADE ROWS, by H. G. Loos, Apr. 1956, 60p. illus. diagrs. refs. (Technical rept. no. 6) (AF 18(600)178) Unclassified

A mathematical model for the non-steady stall flow around a single airfoil is developed. The flow is assumed as inviscid and incompressible; the airfoils are approximated by flat plates. An airfoil together with the separated flow region on its "suction surface" is considered as a thin airfoil with partially fluctuating boundaries. The model is applied to an analysis of propagating stall in a two-dimensional compressor cascade. A simple, approximate solution of the resulting equations seems to be in agreement with experimental data for the propagation speed at stall inception. The theory predicts a transition from a two-region stall to a single-region stall. (Contractor's abstract)

CARBON FORMATION FROM ACETYLENE IN THE SHOCK TUBE, by E. N. Bennett. June 1956, 85p. incl. diagrs. refs. [AFOSR-TN-56-333] (Sponsored jointly by Air Force Office of Scientific Research as technical rept. no. 2 under AF 18(603)2 and Office of Naval Research as technical rept. no. 20 under Nonr-22003) AD 95209 Unclassified

The use of the shock tube for the study of C formation from C_2H_2 was considered theoretically and studied experimentally. In the calculations, the state of the gas was determined behind incident and reflected shocks for a wide range of shock strengths and for various excitation models of the internal degrees of freedom. A simple mechanism was assumed for the thermal decomposition, namely, the formation of solid C and H. Upper and lower limits for the final temperatures are computed for incident and reflected shocks. Estimates are presented for the minimum times spent by the gas in a uniform state at the elevated temperatures behind reflected shocks. The shock strengths required to initiate decomposition of C_2H_2 at various pressures have been investigated experimentally. Temperature estimates and shock velocity measurements suggest that the effective specific heat ratio approaches the equilibrium value. The minimum pressure ratios p_4/p_1 (initial conditions of the high-(p_4) and the low-(p_1) pressure gas) required for C formation were found to be: for C_2H_2 at initial pressures of 10-, 50-, and 150-mm Hg, ratios of about 255, 170 and 160, respectively; for a mixture of 95% A and 5% C_2H_2 at initial pressures of 50-, 100-, and 150-mm Hg, ratios near 42, 39, and 38, respectively. Spectroscopic studies were carried out to determine the light emitted in a narrow wavelength region during chemical decomposition behind reflected shocks. The results show that the intensity distribution follows the black-body emission law. Therefore, a 2-color method may be used in future studies for determining the temperature as a function of time behind C-forming shocks. (Contractor's abstract)

AN INTRODUCTION TO THE USE OF THE SHOCK TUBE FOR THE DETERMINATION OF PHYSICO-CHEMICAL PARAMETERS, by S. S. Penner, F. Harshbarger, and V. Vali. June 1956, 1v. incl. diagrs. refs. [AFOSR-TN-56-334] (Sponsored jointly by Air Force Office of Scientific Research as technical rept. no. 1 under AF 18(603)2 and Office of Naval Research as technical rept. no. 19 under Nonr-22003) AD 95210 Unclassified

Also presented at meeting of the AGARD Combustion Panel, Oslo (Norway), May 1956.

Also published in Combustion Researches and Reviews, London, Butterworths Scientific Publications, 1957, p. 134-172.

A qualitative survey was made of principles and methods which are useful for understanding the application of the shock tube as a research tool for high-temperature investigations. A survey of optical techniques is presented which are suitable for studying processes which occur in a gas behind incident and reflected shock fronts. The techniques include (1) interferometric procedures; (2) schlieren techniques; (3) ionization density and conductivity measurements; (4) temperature measurements behind shocks; (5) light absorption and emission measurements at selected wavelength regions; (6) spectroscopic studies behind shock fronts; and (7) light reflection at the shock front. A description is also given of some representative uses of the shock tube for the determination of physico-chemical parameters. The particular subjects considered are of possible application to problems important in combustion research. They include: (1) reaction-rate measurements for homogeneous gas reactions; (2) ionization rates; (3) measurement of vibrational relaxation times; (4) gas emissivities at elevated temperatures; (5) measurement of heats of dissociation; (6) determination of transport properties; (7) thickness of shock fronts and rotational heat capacities lags; and (8) initiation of detonation with shock waves, and thickness of detonation fronts.

THEORETICAL STUDIES ON THE THERMAL DECOMPOSITION OF NITRIC OXIDE IN A SHOCK TUBE, by S. T. Demetriades and H. Aroeste. June 1956 [39]p. incl. diagrs. tables, refs. [AFOSR-TN-56-335] (Sponsored jointly by Air Force Office of Scientific Research as technical rept. no. 3 under AF 18(603)2 and [Office of Naval Research under Nonr-22003]) AD 95211 Unclassified

Favorable conditions are determined for the study of the kinetics of thermal decomposition of nitric oxide in a shock tube. If the pressure ratios across the diaphragm are of the order of 5000, a test section length between 20 and 25 ft is sufficient to decompose nitric oxide to within 1% of its equilibrium concentration. If the initial pressure and temperature before the shock are about 0.02 atm and 300°K, respectively, the final pressure behind the shock will be about 1 atm. The pressure behind the shock changes by only about 10% as the reaction proceeds to completion. Charts are presented for computing the length of test section necessary for various percentages of decomposition and various initial pressure ratios. (Contractor's abstract)

A STUDY OF TURBULENCE AND DIFFUSION USING TRACERS IN A WATER TUNNEL, by V. A. Vanoni and N. H. Brooks. Jan. 31, 1955, 51p. incl. illus. diagrs. tables, refs. (Rept. no. E-46) [AFOSR-TR-55-18] (AF 18(600)582) AD 66182 Unclassified

A study of turbulence in a water tunnel was made by observing the motion of small liquid droplets having the same density as water. These tracers were injected into the flow, and their trajectories were photographed with a fixed camera using a stroboscopic light. From measurements of the photographic plates, it was possible to calculate instantaneous velocities, turbulence intensities, and Lagrangian correlation coefficients. Runs were made both with and without a turbulence-producing grid. From 11 to 35 separate trajectories were measured for each run. Each point value of the turbulence characteristics is an ensemble average. The biggest limitation on the practical application of this method is the inevitable sampling error in the calculated intensities and correlations. These errors were large, even when 35 trajectories were measured; they can be reduced only by greatly increasing the number of trajectories analyzed. A satisfactory experimental technique for photographing and measuring the trajectories of the tracers was developed, but the computations involved are still very laborious. Results showed that a large fraction of the turbulent energy of the field may be attributed to substantial differences between the mean velocities of different tracers over the 3-ft observation reach. The decay of turbulence energy with distance showed a linear relation between the reciprocal of the energy and the distance, but a strong Reynolds number effect was observed. The correlation curves indicated that the time scale was fairly large; practically all of the energy was associated with relatively low frequencies. Unfortunately, the data were not extensive enough to permit calculation of the diffusion coefficients from the Lagrangian correlations in accordance with Taylor's theory. ON THE SPECIFIC DIRECTIONS OF LONGITUDINAL WAVE PROPAGATION IN ANISOTROPIC MEDIA, by F. E. Borgnis. Dec. 1954, 25p. incl. diagrs. (Technical note no. 2) (AFOSR-TN-54-253) (AF 18(600)593) AD 50987 Unclassified

Also published in Phys. Rev., v. 98: 1000-1005, May 15, 1955.

A method is developed to obtain specific directions in a medium of given anisotropy along which the displacement of 1 of the 3 possible waves is parallel to the direction of wave propagation. If the matrix of elastic coefficients is known, the method leads to the complete set of such longitudinal directions. The method is applied to the trigonal, hexagonal, tetragonal, and cubic groups of crystal symmetry, and general conditions are established under which pure longitudinal waves exist. A numerical calculation shows that there are 5 such distinct directions for α-quartz not counting the ones which are equivalent by symmetry properties. Special conditions are obtained between the elastic constants under which longitudinal waves can be propagated in any direction in a hypothetical anisotropic medium fulfilling these conditions. RESEARCH IN HIGH-FREQUENCY ULTRASONICS, by W. G. Cady. Final rept. Mar. 1955, 17p. incl. diagrs. (AFOSR-TN-55-79) (AF 18(600)593) AD 61828 Unclassified

This final report summarizes the work done during

the 2-yr contract. After a survey of proposed undertakings, abstracts are given of completed work on composite piezoelectric resonators, theory of acoustic filters having a periodic structure, and theory of compressional waves in crystals. A report is given on the attempts to generate acoustic vibrations at a frequency of 3000 mc/sec. Descriptions are given of the transducer and cavity resonator used in the unsuccessful experimental tests. As a result of this research study, it was suggested that improvements should be made by: (1) obtaining a microwave generator with very high frequency stability, and at the same time having the frequency adjustable over a small range, at least; (2) constructing and mounting a transducer in such a manner as to ensure exposure to a strong electric vector without undue heating; (3) providing greater uniformity in the thickness of quartz or other transducer material; and (4) searching for other substances having piezoelectric properties in high-frequency fields which can be prepared as uniform thin films. THEORY OF THE PLANE WAVE ACOUSTIC FILTER WITH PERIODIC STRUCTURE, by W. G. Cady. [1955] [20]p. incl. diagrs. refs. (Technical note no. 3) [AFOSR-TN-55-112] (AF 18(600)593) Unclassified

After a brief discussion of the general properties of filters of different types (e.g., optical, electrical, mechanical), attention is given to an acoustic filter consisting of an arbitrary number of identical sections placed between any 2 media. Each section consists of 2 plane-parallel layers, which may be of any materials and thicknesses. It is assumed that there are no losses due to absorption in these materials, and that plane waves of arbitrary frequency are incident normally on the filter. The theory of filters of this type is developed, involving an expression for the specific acoustic impedance at any point, and also a convenient iteration factor which facilitates the calculation of reflection and transmission. The formulas are then specialized for the case in which the thickness of each layer is the same fraction of a wavelength, including a discussion of quarter-wave layers. A proof is given of the reversibility of the filter. Numerical calculations have been carried out for filters with assumed constants. The results for one case are presented in the form of curves relating the coefficient of reflection to the frequency. (Contractor's abstract)

ASYMPTOTIC EXPANSIONS. 1. FUNDAMENTAL THEOREMS OF ASYMPTOTICS, by J. G. van der Corput. June 1954. 66p. (Technical rept. no. 1) [AF 18(600)958] Unclassified

Summary published in Nederl. Akad. Wetensch. Proc., Indag. Math., Ser. A., v. 57: 206-217, 1954. (Title varies)

This is the first of a number of self-contained reports on asymptotic expansions. As the author points out, the theory of asymptotic expansions is at present incomplete and has suffered neglect over a long period. This is probably due to the fact that, in practice, asymptotic expansions are largely used in certain kinds of boundary-value problems and the methods established by Poincaré are regarded as satisfactory for this purpose. They have also been used in analytic number theory, in statistical mechanics and in coefficient theory, often in conjunction with the method of steepest descent, but in all these cases conventional methods suffice. Recently extensions of the Poincaré theory have been developed by R. San Juan in dealing with asymptotic expansions arising out of the moment problems associated with different kinds of transform [see, e.g., Revista Mat. Hisp. Amer. (4) 11, 65-110 (1951); these Rev. 13, 214]. On the other hand, attempts to sharpen the existing theory have also been made in relation to asymptotic expansions near an irregular singularity (see, e.g., Evans, Quart. Appl. Math., v. 12: 295-300, (1954)). Neither of these are referred to in the present work. The author's aims are both extensive and precise. His intention is to assist mathematicians in the practical use of asymptotic expansions while at the same time building up a rigorous theory on a wide basis. The several reports will cover three successive stages. In the first, the Poincaré theory is subjected to a rigorous analysis. Here a numerical upper bound is not known for the remainder term; all that is known is that its order is the same as that of the first neglected term. For many purposes in applied mathematics this is sufficient. The second stage deals with asymptotic expansions in which the upper bound of the remainder is known. The third stage deals with the transformation of an asymptotic series into one in which the error of approximation may be prescribed. It is with the first stage that this report is largely concerned. The subjects dealt with are asymptotic equality; asymptotic limits; asymptotically convergent series, single and multiple; uniform asymptotic convergence; analytic functions with prescribed asymptotic expansions; and equations involving asymptotic expansions. The chapter on analytic functions deals with conditions under which a function, analytic in a given region, may have an asymptotic expansion about one or more boundary points of that region. The last chapter concerns solutions in s of the equation $f(s) = t$, where $f(s)$ and t are given asymptotically. The treatment is logical and rigorous throughout. All the terms used are clearly defined from the start and the basic ideas are subjected to a detailed analysis. There are many examples, carefully chosen to illustrate the points at issue. Although the author does not claim the work to be exhaustive, if the remaining reports maintain the same standard, then the author's aim to provide a rigorous and com-

CAL. 01:002 - CAL. 01:003

plete basis for the theory of asymptotic expansions will have been largely achieved. (Math. Rev. abstract)

ASYMPTOTIC EXPANSIONS. II. ELEMENTARY METHODS, by J. G. van der Corput. Dec. 18, 1954, 54p. (Technical rept. no. 2) [AF 18(600)958] Unclassified

Summary published in Nederl. Akad. Wetensch. Proc., Indag. Math., Ser. A, v. 58: 139-150, 1955. (Title varies)

In section 1 the theory Pólya and Szegö (Aufgaben und Lehrsätze aus der Analysis, Bd. I, Springer, Berlin, 1925, p. 26) of enveloping series is extended to series of complex terms in the following way: $|\zeta|<\pi$; E_ζ is the closed circle segment bounded by the line segment (0, 1) and by the circle arc with end-points 0 and 1. Which makes at the origin an angle ζ with the + real axis. A number s is enveloped by the formal series Σa_n ($n\geq 0$) with respect to the circle segment Σ_ζ if it is possible to find for each integer $n\geq 0$ an element ϑ_n of E_ζ such that $s = a_0+a_1+\cdots+a_{n-1}+\vartheta_n a_n$. Notation: $s \propto \Sigma_{n=0}^{\infty} a_n(E_\zeta)$; e.g.

$$(1+z)^{-1} \propto \sum_{n=0}^{\infty} (-)^n z^n (E_\zeta) \text{ for } |\zeta| = |\arg z| < \pi.$$

In section 2 this theory is applied to the Γ-function (a.o. determination of general sharp upper bounds for the error term of $\log \Gamma(z)$). In section 3 it is shown that under general conditions for each point z on the line segment (0, w) (w real or complex $\neq 0$) in the Maclaurin expansion

$$f(z) = \sum_{h=0}^{\infty} \frac{f^{(h)}(0)}{h!} z^h + \frac{\lambda_n z^n}{n!},$$

λ_n belongs to a convex set E_n, assuming that $f^{(n)}(z)$ belongs to the same set. In section 4 the author obtains by integration by parts of $\int_a^b g(x)e^{i\omega f(x)}dx$ (a and b real) the expansion $\sum_{h=0}^{n-1} (a_h+\beta_h)\omega^{-1-h} + \omega^{-n}\eta_n$, where the last term is under specified conditions $= O(|\omega|^{-n})$. The asymptotic sum of the asymptotically convergent series

$$\sum a_h \omega^{-1-h} (h>0) \leftrightarrow A$$

is called the asymptotic residue between a and a^+; notation $\int_{a^+} g(x)e^{i\omega f(h)}dx$. In an analogous way

$$B \leftrightarrow \sum \beta_h \omega^{-1-h} = \int_{b^-} g(x)e^{i\omega f(x)}dx.$$

The author proposes to treat, in later reports, the complete theory of asymptotic residues. In section 5 absolutely monotonic and completely monotonic functions are treated. A function f(x) is called absolutely monotonic in an interval j if $f^{(n)}(x)\geq 0$ in j ($n = 0, 1, 2, \ldots$) and completely monotonic in j if $(-1)^n f^{(n)}(x) \geq 0$ in j ($n = 0, 1, 2, \cdots$). For the restricted class of integrals containing such functions a very sharp numerical upper bound for the error term is obtained. In the last chapter 6 sufficient conditions are obtained for

$$\lim_{h\to\infty} \sum_{0<n<mh} f_n(h) = \sum_{n=1}^{\infty} \phi_n \quad (m_h = \text{or} \to\infty \text{ for } h\to\infty)$$

where the last series converges (absolutely resp. unconditionally). Many applications are given (e.g. Γ-function, polynomials of Legendre, ultraspherical polynomials, formula of LaPlace-Heine, values of derivatives of polynomials of Legendre at $x = \pm 1$, (formula of Grosswald, with generalisation), upper bound for the derivatives of the polynomials of Legendre (Picone), generalisation of the formula of Picone for ultraspherical polynomials, polynomials of Fejer, etc.). ASYMPTOTIC EXPANSIONS. III. THE ASYMPTOTIC BEHAVIOR OF THE REAL SOLUTIONS OF CERTAIN SECOND ORDER DIFFERENTIAL EQUATIONS, by J. G. van der Corput. June 1955, 171p. (Technical rept. no. 3) [AF 18(600)958] Unclassified

Summary published in Nederl. Akad. Wetensch. Proc. Indag. Math., Ser. A, v. 59: 1-14, 1956. (Title varies)

$Y(x)$ and $\eta(x)$ are two linearly independent solutions of

(1) $y''+P(x)y' + Q(x)y = 0.$

It is possible to determine the asymptotic behaviour for large positive x of the real solutions of the differential equation (2) $y'' + \{P(x) + f(x)\}y'+\{Q(x)+g(x)\}y = 0$ provided that $f(x)$ and $g(x)$ (perturbations) and their derivatives are sufficiently small for large positive x. (1) is called the related equation. In section 2 are introduced certain transformations, e.g. $y = r(x)(Y \sin\theta+\eta\cos\theta)$; $y' = r(x)(Y'\cos\theta+\eta'\cos\theta)$, by which (2) is transformed into (3) $\theta' = \cdot(x,\theta)$; (4) $2r'r^{-1} = M(x,\theta)$. The advantage is that (3) is a differential equation of the first order not involving r(x). After determination of the asymptotic behaviour of $\theta(x)$ (4) gives the asymptotic behavior of $2\log r(x)$, and therefore also $y(x)$ and $y'(x)$. Special case: $P(x) = 0$, $Q(x) = 1$, $f(x)$ and $g(x)$ absolutely integrable to infinity.

$\cdot(x) \to \nu$; $2\log r(x) \to \nu^*$ for $x \to +\infty$ (ν and ν^* finite).

By putting $2\{\cdot(x) - \nu\} = \epsilon(x)$ it is shown in section 4 that $\epsilon(x)$ satisfies an integral equation of the form

$$\epsilon(x) = \int_x^{\cdot} \{\kappa(t)+\lambda(t)\sin\epsilon(t)+\mu(t)(1-\cos\epsilon(t))\}dt$$

$\kappa(x)$, $\lambda(x)$, $\mu(x)$ given functions, absolutely integrable to $\cdot$). In order to write $\epsilon(x)$ in a simple form an operation called bar-multiplication is introduced, de-

fined as follows:

$$j(x) = \int_{t_1 \geq \cdots \geq t_m \geq x} \cdots \int f(x, t_1, \cdots, t_m) dt_1, \cdots dt_m;$$

$$J(x) = \int \cdots \int_{t_{m+1} \geq \cdots \geq t_{m+M} \geq x} F(x, t_{m+1}, \cdots, t_{m+M}) dt_{m+1} \cdots dt_{m+M}$$

The bar-product $j \cdot J$ is by definition the m+M-tuple integral:

$$\int \cdots \int_{t_1 \geq \cdots \geq t_{m+M} \geq x} f(x_1, t_1, \cdots, t_m) F(x, t_{m+1}, \cdots, t_{m+M}) dt_1 \cdots dt_{m+M}.$$

In section 4 it is shown that $\varepsilon(x)$ possesses an asymptotic expansion of the form

$$\varepsilon(x) \sim k\omega + \overline{kl} + \overline{kll} + \overline{kkm} - \overline{kkll} + \cdots \quad (k = \int_x^\infty \varkappa(t)dt \text{ etc}).$$

The remainder is at most of the order ω^{-r} (r = the number of bar-factors in the first neglected term). An analogous result is obtained for $2 \log r - \int_x^\infty f(t)dt - \gamma^*$. In a purely formal manner the asymptotic expansion for

$$U(x) + iV(x) = \exp\left\{ -\tfrac{1}{2} \int_x^\infty f(t)dt - \tfrac{1}{2}\gamma^* \right\} r \exp\left\{ \tfrac{1}{2} i \varepsilon \right\} \qquad (\tfrac{1}{2}\varepsilon = \theta - \gamma)$$

is computed. In this expansion certain regularities in the formation of the bar-products and in the signature of the terms lead to a conjecture, which is verified in section 4. In the more complicated case in which there is no absolute integrability, the author restricts himself in the sections 5 and 8 to differential equations of the form

$$5)\quad y'' + y'\Big(\sum_{\nu=1}^{n} L_\nu f_\nu(x) \cos 2\alpha_\nu(x) + y\Big(1 + \sum_{\nu=1}^{n} K_\nu f_\nu(x) \cos 2\alpha_\nu(x)\Big) = 0,$$

f_ν and α_ν are given, real, infinitely differentiable functions, K_ν and L_ν are given constants. To determine the asymptotic behaviour of the real solution of $\theta' = \Lambda(x, \theta)$ a certain "smoothness condition" is imposed on the functions f_ν. On the functions α_ν a certain "resonance condition" is imposed which can be formulated roughly by saying that there is either complete resonance or no resonance at all. Under these two conditions it is possible to construct for each real solution $\theta(x)$ a real constant γ such that $\theta(x) - \gamma$ is for large positive x asymptotically equal to the asymptotic sum of an asymptotically convergent series. These two conditions however are not sufficient to deduce from this asymptotic equation an asymptotic expansion whose terms do not involve $\theta(x)$ itself. To that end a certain supplementary condition is needed (section 6). In section 8 the author demonstrates under these three conditions: 1. Uniqueness theorem. If θ and θ^* denote two real solutions of $\theta' = \Lambda(x, \theta)$ with the same constant γ in their asymptotic equation, then $\theta = \theta^*$. II. Existence theorem. If γ denotes an arbitrary given real constant number, then it is possible to construct a real solution θ of $\theta' = \Lambda(x, \theta)$ such that γ is the constant term in the asymptotic equation of that solution. By I this solution is uniquely defined by γ. In the sections 9 and 10 the asymptotic behaviour of the solutions of some more complicated differential equations is investigated. In section 11 the case is treated that in (5) f_ν and α_ν possess asymptotic expansions according to powers of x. In section 12 $\alpha_\nu(x) = a_\nu x + \eta_\nu$ denotes a linear function of x. It is shown that the rationality properties of α_ν play an important role. In section 13 n = 1, $\eta = 0$, f(x) is continuous of bounded variation. In this case however, there are some rational values which may not be assumed by α, e.g. the value zero. In the last section 14 the author obtains a first approximation to θ and $\log \gamma$ under much weaker conditions. This section is closely related to stability theory. (Math. Rev. abstract)

ON SEQUENCES WITH DIVERGENT TOTAL VARIATION, by W. Stenberg. Dec. 18, 1954 [13]p. [AF 18(600)958] Unclassified

Published in Nederl. Akad. Wetensch. Proc., Indag. Math., Ser. A, v. 58: 178-190, 1955.

The paper proves that if $\{a_n\}$ is a sequence of positive terms with $a_n \to 0$ such that $\sum a_n = \infty$, then there exists a "rearrangement" $\{b_n\}$ of $\{a_n\}$ with $\sum b_n = \infty$ such that for every subsequence $\{c_n\}$ of $\{b_n\}$ it is true that

$$\sum_{j=1}^{n-1} |c_j - c_{j+1}| > 2 \sum_{j=1}^{n} |c_j| - 5b^*,$$

where b^* is the largest b_n. Here $\{b_n\}$ is a "rearrangement" of $\{a_n\}$ if $b_n = a_{h(n)}$ where h(n) is a univalent function on the positive integers to the positive integers and includes the notion of rearrangement of a subsequence. This theorem has as corollary an unpublished result of Besicovitch and Erdös that there exists a sequence $\{a_n\}$ of positive terms with $a_n \to 0$ and $\sum a_n = \infty$ such that for every subsequence $\{b_n\}$ with $\sum b_n = \infty$ it is true that $\sum_n |b_n - b_{n+1}| = \infty$. ON SOME PROBLEMS IN TRANSONIC FLOW, by M. H. Protter. Nov. 1954, 23p. incl. diagrs. (Technical rept. no. 1) (AF OSR-TN-54-307) (AF 18(600)1117) AD 48548 Unclassified

A uniqueness theorem previously proved (Jour. Rational Mech. and Analysis, v. 2, 1953) for the

CAL. 02:002 - CAL. 02:004

Tricomi problem for equations of the form $K(y)u_{xx} + u_{yy} = 0$ is extended to a general uniqueness theorem for the problem of the existence of transonic potential flows out of a jet in which K(y) is a specific monotone function. The results are presented as 2 theorems. (1) Let D be the domain enclosed by Γ, γ_1 and γ_2 and suppose that $K(\eta)$ has a continuous third derivative satisfying the condition $K'''(\eta) \leq 0$ whenever $F(\eta) < 0$, $\eta < 0$. If ψ is a solution of $K(\eta)\psi_{\xi\xi} + \psi_{\eta\eta} = 0$ in D which vanishes on Γ and γ_2 then ψ vanishes identically. Γ is a simple rectifiable arc in the upper half-plane with end points on the x-axis; γ_1 is the characteristic of $\frac{d\eta}{d\xi} = \pm \frac{1}{\sqrt{-K(\eta)}}$ passing through the origin and extending into the portion of the plane $\xi > 0$, $\eta < 0$; γ_2 is the characteristic of $\frac{d\eta}{d\xi} = \pm \frac{1}{\sqrt{-K(\eta)}}$ passing through $P(\xi_0, 0)$ which intersects γ_1; and $P(\xi_0, 0)$ is one of the end points of Γ. (2) Let D be the domain described above and suppose Γ coincides with the normal curve of $K(\eta)\psi_{\xi\xi} + \psi_{\eta\eta} = 0$ in some neighborhood of the origin and $P(\xi_0, 0)$; then either there exists a unique quasi-regular solution of $K(\eta)\psi_{\xi\xi} + \psi_{\eta\eta} = 0$ with prescribed values on Γ and γ_2 or there exist nonidentically vanishing solutions of $K(\eta)\psi_{\xi\xi} + \psi_{\eta\eta}$ which vanish on Γ and γ_2. Combining these 2 theorems yields an existence theorem in the hodograph plane for the transonic flow out of a nozzle.

THE PERIODICITY PROBLEM FOR PSEUDO-ANALYTIC FUNCTIONS, by M. H. Protter. Oct. 1955, 45p. (Technical rept. no. 2) ([AF]OSR-TN-55-308) (AF 18(600)1117) AD 75262 Unclassified

Also published in Ann. Math., v. 64: 154-174, July 1956.

The basic theory of pseudo-analytic functions, a theory based on systems of elliptic partial differential equations which parallels the ordinary theory of functions derived from the Cauchy-Riemann equations, is given together with a definition of a generalized derivative. The periodicity problem involves the determination of the circumstances under which the system (B)

$$\begin{cases} u_{1x} - v_{1y} = \eta_{11}u_1 + \eta_{12}v_1 \\ u_{1y} + v_{1x} = \eta_{21}u_1 + \eta_{22}v_1 \end{cases}$$

is identical with the system (A)

$$\begin{cases} u_x - v_y = b_{11}u + b_{12}v \\ u_y + v_x = b_{21}u + b_{22}v \end{cases}$$

when $w = u + iv$ is a pseudo-analytic function which satisfies A, and $\dot{w}$ is its generalized derivative which satisfies B. Stated alternatively, the periodicity problem concerns the existence of sequences $\alpha, \beta, \gamma, \ldots$ in which the members of each class are the generalized derivatives of the functions in the preceding class. Such a sequence has a minimum period n if it has period n, and if it does not have period less than n for all possible choices in the definition of the generalized derivative. The principal results state that for each integer n there exist sequences of minimum period n. Classes α can be found such that the sequences generated by α for all possible choices for the generalized derivative are nonperiodic.

ON THE SOLUTION OF PARABOLIC EQUATIONS BY DIFFERENCE METHODS. I, by M. Lees. Nov. 1955, 26p. (Technical rept. no. 3) ([AF]OSR-TN-55-439) (AF 18(600)1117) AD 80361 Unclassified

A method of obtaining approximate solutions to

$$\frac{\partial u}{\partial t} - a(x,t)\frac{\partial^2 u}{\partial x^2} - 2b(x,t)\frac{\partial u}{\partial x} - c(x,t)u - d(x,t)$$

is given that involves the solution of a suitable backward difference equation over a rectangular lattice. The specific boundary-value problem to which the method applies is the following. Let D be a domain contained in the rectangle $0 \leq t \leq T$, $0 \leq x \leq 1$ such that (1) $\bar{D}$, the closure of D, contains a line segment $\bar{l}$ in which $t = T$, $a_0 \leq x \leq b_0$, and (2) if (x,t) and (x',t) are any 2 points in $\bar{D}$ with the same t-coordinate, then the line segment joining these 2 points lies entirely in $\bar{D}$. Find a function $u(x,t)$ defined in $\bar{D}$ that satisfies the differential equation in D and that takes on prescribed values on the boundary of D minus l. (ASTIA abstract)

ON PARTIAL DIFFERENTIAL EQUATIONS OF MIXED TYPE, by M. H. Protter. [1955] [16]p. incl. refs. (AF 18(600)1117) Unclassifted

Published in Proc. Conference on Differential Equations, Maryland U., College Park (Mar. 17-19, 1955), 1956, p. 91-106.

This is a survey of results (by the author and others) concerning initial and boundary value problems for second order partial differential equations of hyperbolic type which become parabolic on part of the boundary, and includes an extensive bibliography. Confining himself mainly to the theory of equations of the form (1) $K(y)h(x,y)u_{xx} - u_{yy} + au_x + bu_y + cu = f$ in the half plane $y > 0$, with K(y) positive in $y > 0$ and vanishing on $y = 0$, and h positive in $y \geq 0$, the author describes the theory of two problems: (1) the singular Cauchy problem -- where $u(x,0)$, $u_y(x,0)$ are prescribed;

(ii) the boundary value problem in a triangular shaped domain bounded by a segment Γ on the x axis and the characteristics Γ_1, Γ_2 from its end points which are defined by the equations $dy/dx = \pm 1/\sqrt{(Kh)}$. In problem (ii) the boundary values of u on Γ and on one of the characteristics, say Γ_1, are prescribed; this is a problem of Goursat type. We mention just a few results. Berezin has treated problem (i) for $K(y) = y^{\alpha}$, and has shown that it is well posed for $0 < \alpha < 2$ but not for $\alpha > 2$. The author has extended this by showing that the problem is well posed in general provided that (2) $ya(x, y)/\sqrt{K(y)} \rightarrow 0$ as $y \rightarrow 0$; a similar result holds for semi-linear equations (i.e., equations that are linear in the second order derivatives). Hellwig has shown that the critical case $\alpha = 2$ in Berezin's work is well posed provided that $|a(x, 0)| < 2$. The author states some results on existence and uniqueness for problem (ii), and proves a new result of this type, assuming that K(y) is monotonic increasing and satisfies (2). The paper also contains some results for semi-linear equations, and for certain equations in higher dimensions. (Math. Rev. abstract)

A GENERALIZATION OF COMPLETELY CONVEX FUNCTIONS, by M. H. Protter. May 1956, 14p. (Technical rept. no. 5) (AFOSR-TN-56-145) (AF 18(600)1117) AD 86303 Unclassified

Also published in Duke Math. Jour., v. 24: 205-214, June 1957.

The theorem is given that, if f(x) is almost completely convex in an interval (a, b), it is an entire function of exponential type. A function f(x) defined in an interval (a, b) is said to be almost completely convex, if it possesses derivatives of all orders and if $f^{(4k)}(x) \geq 0$, $a \leq x \leq b$, and $f^{(4k+2)}(a) + f^{(4k+2)}(b) \leq \frac{\pi^2}{(b-a)^2}\left[f^{(4k)}(a) + f^{(4k)}(b)\right]$, $k = 0, 1, 2, \ldots$. The theorem of Widder (Proc. Nat. Acad. Sci. U. S., v. 26: 657-659, 1940), that if f(x) is completely convex in (a, b) it is an entire function of exponential type, is extended to functions of 2 variables as follows: if f(x, y) is completely convex in a domain D, it is a real analytic function defined in the entire plane and of exponential type. A function f(x, y), defined in a domain D, is completely convex if it possesses derivatives of all orders with respect to x and y and $\frac{\partial^{2(p+q)}f}{\partial x^{2p}\partial y^{2q}} \geq 0$ for p+q even and $\frac{\partial^{2(p+q)}f}{\partial x^{2p}\partial y^{2q}} \leq 0$ for p+q odd. No conditions are imposed on odd derivatives of the forms $\frac{\partial^{2(p+q)+1}f}{\partial x^{2p}\partial y^{2q+1}}$, $\frac{\partial^{2(p+q)+1}f}{\partial x^{2p+1}\partial y^{2q}}$ or on even derivatives of the form $\frac{\partial^{2(p+q)}f}{\partial x^{2p+1}\partial y^{2q-1}}$. A MAXIMUM PRINCIPLE FOR HYPERBOLIC EQUATIONS IN A NEIGHBORHOOD OF AN INITIAL LINE, by M. H. Protter. Aug. 1956, 20p. (Technical rept. no. 6) [AFOSR-TN-56-304] (AF 18(600)1117) AD 106712 Unclassified

Also published in Trans. Amer. Math. Soc., v. 87: 119-129, Jan. 1958.

Consideration is given to the equation $Lu = (au_y)_x - (bu_y)_y + cu_x + du_y + fu = 0$, $a > 0$, $b > 0$ with respect to a curvilinear triangle T bounded by a segment AB of the x-axis and the characteristic arcs AC and BC which extend into $y > 0$. Proofs of the following theorems are given. Theorem 1. Let $Lu \leq 0$ in D, the common part of T and $0 \leq y \leq y_0$, and suppose that $f \geq 0$ in D, $d(x, 0) \leq 0$. If $u(x, 0) \geq 0$ on AB and $\left(\frac{u}{v}\right)_y \leq 0$ on AB with $v(y) = 1 - \beta e^{-\alpha y}$, $\alpha > 0$, $0 < \beta < 1$, then the maximum of u in D occurs on AB. Theorem 2. Let $Lu \geq 0$ in D and suppose $f \geq 0$ in D, $b(x, 0) = 0$, $d(x, 0) \leq 0$. If $u(x, 0) < 0$ and AB then the maximum of u in D occurs on AB. These theorems are used to obtain certain results for ordinary differential equations among which is a comparison theorem on the distance between zeros of the ordinary differential equations $[f_1(x)\xi'(x)]' + g_1(x)\xi(x) = 0$, $f_1(x) > 0$, $0 \leq x \leq x_0$, and $[f_2(y)\eta'(y)]' + g_2(y)\eta(y) = 0$, $f_2(y) > 0$, $0 \leq y \leq x_0/2$ for which $u(x, y) = \xi(x)\eta(y)$ satisfies a hyperbolic partial differential equation Lu.

THERMODYNAMIC BEHAVIOR OF AN IDEAL FERRO-MAGNET, by F. J. Dyson. June 1, 1956, [15]p. tncl. refs. (Technical rept. no. 77) (Sponsored jotntly by [Air Force Office of Scientific Research] under AF 18(603)46 and National Science Foundation)
Unclassified

Published in Phys. Rev., v. 102: 1230-1244, June 1, 1956.

The free energy of an ideal Heisenberg-model ferromagnet is calculated as a power series in the temperature T. The spontaneous magnetization in zero external field is given by: $[M(T) - M(0)] = S - a_0 T^{3/2} - a_1 T^{5/2} - a_2 T^{7/2} - a_3 S^{-1} T^4 + O(T^{9/2})$. Here T is the temperature in dimensionless units and a_0, a_1, a_2, a_3, are positive numerical coefficients which are computed for the three types of cubic crystal lattice. The first two terms are the result of the simple Bloch theory in which spin waves are treated as noninteracting Bose particles with constant effective mass. The a_1 and a_2 corrections come from the variation of effective mass with velocity. The a_3 term is the lowest order correction arising from interaction between spin waves. Thts result ts in violent contradtctton to earlier published calculations which gave tnteraction effects proportional to $T^{7/4}$ and T^2. The smallness of the thermodynamic effects of spin-wave interactions is discussed in physical terms and partially explained. A general proof is gtven that the thermodynamic effects of the "exclusion prtnctple," whtch forbtds more than (2S) spin deviations to occupy the same atom, are of order $\exp(-a\theta^{-1})$ and gtve zero contributton to any finite power of θ. The restdual dynamical interaction between 2 spin waves gtves rtse to a second virial coeffictent b_2' which is calculated and shown to be of order $T^{5/2}$. The a_3 term tn the magnetization ts proportional to b_2'. Effects of tnteraction of 3 or more sptn waves are estimated and found to be of order θ^5 or higher. (Contractor's abstract)

Dtlute alloys of Mn tn Cu are expected to show marked effects of the exchange tnteraction between the $3d^5$ ton core electrons of the Mn atoms and the 4s conduction electrons of the crystal. The simple model leads to the prediction of indirect exchange ferromagnettsm; electronic Knight shtft of the electron spin resonance line; nuclear Knight shtft of the copper nuclear resonance; electron spin relaxatton by the coupltng with the conductton electrons; and a contrtbution to the electrtcal resistivity by the Elltott-Schnitt mechantsm. The observed wtdth of the electron sptn resonance ltne suggests that the sd exchange tnteraction may be of the order of 0.2 of the interaction tn the free ton. The dilute alloys appear to be anttferromagnettc, but with a ferromagnettc interactton also present which is rather stronger than calculated on the tndtrect exchange model. An unexpected experimental result is that the nuclear Knight shift is unaffected by the presence of Mn, suggesting that the conduction electron magnetization by the coupling is less than 1/50 of what might be expected. PROCEEDINGS OF THE SYMPOSIUM ON HIGH TEMPERATURE - A TOOL FOR THE FUTURE.

Berkeley, Calif. June 25-27, 1956, 218p. incl. illus. diagrs. refs. (In cooperation with Stanford Research Inst., Calif.) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, National Science Foundation, and Office of Ordnance Research)
Unclassified

Emphasis in the symposium was placed on the whys of high-temperature limitations and on the identification of the areas most fruitful for further work. It was believed that an advance in production of high temperatures may help solve problems in materials for high temperatures or in processes employing them. The program was divided into three sections: (1) methods for reaching high temperatures; (2) materials for containing high temperatures; and (3) processes occurring at high temperatures. In the first section, consideration was given to (a) images of very high temperature sources, (b) electrical methods for obtaining high temperatures, and (c) chemical and nuclear methods of obtaining high temperatures.

ENERGY GAP INTERPRETATION OF EXPERIMENTS ON INFRARED TRANSMISSION SUPERCONDUCTING FILMS, by M. Tinkham. [1956] [6]p. incl. diagr. [Technical rept. no. 79] (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)-46], Office of Naval Research under [Nonr-22201], and Signal Corps) AD 126803 Unclassified

Also published in Phys. Rev., v. 104: 845-846, Nov. 1, 1956.

The transmission and reflection properties of a film which is thin compared to a skin depth and in transverse dimensions large compared to a wavelength were determined completely by the complex admittance per square of the film. A means of determining the high frequency limit is given. With the use of an energy-gap model, the observed peak in transmission at intermediate frequencies is obtained and explained.

THERMAL EQUILIBRIUM IN NUCLEAR MAGNETIC COOLING OF METALS, by C. Kittel. [1956] [2]p. (Technical rept. no. 82) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, and [Signal Corps]) AD 126804 Unclassified

Also published in Phys. Rev., v. 104: 1807-1808, Dec. 15, 1956.

Recently there has been reported the attainment of a temperature of 20 μdeg K by nuclear magnetic cooling of metallic copper from an electronic cooling stage at 0.01°K, about 1% of the nuclear entropy being removed during isothermal magnetization at the latter temperature. The purpose of the present paper is to discuss the rate at which conduction electrons and lattice phonons initially at 0.01°K come into thermal equilibrium with the nuclear spins at 20 μdeg. CAL. 04:002 - CAL. 05:001

A method of compensation ts presented, to be applied to continuous as well as to sampled-data systems, which reduces to zero any overshoot or error after a prescribed finite time. This prescribed response is applicable to step or ramp inputs and could be extended to acceleration or higher order inputs. It is shown that this response can be accomplished using the modified z-transform which yields the systems response for all instants of time. The procedure of this method, illustrated in examples, is mainly applicable to general linear physical systems with no inherent delays. The compensated system is so designed that shifts in gain or other dynamical disturbances have a small effect on the prescribed response. In conclusion, the method presented is powerful in synthesizing control systems to tally to a prescribed response and furthermore is straightforward in its appltcation. (Contractor's abstract)

HIDDEN OSCILLATIONS IN SAMPLED-DATA CONTROL SYSTEMS, by E. I. Jury. Dec. 14, 1955 [19]p. incl. diagrs. refs. (Series no. 60, issue no. 155) (AFOSR-TN-56-24) (AF 18(600)1521) AD 101911
Unclassified

Oscillations between sampling instants in the response of sampled-data control systems impose certain limitations on the z-transform method and other methods available for synthesis of such systems. It is shown that these oscillations appear in the response because of certain forms of the open loop transfer function G(s). If the impulsive response of these functions is oscillatory then these oscillations occur in the response, and if the sampling period is larger or equal to half the period of these oscillations, the z-transform method fails to indicate their presence. The modified z-transform can be advantageously applied in these cases. This method is straightforward and simple in detecting the presence of these oscillations and indicating their values. Theorems relating to initial and final values of the response in the form of modified z-transform have been presented. Two examples have been discussed in which such oscillations occur and the modified z-transform method has been applied in their analysis. (Contractor's abstract)

ANALYSIS OF LINEAR SAMPLED-DATA SYSTEMS WITH FINITE PULSE WIDTH (OPEN-LOOP), by G. Farmanfarma. Apr. 12, 1956. 57p. incl. diagrs. tables, refs. (Series no. 60, issue no. 157) (AFOSR-TN-56-186) (AF 18(600)1521) AD 87058
Unclassified

Also published in Trans. Amer. Inst. Elec. Engineers, v. 75: 808-819, Jan. 1957.

An exact method for analysis of sampled-data systems wtth ftntte pulse width ts presented. The results make tt possible to obtain the output of such systems in a closed form, as a continuous function of time, and without recourse to any approximations. The analysis is based on introducing a new transform method analogous to the z-transform, except that the actual pulse width and pulse shape are considered. Thts ts called the p-transform where "p" denotes pulse wtdth. By utiliztng the modifted z-transform, a method for obtaining the inverse Laplace transform of functions involving both e^{Ts} and "s" is developed. This technique has been advantageously applied to evaluate the inverse p transform in a closed form. The limiting cases of the p-transform are investigaged. It is concluded that the p-transformation method provides a powerful technique for analysis of sampled-data systems wtth finite pulse width.

ANALYSIS AND SYNTHESIS OF SAMPLED-DATA AND CONTINUOUS CONTROL SYSTEMS WITH PURE TIME DELAYS, by W. Schroeder. June 8, 1956 [86]p. incl. diagrs. refs. (Series no. 60, issue no. 156) (AFOSR-TN-56-476) (AF 18(600)1521) AD 97360
Unclassified

The investigation has shown that the modified z-transform can be extended so that linear sampled-data systems with arbitrary pure delays can be analyzed and synthestzed to obtain responses with zero steady-state error after a finite transient response. The duration and form of the transient response is also controllable. The advantage of the modified z-transform is that the continuous response is obtained or synthesized, rather than only the sampled response. In addition, the analysis and synthesis procedures for sampled-data systems have been applied to continuous systems with or without pure time delays by approximating the continuous system with a sampled-data system. The synthesis procedure presented for sampled-data systems could have a wide variety of applications. It is particularly well-suited for the compensation of control systems with digital or analog computers. More generally it may be used for compensation with any device capable of processing data, which includes human beings, pulsed networks, delay lines, and mechanical devices, to mention but a few. Examples of systems compensated by the procedure have been analyzed to determine the effect of small shifts in the parameters and the systems were found moderately insensitive to such shifts. This is not always true and therefore, a method of determining a rough idea of the systems sensitivity to shifts is suggested. (Contractor's abstract)

STAMLITY OF A VISCOUS COMPRESSIBLE FLOW BETWEEN ROTATING CYLINDERS, by P. L. Chambré. Technicaf rept. June f5, 1951, 33p. ilfus. diagrs. tables, refs. (Rept. no. lfE-150-85; series no. 20, issue no. 73) (Sponsored jointly by Office of Naval ftesearch and [Air Force] Office of Scientific ftesearch under N7onr-29503) U18758; ATf-195088 Unclassified

This is a theoretical investigation concerned with the hydrodynamic stability of the curved Couette motion of a viscous compressible flow towards a 3-dimensionaf-type disturbance. The problem has been investigated according to the method of small oscillations. The origin of the unstable motion is thought to be due to the centrifugal force field which can be created in a rotating cylinder apparatus in which the inner cylinder is rotating and the outer cylinder is at rest. The effects of slippage of the gas at the boundaries and of compressibility due to high speed motion have been investigated. A study of these effects clarifies the 3-dimensionaf instability mechanism in a gas ffow since previous theoretical investigations have been confined to incompressibfe fluid ffows. A MOLECULAR BEAM INVESTIGATION OF FREE MOLECULE FLOW THROUGH SHORT TUBES, by F. C. Hurlbut. Technical rept. Oct. 15, 1951 [24]p. incl. illus. diagrs. tables. (Rept. no. HE-150-94; series no. 20, issue no. 99) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N7onr-29503) U20183, ATI-155160 Unclassified

An investigation of free molecule flows of nitrogen through short tubes was made, employing a molecular beam device. Probabilities W(i) were experimentally determined, where W(i) is defined as the probability that a molecufe, originating from a gas at rest and striking the entrance and pfane of a short cylindrical tube, passes through the tube without returning to the end pfane. The length to radius ratio $\frac{1}{r}$ of tubes for these tests ranged from 0 to 25. An empirical function E (W(i)) was passed by least squares through the experimental W(i). E (W(i)) was seen to agree within 11% with the Clausing function in the range of the experiment. These results indicate that the basic assumption of diffuse reflection is vafid to a first approximation. The derivation of the empirical function from the Clausing function was such as to suggest a value of the quantity (1-F) of the order of 0.05. (Contractor's abstract)

VISCOUS EFFECTS ON STAGNATION-POINT TEMPERATURES, by S. F. Mack and S. A. Schaaf. Technical rept. Nov. 29, f951, 8p. incl. diagrs. table. (Rept. no. HE-f50-96; series no. 20, issue no. 84) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N7onr-29503) U21266; ATf-f95983 Unclassified

An analysis of viscous effects on stagnation-point temperatures based on continuum-flow in compressible boundary layer theory for the case of the sphere is presented. The principaf result of the analysis is contained in the theoretical expressions obtained for the focal recovery factor, or, at the forward stagnation-point and are indicated in tabular form. ft was concluded that an analysis based on continuum theory for the sphere in a low Reynolds number flow predicts a stagnation-point temperature which is higher than the local reservoir temperature. An approximate extension of the stagna ion-point theory to the case of the sphere in over-all thermal equilibrium provides an empirical result which agrees favorably with experiment.

DESIGN AND PERFORMANCE OF AN ADJUSTABLE TWO-DIMENSIONAL NOZZLE WITH BOUNDARY LAYER CORRECTION, by G. H. Backer. Technical rept. Feb. 4, 1952, 33p. illus. diagrs. table, refs. (Rept. no. HE-150-97; series no. 20, issue no. 86) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) U21636; ATI-196312 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 21: 50-56, Jan. 1954.

A 2-dimensional adjustable throat nozzle was designed to operate in a rarefied-gas stream at an ideal M = 3.106 and a static jet pressure of 85 μ of Hg. A boundary layer correction, applied to both the shaped and parallel walls, required a divergence of 5°14' on the side walls and produced an exit height of 1.31 in. In earlier wind-tunnel tests, the nozzle showed an M = 3.07 and static jet pressure of 93 μ of Hg after correcting pressure instrumentation. A uniform shock-free stream of approximately 0.3-in. square was secured. A 2-dimensional nozzle with diverging side walls appears entirely feasible in a low-density gas flow. No detectable disturbances to the exit flow resulted from the diverging of the side walls. The assumption of a uniform momentum gradient instead of velocity gradient would give better agreement with measured results. A relatively constant static pressure across the nozzle resulted from applying viscous corrections to pressure instrumentation. The inclusion of a variable-nozzle throat produced a nozzle which is operable over a limited Mach-number range without loss in uniformity of flow. The subsonic contour apparently had little effect on the nozzle exit flow. The nozzle substantially met the design conditions and operated adequately over a limited Mach-number range. (ASTIA abstract)

VISCOSITY CORRECTION TO IMPACT PRESSURE ON PROLATE SPHEROID, by D. C. Ipsen. Technical rept. Mar. 12, 1952 [20]p. incl. illus. tables. (Rept. no. HE-150-89; series no. 20, issue no. 85) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) U21567; ATI-162662 Unclassified

The influence of viscosity on the pressure at the forward stagnation point on a prolate spheroid is estimated analytically. Potential flow, Stokes flow, and Oseen flow are utilized in turn to approximate the viscous term of the Navier-Stokes equation for the stagnation streamline. The approximations so obtained establish a basis for estimating the viscosity corrections to the stagnation pressure at any Reynolds number. The effects of slip and compressibility are not considered. The results provide a possible indication of the viscous effect on a source-shaped impact probe at low Reynolds number. (Contractor's abstract)

GENERALIZED THEORY OF CONVECTIVE HEAT TRANSFER IN A FREE-MOLECULE FLOW, by A. K. Oppenheim. Technical rept. Mar. 18, 1952, 11p. illus. diagrs. tables. (Rept. no. HE-150-93; series no. 20, issue no. 81) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) U22064; ATI-158453 Unclassified

The theory of the convective heat transfer in free molecule flow with Maxwellian velocity distribution was generalized by reducing all the relationships to a form common to all gases irrespective of their molecular structure. The heat-transfer characteristics of simple surfaces consisting of a flat plate in the direction of flow, a flat plate normal to flow, a transverse cylinder and a sphere were computed and correlated. A simple method is outlined for extrapolating the results to a flat plate at any angle of incidence, a wedge or a cone, and for the evaluation of heat-transfer parameters for a compound surface. The effect of shape on convective heat-transfer characteristics was small. At low Mach (M) numbers the Stanton number of all shapes approached the value of $\frac{\gamma+1}{\gamma}\cdot\frac{\alpha}{4\sqrt{\pi S}}$, where γ = ratio of specific heat, S = surface area of the body, α = accomodation coefficient. The difference between various shapes grew more distinct at high M numbers. For M > 2 the magnitude of the Stanton number did not exceed the value of $\frac{\gamma+1}{2\gamma}\alpha$. The effect of shape on the recovery factor was more distinct at low Mach numbers and was hardly noticeable for M numbers higher than 5. For the temperature ratio T_{aw}/T_o (T_{aw} = adiabatic wall temperature, T_o free stream temperature), this effect was small for both low and high M numbers and was most noticeable in the vicinity of M = 1.

THEORETICAL AERODYNAMIC PROPERTIES FOR AN INCLINED FLAT PLATE IN SLIP FLOW, by S. F. Mack. Technical rept. Mar. 21, 1952, 14p. illus. diagrs. (Rept. no. HE-150-98; series no. 20, issue no. 67) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 1908 Unclassified

A theory concerning the drag coefficient for the flat plate at zero angle of attack in slip flow was extended

to include the aerodynamic coefficients for drag, lift, and moment at very small angles of attack. The lift coefficient may be taken to equal the skin-friction coefficient. The skin-friction stresses tend to reduce the lift coefficient at high-altitude, high-speed conditions. The moment coefficient will not be significantly greater than $2\alpha/\sqrt{M_\infty^2 - 1}$, the value derived from the ideal linearized 2-dimensional supersonic continuum-flow theory, where α is angle of attack and M_∞ is the free-stream Mach number. Except for the skin-friction coefficient, the corrections to he applied to the aerodynamic formulas of linearized supersonic theory, which account for viscosity and slip, will not generally be significant in the slip-flow region.

HEAT TRANSFER FROM RIGHT CIRCULAR CONES TO A RAREFIED GAS IN SUPERSONIC FLOW, by R. M. Drake, Jr. and C. J. Maslach. Technical rept. Apr. 8, 1952, 13p. diagrs. tables, refs. (Rept. no. HE-150-91; series no. 20, issue no. 91) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) U22770; ATI-158797 Unclassified

The heat transfer from 10°, 20°, 40°, and 60° right circular cones to a rarefied gas was measured at M = 2.16 to 3.54 and Re = 78 to 3270 in the slip-flow region. The 2 nozzles used had diameters at the exit plane of 5.5 and 5.25 in.; the cones were made of Ag, mounted on hollow glass stings, and arranged with cylindrical afterbodies made of horn fiber. Results show that the heat transfer coefficient in the region is a linear function of $\sqrt{Re}/M$ over the range investigated. Comparison of the data with those of Eber indicates that in the continuum region the data can best be represented by the boundary-layer analysis, while in the slip-flow region slip-flow analysis is to be favored. Overall free stream recovery factors exhibited a sharp increase as the gas was rarefied.

DRAG ON A ROTATING CYLINDER AT LOW PRESSURES, by S.-F. Chiang. Technical rept. May 19, 1952, 35p. incl. illus. diagrs. tables, refs. (Rept. no. HE-150-100; series no. 20, issue no. 88) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N7onr-29503) U23199; ATI-158799 Unclassified

Presented at meeting of the Amer. Phys. Soc., Puyokern, Calif., Dec. 27-30, 1952.

Published in Phys. Rev., v. 92: 535, Oct. 15, 1953.

The investigation of the torque transmitted by a rarefied gas, laminar air flow between two concentric cylinders for the case wherein the inner cylinder is rotating while the outer one is held stationary is discussed. A theoretical expression of drag coefficient is derived by the thirteen moment method and the equations of drag coefficient by Millikan and Schamberg are presented. The theoretical results of drag are calculated by these three drag equations and are discussed and compared in the appendices. From the experimental results it was concluded that: (1) the data over the ranges, $0.14 \leq M \leq 0.55$ and $0.0119 \leq M/Re \leq 2.61$, show that the rotor aerodynamic drag is proportional to the speed of rotation and the reduction of drag at low pressures is independent of Mach number; and (2) the critical Reynolds number is found to be 135. No effect of compressibility or slip on the critical Reynolds number has been observed.

CAL. 06:010

SKIN FRICTION IN SUBSONIC LOW DENSITY GAS FLOW, by F. S. Sherman. Technical rept. July 15, 1952, 11p. diagrs. tables. (Rept. no. HE-150-105; series no. 20, issue no. 92) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) U23371; ATI-168736 Unclassified

Skin friction drag was measured on 0.003-in.-thick flat Ta plates at Re = 15 to 480 and M = 0.2 and 0.6. The ISA subsonic nozzle had a 9-in.-diam throat. Total drag coefficients (C_D) were obtained for plate lengths of 0.2, 0.5, 1, and 2 in. with aspect ratios of 0.5, 1, 2, and 5, respectively; the proportional probable error ranged from 0.7 to 4.1%. The lack of correlation of C_D with Re and of C_DM with the slip-flow parameter ($\sqrt{Re}/1.5M$) was attributed to effects of plate geometry and oversimplification of theory. A comparison of subsonic- and supersonic-flow data showed that boundary-layer theory more accurately predicted skin-friction values in supersonic flows; however, the supersonic data showed more slip at the boundary. The best agreement for supersonic and subsonic air streams was exhibited by C_DM vs $\sqrt{Re}/1.5M$ curves, which were considered adequate for design purposes.

NOZZLE CHARACTERISTICS IN HIGH-VACUUM FLOWS — RAREFIED GAS DYNAMICS, by R. G. Folsom. Technical rept. Sept. 10, 1952, 5p. incl. diagrs. (Rept. no. HE-150-102; series no. 20, issue no. 90) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) U24514; ATI-167105 Unclassified

Also published in Trans. Amer. Soc. Mech. Engineers, v. 74: 915-918, Aug. 1952.

Some results of experiments on small ASME shaped nozzles at very low Reynolds numbers, achieved by operating at extremely low pressures over a wide range of pressure ratios are presented. Calibration data were obtained for two small converging ASME nozzles and one large ISA nozzle with dry air in the viscous-compressible flow regime. The discharge-coefficient magnitudes were in the expected range, but no direct comparison with viscous (incompressible) flow regime was possible because of the lack of suitable published coefficients. The results demonstrate the importance of pressure-tap location and installation geometry on coefficients, and a distinctive breakaway characteristic which developed as the pressure ratio across the nozzle decreased. Slip flow may influence the results since tests were conducted in the region where the slip effects are known to be appreciable, but it was not possible to separate the low Reynolds number and slip phenomena.

AERODYNAMIC FORCES ON A CYLINDER FOR THE FREE MOLECULE FLOW OF A NON-UNIFORM GAS, by S. Bell and S. A. Schaaf. Technical rept. Dec. 19, 1952, 10p. illus. tables, refs. (Rept. no. HE-150-110; series no. 20, issue no. 93) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 1910 Unclassified

An analysis is made of the free molecular flow of a nonuniform gas by an extension of the method for the Maxwellian case used by Tsien (Jour. Aeronaut. Sciences, v. 13: 643-664, 1946) and Stalder and Zurick (NACA Technical note no. 2423, 1951). The results are sufficiently general to include arbitrary (small) stresses and heat flux. The body geometry is confined to that of a right circular cylinder oriented perpendicular to the gas-flow velocity; the body's thermal conductivity is assumed so large that it is at a uniform temperature. The aerodynamic force characteristics are determined. The lift and drag forces are shown to be affected by the nonuniformity. Force contributions from the stress and heat-flux terms are generally small compared to the force for the uniform case, except in regions of low flow velocity where the heat-flux terms become important. A method is indicated for obtaining the heat-transfer characteristics and data for other body geometries and bodies of low internal conductivity.

HEAT TRANSFER FROM SPHERES TO A RAREFIED GAS IN SUBSONIC FLOW, by L. L. Kavanau and R. M. Drake, Jr. Technical rept. Jan. 23, 1953 [19]p. incl. diagrs. tables, refs. (Rept. no. HE-150-108; series no. 20, issue no. 94) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 1911 Unclassified

As a result of this investigation experimental average overall heat coefficients were obtained for spheres in a rarefied subsonic air stream where the Mach number and Reynolds number varied from 0.1 to 0.69 and 1.7 to 124, respectively. A semi-empirical formulation of the Nusselts number for sphere in a rarefied subsonic air stream was obtained by correcting the continuum solution for an effective thermal contact resistance as a result of the temperature jump boundary conditions.

VACUUM FACILITIES FOR THE STUDY OF SUPERSONIC FLOW, by G. J. Maslach. Technical rept. Mar. 13, 1953 [5]p. incl. illus. diagr. refs. (Rept. no. HE-150-112; series no. 20, issue no. 83) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 4588 Unclassified

Also published in Chem. Engineering Progress, v. 48: 594-598, Dec. 1952.

A discussion is presented of design and construction

of large scale aerodynamic test equipment which simulates high altitudes flight conditions. Criteria which should be used in the choice of materials, fabrication methods, and gasketing principles are cited. Instruments which would be most suitable for various measurements required in aerodynamic investigations are suggested. Recent experimental results pertaining to instrumentation development are also mentioned.

DESIGN AND OPERATION OF A ROTATING CYLINDER APPARATUS FOR RAREFIED GAS DYNAMICS RESEARCH, by G. J. Maslach and J. Frisch. Technical rept. Apr. 30, 1953, 14p. illus. refs. (Rept. no. HE-150-101; series no. 20, issue no. 89) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 13194 Unclassified

A high-speed rotating-cylinder apparatus is described for studying gas-surface interaction phenomena. The concrete enclosure is equipped with a hand-operated overhead hoist to handle the balance and drive mechanism before vacuum operation. During operation, measurements of drag, pressure, and rotor velocity can be made outside the enclosure. The instrument can be used to provide a shear flow field for the development of instrumentation for nonuniform streams or boundary layers. Initial tests indicated that the apparatus was satisfactory over a wide range of flow conditions from the continuum region ($M/Re < 1/100$) to the free molecular flow region ($M/Re < 10$).

CONE DRAG IN A RAREFIED GAS FLOW, by D. C. Ipsen. Technical rept. Aug. 10, 1953, 39p. illus. diagrs. tables, refs. (Rept. no. HE-150-114; series no. 20, issue no. 95) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 20149 Unclassified

The tests were conducted to obtain empirical cone-drag information about the intermediate slip-flow regime. The mean free path of the gas adjacent to the cone surface ranged from 10 to 15% of the calculated displacement-thickness of the boundary layer at the base of the cone. The total drag on the fore portion of a 15° half-angle cone (3.70-in. slant length) was investigated. A compact remote balance was developed which gave sufficient accuracy for the measurement of the small forces involved. Drag coefficient curves were obtained which are probably accurate to within 2 to 3% or better at $M = 4.0$ and possibly 5% at $M = 2$. The experimental results for viscous drag were 10 to 30% above the predictions based on first-order boundary-layer analysis of shear and pressure distribution. A description of the experimental apparatus and details of the calibration and testing techniques are appended.

HEAT TRANSFER TO A CYLINDER FOR THE FREE MOLECULE FLOW OF A NON-UNIFORM GAS, by S. Bell. Technical rept. Sept. 14, 1953, 10p. illus. (Rept. no. HE-150-115; series no. 20, issue no. 96) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 20150 Unclassified

The work described in report HE-150-110 (item no. CAL. 06:013) in which the aerodynamic forces on a cylinder were determined for the case of a nonuniform gas was continued. It was assumed that the right circular cylinder, which is oriented perpendicular to the gas flow, has so large a thermal conductivity that it has a uniform wall temperature. Possible end effects are neglected. The results depend on a knowledge of the molecular velocity distribution, and the distribution assumed is the one proposed by Grad (Commun. on Pure and Appl. Math., v. 2: 331-407, 1949). The results are complete for the monatomic case but only approximate for the polyatomic case. (ASTIA abstract)

RESULTS OF SOME BASE PRESSURE EXPERIMENTS AT INTERMEDIATE REYNOLDS NUMBERS WITH $M = 2.84$, by L. L. Kavanau. Technical rept. Oct. 22, 1953, 6p. illus. tables. (Rept. no. HE-150-117; series no. 20, issue no. 97) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 23271 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 21: 257-260, 274, Apr. 1954.

Tests were conducted in a supersonic wind tunnel to determine the effect of Reynolds number on models over the range of $Re = 45,000$ to 400,000. The models (fabricated from combinations of aluminum and brass) were 60° apex angle right circular cones with cylindrical afterbodies 2.50 calibers in length. A control for adjusting the effective sting length was provided by moving a coaxial 60° apex angle cone-cylinder along the sting of the desired location. Base pressure data were obtained for a model at $M = 2.84$ over the range of Reynolds numbers. The maximum coefficient of 0.75 occurred at $Re = 140,000$. The variation in size of the critical wake region resulted in increases of the critical sting length from 3.3 to 10.4 as the Reynolds number decreased from 430,000 to 49,000. The base pressure orifice location and the sting diameter had no observable effects on the base pressure coefficient.

AN EXPERIMENTAL MOLECULAR BEAM INVESTIGATION OF THE SCATTERING OF MOLECULES FROM SURFACES, by F. C. Hurlbut. Technical rept. Dec. 1, 1953, 1v. incl. illus. diagrs. tables, refs. (Rept. no. HE-150-118; series no. 20, issue no. 98) [AFOSR-TN-54-97] (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 30192 Unclassified

A molecular beam apparatus was used to investigate the scattering of air and N_2 molecules from surfaces of polished low-C steel, etched low-C steel, polished Al, and polished and unpolished window glass. A beam of molecules was directed against the surface at representative angles of incidence, and polar flux distributions of the scattered molecules were measured by a movable ionization gage beam detection system. Spatial polar plots of the flux distributions approximated closely the form of the cosine scattering distribution for the steel and Al surfaces. Similar plots for the glass surfaces showed well-defined small bulging deviations from the cosine scattering shape on the side away from the incident beam. A procedure was devised for the computation of the specular-reflection coefficient (f), and values were obtained for an unpolished glass surface, oriented tangentially to the direction of mass motion in a free molecular flow, in order to illustrate an aerodynamic application. If all scattered molecules are assumed to have the distribution in speed in the particular direction which they would have had had they issued from a gas in equilibrium at the temperature of the surface, $f \sim 0.97$ as $s \to 0$ while $f \sim 0.99$ at $s = 10$; s is the molecular speed ratio. If those molecules contributing to the deviations from cosine scattering are assumed to issue from the surface with their incident speed while the remainder are assumed to be diffusely scattered, f varies from $f \sim 0.97$ as $s \to 0$ to $f \sim 0.93$ at $s = 10$. These values are in disagreement with the Millikan value for air on glass of 0.89 ($s \sim 0$) (Phys. Rev., v. 21: 217. 1923).

A NOTE ON THE EFFECT OF SLIP ON THE DRAG OF A FINITE FLAT PLATE, by J. A. Laurmann. Technical rept. July 12, 1954, 7p. (Rept. no. HE-150-123; series no. 20, issue no. 99) [AFOSR-TN-54-296] (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 42324 Unclassified

A method of solution of the two-dimensional Navier-Stokes equations for incompressible flow over a finite flat plate introduced by Kuo (Jour. Math. and Phys., v. 32: 83-101, 1953) has been applied to the same problem for the case in which there is a finite velocity of slip at the surface of the plate. It is found that, just as for the semi-infinite plate, with the solution expressed as an ascending power series in $(Re_L)^{-1/2}$ (Re_L is the Reynolds number based on the plate length), the over-all drag of the plate is independent of slip to the second approximation, i.e., up to and including the term of order Re_L^{-1}. DESIGN OF A TWO-COMPONENT MICROBALANCE FOR LOW DENSITY WIND TUNNELS, by R. N. Latz. Technical rept. Aug. 10, 1954, 1v. incl. illus. diagrs. tables, refs. (Rept. no. HE-150-124; series no. 20, issue no. 100) [AFOSR-TN-54-297] (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 42325 Unclassified

The balance consists of a balance group, a power drive and force-measuring system, a null-indicating system, and mounting structure. Tests based on the forces of a model mounted 6 in. from the pivot axis indicated a null sensitivity of 0.019 mg/scale division of the galvanometer, an angular null sensitivity of 0.001°/galvanometer scale division, and a reproducibility of 0.04 mg. The balance met the design requirements of measuring lift and drag to 0.1 mg, had a minimum variation in model displacement from null during the force measurements, and provided remote observations and control. Measurement of lift and drag for various angles of attack can be obtained by mounting the balance so it can rotate about a vertical axis, or by combining 2 of the balances along with an angle-of-attack mechanism to make a platform which will measure lift and drag simultaneously. SKIN FRICTION IN SLIP FLOW, by S. A. Schaaf and F. S. Sherman. [1954] 7p. incl. illus. diagrs. table, refs. (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under [N7onr-29503]) Unclassified

Published in Jour. Aeronaut. Sciences, v. 21: 85-90, 144, Feb. 1954.

Skin-friction data in the slip flow regime are presented, covering the range: $0.008 < M/\sqrt{Re} < 0.38$; $34 < Re < 2,020$ for $2.5 < M < 3.8$; $3 < Re < 500$ for $M \sim 0.2$ and 0.6. The results are discussed in terms of the various relevant theories, and it is inferred that, in the neighborhood of $Re = 1,000$, the dominant effect is the interaction between boundary layer and external flow which increases the skin friction, but that, in the neighborhood of $Re = 50$, the dominant effect is that of slip that decreases the skin friction. MOLECULAR BEAM INVESTIGATION OF THE SCATTERING OF MOLECULES FROM SURFACES (Abstract), by F. C. Hurlbut. [1954] [1]p. (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under [N7onr-29503]) Unclassified

Presented at annual meeting of the Amer. Phys. Soc., Columbia U., New York, Jan. 28-30, 1954.

Published in Phys. Rev., v. 94: 754-755, May 1, 1954.

Polar flux distribution of air and N_2 molecules scattered from surfaces of mild steel, aluminum, and glass were obtained using molecular beam techniques. Several values of incident angle were used. Polar traverses were not confined to the incident plane. An ionization gauge-beam detection system was devised to accomplish these measurements. Spatial polar plots of the measure flux distributions for the steel and aluminum surfaces were found to approximate the form of cosine distribution. Similar plots for the glass surfaces were found to have small, broad, bulging deviations from the cosine scattering shape. These findings are discussed in relation to the Maxwell surface interaction model. A modification of the present concepts concerning the formulation of low-density gas-flow boundary conditions is discussed. (Contractor's abstract)

RECENT IMPROVEMENTS IN A ROTATING CYLINDER APPARATUS FOR RAREFIED GAS DYNAMICS RESEARCH, by J. M. Bowyer, Jr. Technical rept. Dec. 28, 1954, 1v. incl. illus. diagrs. tables, refs. (Rept. no. HE-150-127; series no. 20, issue no. 103) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 54563 Unclassified

An outline is presented of the design and development of a modified rotating cylinder apparatus. Problems are discussed which seem tractable with the modified apparatus. In the regimes of free-molecule flow and near free-molecule intermediate flow, the major problem discussed is the study of the flow between concentric cylinders when only a few of the molecules experience one or more collisions in traversing the annulus. In the slip-flow regime, the major problem discussed is the determination of possible deviations from the first-order solution, i.e., from the solution of the Navier-Stokes equations with slip-boundary conditions and with an accounting for variable viscosity. Tests accomplished with this apparatus demonstrated a nutation of the torsion balance when the chamber pressure exceeded that corresponding to free-molecule flow between the cylinders. Data analysis of the exploratory tests was limited to the free molecule flow regime owing to the nutation of the torsion cage-drag cylinder combination. On the basis of the limited data, a definite prediction of the trend of f (reflection coefficient) with s (the molecular speed ratio) was considered impossible. (ASTIA abstract)

EXPERIMENTAL INVESTIGATION OF THE FLOW ABOUT THE LEADING EDGE OF A FLAT PLATE, by J. A. Laurmann. Technical rept. Oct. 15, 1954, 16p. illus. (Rept. no. HE-150-126; series no. 20, issue no. 102) [AFOSR-TN-55-2] (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 48460 Unclassified

A free-molecule-flow wire probe was used to study the nature of the shock wave and boundary-layer regions in 2-dimensional low-density flow. Measurements were made of the wire temperature (a function of the local velocity and temperature) over a 1-in. length of plate at $M \cong 2$ and 4 and Reynolds numbers/inch from about 150 to 900. For $M \cong 2$, there existed an extensive region of boundary-layer shock-wave interaction extending over approximately 10 free-stream mean paths and reaching in front of the leading edge. At $M = 4$, the scale of the interaction zone was reduced considerably, and details of the flow structure were not so easily seen.

BASE PRESSURE STUDIES IN RAREFIED SUPERSONIC FLOWS, by L. L. Kavanau. Technical rept. Nov. 1, 1954, 88p. illus. refs. (Rept. no. HE-150-125; series no. 20, issue no. 101) [AFOSR-TN-55-4] (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 48459 Unclassified

Base pressures were measured on a simple cone-cylinder configuration over a range of Mach number M and Reynolds number Re_L (based on model length): $159 < Re_L < 800$ for $M \approx 2$ and $920 < Re_L < 7400$ for $M \approx 4$. These data extend into the slip flow regime since the rarefaction parameter $M/\sqrt{Re}$ covered the range $0.05 < M/\sqrt{Re} < 0.15$. The final results indicated that the base pressure decreased with decreasing Reynolds number and increasing Mach number which was attributed to the completely laminar character of the boundary layer and critical wake region. Preliminary tests showed a considerable variation of pressure existing over the base area, thus requiring an area-mean determination of the base pressure for every flow condition. Investigations were made of support interference effects arising from the relative size of both the sting diameter and sting length as compared to the model diameter. Some effects due to heat

CAL. 06:028 - CAL. 06:031

transfer were also studied. Supplementary pressure distributions were taken on the model surface upstream of the base and in the wake at one Mach and Reynolds number which was characteristic of this flow regime. The base pressure coefficient in free molecule flow is calculated for comparison purposes. A discussion is presented of these results together with experimental and theoretical works of other investigators. A precision thermistor manometer was developed for measuring wind tunnel model pressures in the range from 1 to 1000 microns of mercury with an accuracy of better than 1 percent. In addition, a study was made of the effects of "thermal creep" and "drift rate" on the measurement of low pressures. (Contractor's abstract)

NEW EXPERIMENTS ON CONE DRAG IN A RAREFIED GAS FLOW, by D. C. Ipsen. Apr. 1955, 14p. illus. diagrs. tables. (Rept. no. HE-150-128; series no. 20, issue no. 104) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N7onr-29503) AD 67423 Unclassified

Further investigation is made of the total drag on the fore portion of a circular cone of 15° half angle in a rarefied air flow. With new data, the drag curves are extended to Reynolds numbers of about half the previous lower limit, giving a free-stream Reynolds number range based on cone slant length of 70-1500 at Mach 2 and 500-7000 at Mach 4. The experimental drag curves are in fair agreement with available boundary-layer predictions if certain induced-pressure and transverse-curvature effects are included, although the trends of the experimental and theoretical curves are somewhat different.

LIFT ON FLAT PLATES IN LOW-DENSITY SUPERSONIC FLOW, by D. M. Tellep. Technical rept. Aug. 30, 1955 [60] p. incl. illus. diagrs. tables. (Rept. no. HE-150-131; series no. 20 issue no. 104) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N7onr-29503) AD 74291 Unclassified

Presented at meeting of the Amer. Phys. Soc., Pasadena, Calif., Mar. 19-21, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 362, Nov. 23, 1956.

Normal forces on rectangular flat plates in supersonic, rarefied flow were measured over the range 228 $\leq$ R $\leq$ 2412 and 3.69 $\leq$ M $\leq$ 4.12 at angles of attack up to eight degrees. In addition, the effect of aspect ratio on normal forces was determined with a series of models having an aspect ratio range from 1.0 to 2.0. The results were compared to linearized theory and indicated normal forces which were 33 to 77% greater than values predicted by theory, the experimental normal forces decreasing with increasing Reynolds number. The decrease in normal force with decreasing aspect ratios was found to be from 3 to 7% greater in magnitude than predicted by inviscid theory and substantially independent of Reynolds number over the range tested. Weak interaction theory was used to derive a simple expression for the normal force and was found to predict the order of magnitude of the increased normal force as well as the trend of the normal force with Reynolds number. STUDIES OF BOUNDARY LAYER SLIP SOLUTIONS AND ALDEN'S METHOD FOR BOUNDARY LAYER CORRECTION, by S. Bell. Technical rept. Dec. 6, 1955, 23p. incl. illus. refs. (Rept. no. HE-150-133; series no. 20, issue no. 106) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N7onr-29503) AD 81483 Unclassified

Two aspects of incompressible laminar boundary layer flow on a semi-infinite flat plate at zero incidence are discussed. First, Alden's proposed scheme of solution of the Navier-Stokes equations for this problem in terms of an expansion in inverse powers of the local Reynolds number is demonstrated to be invalid, inasmuch as the boundary conditions in the free stream cannot be satisfied to all orders. Second, an account is given of the effect of a velocity slip boundary condition on the solution of the Oseen boundary layer equations for the same problem. It was found that an additional non-uniformity in the solution was caused by the introduction of slip. (Contractor's abstract)

CAL. 06:032

California U. Inst. of Engineering Research, Berkeley.

FREE MOLECULE FLOW FORCES AND HEAT TRANSFER FOR AN INFINITE CIRCULAR CYLINDER AT AN ANGLE OF ATTACK, by L. Talbot. Technical rept. Mar. 26, 1956, 8p. illus. (Rept. no. HE-150-136; series no. 20, issue no. 107) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N7onr-29503) AD 94187 Unclassified

Expressions are derived for the recovery factor and heat transfer and the normal and tangential force characteristics of an infinite circular cylinder at arbitrary angle of attack in free molecule flow. The results are expressed in closed form for a cylinder at arbitrary uniform temperature in terms of three gross molecular surface interaction coefficients, the normal and tangential momentum transfer coefficients and the thermal accommodation coefficient. (Contractor's abstract)

California U. Inst. of Engineering Research, Berkeley.

USE OF A DOUBLE EXPANSION METHOD FOR SOLUTION OF THE INCOMPRESSIBLE VISCOUS FLOW OVER A FLAT PLATE, by J. A. Laurmann. Technical rept. May 28, 1956, 34p. refs. (Rept. no. HE-150-138; series no. 20, issue no. 108) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N7onr-29503) AD 106930 Unclassified

A double expansion method, in the form of an inner "boundary layer" series and an outer "potential flow" series, is used to study the solution of the problem of viscous incompressible flow about a semi-infinite flat plate. Validity is checked by comparison with the closed form solution in the linearized (Oseen) case, and it is found that there is agreement only if an "integrable drag" condition (or some equivalent condition) is imposed on each term of the inner series. For the Navier-Stokes equation the same condition is required for uniqueness of the solution, but in this case the assumption cannot be justified.

FORCED CONVECTION HEAT TRANSFER FROM SPHERES TO A RAREFIED GAS, by D. K. Eberly. Technical rept. July 31, 1956 [52]p. incl. illus. tables, refs. (Rept. no. HE-150-140; series no. 20, issue no. 110) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N7onr-29503) AD 107185 Unclassified

A description is given of a wind tunnel study of the forced-convection heat transfer from spheres in a supersonic, rarefied gas flow at nominal Mach numbers of 4 and 6. Three silver models were used in an effort to obtain the infinite conductivity specification of the transient cooling technique of measurement. The models were polished to minimize radiation losses from the surface, and pyrex sting mountings were used to minimize heat losses by conduction. The models simulate the fluid dynamic (but not thermal) conditions for a sphere of one-foot diameter at altitudes from 45 to 60 miles in steady motion at M = 4 and 6. The free stream Reynolds numbers were in the range of

$59 \cdot \frac{u_1 D}{\nu_1} \cdot 6800$, and the free stream Knudsen numbers were in the range $0.073 \cdot M_1 \Big/ \sqrt{\frac{u_1 D}{\nu_1}} \cdot 0.43$. The results showed that Nusselt numbers are approximately related to $\frac{u_2 D}{\nu_2}$ by an equation of the form

$\frac{h_{aw} D}{k_{aw}} \quad C \frac{(u_2 D)^{0.6}}{\nu_2}$ for $9 \cdot \frac{u_2 D}{\nu_2} \cdot 800$ where $C \approx 0.3$.

CLA. 01:001 - CLA. 02:001

Over-all free-stream recovery factors are primarily dependent upon the stream Reynolds number, $\frac{u_1 D}{\nu_1}$, and are sensibly independent of M_1 for $20 < \frac{u_1 D}{\nu_1} < 6800$. (ASTIA abstract)

CRYSTALLOGRAPHIC CALCULATIONS ON THE HIGH-SPEED DIGITAL COMPUTER SWAC, by R. A. Sparks, R. J. Prosen and others. Aug. 1955 [24]p. incl. diagrs. refs. (Perchlorates technical note no. 1) ([AF]OSR-TN-54-356) (AF 18(600)857) AD 71977 Unclassified

Also published in Acta Crystallographica, v. 9: 350-358, Apr. 1956.

The high-speed digital computer SWAC [National Bureau of Standards Western Automatic Computer] has been used extensively for calculations needed in the determination and refinement of crystal structures. Programs for calculations of structure factors, normal Fourier summations, differential Fourier summations, and least squares refinement are described briefly, and some practical experience with them is discussed. In general, these programs may be used with only minor specified changes for almost any crystal of any symmetry. All programs include provision for use of individual anisotropic atomic temperature factors. A few other programs for more trivial, but nevertheless tedious, calculations are also described. THE CRYSTAL STRUCTURE OF THE SILVER PERCHLORATE-DIOXANE COMPLEX, $AgClO_4 \cdot 3CH_4 \cdot li_6O_2$, by R. J. Prosen and K. N. Trueblood. Sept. 1955 [19 p. incl. diagrs. tables, refs. (Perchlorates technical note no. 3) ([AF]OSR-TN-55-346) (AF 18-(600)857) AD 74791 Unclassified

Also published in Acta Crystallographica, v. 9: 741-746, Sept. 1956.

The structure of the crystalline complex formed by silver perchlorate with 3 molecules of dioxane has been determined. The crystals are cubic (a_o = 7.67Å) with Laue symmetry m3m and probable space group $Pm\bar{3}m$; there is 1 molecule of the complex in the unit cell. The silver atoms, at the corners of the cube, are surrounded by a regular octahedron of dioxane oxygen atoms at a distance of 2.46Å. Both the perchlorate ion, whose center is at (1/2, 1/2, 1/2), and the dioxane molecules, which lie along the axes of the unit cube, appear to be rotating with little or no hindrance. PRECISE STUDIES OF THE CRYSTAL STRUCTURES OF LITHIUM PERCHLORATE TRIHYDRATE, ANHYDROUS LITHIUM PERCHLORATE, AND POTASSIUM PERCHLORATE, by R. J. Prosen and K. N. Trueblood. Nov. 1956 [80]p. incl. diagrs. tables, refs. (Perchlorates technical note no. 2) (AFOSR-TN-56-563) (AF 18(600)857) AD 110384 Unclassified

A structural study is made of the structure of the perchlorate ion and the structural effect of the environment is investigated. Precise position parameters and generalized temperature factor parameters of three crystalline perchlorates are determined by applying three-dimensional Fourier analysis and least squares techniques with the high speed digital computer SWAC. $LiClO_4 \cdot 3H_2O$, $LiClO_4$ and $KClO_4$ are studied.

X-RAY LATTICE STRAINS IN PLASTICALLY DEFORMED METALS, by M. Kaufman and D. Rosenthal. May 1955 [46]p. incl. illus. diagrs. tables, refs. (Rept. no. 55-31) (AFOSR-TN-55-183) (AF 18(600)-1022) Unclassified

It has been observed in the diagrams of lattice strains plotted vs the applied stress that a departure from proportionality occurs with the onset of yielding. In the present study, specimens of an Al alloy (face-centered-cubic structure), a Mg alloy (hexagonal structure), and a mild steel (body-centered-cubic structure) were examined. Data indicated that following the initial departure from proportionality a tendency toward the recovery of the original trend occurs after a few % of plastic strain. This tendency is corroborated by the levelling off of the residual lattice strain diagrams. Similar results were obtained at subzero temperatures (-202° and -320°F). The tendency toward recovery coincides with the change of the strain-hardening exponent found in the ordinary stress-strain diagrams of Al and Al alloys. It can be interpreted in the same way as the changes observed in single crystals and bicrystals of face-centered-cubic metals; that is, the departure from proportionality is associated with the phenomenon of easy slip, while the tendency toward recovery marks the advent of the difficult slip. A simplified model of heterogeneous plastic deformation based on the above interpretation accounts satisfactorily for the magnitude of the variations which have been observed in the Al alloy. X-RAY LATTICE STRAINS IN PLASTICALLY DEFORMED METALS, by D. Rosenthal, M. Kaufman and others. Aug. 1955, 84p. incl. illus. diagrs. tables, refs. (AFOSR-TR-55-31) (AF 18(600)1022) AD 88702 Unclassified

In this study, the following subjects are considered and discussed: Part I. Influence of temperature and crystal structure. Specimens representing face-centered-cubic, body-centered cubic, and hexagonal crystal structures were subjected to uniaxial tension. Macroscopic strain-stress, as well as lattice strain-stress history, was secured for all specimens in both the elastic and plastic range. Lattice strains were determined under load and after unloading, and at room and subzero temperatures. Specimens showed a departure from proportionality at the onset of the plastic flow, and a subsequent tendency toward the recovery of the original trend. These trends were related to the easy and difficult slip observed in single crystals and bicrystals of face-centered-cubic metals. The trends were also accounted for by a simplified model of the heterogeneous plastic deformation in polycrystalline metals. Part II. Influence of grain size. The influence of grain size on the above trends was studied in conjunction with the behavior of the lattice strain in the individual crystals of the aggregate. The study showed the necessity of exploring a large population of grains by means of x-rays to offset the scatter of data resulting from the variation of the lattice strain in the individual grains. The study revealed that the behavior of the grain in the aggregate can be governed by factors other than orientation with respect to the applied stress. Part III. Tests in compression by means of the Geiger counter. Compression tests on 61S aluminum alloy revealed the same general lattice trends as in the strain-stress tests, however, values of stress for equal strains were about 5% higher.

GEIGER-COUNTER DETERMINATIONS OF X-RAY LATTICE STRAINS IN PLASTICALLY DEFORMED ALUMINUM ALLOY, by D. Hadanovitsh, M. Kaufman, and D. Rosenthal. 1956 [2]p. incl. diagrs. (AF 18(600)1022) Unclassified

Published in Acta Metallurgica, v. 4: 218-219, Mar. 1956.

Recent tests performed on various materials at subzero as well as at room temperature, suggested that for the so-called soft orientations the trends in the plastic stage are of a twofold nature. First there was a departure from proportionality at the start of plastic flow, following which the lattice strain-stress diagram showed an opposite trend, toward the recovery of the initial slope. A series of new tests were performed to

CAR. 01:001 - CAR. 03:003

secure additional evidence of this tendency. These were carried out in compression instead of tension, and the Gelger-counter technique of recording the x-ray intensity was substituted for photographic procedures. Reasonable agreement between experiment and computation provided additional proof of the twofold trend observed in the plastic range under load.

ON OSEEN FLOWS IN TWO DIMENSIONS, by R. C. Meacham. Final research rept. Oct. 1, 1954, 9p. (Rept no. CIT-1-AF-t3) [AFOSR-TR-54-30] (AF t8(600)t0t3) AD 45136 Unclassified

An introductory analysis is made of viscous flow problems in which the stream function obeys the Oseen differential equation. The mapping $w = 1/z$ is considered where the stream function is transformed by setting $(z, \bar{z}) = t/_w\bar{w}\, \phi(w, \bar{w})$. These mappings map a biharmonic function of $(z, \bar{z})$ into a biharmonic function of $(w, \bar{w})$, but the Oseen stream function $\psi(z, \bar{z})$ maps into a $\phi(w, \bar{w})$ which satisfies a completely different differential equation in terms of w, $\bar{w}$. A product form of solution is obtained from this equation. The following problems remain unsolved: (1) finding solutions other than product-type solutions; (2) giving a physical interpretation to flows in $(w, \bar{w})$ space; (3) obtaining a family of solutions of the type $f_n(w) = w^n f_n(w)$; and (4) discovering transformations of the type discussed which leave the Oseen equation invariant in $(w, \bar{w})$. A NEW MODIFICATION OF CLASSICAL ELECTRO-MAGNETIC THEORY, by A. Schild. Nov. 15, 1953 [6]p. incl. diagrs. [AF 18(600)1019] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 27-28, 1953.

Published in Phys. Rev., v. 92: 1009-1014, Nov. 15, 1953.

A fundamental particle is treated as a unit charge whose rest mass and space time coordinates are variables of its motion. Classical electrodynamics, in its action at a distance formulation, is obtained from an action principle which is simpler than the usual one. In this new action principle the rest mass of a particle is varied as well as the coordinates. The rest masses of interacting particles, although not assumed constant a priori, become constants as a consequence of the equations of motion. Modifications of the old action principle can yield purely electromagnetic rest masses which are, however, the same for all particles. Similar modification of the new action principle gives purely electromagnetic rest masses to all charged fundamental particles. In this new modification of electrodynamics, particles interacting at small distances no longer have constant rest masses. (Contractor's abstract)

CONSERVATION THEOREMS IN MODIFIED ELECTRODYNAMICS, by J. W. Dettman and A. Schild. Apr. 1954, 16p. (Rept. no. CIT-325-7) ([AF]OSR-TN-54-109) (AF 18(600)1019) AD 35960 Unclassified

Also published in Phys. Rev., v. 95: 1057-1060, Aug. 15, 1954.

A system of interacting particles with variable rest masses is considered, whose motion is governed by a variational principle of general form, in which there are self action terms instead of the usual specifically inertial terms. For suitable restrictions of the action principle it is shown that, when the particles are at distances large compared to the classical electron radius, the new theory reduces to classical electrodynamics, and that the variable rest masses become constants of the motion. The conservation laws of energy-momentum and of angular momentum are derived from the Lorentz invariance of the general action principle. (Contractor's abstract)

AD 81188 Unclassified

Three studies concerning the properties of solids at low temperature are briefly reviewed. In the first, the thermal conductivity of metals at temperatures down to approximately 1.5°K was measured using a cryostat having carbon resistors as thermometers in the 1.5°K to 22°K range. In the second, a series of electrical and galvanometric measurements was made on germanium at low temperatures. In the third, a new method was developed for measuring, with an error of only 1 or 2%, the heat capacity of diamond at temperatures down to 15°K.

AN INTEGRAL EQUATION ASSOCIATED WITH A FUNCTION-THEORETIC EXTERMAL PROBLEM, by Z. Nehari. [1954/1955] [20]p. [AF 18(600)1138] Unclassified

Published in Jour. Analyse Math. (Jerusalem), v. 4: 29-48, 1954/1955.

Let $L^2(D)$ be the family of functions, single-valued and regular in a finite domain D and square-integrable over the boundary C which consists of a finite number of rectifiable Jordan curves. The starting problem is to minimize $\int_C |f(z)|^2 ds$, $ds = |dz|$, for $f(z) \in L^2(D)$ under the condition that $\int_{C_1} |f(z)|^2 ds = 1$, where C_1 is an assigned subset of D consisting of a finite number of rectifiable Jordan arcs or curves. It is shown that $\int_C |g(z)|^2 ds \geq \lambda_1$ for any admissible g(z), where λ_1 ($\neq 0$) is the lowest eigenvalue of the integral equation

$$f(\zeta) = \lambda \int_{C_1} K(z, \zeta) f(z) ds,$$

$K(z, \zeta)$ being the Szegö kernel function of $L^2(D)$; the equality can appear only if g(z) is a solution of the integral equation associated with $\lambda = \lambda_1$. On the other hand, the author proves the following result: Let ζ_ν ($\nu = 1, \cdots, n$) be any points in a subdomain D_1 bounded by C_1 of D; then

$$\lambda_1 \sum_{\nu,\mu=1}^{n} a_\nu \bar{a}_\mu K(\zeta_\mu, \zeta_\nu) \geq \sum_{\nu,\mu=1}^{n} a_\nu \bar{a}_\mu K_1(\zeta_\mu, \zeta_\nu) \quad (n = 1, 2, \cdots),$$

where $K_1(z, \zeta)$ is the kernel associated with D_1 and the a's are indeterminate variables; every inequality is sharp. Analogous problems for the Bergman kernel function are discussed. (Math. Rev. abstract)

ON BOUNDED BILINEAR FORMS, by Z. Nehari. Apr. 1955, 24p. ([Technical] rept. no. 1) ([AF]OSR-TN-55-115) (AF 18(600)1138) AD 63406 Unclassified

Also published in Ann. Math., v. 65: 153-162, Jan. 1957.

If $a_0, a_1, \ldots, b_0, b_1, \ldots$, are complex numbers such that $\sum_{\eta=0}^{\infty} |a_n|^2 = \sum_{\eta=0}^{\infty} |b_n|^2 = 1$, the bilinear form

$A(a, b) = \sum_{\nu=0}^{\infty} \sum_{\mu=0}^{\infty} A_{\nu\mu} a_\nu a_\mu$ is said to be bounded if there exists a number M such that $|A(a, b)| \leq M$ for all such sequences $\{a_\nu\}$, $\{b_\nu\}$. The smallest such number M is called the bound of the form A(a, b). In this study a determination is made of the bound of the particular form A(a, b) for which $A_{\nu\mu} = \alpha(\nu + \mu)$, a form studied by Hilbert, Toeplitz and others. The methods employed are function-theoretic. (Contractor's abstract)

ON THE CONFORMAL MAPPING OF NEARLY-CIRCULAR DOMAINS, by Z. Nehari and V. Singh. May 1955, 13p. ([Technical] rept. no. 3) ([AF]OSR-TN-55-145) (AF 18(600)1138) AD 81189; AD 64234 Unclassified

Also published in Proc. Amer. Math. Soc., v. 7: 370-378, June 1956.

The principal result is stated in the following theorem. Let D be a domain bounded by a Jordan curve C with the

CAR. 04:005 - CAR. 04:008

equation $r = 1 + \varepsilon p(\theta)$, $0 \leq \theta \leq 2\pi$, where $p(\theta)$ and its derivative $p'(\theta)$ are continuous, $p(\theta) > 0$, $p(2\pi) = p(0)$, $|p(\theta)| \leq M$, $|p'(\theta)| \leq M'$, and ε is a small positive quantity. If $K(z, \xi)$ denotes the Szegö kernel of D and $|z| \leq \eta$, $|\xi| \leq \eta$, where η is such that

$\eta \leq 1 - \sqrt{2\varepsilon}\sqrt[4]{M(M+M')}$, then $K(z, \xi)$

$$= \frac{1}{4\pi^2}\int_C \frac{ds}{(z-t)(\xi^* - t^*)} + \varepsilon^2 R(z, \xi),\ ds = |dt|$$

where * denotes the complex conjugate, and $|R(z, \xi)|^2 \leq \rho(|z|)\rho(|\xi|)$, and $\rho(\eta)$

$$= \frac{1}{2\pi(1-\eta^2)}\left\{\frac{(2M+M')^2}{(1-\eta)^4 - 4\varepsilon^2 M(M+M')} + \frac{4M^2}{[1-\eta(1+\varepsilon M)]^2}\right\}.$$

For $z = \xi = 0$, we have the particularly simple estimate $R(0, 0) \leq \frac{1}{2\pi}(M^2 + M'^2)$. (Contractor's abstract, modified)

THEORY OF PLASTICITY FOR POWDERED METALS, by E. M. Shoemaker and H. J. Greenberg. June 1955, 35p. refs. (Technical rept. no. 5) [AFOSR-TN-55-173] (AF 18(600)1138) AD 63408 Unclassified

A plasticity theory is developed to represent the mechanical behavior of a powdered metal in the green state prior to sintering. The theory includes a family of smooth, convex, stress-hardening surfaces and a family of smooth, convex, yield surfaces. Corresponding yield and stress-hardening surfaces intersect and "interact". The theory is chosen to be consistent with the requirements of positivity of plastic work as postulated by D. C. Drucker (Proceedings of the First National Congress of Applied Mechanics, p. 487-491) and to be consistent with the previous perfectly plastic and stress-hardening theories. Stress-strain laws and corresponding loading criteria are developed, and the uniqueness theorems and minimum principles appropriate to the theory are proved. (Contractor's abstract)

PICARD'S THEOREM AND LINEAR DIFFERENTIAL EQUATIONS, by Z. Nehari and R. J. Duffin. July 1955, 15p. (Technical rept. no. 6) ([AF]OSR-TN-55-218) (AF 18(600)1138) AD 73980 Unclassified

The principal result is the following theorem: let $f_1(z), \ldots, f_n(z)$ $(n \geq 3)$ be entire functions for which $a_1 f_1(z) + \ldots + a_n f_n(z) = 0$ and where the coefficients $a_1, \ldots, a_n$ are nonzero constants, then either at least one of the functions $f_\nu(z)$ takes on the value zero or the functions $f_\nu(z)$ are not all essentially different. An immediate consequence of the theorem is the corollary that the linear differential equation

$$y^{(n)}(z) + p_{n-1}(z)\, y^{(n-1)}(z) + \ldots + p_1(z)y'(z) + p_0(z)y(z) = 0$$

$(n \geq 2)$ cannot have more than n essentially different solutions which are entire and do not vanish. Functions are considered essentially different if no function of the set is a constant nonzero multiple of any other function of the set. A sharpened version of the first theorem is that if $f_1(z), \ldots, f_n(z)$ $(n \geq 2)$ are entire functions such that $a_1 f_1(z) + \ldots + a_n f_n(z) = 0$, then either at least one of the functions $f_\nu(z)$ takes all finite values an infinity of times or else the linear relation holds trivially in the following way: the set $\{f_\nu(z)\}$ consists of subsets $f_{\nu 1}, \ldots f_{\nu k}$ $(k \geq 2)$ such that $f_{\nu m}(z) = a_m + l'_m(z)g(z)$, where $g(z)$ is a zero-free entire function, $l'_1(z), \ldots, l'_k(z)$ are polynomials such that

$a_{\nu 1} l'_1(z) + \ldots + a_{\nu k} l'_k(z) = A$ = a constant, and $A = 0$ unless $g(z)$ reduces to a constant.

LINEAR PROGRAMMING AND PLASTIC LIMIT ANALYSIS OF STRUCTURES, by W. S. Dorn and H. J. Greenberg. Aug. 1955, 30p. incl. diagrs. tables. (Technical rept. no. 7) ([AF]OSR-TN-55-274) (AF 18(600)1138) AD 74111 Unclassified

Also published in Quart. Appl. Math., v. 15: 155-167, July 1957.

In this study, the problems of limit analysis are reduced to 3 basic types of linear programming problems chosen so as to keep the size of the problem as small as possible. Appropriate methods of solution for each of these problem types are reviewed, and are adapted

for the special systems adapted. Procedures for determining an initial feasible solution (extreme point solution) for each of these methods are discussed including a new procedure for determining an initial feasible solution for use with Lemke's dual method (The Dual Method of Solving the Linear Programming Problem, Naval Research Logistics Quarterly, v. 1: 36-47, Mar. 1954) The various linear programming solutions of the limit analysis problem are compared, and a simple example is carried through for each method of solution. It is pointed out that the structures considered are plane pin-jointed trusses for the sake of simplicity of description; however, the setup would be the same for the equations governing rigid frames or continuous beams, and for space as well as plane structures. A quantitative comparison of the 3 methods (simplex, dual, and bounded variables formulation) is given by the number of arithmetical operations necessary to obtain a solution. As a measure of these operations, the number of multifications to be performed/1 iteration is (r+2) (s+1) for the first 2 methods, and (s-r+1) (s+2) for the bounded variables method, where s = the number of bars and r = the number of redundancies of the truss.

ON THE COEFFICIENTS OF MEROMORPHIC SCHLICHT FUNCTIONS, by Z. Nehari and E. Netanyahu. Feb. 1956, 12p. (Technical rept. no. 8) [AFOSR-TN-56-86] (AF 18(600)1138) AD 81539
Unclassified

Also published in Proc. Amer. Math. Soc., v. 8: 15-23, Feb. 1957.

It has been conjectured for some time that the coefficients a_n of functions $z^{-1} + a_1 z + a_2 z^2 + \ldots$, which are univalent in the unit disk, are subject to the inequality (i) $|a_n| \leq 2(n+1)^{-1}$ (which was known to hold for $n = 1, 2$). This conjecture was recently disproved by M. Schiffer and P. Garabedian, who showed that the largest value of $|a_n|$ is $1 + e^{-6}$. E. Netanyahu showed, moreover, that (i) does not hold for any odd index larger than 3. In the present study, it is shown that if the univalent function f(z) is, in addition, starlike with respect to the origin, the sharp inequality (i) holds for $n = 3, 4, 5, 6$. ON THE SINGULARITIES OF LEGENDRE EXPANSIONS, by Z. Nehari. Feb. 1956, 10p. (Technical rept. no. 9) (AFOSR-TN-56-96) (AF 18(600)1138) AD 82009
Unclassified

Also published in Jour. Rational Mech. and Analysis, v. 5: 987-992, Nov. 1956.

Let $\limsup_{n \to \infty} |a_n|^{1/n} < 1$, and set $f(z) = \sum_{n=0}^{\infty} a_n z^n$, $g(z) = \sum_{n=0}^{\infty} a_n P_n(t)$, where $P_n(t)$ denotes the Legendre polynomial at degree n. If σ and τ denote, respectively, the singularities of f(z) and g(t), it is proved that to each σ there corresponds a τ such that $1 + 2\sigma\tau + \sigma^2 = 0$, and vice versa. The only exceptions are the points $t = \pm 1$ which may be singularities of g(t) without f(z) being singular for $z = \pm 1$. This theorem generalizes a recent result of Szegö (On the Singularities of Zonal Harmonic Expansions, Jour. Rational Mech. and Anal., v. 3: 561-564, 1954) who proved that the point $(1, \theta)$ will be a singular point of the harmonic function $u(r, \theta)$

$= \sum_{n=0}^{\infty} a_n r^n P_n (\cos\theta)$ ($\limsup |a_n|^{1/n} = 1, a_n$ real)

if, and only if, $z = e^{i\theta}$ is a singularity of $\sum_{n=0}^{\infty} a_n z^n$. (Contractor's abstract)

OSCILLATION CRITERIA FOR SECOND-ORDER LINEAR DIFFERENTIAL EQUATIONS, by Z. Nehari. July 1956, 26p. (Technical rept. no. 12) ([AF]OSR-TN-56-262) (AF 18(600)1138) AD 88982
Unclassified

Also published in Trans. Amer. Math. Soc., v. 85: 428-445, July 1957.

More general oscillation criteria (or nonoscillation criteria) are developed for the equation $y'' + p(x)y = 0$, where p(x) is a continuous nonnegative function for $0 < x < \infty$. The equation is called nonoscillatory, without the interval being mentioned, if there exists a number a such that the equation is nonoscillatory in (a, ∞). The equation is said to be oscillatory, if one (and therefore all) of its solutions have an infinite number of zeros for $x > 0$. The general oscillation criteria developed contains Hille's criteria (Trans. Amer. Math. Soc., v. 64: 234-252, 1948) for the oscillatory and nonoscillatory conditions of the above equation. The basic idea used is the fact that there exists an intimate connection between the oscillation problem for the equation and the eigenvalue problem for the equation $u'' + \lambda p(x)u = 0$, with suitable boundary conditions.

PRESCRIBED INITIAL AND TERMINAL POSITIONS AND TANGENTS, by L. E. Dubins. Apr. 1956 [32]p. incl. diagrs. (Technical rept. no. 10) (AFOSR-TR-56-12) (AF 18(600)1138) AD 86304 Unclassified

Also published in Amer. Jour. Math., v. 79: 497-516, July 1957.

For fixed vectors u, U, v, V in real n-dimensional Euclidean space E_n, and for a fixed positive number R, an investigation is made of the existence and nature in E_n of a path of minimal length among those curves whose average curvature is everywhere less than or equal to 1/R. A curve X in real Euclidean n-space, when parameterized by arc length, is said to have an average curvature less than or equal to 1/R provided its first derivative X' exists everywhere and satisfies the Lipschitz condition $|X'(s_1) - X'(s_2)| \leq \frac{1}{R} |s_1 - s_2|$ for all s_1 and s_2 in the interval of definition of X. Such paths of minimal length are called R-geodesics. The principal result, for n = 2, is given by the following theorem: Every planar R-geodesic is necessarily a continuously differentiable curve which is either (1) an arc of a circle of a circle of radius R, followed by a line segment, followed by an arc of a circle of radius R; or (2) a sequence of 4 arcs of circle of radius R; or (3) a sub-path of one of the former types. A corollary implies that 4 is the least integer for which this is true. The nature of R-geodesics for n > 3 is open. (ASTIA abstract)

ON THE COEFFICIENTS OF UNIVALENT FUNCTIONS, by Z. Nehari. Apr. 1956, 5p. (Technical rept. no. 11) (AFOSR-[TR]-56-14) (AF 18(600)1138) AD 86583 Unclassified

Also published in Proc. Amer. Math. Soc., v. 8: 291-293, Apr. 1957.

The conjecture of Littlewood (Proc. London Math. Soc., v. 23: 481-519, 1925) that $|a_n| < 4|d|n$, $f(z) \neq d(|z| < 1)$ is shown to follow from the proof of the asymptotic Bieberbach conjecture that $\limsup_{n\to\infty} \frac{A_n}{n} = 1$, where $A_n = \sup |a_n|$, and $f(z) = z + a_2z^2 + a_3z^3 + \ldots$ belongs to the family S of regular univalent functions in the unit disk. The result is given in the following theorem. If f(z) is a function of S and d is a value such that $f(z) \neq d$ in $|z| < 1$, then $|a_n| < 4|d|n$ where $= \limsup_{n\to\infty} \frac{A_n}{n}$. The proof is based on the lemma that if $F(z) = b_1z + b_2z^2 + \ldots$ is regular and univalent, and $F(z) \neq 1$ in $|z| < 1$, then the same is true of the function $F_1(z) = b_1^{(1)}z + b_2^{(2)}z^2 + \ldots = 2F(z^2) \cdot 2\sqrt{F(z^2).F(z^2) - 1}$.

SOME EFFECTS OF THE ADDITION OF MASS TO VIBRATING SYSTEMS II, by H. Cohen and G. [H.] Handelman. Jan. 17, 1955 [15]p. incl. diagrs. (Technical rept. no. 1) ([AF]OSR-TN-55-26) (AF 18-(600)1236) AD 56334 Unclassified

A determination is made of the lowest frequency of vibration of a rectangular plate to which a rigid mass of finite area has been rigidly attached. The plate is taken to be simply supported along 2 opposite edges and free on the other 2 edges. The mass is rectangular in shape, centrally located, and runs completely across the plate in a direction parallel to the simply supported edges. The analysis shows that in order to predict the change in vibration characteristics with added mass, it is necessary to know the distribution of the mass and the relationship between the density of the added mass and that of the plate. For concentrated loads of small density, the plate is stiffened and the frequency μ increases. For loads of large density the frequency also increases, but not until the load is distributed across a large portion of the plate.

A NOTE ON THE TRANSVERSE VIBRATION OF A TUBE CONTAINING FLOWING FLUID, by G. H. Handelman. Feb. 1, 1955, 9p. (Technical rept. no. 2) ([AF]OSR-TN-55-50) (AF 18(600)1236) AD 56337 Unclassified

A study was made to determine the characteristics of the low-vibration frequencies for various end conditions for 2 ranges of the flow velocity solely from the structure of the differential equation without determining specific solutions. The differential equation in nondimensional form, developed by Long (Experimental and Theoretical Study of Transverse Vibration of a Tube Containing Flowing Fluid, American Society of Mechanical Engineers, Preprint 54-A-22), was used. A discussion is included on the determination of small flow velocities and velocities near the critical velocity. Data indicated that the perturbation terms can be computed step-by-step by quadratures. In the supported-end cases, the critical velocity can be determined first; perturbation from this point in powers of D serve as a check on the perturbation solution in terms of power u, where D is the eigenvalue found by removing the time-dependent term from the partial differential equation, and u is the flow velocity in nondimensional terms.

EFFECT OF HUB RADIUS ON THE VIBRATIONS OF A UNIFORM BAR, by W. E. Boyce. Feb. 25, 1955 [13]p. incl. diagrs. tables. (Technical rept. no. 3) ([AF]OSR-TN-55-64) (AF 18(600)1236) AD 56340 Unclassified

An investigation was made to determine the frequencies of vibration of a uniform beam rotating at a constant angular speed about an axis at one end perpendicular to the axis of the beam and vibrating transversely to the plane of rotation. The derivation of equations is presented. Upper and lower bounds were computed for the first 2 frequencies for ratios of the hub radius to beam length of 0.005, 0.01, 0.02, 0.05, and 0.10. The frequencies depended almost linearly on the hub radius for various rotational speeds; this behavior differed from that previously found for the case of a nonzero hub radius (Vibrations of Rotating Beams of Constant Section, by W. E. Boyce, R. C. DiPrima, and G. H. Handelman, presented at Proc. of the Second U. S. National Congress of Applied Mechanics). (ASTIA abstract)

FINITE DIFFERENCE METHODS FOR THE SOLUTION OF FLUID FLOW PROBLEMS DESCRIBED BY THE PRANDTL EQUATIONS, by W. T. Rouleau and J. F. Osterle. June 4, 1954, 72p. incl. diagrs. tables, refs. (Technical note no. 1; rept. no. CIT-AF11-TN1) ([AF]OSR-TN-54-122) (AF 18(600)969) AD 32660 Unclassified

The stepwise procedure developed by Friedrich and Forstall is extended to flows characterized by the presence of solid or porous boundaries where the downstream, or longitudinal, velocity is zero. In determining velocities near such a boundary, stability considerations restrict the extended stepwise procedure so that if the mesh spacing in the direction normal to the boundary is reduced, the mesh spacing in the downstream, or tangential, direction must be reduced an even greater amount. An implicit difference representation of the Prandtl equations is developed which is always stable and which does not require a reduction of the tangential mesh spacing as the normal mesh spacing is reduced. These difference equations cannot be solved in stepwise fashion but may be solved by either relaxation or iteration methods, both of which are completely described. Stability criteria are developed, and the dependence of the inherent error on the mesh is determined. The following 4 problems are worked: (1) the flow in the wake behind a flat plate immersed longitudinally in a uniform stream, (2) longitudinal flow over a porous flat plate with an initial boundary layer and an arbitrary distribution of normal velocity at the plate surface; (3) flow of a 2-dimensional jet discharging parallel and adjacent to a flat plate into a uniform stream; and (4) longitudinal flow over a flat plate.

THE APPLICATION OF FINITE DIFFERENCE METHODS TO BOUNDARY-LAYER TYPE FLOWS, by W. T. Rouleau and J. F. Osterle. June 2, 1954, 6p. illus. tables, refs. [AF 18(600)969] Unclassified

Published in Jour. Aeronaut. Sciences, v. 22: 249-254, Apr. 1955.

Finite difference techniques are applied to the problem of slightly viscous, incompressible, constant pressure flow confined by boundaries (solid or porous) on which the "non-slip" condition prevails. The "stepwise" representation and method of solution developed by Friedrich and Forstall, which is unstable at boundaries on which there is no slip, is extended to include this case. An always stable "implicit" form of the difference equations is developed, and for it methods of solution by relaxation and iteration techniques are presented. Both the stepwise and implicit procedures are suitable for programming on digital computers. Several original solutions are obtained by these methods, including the important problems of the boundary layer over a flat plate with an arbitrary distribution of suction and the slot jet issuing adjacent to a plate into a moving stream. ADSORPTION OF OXYGEN BY A SILVER CATALYST, by W. W. Smeltzer, E. L. Tollefson, and A. Cambron. [1956] [15]p. incl. diagrs. table, refs. [AF 18(600)-1572] Unclassified

Published in Canad. Jour. Chem., v. 34: 1046-1060, Aug. 1956.

An apparatus is described to measure volumetrically the amount of gas adsorbed by a catalyst at constant pressure and at exposure times as short as 0.1 min. The volumes of oxygen adsorbed by a technical silver catalyst at pressures of 200, 400, and 700 mm and in the temperature range of 180° to 300°C have been measured. Surface area determinations of 0.33 to 0.38 sq meter per gm of catalyst by physical adsorption and chemisorption methods show that each silver atom of the surface is associated with approximately one oxygen adatom at a monolayer coverage. The initial rate of adsorption of oxygen is directly proportional to its pressure. Observed transitions in the oxygen adsorption rates indicate that more than one type of oxygen complex occurs on the catalyst surface. The Elovich equation provides the best approximation of the adsorption rate data but is of limited applicability in interpretation of the mechanism of adsorption. Values of 22-29 kcal/mole and 17-25 kcal/mole have been calculated for the apparent activation energy and isosteric heat of adsorption respectively.

INVESTIGATION OF ACCELERATION OF REACTION RATES OF SOLIDS BY MEANS OF RAPID DEFORMATION, by F. J. Ewing. Technical rept. Oct. 6, 1955, 1v. incl. diagrs. tables. ([AF]OSR-TR-55-32) (AF 18(600)1396) AD 82476 Unclassified

The use of metals as fuels in place of gasoline is indicated where volume is limited (up to 250% increase) or where oxidizer is also to be carried (up to 350% increase). Aluminum, however, is so well protected by its oxide coating that the only explosive-or rapid reactions with O_2 or H_2O are limited to powdered aluminum. It seemed possible that new surfaces formed by rapid deformation of Al might lead to high velocity reactions. This has been studied in contact with H_2O at explosive deformation rates, and in contact with air at machine rates of 100 ft/sec. No reaction rates of substantial magnitude were observed in either circumstance. A deformation device is also described, and its operation is explained. It is designed to pull a test specimen with a maximum force of 500 lb at a maximum rate of deformation of 100 ft/sec, and for a travel distance of up to 12 in.

THE MECHANISM OF THE THERMAL DECOMPOSITION OF ETHANE-d_6, by F. O. Rice and R. E. Varnerin. Technical note no. 1, Nov. 1, 1952-Aug. 15, 1953. Feb. 11, 1954, 20p. incl. illus. tables, refs. ([AF]OSR-TN-54-50) (AF 18(600)64, Task 2) AD 29027 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 76: 324-327, Jan. 20, 1954.

C_2D_6 decomposes at about 1/3 the rate of C_2H_6 and is inhibited by NO. The inhibition curve for C_2D_6-NO mixtures is similar to that for C_2H_6-NO mixtures, the maximum reduction being to 18%, respectively, of the rate of the uninhibited reaction. When C_2D_6 was decomposed with an equal quantity of CH_4, the amount of isotopic mixing as measured by the CH_3D/CH_4 ratio depended only on the fractional decomposition. The CH_3D/CH_4 ratio for constant fractional decomposition of the C_2D_6 was independent of NO concentration changes. Results indicated that the thermal decomposition of C_2D_6 was a chain reaction and that the direct separation of D_2 occurred to a negligible extent.

MASS SPECTROMETRIC ANALYSIS OF THE PRODUCTS OF THE HOMOGENEOUS REDUCTION OF ETHYLENE WITH DEUTERIUM, by R. E. Varnerin. June 1, 1954, 11p. incl. table, refs. ([AF]OSR-TN-54-96) (AF-18(600)64, Task 2) AD 34457 Unclassified

An analysis was made to determine the products of the interaction of ethylene and deuterium at 570° to 660°C. The main products, in the order of abundance, were C_2H_3D, HD, C_2H_5D, H_2, $C_2H_2D_2$, $C_2H_4D_2$, CH_3D, C_2H_6, and CH_4. The other isotopic ethanes, ethylenes, and methanes appeared when the reaction proceeded towards equilibrium. Analysis for the ethylenes was made at electron accelerating potentials below the appearance potential of ethane; the patterns for the isotopic ethanes, ethylenes, and methanes were calculated according to the method of Schissler, Thompson and Turkevich (Discussions Faraday Soc., v. 10: 46, 1951). The analyses gave results in close agreement with the stoichiometry of the reaction. (ASTIA abstract)

THE THERMAL DECOMPOSITION OF ACETALDEHYDE AND ACETALDEHYDE-d_4, by F. O. Rice and R. E. Varnerin. Technical note no. 2, Sept. 1-Dec. 1, 1953. Mar. 22, 1954, 16p. incl. diagrs. refs. ([AF]OSR-TN-54-99) (AF 18(600)64, Task 2) AD 32315 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 76: 2629-2633, May 20, 1954.

When 50/50 mixtures of CH_3CHO/C_2D_6 or CD_3CDO-C_2H_6 were decomposed, the amount of isotopic mixing, as measured by the CH_3D/CH_4 or CD_3H/CD_4 ratios, was proportional to the fraction of aldehyde decomposed. When different amounts of NO were added to the aldehyde-ethane mixtures, the ratios were independent of the concentration of NO or increased as the NO concentration increased. The decomposition of 50/50 mixtures of CD_3CDO/CH_3CHCH_2 and of CD_3CDO/C_2H_6 gave a CD_3H/CD_4 ratio of 1.8/1 for the 2 reactions. Results indicated that: (1) the thermal decomposition of CH_3CHO and CD_3CDO was similar; (2) both were chain reactions unaccompanied by any significant amount of direct separation into product molecules; and (3) the thermal decomposition of a substrate in the presence of an indicator (in which either the substrate or indicator was fully deuterated) provided a general method for studying elementary reactions.

RADICALS WITH ETHANE, DIMETHYL ETHER, ACETONE, AND PROPYLENE, by R. E. Varnerin. May 1, 1954, 16p. incl. tables, refs. ([AF]OSR-TN-54-139) (AF 18(600)64, Task 2) AD 52799 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 1426-1429, Mar. 20, 1955.

The reactions of methyl radicals with shielded C atoms, O atoms, carbonyl C atoms, and C-C doubly bonded C atoms in organic molecules were investigated. CD_3 radicals, produced in the thermal decomposition of CD_3CHO, were allowed to react with CH_3CH_3, CH_3CCH_3, CH_3COCH_3, and $CH_3CH=CH_2$. According to the CD_3H/CD_3CH_3, CD_3H/CD_3OCH_3, and CD_3H/CD_3COCH_3 ratios, the reactions

$CD_3 + CH_3CH_3 \rightarrow CD_3CH_3 + CH_3$,

$CD_3 + CH_3OCH_3 \rightarrow CD_3OCH_3 + CH_3$, and

$CD_3 + CH_3COCH_3 \rightarrow CD_3COCH_3 + CH_3$ occur to the extent of less than 1 part in 1500, 2500, and 90, respectively, as compared with the reactions

$CD_3 + CH_3CH_3 \rightarrow CD_3H + CH_3CH_2$,

$CD_3 + CH_3OCH_3 \rightarrow CD_3H + CH_3OCH_2$, and

$CD_3 + CH_3COCH_3 \rightarrow CD_3H + CH_3COCH_2$. The reaction $CD_3 + CH_3CH=CH_2 \rightarrow CD_3CH=CH_2 + CH_3$ could not be detected with high precision; the $CD_3H/CD_3CH=CH_2$ ratio indicates that it takes place to the extent of less than 1 part in 10 as compared with the reaction $CD_3 + CH_3CH=CH_2 \rightarrow CD_3H + CH_3CH=CH$. A MOLECULAR ORBITAL TREATMENT OF THE QUADRATIC FORM OF H_4, by V. [F.] Griffing and A. Mecek. Jan. – June 1954, 19p. incl. tables, refs. (Technical note no. 3) ([AF]OSR-TN-54-140) (AF 18(600)64, Task 1) AD 36233 Unclassified

Molecular orbital calculations of the quadratic arrangement of four H atoms were carried out as a function of internuclear distance. The complex was shown to have orbital degeneracy in the ground state. The approximation, which included the lowest orbital and the degenerate orbitals only, yielded a triplet and three singlet states. The triplet was the lowest state in accordance with Hund's rule. Calculations showed that the quadratic H_4 was unstable with respect to a totally symmetrical displacement at all points of the potential energy surface.

ACTIVATION ENERGIES OF REACTIONS OF METHYL RADICALS WITH ORGANIC MOLECULES, by F. O. Rice and R. E. Varnerin. July 1, 1954 [15]p. incl. diagr. tables. ([AF]OSR-TN-54-155) (AF 18(600)64, Task 2) AD 39094 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 221-224, Jan. 5, 1955.

A study was made (1) of the thermal decomposition, at several temperatures, of various organic compounds in the presence of equimolecular amounts of ethane-d_6 and (2) of the thermal decomposition of acetaldehyde-d_4 in the presence of various organic compounds. Fifty-fifty mixtures of propane, butane, isobutane, pentane, neopentane, CH_3CHO, CH_3COCH_3, and CH_3OCH_3 with ethane-d_6 were decomposed at 580°C. The CH_4/CH_3D values were determined at different temperatures for several of these reactions. The activation energies (E) were obtained for the different reactions represented by the general equation $CH_3 + RH \rightarrow CH_4 + R$ by plotting the log $[CH_4]/[CH_3D]$ against 1/T and assuming E=12.1 for the reaction $CH_3 + C_2D_6 \rightarrow CH_3D + C_2D_5$. These values of E were compared with values taken directly from a review of A. F. Trotman-Dickenson (Quart. Revs. (London), v. 7: 198, 1953). Similar experiments were performed on 50-50 mixtures of CH_3CHO, CH_4, C_2H_6, butane, isobutane, pentane, neopentane, 2, 3-dimethylbutane, ethylene, $CH_3CH=CH_2$, CH_3COCH_3, and CH_3OCH_3 with acetaldehyde-d_4 at 527°C. Results were similar to those obtained with the 50-50 mixtures of ethane-d_6 and various compounds. Measurements were also made at different temperatures; the activation energies were compared with published data.

THE THERMAL DECOMPOSITION OF ETHANE, by R. E. Varnerin and J. S. Dooling. Nov 1, 1955, 12p. incl. diagrs. tables. (Technical note no. 8) ([AF] OSR-TN-55-408) (AF 18(600)64, Task 2) AD 86321 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 2042-2044, May 20, 1956.

It has been shown that, in the thermal decomposition of 50-50 mixtures of C_2H_6 and CD_4, the CD_3H/CD_4 ratio is approximately independent of the concentration of nitric oxide. In addition, it has been demonstrated that, in the thermal decomposition of 50-50 mixtures of C_2D_6 and CH_4, the D_2/CH_4 ratio is approximately independent of the concentration of nitric oxide, but the CD_3H/CH_4 ratio increases greatly with increasing concentration of nitric oxide. Mechanisms for these decompositions are proposed and discussed. (Contractor's abstract)

BOND STRENGTHS AND ACTIVATION ENERGIES [Part 1], by V. F. Griffing. DECOMPOSITION KINETICS OF SIMPLE MOLECULES [Part 2], by F. O. Rice. (Final rept.) May 1956, 7p. incl. refs. (AFOSR-TR-56-18 [Pts. 1 and 2]) (AF 18(600)64) AD 87527 Unclassified

Part 1: The work undertaken under this project is reviewed. The Born-Oppenheimer assumption was critically evaluated and used to develop theories to study unimolecular processes. A semi-empirical theory was developed based on a classical mechanical picture and activation energies and reaction mechanisms were elucidated. A quantum mechanical theory of unimolecular processes was also developed. Part 2: The work herein undertaken proved definitely for the first time that in the thermal decomposition of ethane any reaction other than a free radical chain occurs to an insignificant extent. Also, a method was developed for measuring the activation energies of elementary reactions in the course of an ordinary pyrolysis.

STABILITY AND REACTIVITY OF MOLECULES FROM THE STANDPOINT OF MOLECULAR ORBITALS, by V. F. Griffing and J. S. Dooling. June 15, 1956 [9]p. incl. diagrs. refs. (Technical note no. 1) (AFOSR-TN-56-564) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1537 and Office of Naval Research) AD 110385 Unclassified

Also published in Jour. Phys. Chem., v. 61: 11-19, Jan. 1957.

The usefulness of the molecular orbital approximate solution of the Schroedinger equation is shown in the discussion of the stability and reactivity of atoms and molecules. The nature of the activated complex is discussed and the activation energy is identified with promotion energy as the internuclear parameters are adiabatically varied. Four center systems are used to discuss the general aspects of chemical problems which then have the necessary degree of complexity. The importance of the occurrence and removal of orbital and spin degeneracy is demonstrated for atomic systems. Accidental degeneracies are seen to play a similar role in heteronuclear systems.

A survey and review are presented of the present status of knowledge in the field of spontaneous ignition. It deals with the spontaneous ignition of combustibles that are liquid at normal temperature and pressure. Some of the characteristic phenomena that are observed experimentally when combustibles are heated in the presence of an oxidizing atmosphere (generally, air or oxygen) under various conditions are described. A description of various methods of measuring ignition temperatures are given in eight chapters. They include: (1) Moore's heated crucible method; (2) Jentzsch's heated crucible method; (3) static heated crucible and furnace methods; (4) bomb methods; (5) adiabatic compression methods; (6) flow methods; (7) heated surface methods; and (8) the Mackey test, diesel engine methods, and other miscellaneous methods. This is followed up by chapters on (1) spontaneous ignition temperature data, (2) effect of fuel additives, (3) factors affecting ignition delay, and (4) the aeronautical applications of spontaneous ignition data (including the spark-ignition engine, the aero-gas turbine, and the rocket and the pulse jets).

INTRODUCTION TO THE STUDY OF CHEMICAL REACTIONS IN FLOW SYSTEMS, by S. S. Penner. London, Butterworths Scientific Publications, 1955, 86p. incl. diagrs. refs. (NATO AGARDograph rept. no. 7) (AF 18(600)972)
Unclassified

This report is intended as an introduction to the study of chemical reactions in moving gas mixtures. The manuscript is divided into four chapters. Chapter 1 contains a résumé of classical chemical kinetics with special reference to the limitations of the steady-state approximation for chain reactions. Chapter 2 contains a brief summary of the conversion laws for reacting fluids and suitable expressions for the determination of transport coefficients. Chapter 3 contains an analysis. A simple example of chemical reactions in flow systems on the problem of chemical reactions during adiabatic flow through a de Laval nozzle which is a flow problem with negligible diffusion is analyzed. Chapter 4 contains a brief discussion of stationary, isothermal gas-solid systems and some of the important features of heterogeneous diffusion flames. Seventy-one references and a subject index are also included.

RESEARCH ON A NEW CLASS OF INORGANIC COMPOUNDS CAPABLE OF POLYMERIZING INTO USEFUL STRUCTURAL MATERIALS, by I. Hornstein. Final technical rept. Mar. 1, 1953 - Feb. 28, 1954. Mar. 24, 1954 [18]p. incl. diagrs. [AFOSR-TR-54-12] (AF 18(600)656; continued by AF 18(600)1163)
AD 29764 Unclassified

A series of reactions were developed for converting the reaction products of a polyvalent halide and a Grignard reagent into a new type of thermoplastic material. Laboratory studies established that $FeCl_3$, $VOCl_3$, and ethylmagnesium chloride (C_2H_5MgCl) reacted to form a mixture of $FeVO(C_2H_5)_6$ and $MgCl_2$.

An organo-Fe-V compound was isolated from the mixture by treatment with dimethylformamide and was purified by chromatographic adsorption on an alumina column. The organometallic compound was pyrolyzed under argon to form a polymeric material consisting essentially of Fe, V, and O with 10% or less of C, H, and N. Compression-molded disks of the polymeric material were heated to 700°C in an inert atmosphere without loss in thermal plasticity. Surface oxidation appeared when disks were heated in air to 500°C, but no changes were observed in their dimensional stability or in the clarity of the surface details. The material was leached with H_2O without deletertous effects. A series of reaction mechanisms was postulated to explain the nature and formation of the organo-Fe-V thermoplastic materials. Thermoplastic materials of a similar nature were prepared by using polyvalent halides of B, Fe, Si, Ti, and V with the Grignard reagent ethylmagnesium bromide. (ASTIA abstract)

RESEARCH ON A NEW TYPE OF ORGANO-METALLIC THERMOPLASTIC, by I. Hornstein and R. S.

Dean. Final rept. Mar. 1, 1953 – Oct. 4, 1954. Oct. 29, 1954 [40]p. incl. diagrs. (Rept. no. 18) ([AF]OSR-TR-55-5) (AF 18(600)1163; continuation of AF 18(600)656) Unclassified

In this study, a series of reactions has been developed for converting the reaction products of a polyvalent halide and a Grignard reagent into a new type of thermoplastic material. Polymers consisting essentially of Fe, V, O_2 with small amounts (10%) of C, H_2, and N_2 have been prepared which can be heated to 700°C without loss of thermal plasticity. Molded parts of these polymers retain their dimensional stability and detail without distortion even at this temperature. These molded products also maintain their integrity when heated in air for short periods to 500°C. When heated for longer periods at this temperature, surface oxidation appears to take place, but again the molded parts retain their shape, size, and surface details. This material can be leached with water without any deleterious effect effects. Reaction mechanisms have been postulated to explain the nature and formation of these new Fe-V-O thermoplastic materials. In addition, thermoplastic materials of a similar nature have been prepared in which polyvalent halides of the following elements have been used: (a) V, (b) Fe, (c) Ti, (d) Si, and (e) B. Additional studies have been made on the molecular structure of the $VOCl_3$ - $FECl_3$ intermediate in a new type organometallic thermoplastic. Experimental evidence is offered to show that anhydrous $FeCl_3$ and anhydrous $VOCl_3$ can react in dry ether to form a new product. The empirical formula of a product obtained by treating $VOCl_3$ in ether with a large excess of $FeCl_3$ is shown to be $7FeCl_3 \cdot 2VOCl_3$. A description of this study is given in order to gain some understanding of the nature of this and similar $FeCl_3 \cdot VOCl_3$ complexes having different ratios of $FeCl_3$ to $VOCl_3$. USE OF RANKS IN ONE-CRITERION VARIANCE ANALYSIS, by W. H. Kruskal and W. A. Wallis. Dec. 1952 [39]p. incl. diagrs. tables, refs. [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N6ori-02035] AD 14193 Unclassified

Also published in Jour. Amer. Stat. Assoc., v. 47: 583-621, Dec. 1952.

Given C samples, with n_i observations in the ith sample, a test of the hypothesis that the samples are from the same population may be made by ranking the observations from from 1 to $\sum n_i$ (giving each observation in a group of ties the mean of the ranks tied for), finding the C sums of ranks, and computing a statistic H. Under the stated hypothesis, H is distributed approximately as $\chi^2(C-1)$, unless the samples are too small, in which case special approximations or exact tables are provided. One of the most important applications of the test is in detecting differences among the population means. (Contractor's abstract)

THE WAGR SEQUENTIAL t-TEST REACHES A DECISION WITH PROBABILITY ONE, by H. T. David and W. H. Kruskal. [Sept. 1956] [9]p. [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N6ori-02035] AD 139360 Unclassified

Also published in Ann. Math. Stat., v. 27: 797-805, Sept. 1956.

The WAGR test is a sequential procedure for testing the null hypothesis that the proportion of a normal population greater than a given constant is P_0 (given) against the alternative that it is P_1 (given). These are equivalent (after a translation) to hypotheses specifying the value of μ/δ, where μ and δ^2 are the mean and the variance of the normal population under test. We prove that, with probability one, a decision is reached when the WAGR test is applied. This fact is of importance in its own right; it also has indirect interest because, unless it were true, the standard Wald inequalities on probabilities of error at the two hypothesis points could not be applied.

SOME CONSEQUENCES OF POSSIBLE DEGENERACY BANDS IN Ge, by E. N. Adams, II. [1953] [?] [AF 33(038)25913]

CHI. 02:002 - CHI. 02:006

Published in Phys. Rev., v. 92: 1063-1064, Nov. 15, 1953.

Calculations of Herman (Phys. Rev., v. 88: 1210, 1952) and Herman and Callaway (Phys. Rev., v. 89: 518, 1953) indicate a triple degeneracy for diamond and germanium at the band edge for both the conducting and valence bands, the degeneracy in the conduction band being probably sixfold. Such degeneracies would require a significant modification of the interpretation of certain experimental results on carrier densities. A theoretical consideration indicates that effective masses would have to be smaller than unity, the range of values being such that $a_e a_h \sim 4$-6. The deformation potential as the dominant source of lattice scattering would have to be abandoned. These conclusions also apply to silicon since silicon probably has the same band structure as germanium to the approximation of Herman's calculation. The present harmony between theory and experimental data would disappear when account is taken of the degeneracy. The weak but definite evidence discussed is considered to indicate that the predicted degeneracy in the band structure of germanium and silicon does not occur.

OCCURRENCE OF NATURAL P-N JUNCTIONS IN LEAD SELENIDE, by A. E. Goldberg and G. R. Mitchell. July 1953 9 p. incl. illus. (Rept. no. CML-R-P1) (AFOSR-TN 54-17) (AF 33(038)25913) AD 15047 Unclassified

Also published in Jour. Chem. Phys., v. 22: 220-221, Feb. 1954.

Single crystals of PbSe were grown from melts in sealed quartz tubes. Except for a very narrow range of initial melt compositions, stoichiometric excesses of Pb or Se in the melt resulted in crystals that were wholly n- or p-type, respectively. Initial compositions within the critical range yielded crystals showing both p- and n-regions. The electrical resistivities were related to crystal compositions permitting the construction of the Pb-Se phase diagram in a narrow region about the compound PbSe. The invariant melting point for the system falls in the Se-rich region. This precludes the possibility of growing a crystal from a melt which is of stoichiometric composition throughout. ELASTORESISTANCE IN p-TYPE Ge and Si, by E. N. Adams, II. [Sept. 1954] 4p. ([AF]OSR-TN-54-241) (AF 33(038)25913) Unclassified

Also published in Phys. Rev., v. 96: 803-804, Nov. 1, 1954.

Elastoresistance in n-type Ge and Si is considered to be brought about by a strain induced transfer of electrons between nonequivalent anistropic energy minima in the conduction band. In p-type specimens, however, it is believed that the great elasloresistance originates in a strain induced mixing of the nearly degenerate bands and a consequent strong warping of the energy surfaces. An experiment was carried out employing a spin orbit coupling model to add validity to this concept.

GENERALIZED DEFORMATION POTENTIAL THEORY FOR N-TYPE Ge (Abstract), by W. P. Dumke. Sept. 23, 1954, 1p. (AF 33(038)25913) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 26-27, 1954.

Published in Phys. Rev., v. 98: 230, Apr. 1, 1955.

The deformation potential theory has been reexamined taking into account the ellipsoidal shape of the surfaces of constant energy in reciprocal lattice space, and the effect of shear wave scattering in n-type Ge. We find that if scattering by compressional waves were the dominant scattering process, a simple relaxation time exists proportional to $E^{-1/2}$, just as for spherical energy surfaces. However, the scattering due to shear waves

CHI. 02:014 - CHI. 02:018

ts strongly anisotroptc and cannot be described by a stmple relaxation time. We have been able to show that when shear wave scattering ts taken tnto account the dtstrtbution function for electrtcal conduction takes the usual form

$$f_1 = -eE \cdot \langle \bar{\tau} \rangle \ddagger \cdot \nabla_p f_o,$$

except that the relaxation time ıs a second rank tensor with components that depend on direction. Prelimtnary calculations indicate that shear wave scattering is the domtnent scattering mechanism for n-type Ge. (Contractor's abstract)

DEPOSITION OF LEAD SULFIDE AND LEAD SELENIDE FILM FROM SOLUTIONS, by S. Whitcher. Dec. 1954, 25p. tncl. tables, refs. (Rept. no. CML-TN-P9) (AF 33(038)25913) AD 53104 Unclassified

The development of detector materials ts a part of a general program which is aimed at improvtng night seeing devices for the Air Force. Lead sulfide films for mirrors and photocells were chemically prepared by mixing a soluble plumbous salt, thiourea and sodium hydroxide. Methods of preparation used in the past by other workers are discussed. The concentrations of the reactants can be varied as well as the order in which the compounds are mixed. Further investigation of these variables is reported in this paper. Impurity cations such as Cu^{++} are known to enhance film deposition. This has been verified in this work by use of highly pure materials. The effect of several ions not previously studied has been investigated. A search was made for other organic sulfur compounds to use in film preparation. None were found to be as good as thiourea, and in general the quality of the film produced was related to the similiarity to thiourea of the molecular structure of the organic sulfide. A method for the preparation of PbSe films is described. Several coordination complex compounds of lead and thiourea have been isolated and analyzed. These do not seem to be intermediates in the deposition mechanism, however. The mechanism which is proposed is based on the slow generation of sulfide ions by the decomposition of thiourea. Evidence is advanced to support this hypothesis. (Contractor's abstract)

EFFECTS OF OXYGEN ON PbS FILMS, by H. T. Minden. Dec. 23, 1954 [33]p. incl. diagrs. refs. (AF 33(033)25913) Unclassified

The conductivity changes produced in lead sulfide films by the sorption of oxygen have been determined. At temperatures less than about 210°C sorption is less than 7×10^{-4} mol of oxygen per mol of PbS. Nonetheless, initial exposure to oxygen at these temperatures produces an abrupt decrease in conductivity; further exposure increases the conductivity slightly. At temperatures higher than about 210°C the conductivity decreases immediately and stays low while sorption of the order of .1 mol oxygen per mol PbS slowly occurs. When the sorption is almost complete the conductivity gradually rises to its initial value. The cycle can be repeated by admitting more oxygen in contact with the same film. These effects are explained by assuming the formation of surface acceptor states by the oxygen. At higher temperatures the oxygen acceptors diffuse inward and reacts chemically with excess lead atoms and with the sulfide ions. (Contractor's abstract)

PHOTO-EFFECTS IN InSb, by S. W. Kurnick, A. E. Goldberg and others. Jan. 10, 1955 [14]p. incl. diagrs. refs. [AFOSR-TN-55-33] (AF 33(038)25913) Unclassified

Phototransistor, photoelectromagnetic (PEM) and photoconductive effects occur in InSb. P-n junctions have been pulled from the melt; at liquid nitrogen temperatures these junctions show photovoltaic and phototransistor responses. Surface recombination rates and bulk lifetimes have been evaluated from the PEM and photoconductive response at liquid N_2 temperatures using a constant-relaxation-time model for carrier transport. Response is strongly dependent on surface preparation (electro-polished or mechanically polished). The temperature-dependence of the PEM effect is discussed. (Contractor's abstract)

InSb PHOTODIODES, by G. R. Mitchell, A. E. Goldberg, and S. W. Kurnick. [June 22, 1955] 8p. ([AF]OSR-TN-55-129) (AF 33(038)25913) Unclassified

Presented at the IRE-AIEE Semiconductor Conference, June 20-22, 1955.

The purpose of this paper is to describe the photoproperties of InSb p-n junctions. The photovoltaic response to an equal quantum spectrum was obtained. The characteristic of the junction when exposed to room temperature radiation is described. The noise, signal, and signal-to-noise ratio were measured as a function of reverse bias.

PHOTOEFFECTS IN InSb, by S. W. Kurnick and R. N. Zitter. [1955] [8]p. incl. diagrs. [AFOSR-TN-55-130] (AF 33(038)25913) AD 113839 Unclassified

Also published in Photoconductivity Conference, p. 531-538, 1956.

Surface conditions in p-type InSb at liquid-nitrogen temperatures influence the magnitude of photoconductive and PEM (photoelectromagnetic) responses and strongly alter the variation of the PEM response with magnetic field. The response of mechanically polished samples exhibits a peak value with increasing magnetic field, whereas the response of electrolytically polished samples reaches a saturation value. A simple theory using the concept of surface-recombination speeds has been developed to analyze these effects. Values of minority-carrier (bulk) liketimes and mobilities obtained from mechanically polished samples are consistent with the values from the same samples after electropolishing. In addition, the theory may be used to estimate surface-recombination speeds. (Contractor's summary)

SURFACE AREA AND PARTICLE SIZE OF EVAPORATED LEAD SULFIDE FILMS, by R. H. Harada. May 19, 1955 [6]p. incl. diagrs. tables. refs. [AFOSR-TN-55-150] [AF 33(038)25913] AD 94125 Unclassified

Also published in Jour. Chem. Phys., v. 24: 447-452, Feb. 1956.

Physical adsorption isotherms of lead sulfide films evaporated in vacuum and through oxygen were measured in order to determine their surface area and particle size. The surface areas of fresh and of annealed-vacuum evaporated films were found to increase linearly with film thickness. Annealing the films in vacuum decreased the surface area considerably. The average specific surfaces of the fresh and

CHI. 02:025 - CHI. 02:028

annealed films were 63 sq m/g and 6 sq m/g, corresponding to particle sizes of 0.013μ and 0.13μ, respectively. The surface area of fresh films evaporated through oxygen depended upon the rate of evaporation. The average specific surface of the fresh slowly evaporated films was 66 sq m/g; for those evaporated faster, it was 118 sq m/g. The corresponding particle sizes were 0.012μ and 0.0068μ. When these films were annealed in a closed vacuum system, the specific surface became 12 sq m/g and 14 sq m/g, corresponding to particle sizes of 0.067μ and 0.056μ, respectively. For films evaporated through oxygen, the oxygen is chemisorbed on the surface of the film during evaporation. When such a film is annealed sulfur dioxide is evolved and sulfate is formed. EFFECTS OF OXYGEN ON PbS FILMS, by H. T. Minden. Dec. 28, 1954 [8]p. incl. diagrs. table. [AFOSR-TN-55-177] (AF 33(038)25913) AD 94127 Unclassified

Also published in Jour. Chem. Phys., v. 23: 1948-1955, Oct. 1955.

The effect of oxygen on the conductivity of vacuum-evaporated PbS films has been experimentally investigated. When outgassed, these films are n-type semiconductors. If they are exposed to oxygen at temperatures below about 200°C, the conductivity decreases with increasing pressure and then increases again. The thermoelectric power changes from negative to positive, but less than 10^{-3} mole 0_2/mole PbS is sorbed by the film. Above 200°C the conductivity merely decreases when oxygen is admitted, and the thermoelectric power becomes small. The film gradually absorbs all the oxygen in the vacuum system and evolves a good deal of SO_2. When the reaction is complete, the conductivity returns to its initial value, and the thermoelectric power is once again negative. The film can repeatedly absorb large amounts of oxygen without undergoing any permanent change in electrical properties. It is concluded that these films are composed of 2 layers. Next to the substrate there is a conducting layer that chemisorbs oxygen, but does not react with it. The chemisorbed oxygen acceptors are responsible for the observed changes in conductivity. The upper layer of the film is nonconducting and reacts to completion with oxygen, possibly forming $PbSO_3$:PbO, and evolving SO_2. (Contractor's abstract)

PHOTOCONDUCTIVE AND PHOTOELECTROMAGNETIC EFFECTS IN InSb, by S. W. Kurnick and R. N. Zitter. Sept. 2, 1955 [8]p. incl. diagrs. tables, refs. [AFOSR-TN-55-293] [AF 33(038)-25913] AD 94128 Unclassified

Also published in Jour. Appl. Phys., v. 27: 278-285, Mar. 1956.

Photoconductive (PC) and photoelectromagnetic (PEM) effects have been observed in p-type InSb single crystals of high purity at 77°K (extrinsic range) and 301°K (intrinsic range). Because of the large electron mobilities in InSb, and because the variation of the PEM response with magnetic field was found to be strongly dependent on surface treatment, it was necessary to develop a new theoretical model to describe the PEM effect, permitting the evaluation of bulk lifetime and both electron and hole mobilities. In addition, the model affords an interpretation of Hall and magnetoresistance effects in intrinsic InSb. When the PEM effect is analyzed using impurity- or thermal-scattering, assuming Boltzmann statistics, the result does not fit the data as well as the simple model presented here.

INFRARED ABSORPTION OF INDIUM ANTIMONIDE, by E. Blount, J. Callaway and others. Sept. 12, 1955 [2]p. incl. diagrs. refs. [AFOSR-TN-55-306] [AF 33(038)25913] AD 94126 Unclassified

Also published in Phys. Rev., v. 101: 563-564, Jan. 15, 1956.

Infrared absorption in InSb near the absorption edge has been interpreted as the superposition of 2 indirect transitions requiring phonons of 100° and 30°, the former transition involving the smaller electronic energy gap. The first transition is consistent with a band scheme having electrons at the center of the zone and holes either at the corner of the zone or about halfway along the [1, 1, 1] line. The other transition may indicate a second hole with an energy gap about 0.025 ev larger than that of the first.

SPACE-CHARGE FORMATION IN SMALL PbS PARTICLES, by H. T. Minden. Sept. 15, 1955 [8]p. incl. diagrs. refs. [AFOSR-TN-55-322] [AF 33(038) 25913] AD 114587 Unclassified

Also published in Jour. Chem. Phys., v. 25: 241-248, Aug. 1956.

A theoretical model is discussed for the effect of oxygen on the electrical properties of PbS thin films. The films are assumed to be composed of very small n-type microcrystals, on the surface of which oxygen is adsorbed. The adsorbed atoms are singly ionized by electrons from the interior of the microcrystals. The appropriate Potsson-Boltzmann equation is solved for particles of radius 5×10^{-8}m and $5\sqrt{10} \times 10^{-8}$m, and for donor concentrations of 10^{23} m^{-3} and 10^{24} m^{-3}. The potential distribution is given as a function of the surface acceptor concentration required for the conservation of charge. Models for the electron and hole conductivities are given, and the results of calculations based on these models are compared with experiment. This theory is contrasted with the earlier bulk diffusion theory of the effect of oxygen. The free energy of adsorption is roughly calculated. Implications of this theory are discussed on the general character of conduction in PbS films, on the temperature coefficient of conduction, and on the nature of photoconduction. DEFORMATION POTENTIAL THEORY FOR n-TYPE Ge, by W. P. Dumke. June 29, 1955 [6]p. incl. tables, refs. [AFOSR-TN-55-327] [AF 33(038)25913] AD 113840 Unclassified

Also published in Phys. Rev., v. 101. 531-536, Jan. 15, 1956.

The deformation potential theory has been reexamined for electrons in Ge to take into account the ellipsoidal nature of the energy surfaces, and the effect of shear wave scattering. The coupling between shears and the conduction band energy minima is calculated from Smith's piezoresistance data under the assumption that any changes in mobility due to strain may be neglected. The scattering by shears, which is the dominant mechanism, is strongly anistropic and cannot be described by a simple relaxation time. We have shown that the distribution function for electrical conductivity has a tensor dependence on the orientation of the electric field. The mobility is calculated assuming several values of E_{1c}, the shift of the conduction band edge with dilation. The calculated values of the mobility are approximately $3 \times 10^{7} T^{-3/2}$ cm^2 / v-sec. Methods of accounting for discrepancies between the experimental and theoretical values of the mobility and their temperature dependence are discussed. (Contractor's abstract)

HIGH-PRECISION FREQUENCY STANDARDS, by J. Burns, III. Final rept. Jan. 1955, 82p. incl. diagrs. tables, refs. (Rept. no. CML-TN-P10) (AF 33(038)25913) AD 74915 Unclassified

The essential features of phase comparison navigation system and narrow-band secure communtcations systems are examined to determine the frequency stability required of radiofrequency oscillators to be used with them. It is estimated that the ultimate accuracy of a phase compartson navigation system ts limited to several hundred feet by radio propagation uncertainties. For a system operating at 100 kc these propagation errors amount to a few hundred feet until the range exceeds several hundred miles beyond which the accuracy deteriorates rapidly due to sky-wave interference. Accordingly, the oscillator stability requirements were established with these accuracy limitations in mind so errors arising from frequency instability should be somewhat smaller than the propagation errors. It is shown that frequency stabilities of one part in 10^6 averaging over one second and one part in 10^{11} over three hr are necessary to give the desired accuracy in position fixes. Oscillators for narrow-band voice communtcations systems operating in the VHF frequency band must be stable to one part in 10^7 averaging over one second and must have a long-time stability of about the same order. Several methods of generating radiofrequencies with these stabilities are examined and the results are summarized in a table.

CHI. 02:033 - CHI. 02:038

All of these except the first and last serve the purpose of synchronizing an external oscillator. The crystal and molecular oscillators are self-excited. The essential features of a suitable technique for performing this synchronization are analyzed to show how the precision of synchronization depends upon the properties of the particular atomic or molecular resonance phenomena with which it is achieved. This report gives an elementary review of the factors and the philosophy upon which fire control filter theory is based. A close analogy between fire control system sensors and classes of measuring instruments is maintained so that, while the theory of random noise filtering is developed, the difficulties of the measurement and evaluation of such filtering are indicated. The first section indicates the necessity for filtering of noisy signals, the second section develops the required theory, and the third section applies the theory to fire control system sensors and computers and to measuring instruments. The final section contains preliminary conclusions and recommendations for applying filter theory concepts in the selection of instrumentation for evaluating airborne fire control systems. DETECTOR DEVELOPMENT AT CHICAGO MIDWAY LABORATORIES (Abstract), by F. F. Rieke. Oct. 18, 1955, 1p. (AF 33(038)25913) Unclassified

Presented at the Symposium on Military Applications of Infrared Physics, Johns Hopkins U. Radiation Lab., Baltimore, Md., Jan. 25-26, 1956.

A photovoltaic cell, based on a p-n junction of indium antimonide operated at liquid nitrogen temperature, has been developed within the last year. Such detectors have a sensitive area of 0.2 sq mm, a noise equivalent power of 2×10^{-11} watts at 5.5 microns, and a response-time of 10 microseconds or less, the internal impedance is approximately 50,000 ohms. Indium antimonide at room temperature may also be used as a photodetector, employing either the photoconductive or the photoelectromagnetic effect to generate an electric response. The peak sensitivity occurs at 7.5 microns, but the NEP is approximately 100 times greater than for the cooled detector discussed above. Performance can be somewhat improved by cooling to -20°C. Response-times are very short and internal impedances are of the order of 1 ohm. Recent improvements in a dielectric thermal detector, developed some time ago, will be discussed briefly. INFRARED ABSORPTION AND THE BAND STRUCTURE OF INDIUM ANTIMONIDE, by J. Callaway. Dec. 1955, 38p. incl. diagrs. tables, refs. (Rept. no. CML-TN-55-A. 2-13) (AF 33(038)25913) AD 83637 Unclassified

The experimental data on infrared absorption in InSb are studied in the light of current theories of absorption, considering both direct and indirect transition mechanisms. It is shown that direct transition theory is not compatible with the data, while a satisfactory agreement can be obtained with the indirect theory. In particular, there are indications of two indirect transitions, requiring 100° phonons and 30° phonons. These results are related to current ideas on the band structure of InSb by use of simple theoretical considerations on lattice vibrations in InSb. We conclude that further evidence from magneto- and elasto-resistance is highly desirable at this time, and a summary of considerations relevant to these phenomena closes this report. A bibliography of the literature on InSb is appended. (Contractor's abstract)

PHOTOSENSITIZATION OF PbS FILMS, by R. H. Harada and H. T. Minden. [Jan. 12, 1956] 22p. incl. refs. (AF 33(038)25913; continued by AF 18(603)9) Unclassified

Also published in Phys. Rev., v. 102: 1258-1262, June 1, 1956.

The effect of O_2 on the photoconductive response of evaporated PbS films has been experimentally investigated. The dark conductance g, the photoconductance Δg, and the time constant τ for the photoconductive response of PbS evaporated films vary when the films are exposed to oxygen. The g initially decreases several orders of magnitude when an outgassed film is exposed to oxygen; it reaches a minimum and then increases. The thermoelectric power changes from negative to positive at the minimum in conductance. Δg and τ are given as a function of g. Δg decreases with increasing oxygenation, reaches a minimum near the minimum in g and then increases as g increases; after the film becomes p-type; $\Delta g/g$ is a maximum however, near the minimum in g. On the other hand, τ increases steadily as the film changes from n- to p-type. These results are attributed to the effect of two oxygen surface states. A low lying O^- state alters the Fermi level of the originally n-type film. The surface charge thus formed lowers the effective carrier mobility. A higher energy O^{--} state, when empty, traps photoelectrons and, hence, enhances the hole photoconductivity. (Contractor's abstract)

THE VARIATION WITH OXYGEN TREATMENT OF PHOTOCURRENT IN PbS FILMS (Abstract), by R. H. Harada and H. T. Minden. Dec. 1955, 1p. ([AF]OSR-TN-55-478) [AF 18(603)9] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 31, 1956.

Freshly evaporated PbS films are n-type and highly conducting. When a film is exposed to oxygen the conductance g decreases 3 to 5 orders of magnitude, reaches a minimum and then increases. The sign of the thermoelectric power changes at the minimum in conductance. The photoconductance g also decreases with initial oxygen treatment, but as the oxygen pressure is raised and g begins to increase, g also increases. This anomalous effect is explained by the following theory. Oxygen acceptors adsorbed on PbS films reduce the photocurrent by lowering the free carrier mobility. If enough oxygen is present, however, the Fermi level is lowered sufficiently, so that some of the oxygen surface states are emptied. These states can act as special electron traps, from which recombination does not take place. The lifetime photoholes becomes essentially the dwell time of the photoelectrons in the traps, and the photocurrent is enhanced. (Contractor's abstract)

SPONTANEOUS RADIATIVE RECOMBINATION IN SEMICONDUCTORS, by W. P. Dumke. Sept. 20, 1956 [6]p. incl. diagrs. refs. ([AF]OSR-TN-56-438) (AF 18(603)9) AD 96781 Unclassified

Also published in Phys. Rev., v. 105: 139-144, Jan. 1, 1957.

The mechanisms by which electrons and holes recombine with the emission of radiation are examined. Expressions are derived for the radiative recombination lifetimes due to direct and indirect transitions, and these are applied to Ge and Si. Matrix elements in the transition probability for direct and indirect transitions are obtained from analyses of the cyclotron resonance effective mass data, and the optical absorption data close to the band edge, respectively. For indirect transitions, the calculated lifetimes were of the order of seconds, and agreed within a factor of 3 with lifetimes calculated by the method of Van Roosbroeck and Shockley. It is shown that in Ge at room temperature, while the density of filled states in the conduction band at k = 0 is very low, the rate of recombination by direct transitions is nevertheless somewhat greater than that by indirect transitions. This is consistent with the findings of Haynes. The role of radiative recombination in the observed lifetimes of excess carriers is questioned. It is concluded that for those semiconductors which have a rather high absorption constant close to the band edge (InSb), an emitted photon is usually reabsorbed before it can escape from the crystal, producing another hole-electron pair, without contributing to the macroscopically observed lifetime. In the limit of a very high absorption constant, this emission and absorption of photons acts as an additional mechanism for the diffusion of hole-electron pairs. (Contractor's abstract)

THERMAL IMAGE TUBE, by J. Burns, III. First interim rept. June 1956 [56]p. incl. diagrs. (Rept. no. CML-56-TN-P108-2) (AFOSR-TN-56-460) (AF t8(600)9) AD 106094 Unclassified

The ferroelectric thermal image tube was developed in the form of a very thin wafer an inch or more in diameter. Three methods were considered for measurtng the thermally induced surface potential variations of the ferroelectric. The first method is deflection modulation in which surface potentiats deftect an electron beam, causing proportional amounts to pass the edges of a suitably placed grid structure. The second method is aberration modulation which is structurally similar to the first except that the grid structure is operated at such a potential that a repulsive electric field is established close to the ferroelectric surface. The large electron-optical aberrations of the field produce a strong defocusing of the reading beam as it is reflected back from the vicinity of the ferroelectric surface. The third method is absorption modutation which is a capacitor-discharge reading method in which the beam is allowed to charge up the detector surface, after which the beam is repelled by the charged surface. The amount of charge abstracted from the beam to perform this charging operation depends upon the initial surface potential. The deflection and absorption modulation methods are capable of linear response to a wide range of surface-potential differences, although linearity can be achieved in deflection modulation only by employing a very nearly monoenergetic scanning beam. The absorption modulation method is more conventional, and resembles the techniques used in several types of TV pickup tubes. Its sensitivity is not as good as deflection modulation for small signals although its response is linear over a wide range. The feasibility was apparently established in principle of a ferroelectric thermal-image tube capable of giving at least a 200-line picture and of detecting objects differing in temperature by about 1° from the background.

MAGNETICALLY FOCUSED SECONDARY EMISSION SCREEN-TYPE IMAGE INTENSIFIER, by F. F. Rteke. Final rept. Aug. t956, 38p. tncl. ttlus. diagrs. (Rept. no. CML-56-TN-Pt08-4) (AFOSR-TN-56-603) (AF 18(603)9) AD 108437; PB 124263 Unclassifted

Development of an tmage tntensifier is descrtbed which makes use of cascaded ftne mesh screens coated with an efficient secondary emttter, cesium-anttmony, to achteve muttiplication of weak photoelectron tmages from a cesium-antimony photocathode. An axial magnetic field is used together with appropriate potentials and spacings of the screens to keep the electron image in focus. Defocusing caused by the spread in vetocities of electrons from each multiplier screen is minimized but not eliminated by varying the spacings and potential differences between screens in such a way that electrons having two different initial velocities can be brought to focus in the same plane. The residual focusing errors, arising chiefly from the incomplete correction of chromatic aberration from the initial velocity spread, holds the resolution of a nine-stage tube to two or three line pairs per mitlimeter. Production of htgh yield cestum-anttmony secondary emission surfaces cotncidentally with high sensitivity photocathodes of the same material in a common tube envelope has not proved feasible. Maximum secondary ytetd and peak photosensitivity have been shown to occur in thts compound for such widety different concentrations of cesium that it does not seem possibte to achieve a satisfactory compromise. Forty-five image tubes were produced under this contract, and the methods of production together with the results of tests and experiments on these tubes are descrtbed. Recommendattons for the course to be followed tn the further development of the screen-type intensifier to overcome the drawbacks of the present design are discussed. (Contractor's abstract)

THE EFFECTIVE MASS APPROXIMATION FOR EXCITONS, by G. Dresselhaus. [1956] [13]p. incl. diagrs. refs. (Bound with the Forty-First Quarterly rept. to Sponsors of Chicago U. Inst. for the Study of Metals, June 1956, p. 149-161; AD 103589) (AF 18-(603)9) Unclassified

Also published in Phys. and Chem. of Solids, v. 1: 14-22, Sept.-Oct. 1956.

The effective mass approximation for degenerate electronic energy bands is applied to the interaction of electrons and holes in an insulator. It is shown that bound exciton states result from this treatment. The exciton Hamiltonian is of the form derived previously for impurity state problems. The criterion for the validity of the effective mass approximation is that the

lowest state be bound with an energy < 0.2 ev. Corrections to the approximation to account for the effective magnetic moments of the electron and hole are indicated. Selection rules and line widths for optical excitation of excitons are discussed. The question of the existence of positronium in crystalline solids is also considered. (Contractor's abstract)

INFRARED ABSORPTION EDGE, BAND STRUCTURE, AND ELECTRON MOBILITY IN InSb, by W. P. Dumke. [Oct. 1956] 6p. incl. diagr. refs. [AF 18(603)9] Unclassified

The absorption edge tail for InSb was fitted by the following indirect transition model: The valence and conduction band edges are at the center of the Brillouin Zone. Below the threshold for direct transitions, electrons may make a second order transition involving, first, a vertical optical transition to an intermediate virtual state in the conduction band from which they may be scattered to a real state in the conduction band by absorption of an optical mode phonon of essentially reststrahlen energy (.024 ev). Transitions through intermediate states in higher conduction bands are infrequent because of the large energy denominators for such processes. This model is simple and consistent with the various experiments on InSb.

MATHEMATICAL BIOPHYSICS OF COLOR VISION. II. THEORY OF COLOR CHANGES INDUCED BY THE ALTERNATION OF COLORS AT VARIOUS FREQUENCIES, by H. D. Landahl. Feb. 10, 1956, 14p. incl. diagrs. (AFOSR-TN-56-267) (AF 18(600)1454) AD 88987 Unclassified

Also published in Bull. Math. Biophysics, v. 18: 137-149, 1956.

A model previously introduced to account for a number of phenomena of color vision is studied for the conditions in which the alternation of colors is periodic. The case of three primary receptors having no differences in their time constants is considered for the situations such as the temporal alternation of two primaries, a primary and a neighboring binary, a primary and white, a binary and white, etc. Using the same mathematical model which was used to account for the enhancement effect of interrupted illumination, it is found possible to account for observed changes in hue in a qualitative manner. A method is suggested for measuring the color changes quantitatively. This method is readily adapted for demonstration purposes. The model shows that there should be differences between "primaries" and "binaries" with respect to change in hue. In principle, therefore, comparison between theory and experiment should yield information regarding the physiological primaries. (Contractor's abstract)

CONTRIBUTIONS TO THE THEORY OF ACTIVE TRANSPORT, by C. S. Patlak. May 15, 1956 [45]p. refs. (AFOSR-TN-56-411) (AF 18(600)1454) AD 96220 Unclassified

Also published in Bull. Math. Biophysics, v. 18: 271-315, 1956.

In many biological situations, the net transport of material from one region to another cannot be explained by a passive movement following thermodynamic laws. The term "active transport" has been applied to such cases, and is discussed in this study. It is pointed out that a system consisting of 2 solutions separated by a membrane may be in one of four possible states: (1) transient; (2) steady; (3) equilibrium; or (4) pseudo-equilibrium. The latter state denotes that in the solutions the net flow of all components is zero, but at least one of the components is not in thermodynamic equilibrium. Transient and steady-state systems may or may not have active transport; thus only systems in either equilibrium or pseudoequilibrium are considered here, since the former indicates that there is no active transport, whereas, in the latter case there always is active transport. This simplifies the problem of finding whether a system does or does not have an active transport mechanism, since it is frequently fairly easy to determine experimentally whether a system is in equilibrium or pseudoequilibrium. The assumption that electric neutrality exists within very thin membranes is shown not be be valid; however, electric neutrality does exist in the solutions in a system in a pseudo-equilibrium state with fixed charges and impermeative ions. It is then shown how the presence and sign of an electric potential may be found by use of electroneutrality. The mechanism of active transport may result from a general force acting on all particles of a particular component or to an individual force acting on the individual particles of a particular component. A general solvent flow or a diffusion drag force illustrates the first mechanism, while the second is accomplished by either a carrier or a Maxwell Demon. The Maxwell Demon is a hypothetical mechanism which allows each particle of A to cross a potential barrier by itself more readily in one direction than in the other. It differs from a carrier in that no part of it in contact with A moves while A is crossing the barrier. The Demon operates either by lowering the potential barrier height for A, by increasing A's speed of crossing the barrier, or by modifying A so that it can cross the potential barrier more readily. The general type of active transport has been extensively treated in the literature, while the individual type has not been treated in a generalized form. Therefore, the individual type of active transport is discussed at length, and a simple illustrative model is intensively analyzed. Following this, there is a discussion of the Maxwell

Demon, and some models of it are presented. (Contractor's abstract, modified)

PROBLEMS RELATED TO CHARACTERISTIC SURFACES, by M. Riesz. Technical rept. June 15, 1954, 26p. [AFOSR-TN-54-186] (AF 18(600)659) AD 49912 Unclassified

Also published in Proc. of the Conference on Differential Equations, Maryland U., College Park (Mar. 17-19, 1955), 1956, p. 57-71.

Multiple integrals of the Riemann-Liouville type are introduced which depend on a parameter α and which converge for sufficiently large values of α. The Cauchy problem for the wave equation with a space-like boundary is given by a unique formula which is the same for odd or even dimensional space-time; the formula implies an analytic continuation with respect to α. After the analytic continuation is carried out, quite different formulas are obtained for odd or even dimensions; the one relative to even dimensions is ruled by the Huygens principle. A geometric interpretation of the solution is given relative to ordinary 4-dimensional space-time. A solution of the wave equation is given for a very general class of characteristic boundaries in which the restrictions are of a topological nature. In the 3-dimensional case, a specialization of the solution formula leads to a case of curvatura integra for twisted curves. A sequence of special functions is constructed whose members are related to a given characteristic surface in the same way as different powers of the Lorentz distance are related to a characteristic cone. An explicit solution is given of the homogeneous wave equation which becomes infinite on the characteristic surface in the same way as the classical elementary solution does on a characteristic cone. This provides a complement to Delassus theorem. One of the special functions furnishes a formula of curvatura integra in the even-dimensional case.

ON CONSERVATION LAWS, by I. Osborn. June 15, 1954, 5p. (AF 18(600)659) ([AF]OSR-TN-54-262) AD 49911 Unclassified

A first order quasi-steady homogeneous partial differential equation in the independent variables x^i, $i = 1, \ldots, n$, and dependent variables u^j, $j = 1, \ldots, p$ is a conservation law if it is of the form

$$\sum_{i=1}^{n} \frac{\partial}{\partial x^i} \phi^i = 0$$

Since it is of interest to know when conservation laws can be formed by linear combination of the members of a given system of partial differential equations, some examples are given.

JORDAN ALGEBRAS OF CHARACTERISTIC TWO, by E. C. Paige, Jr. June 15, 1954, 1p. [AFOSR-TN-54-263] (AF 18(600)659) Unclassified

The author has concluded his investigations of Jordan algebras of characteristic two, and has deduced a partial structure theory for a special class of simple algebras which are designated as single string connected algebras. The dimensions and partial multiplication tables for these algebras were obtained. Moreover, special examples of these algebras were derived consisting of several infinite classes of simple Jordan algebras. Finally, in finding these special examples, the author was able to develop a new proof for the multilinear Jordan identity. This method may also be applied to the proof of other multilinear identities, and it is hoped that the author will be able to use it very soon in the study of simple Lie algebras of characteristic p. (Contractor's summary)

THE EXISTENCE OF CONSERVATION LAWS, by H. Osborn. Oct. 28, 1954, 70p. (Technical rept. no. 27) (Sponsored jointly by Office of Naval Research under Nonr-22511 and [Air Force Office of Scientific Research] under AF 18(600)659) AD 46283 Unclassified

A first-order quasi-linear homogeneous partial differential equation in the independent variables x^i, $i = 1, \ldots, n$ and the dependent variables u^j, $j = 1, \ldots, p$ is said to be a conservation law if it is of the form

$$\frac{\partial \phi^1}{\partial x^1} + \ldots + \frac{\partial \phi^n}{\partial x^n} = 0$$

for some ϕ^i which are functions of $x = \{x^i\}$ and $u = \{u^j\}$. If a given system is equivalent to a system, one of whose equations is a conservation law, the original system is said to contain the conservation law. The problem is that of determining the number of conservation laws contained in a given system. The problem of when a system is equivalent to another system consisting entirely of conservation laws and in how many ways such a representation can be found is also treated. One result is that even if those representations which can be obtained from one another by linear combination with constant coefficients are included in the same equivalence class, there is still a wide variety of systems which can be represented by infinitely many equivalence classes. The problem is first reduced to that of solving an over-determined system of linear homogeneous partial-differential

equations. An existence theorem ts given for thts system under certain integrabtlity-condition restrtctions. The more general problem ts then stated in therms of extertor differential forms in order to utilize the existence theorem of E. Cartan (Les systèmes différentiels extérieurs et leurs applications géométrtques, Paris, 1945) and E. Kähler (Einführung in die Theorie der Systeme von Differentialgletchungen, Letpztg, 1934). A NOTE ON THE INTERPOLATION OF SUBLINEAR OPERATIONS, by A. P. Calderón and A. Zygmund. Jan. 1956, 8p. (Technical rept. no. 1) (AFOSR-TN-56-470, Pt. 1) (AF 18(600)1111) AD 97354 Unclassified

Also published in Amer. Jour. Math., v. 78: 282-288, Apr. 1956.

Let (α_1, β_1), (α_2, β_2) be two points of the square $0 \leq \alpha \leq 1$, $0 \leq \beta \leq 1$. Let R be a measure space and let T be simultaneously a bounded operator from $L^{1/\alpha}1$ to $L^{1/\beta}1$ and from $L^{1/\alpha}2$ to $L^{1/\beta}2$ defined on R and having the following properties, (a) if $f = f_1 + f_2$ and Tf_1, Tf_2 are defined, then Tf is defined, (b) if Tf is defined T(kf) is defined for any scalar k, (c) $\|Tf_1 + Tf_2\| \leq \|Tf_1\| + \|Tf_2\|$, (d) $\|T(kf)\| = |k| \cdot \|Tf\|$. Let $\|T\|_1 = M_1$ for T considered as an operator from $L^{1/\alpha}1$ to $L^{1/\beta}1$, and $\|T\|_2 = M_2$ for T considered as an operator from $L^{1/\alpha}2$ to $L^{1/\beta}2$. Then if $0 \leq t \leq 1$, $\alpha = (1-t)\alpha_1 + t\alpha_2$, $\beta = (1-t)\beta_1 + t\beta_2$, T is also a bounded operator from $L^{1/\alpha}$ to $L^{1/\beta}$ with norm $M \leq M_1^{(1-t)}M_2^{t}$. Tnis is a generalization of a theorem of M. Riesz (Acta Math., v. 49: 465-497, 1927) who proved the result for bounded linear operators. (Math. Rev. abstract)

ALGEBRAS OF CERTAIN SINGULAR OPERATORS, by A. P. Calderón and A. Zygmund. Jan. 1956, 17p. (Technical rept. no. 2) (Also bound with its Technical rept. no. 1; AFOSR-TN-56-470, Pt. I) (AFOSR-TN-56-470, Pt. II) (AF 18(600)1111) AD 97354(a) Unclassified

Also published in Amer. Jour. Math., v. 78: 310-320, Apr. 1956.

Let $x = (\zeta_1, \cdots, \zeta_n)$ be an element of Euclidean n-space, and $|x| = (\zeta_1^2 + \cdots + \zeta_n^2)^{1/2}$. Let K(x) be a homogeneous function of degree $-n$, such that $K(\lambda x) = \lambda^{-n}K(x)$ for every x and every $\lambda > 0$, and let $\int K(x)d\sigma = 0$, $\int |K(x)|^p d\sigma < \infty$, $p > 1$, where the integrals are taken over the unit sphere $|x| = 1$, and $d\sigma$ denotes the area-element. Then, according to the previous work of the authors (Acta Math., v. 88: 85-139, 1952; Amer. Jour. Math., v. 78: 289-309, 1956) for $f \in L^r$ one can consider

$$\tilde{f}_\varepsilon(x) = \int_{|x-y|>\varepsilon} K(x-y)f(y)dy,$$

and show that tt converges pointwtse almost everywhere, and in the mean of order r, as $\varepsilon \to 0$. Let the limit be denoted by $\tilde{f}$. The authors consider operators K(f) of the form $K(f) = af + \tilde{f}$, a being a complex constant. Let A be the class of operators K with K(x) in C^∞ for $|x| > 0$, and A_p $(p>1)$ the class of operators K for which

$$(*) \quad \|K\|_p = |a| + \left[\int_{|x|=1} |K(x)|^p d\sigma\right]^{1/p} < \infty.$$

It is proved that A is closed under addition and operator multiplication, while A_p, with the norm (*), is a commutative, semi-simple Banach algebra, under operator multiplication. A Fourier transform of the operator K is defined, and some of its properties established. An operator in A (or A_p) has an inverse in A (or A_p) if and only if its Fourier transform does not vanish. The space of maximal ideals of A_p is homeomorphic to the sphere $|x| = 1$. (Math. Rev. abstract)

CHI. 06:005 - CHI. 06:006

As in a previous paper (Acta Math., v. 88: 85-139, 1952) the authors deal with extensions of Hilbert transforms to the n-dimensional space E_n. Let $x, y, x, \cdots$ be vectors in E_n $|x|$ the length of x, and

$$\tilde{f}_\varepsilon(x) = \int_{|x-y|>\varepsilon} K(x,y)f(y)dy,$$

where dy is the element of volume in E_n. The method which the authors use to deduce properties of $\tilde{f}_\varepsilon$ is entirely different from their previous procedure. It is based on the classical theory of Hilbert transforms in E_1 (where the kernel $K(x,y)$ is $\pi^{-1}(x-y)^{-1}$); and it yields, except for some cases including $f \in L$, their previous results under far less restrictive assumptions. In Theorem 1, the kernel is $K(x,y) = N(x-y)$, where $N(x)$ is homogeneous of degree $-n$; in Theorem 2, $K(x,y) = N(x, x-y)$, where $N(x,y)$ is homogeneous in y; in Theorems 3 and 4, $K = N(x, x-y)\psi(|x-y|)$, where $\psi(t)$ is an even or odd Fourier-Stieltjes transform, while $N(x,y)$ is odd or even, respectively, and homogeneous in y and its modulus is majorised by a homogeneous function $F(y)$. In each case, $f(x) \in L^p$, and N satisfies some conditions of integrability. Then, as in the classical case, $\tilde{f}_\varepsilon(x)$ tends to a function $\tilde{f}(x)$ both in the mean of order p, and pointwise almost everywhere, as $\varepsilon \to 0$, provided that p exceeds 1 and is subject to some further restrictions in Theorems 2 and 4. Again

$$\int_{-\infty}^{\infty} (\sup_\varepsilon |\tilde{f}_\varepsilon(x)|)^p dx \leq A^p \int_{-\infty}^{\infty} |f(x)|^p dx,$$

where A is independent of $f(x)$. Two other kernels are dealt with in Theorems 6 and 7, while in Theorem 5 the convergence to f, in the mean of order p, of the spherical means of order $\frac{1}{2}n(n-1)$ of the Fourier integral representation of $f \in L^p$ (n variables, n odd; $1 < p \leq 2$) is stated, which is proved at the end of the paper. First the Theorems 3, 4, 6 and 7 are deduced from the classical case and by interesting technique; while the proofs of 1 and 2 are more complicated: they depend on vector valued functions and are based on theorems 3 and 4 and on the transforms

$$\int_{|x-y|>\varepsilon} R(x-y)F(y)dy, \quad \int_{|x-y|>\varepsilon} R(x-y)F(y)\phi(|y|)dy,$$

where $R(x)$ is the (vector valued and odd) Riesz kernel $R(x) = \pi^{-\frac{1}{2}(n+1)}\Gamma(\frac{1}{2}n+\frac{1}{2})x|x|^{-n-1}$, $F(x)$ is even, homogeneous and satisfies some condition of integrability, and where $\phi(t)$ $(0 \leq t < \infty)$ is some continuously differentiable function. (Math. Rev. abstract)

ON A THEOREM OF MARCINKIEWICZ CONCERNING INTERPOLATION OF OPERATIONS, by A. Zygmund. [1956] [26]p. incl. refs. [AF 18(600)1111] Unclassified

Published in Jour. Math. Pures Appl., v. 35: 223-248, 1956.

To M. Riesz and G. O. Thorin (Thorin, Kungl. Fysiogr. Sällsk. i. Lund Förh., v. 8: 166-170, 1938) is due the following theorem. Let T be a linear bounded operator from $L^a(\mu)$ to $L^b(\nu)$, $\|f\|_{a,\mu} = \left[\int_R |f|^a d\mu\right]^{1/a}$ and $M_{a,b}$ its bound. Then the assertion is that if T is a bounded operator for a_1, b_1 and a_2, b_2, then it is a bounded operator for a_3, b_3, where

$$\frac{1}{a_3} = \frac{t}{a_1} + \frac{1-t}{a_2}, \quad \frac{1}{b_3} = \frac{t}{b_1} + \frac{1-t}{b_2};$$

$$M_{a_3b_3} \leq M_{a_1b_1}^{t} M_{a_2b_2}^{1-t}.$$

Below is given the definition of "weak boundedness" (reviewer's term) which is such that if T is weakly bounded for a_1, b_1 and for a_2, b_2, then T is bounded for a_3, b_3 given as above. In this case T may not even be linear, but satisfy only $\|T(f_1+f_2)\| \leq k(\|Tf_1\| + \|Tf_2\|)$, k independent of f_1. Also

$M_{a_3b_3} \leq KM_{a_1b_1}^{t} M_{a_2h_2}^{1-t}$, where K depends only on a_1, b_1, k and stays bounded, if t stays away from 0 and 1. This is the theorem of Marcinkiewicz in a form given and proved in this paper. It remains to give the definition of weak boundedness. T will be called weakly bounded with respect to a, b, if there exists an M_{ab} such that

$$\nu\{t \mid |Tf(t)| > y\} \leq (M_{ab}\|f\|_{a,\dots}/y)^b.$$

Numerous corollaries are given, especially some to spaces whose norm is of the form $\int \varphi(|f|)dx$, and to Fourier expansions into orthonormal series. If T is a Hilbert transform, then it is well-known, that it is bounded p, p for all $p > 1$. It is interesting to note that it is weak bounded 1, 1. (Math. Rev. abstract)

ON THE LITTLEWOOD-PALEY FUNCTION $g^*(\theta)$, by A. Zygmund. [Feb. 1956] [5]p. (AF 18(600)1111) Unclassified

Published in Proc. Nat'l. Academy Sciences, v. 42: 208-212, Apr. 1956.

Let $\Phi(z) = \Sigma_0^\infty c_n z^n$ be regular for $|z| < 1$ and of class H^λ, $0 < \lambda$, and $\Phi(e^{i\theta}) = \lim_{r \to 1} \Phi(re^{i\theta})$. Let $\sigma_n^\alpha(\theta)$ be the nth (C, α) mean of the series $\Sigma_0^\infty c_n e^{in\theta}$ and let

$$M_a(f) = M_a(f(\theta)) = \left\{ (2\pi)^{-1} \int_0^{2\pi} |f(\theta)|^a d\theta \right\}^{1/a}.$$

Among the functions concerning which integral inequalities are obtained are the following:

$$g^*(\theta) = \left\{ \int_0^1 (1-\rho)\, X^2(\rho, \theta) d\rho \right\}^{1/2},$$

where

$$X(\rho, \theta) = \left\{ \frac{1}{2\pi} \int_0^1 \frac{(1-\rho^2)\,|\Phi'(\rho e^{i(\theta+t)})|^2}{(1-2\rho\cos t+t^2)} dt \right\}^{1/2}$$

Among the new inequalities obtained are

$$M_\mu(g^*) \leq A_\mu M_1(\Phi(e^{i\theta})) \quad (0 < \mu < 1),$$

$$M_1(g^*) \leq A \int_0^{2\pi} \Phi(e^{i\vartheta}) |\log^+ |\Phi(e^{i\theta})| \, d\theta + B,$$

where in the last relation it is assumed that Φ belongs to H $\log^+$ H. Also obtained are the inequalities

$$M_{\lambda,\eta}[\gamma] \leq C_{\lambda,\eta}(\Phi), \quad \alpha = \lambda^{-1} - 1 \quad (0 < \lambda \leq 1),$$

$$M\lambda[\gamma] \leq C_\lambda \left\{ \int_0^{2\pi} |\Phi(e^{i\theta})| \log^+ |\Phi(e^{i\theta})| \, d\theta + 1 \right\}^{1/\lambda}$$

for $\Phi \in H_\lambda \log^+ H$, which have also been observed by

Sunouchi (Tôhoku Math. Jour., v. 7: 96-109, 1955). These are applied to partially settle the conjecture of the author (Proc. London Math. Soc., v. 47: 326-350, 1942) that $\sup_r |\sigma_r^\alpha(\theta)|$ is in L^λ for $0 < \lambda \leq \frac{1}{2}$ for Φ in $H^\lambda \log^+ H$. The case $\frac{1}{2} < \lambda < 1$ remains open. SOME ALGEBRAIC ASPECTS OF LOGIC, by M. H. Stone. Technical rept. July 1, 1955-June 30, 1956. Sept. 1956, 78p. refs. (AFOSR-TN-56-434) (AF 18-(600)1125) AD 96517 Unclassified

An analysis is made of those algebraic aspects of logic which may conveniently be studied in terms of certain free algebras, with emphasis on the algebraic treatment of the predicate calculus. The symbolism employed is essentially that introduced by E. L. Post (Amer. Jour. Math., v. 65: 197-215, 1943). A method is given for constructing algebras of arbitrary type generated by an arbitrary number of elements. Each algebra is obtained as a homomorph of a free algebra of the same nature. The analysis is completed by an isomorphism theorem which shows that any algebra whatever is isomorphic to such a canonical algebra.

SLIDE AND TORSION PRODUCTS FOR MODULES, by S. MacLane. Oct. 1956 [29]p. (AFOSR-TN-56-488) (AF 18(600)1383) AD 110303 Unclassified

Also published in Univ. e Politec. Torino. Rend. Sem. Mat., v. 15: 281-309, 1955-56.

A direct definition of the functor $\mathrm{Tor}_n(C, G)$ by generators and relations is compared with that introduced by Cartan-Eilenberg who defined $\mathrm{Tor}_n(C, G)$ as the nth homology group with coefficients in G of an arbitrary free resolution of the module C. This invariant definition is an application of the method used in finding generators for the group Tor (C, G) which repairs an inexact sequence by describing the sources of inexactitude by generators and relations. With the aid of new slide products, a functor is defined which satisfies an exact sequence theorem and coincides with the nth torsion product of C and G. Some examples and problems were formulated concerning the possible independent interest related to the slide products themselves.

NEGATIVE PION ACTIVATION OF BROMINE, by T. T. Sugihara and W. F. Libby. [1952] [2]p. incl. tables. [AF 33(038)18013] Unclassified

Published in Phys. Rev., v. 88: 587-586, Nov. 1, 1952.

Radiochemical studies of the reactions of π^- mesons with bromine, silver, and the light elements present in photographic emulsions should assist considerably in the interpretation of data obtained with photographic plates. The results for bromine with 122-Mev negative pions expending their full range in the element include: Peak yield of about 7 percent for As^{76} (ejection of 1 proton and 2 or 4 neutrons depending on which Br isotope absorbs the pion); the ratio of number of neutrons to the number of protons ejected was three to four in the most probable cases, the distribution of radioactivities appears to be reconcilable with photographic plate data if one guesses that the silver data will resemble those for bromine. NATURAL TRITIUM ASSAY. ROUTINE METHOD FOR ABSOLUTE ASSAY OF BETA RADIOACTIVITY, AND THE REACTIONS OF NEGATIVE PI MESONS WITH ELEMENTARY BROMINE, by W. F. Libby. Final repl. Dec. 1, 1952, 107p. incl. diagrs. tables, refs. (AF 33(038)18013; continued by AF 18(600)564)
AD 13760 Unclassified

In this study, the abundance of H^3 (tritium) in natural waters is determined. It is pointed out that about 200 g of H^3 appear to be present in the atmosphere at any given time. Some 15 kg are estimated to make up the total world assay. It is suggested that the H^3 in the atmosphere offers a means of dating organic materials on a 12.5-yr halflife basis. A routine method is described for obtaining an absolute assay of β "radioactivities", which are pure β emitters and do not emit γ radiations or possess complicated decay spectra. An error of not more than 5 - 10% is expected. Reactions involving the emission of neutrons are measured to elucidate the reactions of π mesons with photographic plate materials. Br is irradiated, and radioactivities are produced for Se, As, Ge, Ga, and Zn. Absolute yields of the elements are determined by γ assays, and an absolute measurement of the number of mesons entering the Br target is made. Measurements indicate that neutron emission is more probable than charged-particle emission. For Br, the most probable occurrence is the emission of about 3 neutrons and 1 proton which corresponds to a mountain peak on the yield map at a height of about 8%. The slope of the yield peak is steep in all directions from the peak. The lowest slope corresponds to about 3 neutrons for each proton. (ASTIA abstract, modified)

THE POTENTIAL USEFULNESS OF NATURAL TRITIUM, by W. F. Libby. [1953] 5p. refs. (AF 18(600)564; continuation of AF 33(038)18013)
Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 39: 245, 1953.

It has been established that rainwater contains tritium (T) in amounts corresponding to values ranging from 5×10^{-18} up to 40×10^{-18} T atoms/H atom. In this study, the possible applications of natural T measurements are considered. They include: (1) age estimation of rain and agricultural products; (2) hydrology and identification of water sources; (3) meterology and test of vertical mixing in air masses and source of the moisture in air masses; and (4) rate of escape of He^3 (the isotope formed by T during its radioactive decay) from the earth's atmosphere. An equation is presented for determining the residence time of sea moisture air masses. It is expressed as: , (T,) = 470 Qt, where , is the moisture content of the air masses (a sq cm), T, is the tritium content of the rain (10^{-18} T atoms H atom), Q is the tritium production rate (T atoms sq cm sec), and t is the time (yr) spent by the moisture in the air mass since it left the ocean.

RESEARCH TO ASSAY RAIN AND SURFACE WATER FOR NATURAL TRITIUM CONTENT, by W. F. Libby. Final rept. June 1, 1954, 26p. incl. tables, refs. ([AF]OSR-TN-54-142) (AF 18(600)564) AD 34458 Unclassified

The method used for the quantitative measurement of tritium in natural waters consisted of: (1) electrolytic concentration of water samples; (2) measurement of the deuterium concentration in the final product; and (3) determination of the tritium content of the concentrate by placing it as gaseous H in a Geiger counter. The results obtained are expressed as units of the number of tritium atoms/10^{18} H atoms present in the original sample. The data obtained were in accord with an average cosmic-ray production rate of about 0.14 tritium/sq cm/sec. Essentially, all of this tritium is passing into water without decaying into He, and the tritiated water is rained out and goes into the sea. The average tritium content of oceanic rain appeared to be about 1; the continental rains have higher assays. The Mississippi Valley shows about 6, and the western coast of Europe shows about 2.5. Changes in the natural tritium manufacturing rate are discussed in relation to old-water examination. Accumulation of He^3 in the atmosphere from the decay of cosmic-ray tritium indicated that He must leave the earth in a time not in excess of about 50,000,000 yr.

NATURAL DISTRIBUTION OF COSMIC-RAY-PRODUCED TRITIUM II, by H. von Buttlar and W. F. Libby. Nov. 1954, 33p. incl. tables. ([AF]OSR-TN-54-338) (AF 18(600)564) AD 50983 Unclassified

Also published in Jour. Inorg. and Nuclear Chem., v. 1: 75-91, Mar. 1955.

The measurement of the abundance of tritium in natural waters has been continued during the last eighteen months. The method used consists of the electrolytic concentration of the water samples, the measurement of the deuterium concentration in the final product from which the enrichment factor for any tritium present in the original sample can be calculated, followed by the determination of the tritium content of the concentrate by placing it as gaseous hydrogen in a Geiger counter. It is shown that the data are in agreement with an average cosmic ray production rate of about 0.14 tritium atoms/cm^2/sec of the earth's surface on the assumption that essentially all of this tritium passes into water without decaying into helium, and the titrated water is precipitated out and goes into the sea. The average tritium content of oceanic rain appears to be about 1 tritium atom per 10^{18} hydrogen atoms, whereas the continental rains have higher assays. The great Mississippi Valley shows about 6. The western coast of Europe runs about 2.5. Several hot springs have been tested and most found to be rain water. Tests on wells agreed with expectations. As yet there is no significant meterological understanding of the erratic fluctuations in the tritium assays for rain in a given location. It probably is due to variation in air mass trajectories, origins, and water contents. (Contractor's abstract)

THE NATURAL DISTRIBUTION OF TRITIUM, by S. Kaufman and W. F. Libby. [1954] 8p. incl. diagr. tables. [AF 18(600)564] Unclassified

Published in Phys. Rev., v. 93: 1337-1344, Mar. 15, 1954.

The abundance of cosmic-ray-produced tritium has been measured in a variety of natural waters in the Mississippi Valley, the Chicago, Ill. area, and in a few places elsewhere in the northern hemisphere. Contents ranging between 0.5 and 67 tritium atoms per 10^{18} hydrogen atoms have been found. These correspond to an average cosmic-ray production rate of about 0.12 tritium atoms/cm^2/sec if the total rate of transfer of tritium into the oceans by oceanic rain and snow and by rivers carrying continental water is taken as being equal to the total production rate. This is equivalent to assuming short land storage time in terms of eighteen years, the tritium average life. This production rate corresponds to an inventory of about 1800 g, with only about one percent of this in the atmosphere. The tritium contents of vintage wines appear to agree with the time elapsed since bottling, indicating the tritium abundances over the last eighteen years to have been essentially equal to the present ones. Some of the possible applications of natural tritium to problems of hydrology and meterology are discussed. The present production rate for tritium corresponds to an He^3 escape rate from the earth of about 5 x 10 years or less. (Contractor's abstract)

CONTINENTAL WATER BALANCE, GROUND WATER INVENTORY AND STORAGE TIMES, SURFACE OCEAN MIXING RATES AND WORLD-WIDE WATER CIRCULATION PATTERNS FROM COSMIC RAY AND BOMB TRITIUM, by E. Begemann and W. F. Libby. Nov. 15, 1956 [33]p. incl. diagrs. tables, refs. (AFOSR-TN-56-561) (AF 18(600)564) AD 110381 Unclassified

Also published in Geochimica et Cosmochimica Acta, v. 12: 277-296, 1957.

The tritium (T) produced during the Castel Operation in the spring of 1954 was used to study the circulatory

CHI. 10:006 - CHI. 11:002

rates of waters in the Northern Hemisphere, particularly in the northern Mississippi Valley. Observations indicated that rains following the Castle Operation were lower in T content than the ground water, and this difference revealed that about 67% of the rain in the Mississippi Valley is ocean water and about 33% re-evaporated ground water. The total inward transport of ocean water was calculated as about 1.00 m/yr. The average T residence half-life was determined as 6 yr on continental North America. Water from the oceans stays an average of 15 yr in the northern Mississippi Valley. Data on the northern Mississippi Valley indicated that about 8 m of ground water are available for mixing with the rainfall, about 0.28 m of water runs off annually in rivers, and 0.24 m/yr is carried back to the oceans by winds. The atmospheric residence time for the Castle T was about 40 days. Evidence suggests that the residence time for mixing of water above and below the thermocline may be as short as 5 yr. The direct measurement of T production cross sections and calculation of $\bar{Q}$ from cosmic ray intensities predict that the average cosmic-ray production rate for T is 0.7 T-atoms/sq cm/sec averaged over the whole world, the intensity varying strongly as the cosine of the latitude with a factor of 4 in intensity between the equator and the poles. Studies of the circulatory pattern of hot springs showed that the spring water is mainly rainwater which was stored for brief periods. (ASTIA abstract)

DISTRIBUTION OF ARTIFICIALLY PRODUCED TRITIUM IN NATURE, by F. Begemann. [1956] [6]p. incl. diagrs. table. [AF 18(600)564] Unclassified

Published in Proc. Second Conference on Nuclear Processes in Geologic Settings, July 31, 1956, p. 166-171.

Previous detailed measurements on the occurrence of tritium in nature had shown that there was an equilibrium amount of about 1800 g of cosmic ray-produced tritium present on the earth. As a consequence of the test of thermonuclear weapons in the Pacific in Spring 1954, the situation has changed completely. Now the equilibrium amount of tritium produced by cosmic radiation is only about 10% of the total tritium present on the earth. In the basic nuclear reactions leading to the production of this "excess tritium," it is produced as atomic tritium. Immediately following in the more moderate temperature zones of the fireball of the explosion, it is burned completely to HTO. The further history of the tritium is that of the water vapor in the atmosphere. It will be carried around the earth, distributed more or less homogeneously in the northern hemisphere, and finally rained out of the atmosphere and carried into the oceans.

DIRECT PRODUCTION OF RADIOACTIVE ALIPHATIC HYDROCARBONS BY PILE IRRADIATION, by A. G. Schrodt and W. F. Libby. May 5, 1954, 3p. incl. table. (Technical note no. 1) ([AF]OSR-TN-54-121) (AF 18(600)663) AD 106914 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 76: 3100, June 5, 1954.

A 5-mole solution of aniline in normal pentane was enclosed in a quartz tube and irradiated in the heavy-water pile at the Argonne National Lab. for one week at a flux of 10^{11} neutrons/cm^2/sec. The irradiation yielded radiocarbon in the form of normal pentane (25%), isopentane (less than 1%), hexane (15%), and heavier hydrocarbons (remainder). Similarly, radioactive hydrocarbons were produced by irradiation of ethyl amine in pentane. It is concluded that a high-velocity C^{14} on colliding with the liquid aliphatic hydrocarbon has a good chance of entering the chain. The possibility is mentioned that this process could also serve to introduce hydrocarbons into heavy lubricating oils.

HOT ATOM CHEMISTRY OF CARBON, by A. G. Schrodt and W. F. Libby. Dec. 1954 [36]p. incl. diagrs. tables, refs. ([AF]OSR-TN-54-368) (AF 18(600)663) AD 53028 Unclassified

The reactions of radioactive C^{14} atoms moving with the high velocities corresponding to energies up to 40,000 ev were studied in $PhNH_2$, C_6H_6, C_5H_{12}, MeOH, Ph_3N, $PhNH_2$, HF, $EtNH_2$, and $MeNH_2$.HF, all at room temperature. The hot C^{14} atoms were generated by the reaction of thermal neutrons with N^{14} and $N^{14}(n,p)C^{14}$. For hydrocarbons not containing N, about 5 mol-% of a nitrogenous material, such as $PhNH_2$, was dissolved in the hydrocarbon and the solution irradiated and studied. The nature of the C hot atom reactions was essentially independent of the choice of nitrogenous solute. The radioactive C atoms were incorporated into the solvent molecule in high yields in the case of saturated compounds, such as C_5H_{12} for which about 25% of the radiocarbon appeared as C_5H_{12}; while the aromatic compounds, such as C_6H_6 and $PhNH_2$, gave low yields of 1 or 2%. In all cases a variety of products differing from the molecules struck by the high-velocity C atom were produced, ranging from light gases to heavy molecules, with a tendency to yield heavy materials in the case of aromatic compounds and solid phases. In the case of aliphatic hydrocarbons, the radical produced by the collision stopping the C^{14} atom is not so reactive and merely combines with the neighboring C^{14} atom resulting from the collision and reforms the original molecule with high yield. Other processes also occur in lower yield, resulting in a wide distribution in molecular weights peaked at the parent molecule.

NATURAL RADIOACTIVITY OF RHENIUM, by A. D. Suttle, Jr. and W. F. Libby. Aug. 1, t954 [2]p. [AF 18(600)663] Unclassified

Published in Phys. Rev., v. 95: 866-867, Aug. t, t954.

Gaseous compounds of rhentum such as rhenium oxychloride and rhenium hexafluoride are considered useful in proportional counters to determine the half-life and the energy of radiation of rhenium. Reference is made to the shell model and beta decay systematics which imply that R_n^{187} should have an ft value of about 10^{t0} and be only first-forbidden with a spin change of 2. This indicates that a one-kev transition could correspond to a half-life of about $t0^{-tt}$ years.

ABSOLUTE ASSAY OF BETA RADIOACTIVITY tN THICK SOLIDS. APPLICATION TO NATURALLY RADIOACTIVE POTASSIUM, by A. D. Suttle, Jr. and W. F. Libby. June t955 [8]p. incl. diagrs. tables, refs. [AF t8(600)663] Unclassified

Published in Anal. Chem., v. 27: 921-927, June 1955.

The method of absolute measurement of beta radioactivity in solids has been found reliable within about 5%. The simplicity of this method and the scarcity of other practical absolute assay techniques led to this study. A wide variety of simple beta emitters display exponential absorption curves when the sample, absorber, and counter are placed close in cylindrical geometry. The absorption coefficient for the material constituting the sample can be used to calculate the absolute specific radioactivity of the solid sample. The absorption coefficients for a given absorbing material vary smoothly with the energy of the beta radioactivity transition, so that reliable values of the energies of such radioactivities can be obtained form the absorption coefficients. The coefficients vary with the atomic weight of the absorber. This effect is only partially elucidated. (Contractor's abstract)

ABSOLUTE CROSS SECTIONS FOR DEUTERONS ON BERYLLIUM, by R. E. Heft and W. F. Libby. Mar. 1, 1955 [t5]p. incl. diagrs. tables, refs. (AFOSR-TN-56-55) (AF 18(600)663) AD 81047 Unclassified

Also published in Phys. Rev., v. 100: 799-813, Nov. 1, 1955.

The absolute cross section for the reactions of deuterons on Be which produce tritium and Be^{10} have been measured up to energies of t7 to 20 mev. Data of Dejong, Endt, and Simons show no threshold which is as expected for exothermic (d, p) and (d, t) processes. For the reaction producing Be^{10}, which is equivalent to the introduction of a neutron into the Be nucleus by the bombarding deuteron, the cross section rises to a peak value of about 0.34 barn, at about 4 mev. It then falls almost linearly to the low value of 0.08 barn at 20 mev. There are evidences of fine structure in the curve, but it is possible that these are not really significant. The reaction producing tritium rises to a peak value of about 0.23 barn at about 5 mev, and then falls to a low value of about 0.03 barn at 13 mev. The reaction cross section appears to remain essentially constant at this low value, although it may rise slightly as the energy is raised to about 20 mev. A new reaction producing tritium begins at t7.47 mev, namely one which produces both tritium and Be^7 simultaneously. This corresponds to the ejection of both a triton and a neutron as a result of the deuteron Be^9 collision. This cross section rises from zero at the threshold linearly to a value of 8×10^{-5} barn at 21.5 mev. (Contractor's abstract)

TRITIUM PRODUCTION BY HIGH ENERGY PROTONS, by L. A. Currie, W. F. Libby, and R. L. Wolfgang. Nov. 1955 [29]p. incl. diagrs. tables, refs. (AFOSR-TN-56-56) (AF t8(600)663) AD 81048 Unclassified

Also published in Phys. Rev., v. 10t: 1557-t563, Mar. 1, 1956.

The cross sections for tritium production in various substances by 450 mev and 2.05 bev protons have been measured and the data tabulated. The N_2 and O_2 cross sections 25 ± 4 mb and 30 ± 4 mb, respectively, at 2.05 bev lead to a world-wide average tritium production rate by cosmic rays of $0.14 \pm {}^{0.10}_{0.03}$ tritons/sq cm/sec in good agreement with the observed value. The Fe cross section 53 ± 8 mb at 2.05 bev suggests a rate of production of 8.8×10^{-4} tritons/gm/sec near the surface of a large meteorite in outer space. For the small Mt. Ayliff Fe meteorite an age of $1.4 \times t0^9$ yr was calculated from the observed He^3 content. Finally, the results for tritium production have been compared to those for other light particles. NEGATIVE PION ACTIVATION OF SILVER, by W. Goishi and W. F. Libby. Aug. 1, 1956 [5]p. incl. table. (AFOSR-TN-56-350) (AF 18(600)663) AD 95436 Unclassified

Also published in Phys. Rev., v. 104: 1717, Dec. 15, 1956.

A sludy was made of lhe reaction with Ag of π-mesons, using a collimaled 5 sq cm beam of 122 mev negative pions on 2 to 4 kg of powdered Ag largels thicker than the pion range. Irradiation was conducled for 7-12 hr at intensities of about 5000 mesons sec. The % yields of some isotopes of Pd, Rh, and Ru, determined radiochemically on tne basis of their half-lives were: Pd^{103}, 4.9 ± 0.8; Pd^{101}, 6.8 ± 0.6; Pd^{100}, 1.9 ± 0.3; Rh^{105}, 0.9 ± 0.1; Rh^{102}, 3.8 ± 0.4; Rh^{101}, -0.2 ± 1.2; Rh^{100}, 1.8 ± 0.3; Ru^{103}, 1.1 ± 0.2; and Ru^{97}, 0.8 ± 0.2. The % yields signify the fraction of the incident mesons which produced the given nuclide. The yield of Pd^{101} appeared to be too high, that of Rh^{101} too low, possibly because some activity should be assigned to Pd^{109}. The total elemental yields were estimated at 22% for Pd, 16% for Rh, and 22% for Ru. Considering the rather large uncertainties in the present work, rough agreement was found wtth published data.

RADIOCHEMICAL RESEARCHES, by E. A. Martell. Ftnal rept. Aug. 31, 1956, 29p. Incl. tables, refs. [AFOSR-TR-56-35] (AF 18(600)663) AD 96501 Unclassifted

Studies were made of (1) reaction rates of slow reactions, (2) hol atom chemisiry of radiocarbon, and (3) negative π-meson activation of Ag. Under study 1, a general method was developed for measuring the rales of very slow rate reactions. A study of the HT-HTO reaction indicaled that the reaclton is 0 order with respecl lo O pressure and ftrst order with respect lo H pressure and the amounl of surface present. From 373 to 569°K, the reaction rale ls independent of the nature of the surface of the reaction vessel. The decarboxylation of dl-α-alanine was sludied. Resulls showed about the same activation energy between 154 and 118°C as Abelson obtained (~40 kcal compared with 41 kcal) with a factor of ~4 difference tn half-life. Below 118°C, a side reaction apparently occurs which resulls in considerable variations between expertmenial results and the extrapolated values of Abelson (Science, v. 119: 576, 1954). Sludy 2 resulled ln the direct-pile-trradiation production of a wide variety of useful alkyl radioactive compounds. The method used was thal of irradiating nonnitrogenous aliphatic compounds in the presence of amines with the purpose of lagging the aliphatic compound by the $N^{14}(n,p)C^{14}$ reaction. In lhe hol range, any C of the bombarded compound can slop a recoiling C^{14}. Only those producls are formed which can be formed by dtrecl H subslitution. Under study 3, the absolule yields are presenled for Pd, Rh, and Ru lsotopes which resulled from 122-mev negative π-meson bombardment of Ag. The 4.5-hr Ru^{105} was nol observed. Plols of smooth single-reaclion yield curves show the strong preference for the emission of 5 lo 6 neulrons. A comparison is made belween a combination of the resulls for Br research by Sugihara and Libby (Phys. Rev., v. 88: 587, 1952) and for Ag with the heavy slar-prong distribution deduced by Menon, Mulrhead, and Rochat (Phil Mag., v. 41: 583, 1950).

RECURRING DAILY CYCLES OF NUCLEONIC COMPONENT INTENSITY (Abstract), by W. H. Fonger, J. W. Firor, and J. A. Simpson. Nov. 28, 1952 [1]p. [AF 18(600)666] Unclassified

Presented at meeting of the Amer. Phys. Soc., St. Louis, Mo., Nov. 28-29, 1952.

Published in Phys. Rev., v. 89: 891, Feb. 15, 1953.

A variation of neutron tntensity wtth a period of one sotar day was found by averaging data over a pertod of ~65 days. The detectors were tead-paraffin piles containing BF_3 proportional counters to measure the local neutron production from the nucteonic component. Measurements were obtained at geomagnetic latttudes 48°N 0.5°S at an atmospheric depth of 680 g-cm^{-2}. The mean counting rates at 48°N and 0.5°S were 620 and 380 counts per min,respectivety. After pressure correction the averaged cyctes were simitar to stne functions with peak to peak ampttude ~1 percent and wlth maxima near local noon. Ustng the data at 48° N, significant departures from the average cycle were found for individual days. It was also found that these departures persist for intervals of 2-3 days and reoccur. The results are insensitive to choice of barometric coefficient. (Contractor's abstract)

COSMIC RADIATION INTENSITY-TIME VARIATtONS AND THEIR ORIGIN. tt. ENERGY DEtENDENCE OF 27-DAY VARIATIONS, by W. H. Fonger. Mar. 1953, 40p. incl. diagrs. refs. [AF 18(600)666] Unclassified

Also published in Phys Rev., v. 91: 351-361, July 15, 1953.

In this study, cosmic ray intensity-time variations, recorded in the lower atmosphere by 1 neutron detector (D-1, Climax, Colorado) and 3 ionization detectors (Freiburg, Germany; Cheltenham, Marytand; and Huancay Peru) are compared. Irregular intensity variations, characterized by time parameters of 27 days and 24 hr, are shown to occur coincidentally in the records of both types of detectors. Therefore, tt seems reasonabte to ascribe correlated neutron and lontzation intensity variations to a common origin. tt has been shown that 27-day neutron intenstty variations are produced by primary tntensity vartations. The magnitude of these vartations must be greater for low energy prtmartes as 27-day neutron intensity vartations at Climax are ≈5 times targer than correspondtng tonization intenstty variations at Fretburg, Cheltenham, and Huancayo. These vartations must extend, however, to high energy primartes as thetr effects are observed at the geomagnetic equator. From the ≈3.1 relative response (Climax neutron. northern sea level lonization detector) 1 parameter describing the energy dependence of 27-day primary intensity vartations can be evaluated empirically. Assuming a power taw stmttar to that descrtbtng the energy dependence of the time average prtmary intensity spectrum, tt is found that the amplitude of 27-day primary intensity vartations is required to decrease with increasing primary energy approximately 1 power of energy more rapidly than the time average prtmary spectrum itself. The etectric ftetd acceteration process hypothests predtcts primary intensity variations with approximately this energy dependence. 24-hr neutron (Climax) and ionization (Freiburg) intensity variations are corretated in tocal time. It is not certain that these variations are produced by primary intensity variations. Even if this were the case, the retative response (Climax: Freiburg) to such primary intensity variations cannot be determined accurately from the data studied here. (Contractor's abstract)

COSMIC-RAY NEUTRON PRODUCTION IN ELEMENTS AS A FUNCTION OF LATITUDE AND ALTITUDE, by J. A. Simpson and R. H. Uretz. Apr. 1, 1953 [7]p. incl. diagrs. tabtes, refs. (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under [AF t8(600)666]) Unclassified

Published in Phys. Rev., v. 90: 44-50, Apr. 1, t953.

The relattve rates of tocat neutron production in Al, Cu, Sn, and Pb were obtained at geomagnetic lattitudes λ = 40° and 54° at atmospheric depth 312 g-cm^{-2} (30,000 ft pressure altitude). The tatitude and altitude dependence of local neutron production in carbon and lead were measured in the latitude intervat 0° - 54° with pile geometries containing BF_3 proportional counters. From these observattons several resutts were obtained: (1) the relative neutron muttipttcittes in etements were measured and found to be in good agreement with reported low attitude observations; (2) a neutron transition maximum in tead at ~20 g-cm^{-2} Pb was obtained at 23,000 ft pressure attitude; (3) the absorption mean free path for the neutron producing radiation in lead was 350 g-cm^{-2}; (4) an anomatous air absorption mean free path for the nucleonic component has been found for measurements derived from local

CHI. 12:005 - CHI. 12:008

neutron production in lead at $\lambda \gtrsim 40°$; (5) aside from the absorption anomaly in elements of htgh atomtc wetght A, local neutron production in elements of high A as a function of λ is in fair agreement with the free air neutron latitude effect; and (6) local production in carbon as a function of λ and altitude is tn agreement with corresponding free air neutron measurements. PROPERTIES OF THE LOW ENERGY NUCLEONIC COMPONENT AT LARGE ATMOSPHERIC DEPTHS, by J. A. Simpson and W. C. Fagot. [1953] [5]p. incl. diagrs. tables. [AF 18(600)666] Unclassified

Published in Phys. Rev., v. 90: 1068-1072, June 15, 1953.

This is a report on the absorption properties of the cosmic radiation low energy nucleonic component measured by detectors of disintegration product neutrons as the nucleonic cascade develops deep within the atmosphere. The air absorption mean free path L of the star- or neutron-producing radiation was measured as a function of atmospheric depth x (in g-cm^{-2} atmosphere) at the geomagnetic latitudes $\lambda = 0°, 41°, 52°$. $L(x, \lambda)$ was obtained for carbon or free atmosphere and for a lead plus carbon pile geometry. As reported earlier, for small x the absorption mfp, L, is dependent upon λ (L is a function of the average energy of the primary nucleons whtch tntttate the nucleonic chain or cascade. However, it is shown by the present measurements that, for $x > 600$ g-cm^{-2}, $L \rightarrow \sim 140$ g-cm^{-2} independent of latitude λ. The latitude dependence of neutron component intensity was measured at $x = 680$ g-cm^{-2} (11,200 ft) between $\lambda = 0°$ and 58°N. The latitude factor of intenstty increase is 2.55. In view of the independence of $L(x)$ on λ at large atmospheric depths thts latttude effect is nearly constant down to sea level ($x = 1030$). It is shown that at large atmospheric depths neutron production ts observed from primary protons with energies as low as ~1 bev. The specific yield of neutrons at t1,200 ft has been computed by taking into account protons, alpha-particles, and heavter primary nuclei. These measurements resolve discrepancies reported in the ltterature between high altitude measurements and measurements between sea level and mountain altitudes for the low energy nucleonic component. CHANGES IN AMPLITUDE OF THE COSMIC RAY 27-DAY INTENSITY VARIATION WITH SOLAR ACTIVITY, by P. Meyer and J. A. Simpson. [1954] 8p. illus. tables, refs. ([AF OSR-TN-54-198] [AF t8(600)666] Unclassified

Also published in Phys. Rev., v. 96: 1085-t088, Nov. 15, 1954.

Both cosmtc ray neutron and ionization chamber intenstty observations reveal that the amplttude of the 27-day recurring intensity vartation has been changing over an interval of several years. A method of studying thts phenomenon, using tonizatton chamber data for the period 1936-1946 and neutron tntensity data for 1951-53, ts described whtch not only selects preferentially the 27-day vartations, but also selects the variations which are worldwide. The amplitude of the 27-day intenstty variation over these years displays minima and a maxima closely related in time to the minima and maxima of the approximately 11-year cycle in general solar activity. These results, thus, provide additional and independent evidence that solar active regions are responsible for producing the mechanism which controls the 27-day cosmic ray primary intensity variations. COSMIC-RADIATION INTENSITY-TIME VARIATIONS AND THEIR ORIGIN. III. THE ORIGIN OF 27-DAY VARIATIONS, by J. A. Simpson. [1954] [15]p. incl. diagrs. tables, refs. [AF t8(600)666] Unclassified

Published in Phys. Rev., v. 94: 426-440, Apr. t5, 1954.

Expertmental observaltons of variations in cosmic ray intensity measured by means of neutron-intensity monitor piles over a 19-month period (t95t-t952) show a 27-day cycle of vartatton in primary radiation intensity, associated with geomagnetic field disturbances which usually occur about 2 days after the 27-day maxima of cosmic ray intensity. Occasionally radiation intensity changes of ~3-6 percent are not followed by geomagnetic disturbances. These results suggest a

common mechanism producing both cosmic-ray particle acceleration and, indirectly, the geomagnetic disturbances. Investigation of various terrestrial fields whereby the incoming radiation would undergo acceleration or deceleration either before entering the field, within the field, or after passing through it, show that neither these possibilities nor a combined geomagnetic-geoelectric field storm can account for all established experimental facts. The accelerating mechanism is concluded to be probably of nonterrestrial origin. The 27-day cycle corresponds in time to the proper rotation of the solar equatorial latitudes; since active solar regions at these latitudes are associated with the 27-day cosmic-radiation intensity variations, the required accelerating mechanism is probably controlled by solar processes and may be located near the sun.

COSMIC RADIATION INTENSITY-TIME VARIATIONS AND THEIR ORIGIN. IV. INCREASES ASSOCIATED WITH SOLAR FLARES, by J. W. Firor. [1954] [12]p. incl. diagrs. tables, refs. [AF 18(600)666]
Unclassified

Published in Phys. Rev., v. 94: 1017-1028, May 15, 1954.

The distribution on the earth of the impact points for particles of magnetic rigidities 1 to 10 Bv, which originally approach the earth from the direction of the sun, is derived, using principally the published results of numerical integrations of cosmic-ray orbits and model experiments on the motion of charged particles in a dipole magnetic field. Three impact zones for such particles are discussed. Two of these zones include only a small range of local times, and for the special case of the sun in the plane of the geomagnetic equator, are centered near 4 AM and 9 AM. The third zone has no strong local time dependence. Assuming the source of charged particles to subtend a finite angle at the earth, the relative counting rates for detectors in the 3 zones are estimated. The counting rate due to particles from the sun is expected to be 3 to 7 times larger in the morning zones than in the background, or non-local-time-dependent zone. The morning impact zones are shown to have a seasonal motion of several hr in local time. Reports of observations made during 4 large increases of cosmic-ray intensity at the times of solar flares are compared with the distribution predicted for particles from the sun. The observed increases agree with the predicted distribution and counting rate except at very high latitudes on the earth. A possible reason for this discrepancy is suggested. Cosmic-ray data from the Climax, Colorado, neutron detectors are analyzed for possible increases associated with small solar flares. An increase of $\approx 1\%$ is found for flares occurring when the detector is in a morning impact zone for particles from the sun. No increase of more than $\approx 0.3\%$ is found for flares occurring when the detector is not in these zones. The mean daily cycle of cosmic-ray intensity is also shown to depend on the rate of flares occurring on the sun. The intensity curve is peaked during the early morning hr for flare periods relative to periods in which few or no flares occurred, in agreement with the supposition that new particles approach the earth from the direction of the sun at the times of flares. Published in Phys. Rev., v. 94: 1031-1036, May 15, 1954.

Properties of the 24 hr intensity variations which were established by ion chamber and counter telescope measurements at high primary-particle energies have now been extended to the low-energy portion of the primary spectrum by measurements with high-altitude neutron piles at geomagnetic latitudes 0° and 48°. The observations demonstrate that the peak-to-peak amplitude of the 24 hr variation increases with latitude and, hence, is dependent on primary-particle rigidity. The latitude ratio for the peak-to-peak variation is $\sim 1.4 \pm 0.2$, and the amplitude at 48° is of the order 1%. These facts preclude primary neutrons or a general solar dipole field as the origin of this intensity variation. It is shown that although the amplitude of the variation changes from day to day, the amplitudes of the intensity variations of particles at low and at high energy are related. It is further shown that the amplitude on 1 day persists for only the next 1 or 2 days, and that there is not a strong 27-day recurrence tendency. The general features of the changes in peak-to-peak amplitudes of the monthly average 24 hr variations appear in both neutron detectors and in the Freiburg ionization chamber. Arguments based on the experimental observations are presented to exclude meteorological factors, the terrestrial magnetic field variations, and simple geoelectric field accelerations as the origin of the variation. Since it is shown that the particles which produce the 24 hr variation are charged and have their highest intensity near or after noon local time, it does not appear probable that they come from the direction of the sun. Although it is doubtful that this variation is of terrestrial origin, no proof has yet been given that the variation is of extra terrestrial origin. (Contractor's abstract)

CHI. 12:012 - CHI. 12:014

Published in Phys. Rev., v. 94: 1029-1030, May 15, 1954.

A close correlation between solar flares and small cosmic-ray intensity increases has recently been established by the Climax, Colorado, neutron monitor data. The correlation, however, is restricted only to those flares which occur when the station lies within a certain interval of local solar time. This has been explained by supposing that the new cosmic-ray particles approach the earth preferentially along the earth-sun line, before deflection in the terrestrial magnetic field takes place. In the present paper, this evidence is used to establish an upper limit to a possible solar magnetic dipole field. Allowance is made for the fact that the dipole field may be seriously perturbed by local fields near the sun; but on the assumption that the dipole field predominates far from the sun (at distances greater than one-fifth the earth-sun distance), the upper limit on the solar dipole moment is 5×10^{32} gauss-cm^3. PRODUCTION OF COSMIC RADIATION AT THE SUN, by J. W. Firor, J. A. Simpson, and S. B. Treiman. [1954] 17p. incl. illus. (AF 18(600)666)
Unclassified

Published in Phys. Rev., v. 95: 1015-1019, Aug. 15, 1954.

A calculation is made of the average production rate of 4-Bv cosmic-ray particles at the sun. The calculation is based upon the recent experimental evidence that the frequently occurring small solar flares produce temporary increases of neutron intensity in suitably located neutron pile detectors. This production rate, averaged over the 11-yr solar cycle, is somewhat in excess of the absorption rate of 4-Bv particles by bodies in the solar system. If the production at the sun is to account for most of the observed cosmic radiation intensity, a trapping magnetic field is required. Limits on the size of such a trapping volume are estimated by considering the limits of cosmic ray lifetime; the requirement of a high degree of radiation isotropy at the earth is satisfied. The existence of high energy particles in the cosmic radiation imposes the principal difficulty for any solar origin hypothesis. (Contractor's abstract)

RECURRENCE PHENOMENON IN THE 24 HOUR VARIATION OF COSMIC RAY INTENSITY, by R. P. Kane. [Dec. 1, 1954] 25 p. incl. diagrs. table. [AF 18-(600)666] Unclassified

Also published in Phys. Rev., v. 98: 130-135, Apr. 1, 1955.

In this study evidence is presented that the fluctuations in the amplitude of the 24-hr variation of cosmic-ray intensity have a recurrence tendency of 27-28 days. Recurrence tendencies of the same period are known to exist in the mean daily intensity of cosmic rays; however, at present there does not appear to be any unique relationship between the mean daily intensity and the amplitude of the 24-hr variation. Phase relationships with the 27-day recurrence phenomenon in the intensity of geomagnetic disturbances, represented by worldwide K_p indices, have also been studied. In general, it is not possible to identify a phase relationship of all the K_p maxima with either the daily mean cosmic-ray intensity or the amplitude of the 24-hr variation. Nevertheless it seems to be true for particular 27-day sequences of K_p maxima that the daily mean cosmic-ray intensity precede the K_p maxima by about 3 days, whereas the maxima of the amplitude of the 24-hr variation of cosmic-ray intensity coincide with the maxima of K_p values. This latter relation is in agreement with the increase found in the amplitude of the 24-hr variation of cosmic-ray intensity on magnetically disturbed days.

Presented at the International Conference on Cosmic Rays, Guanajuato (Mexico), Sept. 1955.

The distribution of the geomagnetic field extending far from the surface of the earth is investigated by using cosmic ray particles as probes. Since for any longitude the cosmic-ray intensity reaches a minimum at the effective geomagnetic equator of this outer field, a series of determinations of the minimum intensity at several longitudes defines its effective equatorial plane. Measurements using the neutron intensity from the nucleonic component prove that large discrepancies exist between experimental observations and the presently accepted geomagentic coordinates derived from surface magnetic field measurements. It is also found that meson intensity data from the past 20 yr or more may be used to determine minima at other longitudes. The results indicate that the effective geomagnetic equator for cosmic rays is represented by a westward shift of the inclined magnetic dipole of the earth by about 40° - 45°, without requiring an appreciable change in the angle of inclination. Several anomalous results, which have been reported at intermediate and equatorial latitudes for primary α particles and heavy-stripped nuclei detected in photoemulsions, are readily explained by this shift in coordinates, supporting the

view that the discrepancies are worldwide in character. Since the surface magnetic field measurements do not account for this large scale effect, it is suspected that the explanation may be found from the interaction of the rotating and inclined magnetic dipole field with the highly ionized interplanetary medium. The altitude dependence of neutron intensity in the atmosphere had been determined for different mean neutron energies. For neutrons below 0.4 ev the intensity maximum has been obtained by Yuan at a pressure of 83 mm Hg. For energies above 0.4 ev we find the intensity maximum at 50 mm Hg and for energies above ~1 kev at 35 mm Hg. This shift in the position of the maximum is predicted by the slowing down theory of neutrons in the atmosphere. A comparison with work on the altitude dependence of nuclear disintegrations shows a coincidence between the position of the maximum for these processes and that for fast neutrons. ASSOCIATION OF A "UNIPOLAR" MAGNETIC REGION ON THE SUN WITH CHANGES OF PRIMARY COSMIC-RAY INTENSITY, by J. A. Simpson, H. W. Babcock, and H. D. Babcock. [1955] 19p. incl. illus. tables. (In cooperation with Carnegie Inst. of Washington and Calif. Inst. of Tech.) (AF 18(600)666) Unclassified

Published in Phys. Rev., v. 98: 1402-1406, June 1, 1955.

A new instrument for observing weak magnetic fields on the photosphere of the sun has recently revealed the presence of an unusual area on the solar surface which may be called a "unipolar" magnetic (UM) region because the field is of one sign and no magnetic flux has been found returning to the sun. This UM region was observed at central solar meridian on seven consecutive solar rotations in 1953. In the present paper it is shown that there is a striking association of this UM region with: (1) times of maximum primary cosmic ray intensity as measured by neutron detectors and an ionization chamber; and with (2) the recurring geomagnetic storms, the geomagnetic disturbances being most pronounced ~3-4 days after both the central meridian passage of the UM region and the time of maximum cosmic ray intensity. CHANGES IN THE LOW-ENERGY PARTICLE CUTOFF AND PRIMARY SPECTRUM OF COSMIC RADIATION, by P. Meyer and J. A. Simpson. [1955] [7]p. incl. diagrs. [AF 18(600)666] Unclassified

Published in Phys. Rev., v. 99: 1517-1523, Sept. 1, 1955.

The low-rigidity cutoff for particles in the primary cosmic-ray spectrum has decreased within the period 1948 through 1951. This decrease corresponds to a 3° change (northward) in the "knee" position of the geomagnetic latitude curve for the nucleonic component. The phenomenon is accompanied by both a change in the primary spectrum for particle rigidities less than approximately 4 Bv and by an increase in total primary intensity. The spectral change is such that if the differential primary intensity, j, at low rigidities in 1948 was $j = C(p/z)^{-2}$, then the new spectrum for 1951 through 1954 is approximately $j = C'(p/z)^{-2.7}$. The total change of intensity arising from the changes in spectrum and low-rigidity cutoff is more than 13%. The measurements were obtained in 1948 and 1951, and have been confirmed and extended in November 1954 using nucleonic component detectors. The vertical charged particle intensity was also measured and displays changes equivalent to those reported for the

CHI. 12:019 - CHI. 12:022

nucleonic component. Three regions of space are considered for the location of the mechanism producing the low energy cutoff; namely, the vicinity of the earth, the region of the solar system, and regions of the galaxy outside our solar system. Although the general solar dipole moment is at least an order of magnitude too small to account for the observations, it is concluded that the mechanism is operative within the solar system and is not a terrestrial phenomenon. ON DERIVING GEOMAGNETIC DIPOLE FIELD COORDINATES FROM COSMIC RAY OBSERVATIONS, by J. A. Simpson, F. Jory, and M. Pyka. [1956] [24] p. incl. diagrs. refs. [AF 18(600)666] Unclassified

Published in Jour. Geophysical Res., v. 61: 11-22, Mar. 1956.

It is pointed out that the earth's external magnetic field, extending far beyond the ionosphere, is presently inaccessible to direct observation. By measuring the nucleonic component longitude and latitude effects in the region of the geomagnetic equation, however, the coordinates of an equivalent geomagnetic dipole may be determined which represents this external field. The method of measurement and the theory relating cosmic ray intensity changes to the geomagnetic coordinates are outlined for deriving the two angles which determine the orientation of the dipole, and the three coordinates giving the position of the magnetic center with respect to the earth's center. In appendixes, the effect of local magnetic surface anomalies upon the trajectories of cosmic ray particles moving in the magnetic dipole field of the earth are evaluated and the effect of an overhead horizontal, electric-current system in the upper atmosphere (ionosphere) is discussed.

THE INFLUENCE OF GEOMAGNETIC QUADRUPOLE FIELDS UPON COSMIC-RAY INTENSITY, by F. S. Jory. [1956] [7] p. [AF 18(600)666] Unclassified

Published in Phys. Rev., v. 102: 1167-1173, May 15, 1956.

The effect upon cosmic ray particles of the quadrupole part of the earth's magnetic field has been calculated, using the results of the magnetic survey of 1945. The effect predicted from the zonal quadrupole term is a northern shift of the cosmic ray latitude curve. The 1945 magnetic center was calculated, using Schmidt's method, and it is 0.0629 earth radii from the center of the earth, as compared to 0.0536 earth radii in 1922. The shift in magnetic center results in an increase in the predicted longitude effect. The residual or sectorial quadrupole effect upon cosmic-ray intensity is predicted to be a 2-period sine curve in the longitude effect. (Contractor's abstract)

THE SOLAR COSMIC RAYS OF FEBRUARY 1956 AND THEIR PROPAGATION THROUGH INTERPLANETARY SPACE, by P. Meyer, E. N. Parker, and J. A. Simpson. June 1956 [56]p. incl. diagrs. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)666] and AFCRC Geophysics Research Directorate) Unclassified

Also published in Phys. Rev., v. 104: 768-783, Nov. 1, 1956.

The data from 6 neutron intensity monitors distributed over a wide range of geomagnetic latitudes have been used to study the large and temporary increase of cosmic ray intensity which occurred on Feb. 23, 1956, in association with a solar flare. During the period of enhanced intensity a balloon-borne neutron detector measured the absorption mean free path and intensity of the flare particles at high altitudes. From these experiments, the primary particle intensity spectrum as a function of particle rigidity, over the range < 2 to > 15-30 Bv rigidity, has been deduced for different times during the period of enhanced intensity. It is shown that the region between the sun and the earth must be free of magnetic fields greater than $\sim 10^{-6}$ gauss, and that the incoming radiation was practically isotropic for more than 16 hr following maximum flare particle intensity. The decline of particle intensity as a function of time t depends upon the power law $t^{-3/2}$, except for high energy particles and late times, where the time dependence approaches an exponential. The experiments lead to a unique model for the inner solar system which requires a field-free cavity of radius greater than the sun-earth distance enclosed by a continuous barrier region of irregular magnetic fields [B (rms) $\approx 10^{-5}$ gauss] through which the cosmic-ray particles must diffuse to reach interstellar space. This barrier is also invoked to scatter flare particles back into the field-free cavity and to determine the rate of declining intensity observed at the earth. The diffusion mechanism is strongly supported by the fact that the time dependence $t^{-3/2}$ represents a special solution of the diffusion equation under initial and boundary conditions required by experimental evidence. The coefficient of diffusion, the magnitude of the magnetic field regions, the dimensions of the barrier and cavity, and the total kinetic energy of the high-energy solar-injected particles have been estimated for this model. Recent studies of interplanetary space indicate that the model prescribed by the experiments may be established from time to time in the solar system. The extension of the model to the explanation of earlier cosmic ray flare observations appears to be satisfactory. The solar flare event was superposed by chance upon a large but typical intensity decrease of nonsolar cosmic rays which began several days prior to Feb. 23, 1956. Hence, the flare particles have been used as probes to explore the intensity modulation mechanism responsible for this decrease of background cosmic-ray intensity. (Contractor's abstract)

CHI. 12:026 - CHI. 13:002

Published in Canad. Jour. Phys., v. 34: 968-984, Sept. 1956.

Results are presented of cosmic ray measurements taken at sea level during 1954-55 from the Arctic to the Antarctic. The equipment consisted of a neutron monitor and a meson telescope. Latitude effects of 1.77 for the nucleonic component and 1.15 for the meson component were measured. The longitude effect at the equator was much less than expected on the basis of the geomagnetic eccentric dipole, and the longitude effect at intermediate northern latitudes shows that the longitude of the effective eccentric dipole is considerably west of that of the geomagnetic eccentric dipole. In a previous paper by the same authors, the positions of the equatorial minima were combined with other published cosmic ray measurements to calculate a new cosmic ray geomagnetic equator. In this paper new coordinates are derived on the assumption that these equatorial coordinates apply to a new eccentric dipole, and, therefore, that the equatorial coordinates may be extended to high latitudes. When the complete results are plotted on these coordinates, it is found that an eccentric dipole representation of the earth's magnetic field is inconsistent with the combined observations at all latitudes. MODULATION OF PRIMARY COSMIC-RAY INTENSITY, by E. N. Parker. [1956] [16]p. incl. diagrs. refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)666] and AFCRC Geophysics Research Directorate) Unclassified

Published in Phys. Rev., v. 103: 1518-1533, Sept. 1, 1956.

The cosmic-ray particles observed at the earth are assumed to be of galactic origin, except for the occasional bursts from solar flares. With this interpretation the 11-year variation of the cosmic-ray intensity and the Forbush decreases represent depressions of the steady galactic intensity. The observed rigidity dependence of the depression indicates that magnetic fields are responsible. A quantitative investigation of the possible motion and configuration of magnetic fields capable of producing the observed effects is carried out. It is shown that, within the limitations imposed by what we think we know today of the galactic magnetic field, of solar activity, and of interplanetary fields, serious difficulties are encountered by any mechanism, such as Morrison's interplanetary cloud model, modulating the galactic cosmic-ray intensity throughout the solar system. It is proposed that the modulation of the intensity is produced locally, within a few earth's radii, by interplanetary magnetic gas clouds captured by the terrestrial gravitational field. Such a model seems to produce the observed effects on the basis of the known facts about solar activity. The most straightforward test of this geocentric model, independent of inferences from cosmic-ray effects, is the question of whether the absorption of the captured magnetic hydrogen gas can be detected as a narrow line in the center of the broad solar L_α emission line. SELF-DIFFUSION IN SODIUM NEAR THE MELTING POINT, by R. E. Meyer and N. H. Nachtrieb. [1955] [1]p. incl. table. [AF 18(600)1489] Unclassified

Published in Jour. Chem. Phys., v. 23: 405, Feb. 1955.

Self-diffusion coefficients for solid Na, previously reported for the 0°-94.5°C temperature range (Jour. Chem. Phys., v. 20: 1185, 1952) are determined for temperatures to within 0.10°C of the melting point of polycrystalline and single crystal states of the metal. Spectrographic examination of the once-distilled metal revealed 0.05 percent K, 0.001 percent Si, and less than 0.001 percent of Fe, Mg, and Cu. Its melting point was determined to be 97.91 ± 0.06°C by means of a cooling curve taken in vacuum with a chromel-alumel thermocouple calibrated at the steam point and several other standard thermometric points. Cylinders of radioactive and ordinary Na of very coarse grain size (~2 mm diam) were pressure-welded together at liquid nitrogen temperatures and diffusion was allowed to proceed in an oil thermostat which was controlled to ± 0.015°C. The composite cylinder was then sectioned in a microtome and the diffusion coefficient calculated. The results of four runs are tabulated, together with values of D calculated for 94.4° and the melting point from the empirical equation resulting from the earlier study. The newer values are slightly higher, but the agreement is to within the limits of error. Diffusion coefficients for the liquid were measured from 98.0° to 226° by the capillary reservoir technique. The results of these runs may be represented by the equation: $D = 1.10 \times 10^{-3} \exp(-2450/RT)$. The values found just above the melting point, also tabulated, deviate only slightly from the value of 4.06×10^{-7} cm^{2}sec^{-1} calculated for 98.0° by means of this equation. It appears that the transition from the rate of solid state self-diffusion to the rate of liquid state self-diffusion is as discontinuous in Na as the melting process, itself.

SELF-DIFFUSION OF SILVER IN SILVER-PALLADIUM ALLOYS, by N. H. Nachtrieb. Feb. 27, 1956 [17]p. incl. diagrs. table, refs. (AFOSR TN-56-89) (AF 18-(600)1489) AD 82003 Unclassified

Also published in Jour. Chem. Phys., v. 26: 106-109, Jan. 1957.

The self-diffusion of Ag has been studied in alloys

containing 0.00, 1.49, 3.69, 9.87, and 21.84 at-% Pd at 4 temperatures: 715.4°, 799.4°, 861.8°, and 942.0°C. The rate decreases with increasing Pd atom fraction according to the relation: $D_{Ag} = 0.270\, e^{-8.20X}\, e^{-43,700/RT}$. An alternative expression is $D_{Ag} = 0.270\, e^{-17.75T_m/T}$. Within experimental error, the activation energy is independent of Pd content. The rate of self-diffusion of Ag is related to the solidus line of the Ag-Pd phase diagram, and a simple corresponding states explanation is given. (Contractor's abstract)

THE EFFECT OF HIGH PRESSURES ON THE RATES OF ATOM MOVEMENTS IN CRYSTALS, by N. H. Nachtrieb. Apr. 30, 1956 [24]p. incl. diagrs. table. (AFOSR-TN-56-174) (AF 18(600)1489) AD 86594 Unclassified

Presented at Third International Meeting on the Reactivity of Solids, Madrid (Spain), Apr. 3-7, 1956.

Also published in Trans. Third International Conference on the Reactivity of Solids, Madrid (Spain), 1957, p. 545-564.

Also published in its Forty-first Quarterly rept. to sponsors of the Inst. for the Study of Metals, June 1956, p. 137-148; AD 103589.

The significance of diffusion measurements as a function of pressure is considered for the provision of information about the volume of the activated state. The basic assumption is that diffusing atoms pass through a transition state whose existence is sufficiently well defined to have meaningful thermodynamic functions ΔF, ΔH, ΔS, ΔV, etc. Two crystalline solids (Na and P) were studied. Curves are presented which show (1) the effect of pressure on 90°C diffusion profiles for Na for pressures up to 12,000 kg/sq cm^{-2}; (2) the variation of ln D (diffusion coefficient) with pressure for Na at 90°C and for P at 30° and 41.30°C; and (3) $\overline{V}_{act}$ (activated volume) as a function of pressure. Results indicate that the volume of the defect (presumably a moving lattice vacancy) is not greater than half the atomic or molecular volume which implies an inward relaxation of atoms toward a lattice vacancy. Experiments showed no temperature dependence in the enthalpy of activation for self diffusion and a significant variation of ΔH with pressure. The simularity of the ratio of the enthalpies of activation and fusion to the ratio of the volumes of activation and fusion suggests that the fusion mechanism is the same as the self-diffusion mechanism. The proposition is being examined that an atom neighboring a vacancy in a solid must surmount the same activation barrier as in the liquid state.

AN EXPERIMENTAL STUDY OF THE OPTICAL PROPERTIES OF LIQUID HG AND LIQUID GA IN THE WAVELENGTH RANGE OF 0.23μ TO 13μ, by L. G. Schulz. Nov. 30, 1956 [21]p. incl. diagrs. tables, refs. (AFOSR-TN-56-468) (AF 18(600)1489) AD 97352 Unclassified

Also published in Jour. Opt. Soc. Amer., v. 47: 64-69, Jan. 1957.

Modifications were used of methods previously developed for studying the optical properties of solid metals. Reflectivities were measured at an angle of incidence of 45° at glass-metal, quartz-metal and NaCl-metal interfaces in the wavelength range of 0.23μ to 13μ. In a 2nd type of experiment the phase change accompanying reflection at normal incidence at a mica-metal interface was measured in the range 0.4μ to 0.87μ. In this range the measured quantities reflectivity and phase change were used to compute the optical constants n and k. The values thus obtained agreed to within the experimental accuracy with those calculated with the Drude free electron theory. The fact that the experimentally determined reflectivity for the complete range of 0.23μ to 13μ agreed closely with that predicted by the Drude theory strongly suggests that the theory applies throughout this entire wavelength range. (Contractor's abstract)

COMPARISON OF CALCULATED AND EXPERIMENTAL VALUES FOR THE OPTICAL REFLECTIVITY OF THE LIQUID ALLOYS Hg-In, Hg-Tl, Ga-In AT 25°C, by L. G. Schulz. Nov. 30, 1956 [13]p. incl. diagrs. (AFOSR-TN-56-469) (AF 18(600)1489) AD 97353 Unclassified

Also published in Jour. Opt. Soc. Amer., v. 47: 70-72, Jan. 1957.

The alloys (Hg-In), (Hg-Tl) and (Ga-In) are inspected for optical reflectivity in the wavelength range of 0.3μ to 10μ. The results from the alloys with components of different valences can possibly be explained by chemical union in the alloy. The experimental results on reflectivity measurements are insufficient for n or k ($\bar{n} = n - ik$ with $\bar{n}$ the complex index of refraction), but they are adequate for indicating the extent of agreement with the Drude theory. Different valence combinations gave disagreement of experimental and calculated values for the reflectivity. Ga and In combined gave agreement of experiment and theory apparently due to the agreement in valence.

THE EXPERIMENTAL STUDY OF THE OPTICAL PROPERTIES OF METALS AND THE RELATION OF THE RESULTS TO THE DRUDE FREE ELECTRON THEORY, by L. G. Schulz. Nov. 30, 1956 [86]p. incl. diagrs. tables, refs. (AFOSR-TN-56-499) (AF 18(600)1489) AD 110335 Unclassified

Also published in Advances in Phys., v. 6: 102-144, Jan. 1957.

Better experimental values of the index of refraction and the absorption index were sought to find (1) the limits of validity of the free-electron theory of metals proposed by Drude and (2) experimental procedures yielding information of interest to solid state physics. The Drude theory was valid to within the experimental accuracy from $\lambda = 0.4$ to 0.57μ for both liquid Hg and liquid Ga at room temperature (25°C). Reflectivity measurements alone suggest that the theory is valid down to $\lambda = 0.25\mu$. Beyond about 2μ the Drude theory passes into that for the classical skin effect where the number of free electrons is of no significance and only the dc conductivity of the metal determines the optical properties. For $\lambda > 2\mu$, good agreement with theory resulted for solid Ag and Au when the mass (m) of the electron equalled its effective mass (m^*) and for solid Cu when $m^*/m = 1.45$. The liquid Hg-In and Hg-Tl alloys showed no agreement with the Drude theory. The reflectivity of a liquid Ga-In alloy was independent of the composition. Preliminary reflectivity measurements on pure liquid In agreed with the Drude theory to the limits of the experimental accuracy. When 2 liquid metals which follow the Drude theory are combined the resulting alloy does not necessarily follow the theory. Values of m^*/m are tabulated for Ag, Au, Cu, and Al and compared with previous literature values obtained from optical experiments and from electronic specific heat determinations. Agreement is sufficiently close to show that the respective values are concerned with the same quantity.

EVIDENCE FOR VACANCY MECHANISM IN INTERMETALLIC DIFFUSION, by L. Slifkin and C. T. Tomizuka. [1956] [2]p. incl. diagr. (Sponsored jointly by Atomic Energy Commission and [Air Force Office of Scientific Research under AF 18(600)1489]) Unclassified

Published in Phys. Rev., v. 104: 1803 1804, Dec. 15, 1956.

An analysis is made of recent data (Kuper, et al, Phys. Rev., v. 104: 1536 1541, Dec. 15, 1956) of self diffusion in 47-48 atomic % Zn copper-zinc (beta brass) with regard to the ratio (G) of the coefficients of self-diffusion. Atomic movement by a vacancy mechanism involving nearest neighbor jumps would result in equal diffusion coefficients for both species whereas migration of atoms interstitially would not. Comparison of the experimental results and the calculated dependence of G on the long-range order parameter s for beta brass indicate a satisfactory agreement between the experimental and predicted results. The experimental results on the diffusion of antimony in the beta brass, which are explainable in terms of the interstitialcy mechanism, appear to require further experimental confirmation. Investigation of the diffusion of other impurities is also required before definite conclusions can be made as to the behavior of the impurity atoms in the ordered lattice. It is proposed that the experiments on beta brass constitute convincing evidence for the vacancy mechanism.

CONCERNING THE USE OF HIGH ENERGY PARTICLES AND QUANTA IN THE DETERMINATION OF THE STRUCTURE OF LIVING ORGANISMS, by R. J. Moon. [1953] 7p. illus. diagr. (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)566, Public Health Service, and Office of Naval Research under N6ori-02029) Unclassified

Presented at the I. R. E. Convention, New York, Mar. 26, 1953.

The important basic principles for the determination of the structure of living organisms by means of high energy quanta and particles are developed. Primary emphasis is put upon obtaining the information relative to structure of the organisms with a minimum amount of damage to it and a maximization of the amount of information derived. Several instruments are considered with reference to their ability to fulfill these conditions. Systems which employ "thick detectors" and derive their information in serial time sequence seem to fulfill these conditions best. Experimental work, with a scanning x-ray system, which has been performed with regard to these principles is described. (Contractor's abstract)

THE SCANNING X-RAY SYSTEM AS A FLUOROSCOPE AND MICROSCOPE, by R. J. Moon. [1953] 9p. illus. diagrs. (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)566, Public Health Service, and Office of Naval Research under N6ori-02029) Unclassified

Presented at the Seventh International Congress of Radiology, Copenhagen (Denmark), 1953.

The development, characteristics, and use are described of an x-ray scanning system employing single large fluorescent crystal detectors to study

microscopic and macroscopic objects, including living tissue, with minimal distortion. X-ray quanta transmitted from the intense scanning microbeam, are converted by the thick detector into proportional fluorescent light which is converted into electrical impulses by a photomultiplier tube, then amplified and passed through a pulse sorter to produce "color x-ray images" on a kinescope. When quantum yields are low, a memory tube driven by the timing device of the scanning x-ray tube produces a sharp image which is then read out by the kinescope.

A non-iterative numerical method has been found for solving a partial differential equation, when its boundary conditions are not known, on the entirety of a closed boundary. Under such conditions, the iterative numerical methods which are generally used, such as the relaxation technique, are not applicable. As an example, this non-iterative numerical method has been used to calculate the shapes of a pair of beam-forming electrodes for use in an electron gun in which rectilinear flow is desired. The calculated shapes are in almost complete agreement with Pierce's experimental results. Equipotential surfaces calculated by this method have been checked by means of an electrolytic trough which employs a semi-automatic detecting and plotting system. (Contractor's abstract)

THE SCANNING ROENTGEN SYSTEM AS A FLUOROSCOPE AND MICROSCOPE, by R. J. Moon. [1954] [9]p. incl. illus. diagrs. (AF 18(600)566) Unclassified

Also published in Acta Radiologica (Stockholm), Supplementum 116: 479-487, 1954.

The scanning roentgen system has been used for the study of structure of microscopic and macroscopic objects. The resolution of the instrument has been measured. An extrapolation of the results so far achieved indicates that a microscope with 10 to 100 times resolving power of the usual optical microscope may be achieved with sufficiently minute pinholes. If a Patterson B screen is placed between the object and the detector and its brightness photometered while the object is being scanned, and this brightness compared with the photometered brightness of the kinescope screen, the brightness gain is found to be of the order of a million to one. Useful magnifications of several hundred times have been achieved. (Contractor's summary)

In this study, it is pointed out that a very low dissociation energy for F_2 is consistent with the exceptionally large observed reduced interatomic distance and with other empirical properties of F_2. Theoretical reasons for a low value are discussed in terms of MO (molecular orbital) and VB (valence-bond) theory. In MO theory, the fact that antibonding MO's are more powerfully antibonding than bonding MO's are bonding provides a reasonable explanation, in view of the fact that F_2 contains 3 pairs of antibonding as against 4 pairs of bonding electrons. The corresponding explanation in VB theory is that the numerous lone-pair and other nonbonded repulsions largely cancel out the effect of the 1 bonding electron pair. In Cl_2 and higher-row halogens, on the other hand, even rather small amounts of $d\sigma$ and $d\pi$ hybridization should suffice, in MO theory, to strengthen the bonding MO's and to weaken the antibonding MO's very considerably. Thus d hybridization may reasonably account, in spite of the adverse factor of increased inner-shell: outer-shell nonbonded repulsions in VB theory, or "forced hybridization" in MO theory, for the observed relatively much smaller reduced interatomic distance and larger dissociation energy in Cl_2 than in F_2. In VB theory, d hybridization involves a considerable amount of multiple bond character in the Cl-Cl "single" bond, this being absent in F_2. Similar considerations apply to other second-row (e.g., P-P and S-S) and analogous higher row single bonds. In connection with the discussion of Cl_2, it is shown how the use of "unnatural" d orbitals with increased Z values can be legitimate and important in p-d hybridization. (Contractor's abstract)

In this study, the factors which may determine the smaller bond angles in the hydrides of the higher-row fifth-column and sixth-column atoms as compared with NH_3 and H_2O, and the much larger energies required to flatten PH_3 and AsH_3 to planar form than for NH_3, are discussed using LCAO (linear combination of atomic orbitals) molecular-orbital and valence-bond theory. It is shown that the observed differences can reasonably be understood as a result of d hybridization in the e-type or b_2 type bonding molecular orbitals, together, perhaps, with smaller nonbonded repulsions between H atoms, in the higher-row hydrides. Significant factors affecting the bond angles in the halides of fifth-column and sixth-column atoms are also surveyed. (Contractor's abstract)

ELECTRONIC POPULATION ANALYSIS ON LCAO-MO MOLECULAR WAVE FUNCTIONS, by R. S. Mulliken. [1955] [43]p. incl. diagrs. tables, refs. (Rept. no. 4) (Bound with its Technical rept. 1953-1954, Part II, [AFOSR-TN-55-94]; AD 62123) (AF 18(600)471) Unclassifted

Also published in Jour. Chem. Phys., v. 23: 1833-1846; 2338-2346, Oct., Dec. 1955.

In this study, it is pointed out that with the increasing availability of good all-electron LCAO MO (linear combination of atomic orbital-molecular orbital) wave functions for molecules, a systematic procedure for obtaining maximum insight from such data has become desirable. A useful analysis in quantitative form can be made in terms of various breakdowns of the electronic population into partial and total "gross atomic populations," or into partial and total "net atomic populations" together with "overlap populations." Gross atomic populations are so defined as to distribute the electrons almost perfectly among the various AO's (atomic orbitals) of the various atoms in the molecule. From these numbers, a definite figure is obtained for the amount of promotion (e.g., from 2s to 2p) or (what is the same thing) of "gross hybridization," in each atom, and

also for the gross charge Q on each atom if the bonds are polar. The total overlap population for any pair of atoms in a molecule is in general made up of positive and negative contributions. If the total overlap population for 2 atoms is positive, they are bonded; if negative, they are antibonded. The latter situation is described in the language of AO-VB [valence-bond] (generalized Heitler-London) theory, by saying that there is a nonbonded repulsion between them. In LCAO-MO theory, besides gross hybridization, "forced" and "free" hybridization must be distinguished. The former makes negative and the latter positive contributions to overlap populations and covalent resonance energies. The negative contributions from forced hybridization in LCAO theory correspond to various nonbonded repulsions which occur even between bonded atoms in AO-VB theory. Free hybridization in LCAO theory corresponds to ordinary hybridization in AO-VB theory. Its effect can be determined from the gross atomic populations, and expressed as amount of promotion or gross hybridization. Overlap populations give in general more flexible and probably better measures of covalent resonant and bond energies than do bond orders, since they reflect directly the effects of both forced and free hybridization, as well as of conjugation or mesomerism. Bond orders are, essentially, covalent resonance energies expressed in units of LCAO parameters β. Various kinds of bond orders are discussed in the appendix. In general, if all β's are assumed to be proportional to corresponding overlap integrals S times suitable mean atomic ionization energies Ī, a simple approximate formula for covalent resonance energies is obtained in terms of partial overlap populations and Ī's, including 1 or 2 empirical coefficients. This formula indicates that forced hybridization resulting from inner shells should make important negative contributions to bond energies. The application of the formula to H_2, CO, and H_2O is discussed. The assumption of proportionality of β values to SĪ values may also be useful in estimating unknown β values. Tables of gross atomic populations, overlap populations, and gross atomic charges Q computed from SCF (self-consistent-field) LCAO-MO data on CO and H_2O, are given. The degree of s-p promotion or gross isovalent hybridization is found to be nearly the same for the O atom in CO and in H_2O (14% in CO and 15% in H_2O). For the C atom in CO it is 50%. For the N atom in N_2 it is 26% according to calculations by Scherr. In spite of very strong polarity in the π bonds in CO, the σ and π overlap populations are very similar to those in N_2. In CO the total overlap population for the π electrons is about twice that of the σ electrons. The most easily ionized electrons of CO are in a MO such that the gross atomic population is 94% localized on the C atom. These electrons account for the (weak) electron donor properties of CO. A comparison between changes of bond lengths observed on removal of an electron from one or another MO of CO and H_2 and corresponding changes in computed overlap populations shows good correlation. AN SCF LCAO MO STUDY OF N_2, by C. W. Scherr. [1955] [23]p. incl. diagrs. tables, refs. (Bound with its Technical rept. 1953-1954, Part II; [AFOSR-TN-55-94]; AD 62123) (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)-471, and Office of Naval Research under N6ori-20, T. O. 9) Unclassified

Also published in Jour. Chem. Phys., v. 23: 569-578, Mar. 1955.

The self-consistent-field molecular orbital (SCF MO) method in the LCAO (linear combination of atomic orbitals) approximation is applied to the ground-state configuration of the N_2 molecule at the observed equilibrium internuclear separation. No other approximations are used. All electrons are included. The forms of the resulting molecular orbitals are discussed. The s-p hybridization is computed to be 26.1% in agreement with Mulliken's Magic Formula estimation of 21%. The quadrupole moment is computed to be -1.87 atomic units (experiment, 1.11 atomic units of undetermined sign). The ratio of the computed to the experimental total molecular energy is found to be .9905. Ionization potentials and single-electron excitation energies are computed, and compared with experimental spectroscopic values. The spectral results are more encouraging than have been hitherto reported from calculations by the LCAO MO method. The approximation of neglecting the inner-outer-shell mixing, as it has usually been done in computations of this type, changes the present results and is not recommended. (Contractor's abstract)

A STUDY OF SELECTIVE OXIDATIVE CLEAVAGE OF OLEFINIC BONDS, by W. Soller, C. E. Frank and others. Final rept. Oct. 1, 1954, 22p. incl. tables, refs. [AFOSR-TR-55-2] (AF 18(600)351) Unclassified

Research was conducted to define conditions such that oxidative attack by atmospheric oxygen would occur at the double bond. Cyclohexene was employed as a model compound in the hope of achieving the following transformation: $CH_2CH_2CH_2CH_2CH = CH \longrightarrow$

$$HOOCCH_2CH_2CH_2CH_2COOH.$$

In the first series of experiments, homogeneous free radical conditions were employed. A stream of air was passed through a solution of the hydrocarbon in the presence of free radical initiators, ultraviolet light, and transition metal catalysts. When the reaction was conducted in the presence of CH_3COOH-$(CH_3CO)_2O$, it was possible to isolate 3-cyclohexenol acetate and 1,2-cyclohexanediol diacetate. Neither adipic acid nor its ester could be isolated. The original objective was abandoned, and attempts were made to devise alternate processes of producing dibasic acids. Preliminary studies with undecylenic acid, utilizing an alkaline fusion technique, gave pelargonic acid under extreme conditions. The only identifiable products were 3-cyclohexenol acetate, and 1,2-cyclohexanediol diacetate. Adipic acid could not be found in the undistillable residue.

DIELECTRIC DISPERSION IN VISCOUS POLAR LIQUIDS (Abstract), by J. W. Winslow, R. J. Good, and P. E. Berghausen. [Dec. 17, 1956] [4]p. incl. diagrs. tables, refs. (AFOSR-TN-56-290) (AF 18-(600)1318) AD 90001 Unclassified

Presented at the National Research Council Conference on Electrical Insulation, Schenectady, N. Y., Oct. 8-10, 1956.

Also published in Jour. Chem. Phys., v. 27: 309-312, July 1957.

The low-frequency dielectric dispersion of tolyl xylyl sulfone, pentachlorobiphenyl and hexachlorobiphenyl follow the Davidson-Cole equation for "skewed arc":

$$\varepsilon^* = \varepsilon_\infty + \frac{\varepsilon_0 - \varepsilon_\infty}{(1 + i\omega\tau_0)^\beta}$$

rather than the Cole-Cole equation for "semicircular arc with depressed center." β lay in the range 0.50-0.65. This behavior (with β in the range 0.50-0.65) had previously been observed only for glycerol and propylene glycol. On dilution with o-terphenyl, obedience to equation with low values of β was maintained rather than the expected approach of β to unity ("Debye behavior"). It is concluded that departure from "Debye behavior" is not directly related to chemical structure or to the effect of dipoles on the internal field. (Contractor's abstract)

QUESTIONS OF SIGNS IN POWER SERIES, by W. B. Jurkat. Sept. 30, 1953, 12p. (AF 18(600)691) Unclassified

Published in Proc. Amer. Math. Soc., v. 5: 964-970, Dec. 1954.

This paper deals with the signs of the (real) coefficients of a power series $k(x) = \sum_{\nu=0}^{\infty} k_\nu x^\nu$, which is the quotient of the two power series $q(x) = \sum_{\nu=0}^{\infty} q_\nu x^\nu$ and $p(x) = \sum_{\nu=0}^{\infty} p_\nu x^\nu$. Questions of this type have been previously treated by Kaluza (1928) and Szegö (1926) in the special case of $q(x) = 1$. By consideration of a general power series $q(x)$ instead of $q(x) = 1$, it is possible to include the known results of this subject in a single theorem. Moreover the method of proof used allows us to establish a second type of theorem using simpler conditions. For this second type of theorem the introduction of a general $g(x)$ is essential for applications, because the results are still trivial for $g(x) = 1$. There are two different principles to generalize. Thereby the second kind of theorem becomes also applicable in the case of $q(x) = 1$. The statements now obtained can even be used

conversely for a second proof of the theorems first obtained. The results of this paper are fundamentally for application to inclusion of Nörlund means and related questions. (Contractor's abstract, modified)

ON RELATIONSHIPS BETWEEN NÖRLUND MEANS FOR DOUBLE SERIES, by C. N. Moore. [1954] [7]p. (AFOSR-TN-54-1) (AF 18(600)691) AD 36739 Unclassified

Also published in Proc. Amer. Math. Soc., v. 5: 957-963, Dec. 1954.

Certain theorems concerning relationships between Nörlund means for single series are generalized to double series. If p_{ij}, q_{ij} are two infinite sequences of non-negative numbers, the author writes

$$P_{mn} = \sum_{i=0,\ j=0}^{m,\ n} p_{ij}, \qquad Q_{mn} = \sum_{i=0,\ j=0}^{m,\ n} q_{ij},$$

$$N_{mn}^{(p)}(s) = \sum_{i=0,\ j=0}^{m,\ n} p_{m-i,\,n-j} s_{ij} / P_{mn}$$

(and p, P replaced by q, Q), where the s_{ij} are the partial sums of a double series $\sum u_{ij}$, which remain bounded for all (i, j). Necessary and sufficient conditions for the regularity of Nörlund means for such double series have been given by the author in his book (Summable Series and Convergence Factors. Amer. Math. Soc. Colloq. Publ., v. 22, New York, 1938, Ch. II, Th. II). It is now shown that any two regular Nörlund methods for summing double series where each row and each column furnishes a regular method for simple series are consistent. Next, if (N, p_{mn}) and (N, q_{mn}) are two such regular Nörlund methods, necessary and sufficient conditions are found in order that (N, q_{mn}) should include (N, p_{mn}). Finally, necessary and sufficient conditions are obtained in order that (N, p_{mn}) and (N, q_{mn}) should be equivalent (mutually consistent). (Math. Rev. abstract)

FUNCTIONAL NÖRLUND METHODS, I, by K. Knopp and B. Vanderburg. Mar. 1954, 45p. (Rept. no. 6) ([AF]OSR-TN-54-68) (AF 18(600)691) AD 29030 Unclassified

Also published in Rend. Circ. Mat. Palermo, v. 4: 5-32, 1955.

The treatment of R. Kuttner (Proc. London Math. Soc., v. 47: 142-173, Feb. 1941) of the Nörlund methods for the summability of series or the limitability of sequences is extended to a consideration of integrals and functions. Special inclusion theorems are proved, and proofs are presented for the functional case of the analogs to the theorem of M. Riesz for series (Proc. London Math. Soc., v. 22: 412-419, Feb. 1924). Necessary and sufficient conditions are given for the inclusion $N_p \subseteq N_q$ and the equivalence $N_p \sim N_q$; N_p and N_q denote different Nörlund methods. The proofs contain weaker hypotheses than those of Kuttner and remain in the real domain.

FUNCTIONAL NÖRLUND METHODS, II, by K. Knopp. Apr. 1954, 21p. (Rept. no. 7) ([AF]OSR-TN-54-100) (AF 18(600)691) AD 32359 Unclassified

Two general theorems are proved about integral transformations $\sigma(x) = \int_0^{\infty} a(x, t)s(t)dt$ with sufficient conditions given to transform a function s(t) of bounded variation into a function $\sigma(x)$ of the same kind or into a convergent function. Based on these theorems, 2 theorems on absolute inclusion and 3 theorems on multiplication are given; the latter are analogs of certain theorems proved by F. M. Mears for series. The 3 theorems correspond to known theorems on series by Cesaro, Belinfante, and Mertens. (ASTIA abstract)

AN EXTENSION PROBLEM FOR FUNCTIONS WITH MONOTONIC DERIVATIVE, by W. B. Jurkat. May 1954, 14p. (Rept. no. 8) ([AF]OSR-TN-54-118) (AF 18(600)691) AD 32470 Unclassified

The problem is to find a function f(x), that is the n^{th} integral of a nondecreasing function for all $x(-\infty < x < \infty)$, with the property $f(x) = F(x)$ for all large positive x and $f(x) = 0$ for all large negative x. F(x) is the n^{th} integral of a positive nondecreasing function for all large positive x. A complete solution is given by means of the theory of moment problems, and for a large class of functions F(x) the problem can easily be settled.

ON CONVERGENCE FIELDS OF NÖRLUND MEANS, by A. Peyerimhoff. June 1954, 15p. (Rept. no. 9) ([AF]OSR-TN-54-136) (AF 18(600)691) AD 35483 Unclassified

CIN. 03:007 - COL. 01:001

Also published in Proc. Amer. Math. Soc., v. 7: 335-347, June 1956.

Given a function $p(z) = \sum P_n z^n$, regular for $|z|<1$, and corresponding to a Nörlund mean, the convergence fields of $p(z)$ and $\zeta(z);(z)$, where $\zeta(z)$ is a polynomial, are compared. The following result is obtained. If $p_n = O(P_n)$ $(P_n = \sum_{v=0}^{n} p_v)$, and if $\zeta(z) \neq 0$ for $|z| = 0$, the convergence field corresponding to $\zeta(z)p(z)$ is obtained by adding the sequences of the convergence fields corresponding to $p(z)$ and $\zeta(z)$. A similar result is obtained for absolute Nörlund summability. The convergence fields of some Cesàro and discontinuous Riesz means are compared.

THE CONSISTENCY OF NÖRLUND AND HAUSDORFF METHODS (SOLUTION OF A PROBLEM OF E. ELIRICH), by W. B. Jurat and A. Peyerimhoff. June 1954, 11p. (Rept. no. 11) ([AF]OSR-TN-54-145) (AF 18(600)691) AD 75436 Unclassified

Also published in Ann. Math., v. 62: 498-503, Nov. 1955.

Two summability methods are said to be consistent if they cannot sum the same series to different sums. It is well-known that all regular Hausdorff methods are consistent, as well as all regular (real) Nörlund methods. It is the problem of E. Ullrich whether these two classes of methods together are consistent. The paper gives an affirmative answer to this question, and the corresponding question for functional methods. In the course of our proof we obtain a result concerning the analytic extension by Hausdorff methods which is interesting in itself. A special case of this result was previously obtained by Agnew. (Contractor's abstract)

ON THE PROOF OF THE MAIN TAUBERIAN THEOREM FOR THE C_k- AND H_k- METHODS, by K. Knopp. [1954] 4p. (AF 18(600)691) AD 35966 Unclassified

Also published in Proc. Amer. Math. Soc., v. 5: 571-573, Aug. 1954.

An inductive proof is given of the following theorem: if the a_v are real, $k>0$, and (1) $\sum_0^\infty a_v = s\ (C_k)$ (2) $va_v \leq M$, $(v = 0, 1, 2, \ldots)$, where M is independent of v, then (3) $\sum a_v = s$. The theorem for $k = 1$, the fundamental Hardy-Landau theorem (Hardy, G. H., Divergent Series, p. 145, Oxford, 1949), is assumed to be true. The theorem is first proved for the H_k-method, and then proved again more directly with the aid of the fact that C_k implies $C_1 C_{k-1}$. The following result is also given: Let (B) $a_n = \sum_v b_{nv} a_v$, $(n = 0, 1, 2, \ldots)$, be a series-to-series transform of the series $\sum a_v$ into the series $\sum a_n$. Let (4) $a_v = 0(c_v)$ be a Tauberian condition for the summation method B. Then condition 4 is also a Tauberian condition for the method $B \cdot B = B^2$ and therefore for all iterated methods $B^k = B \cdot B^{k-1}$, $(k = 2, 3, \ldots)$, if $\sum |b_{nv} c_v| = 0(c_n)$. If B is regular and 4 is a best Tauberian condition for the method B, then it is also a best condition for the method B^k. This theorem, and the last addition to it, are true for a 1-sided Tauberian condition $a_v = 0_R(c_v)$ for real a_v if the b_{nv} are ≥ 0 and $\sum_v b_{nv} c_v = 0_R(c_n)$.

SOME DERIVATIVES OF 2-AMINO-3-BROMOTETRAHYDROPYRAN, by E. F. Godefroi, J. S. Meek, and J. R. Clopton. Nov. 20, 1954 [2]p. [AF 18(600)648] Unclassified

Published in Jour. Amer. Chem. Soc., v. 76: 5788-5789, Nov. 20, 1954.

During the course of investigation of the preparation of nucleotide-like compounds a number of derivatives of 2-amino-3-hromotetrahydropyran were prepared. Dihydropyran was quantitatively converted to 2, 3-dibromotetrahydropyran (I). Treatment of I with silver cyanate resulted in a 92% yield of 3-bromo-2-tetrahydropyranyl isocyanate (II). The action of aqueous ammonia on II gave the corresponding urea (III); the disubstituted urea, 1, 2, bis-(3-bromo-2-tetrahydropyranyl)-urea (IV), could be obtained by the hydrolysis of II, whereas the reaction of II with absolute ethyl alcohol afforded the urethan (V). Furthermore,

when II reacted with ethyl glycinate, ethyl-3-bromo-2-tetrahydropyranylhydantoate (VI) was obtained. The reaction of 2,3-dibromotetrahydropyran with silver thiocyanate gave upon distillation the thiocyanate (VII). The reaction of 2,3-dibromotetrahydropyran and o-bromoaniline gave N-(3-bromo-2-tetrahydropyranyl)-o-bromoaniline (VIII), in good yield. (Contractor's abstract, modified)

THE OXIMES OF 9-ANTHRALDEHYDE, by J. S. Meek and J. R. Dann. Dec. 20, 1955 [2]p. [AF 18(600)-648] Unclassified

Published in Jour. Amer. Chem. Soc., v. 76: 6677-6678, Dec. 20, 1955.

$NH_2OH.HCl$ (I) (7 g) and 15 g 9-anthraldehyde (II) gave 15.5 g syn-9-anthraldoxime (III), long yellow needles, mp 165-6° (from EtOH). II (5 g) and 5 g I in 25 cc pyridine and 25 cc absolute EtOH heated 1.5 hr on the steam bath, the pyridine and EtOH removed during 4 hr on the steam bath under an air jet, and the solid residue ground with 25 cc H_2O, filtered, and washed with 10 cc. H_2O gave 5.2 g anti-9-anthraldoxime (IV), mp 218-20° (from EtOH). IV (2 g) heated on the steam bath 0.5 hr in 50 cc 5% aq NaOH was dissolved only to a trace amount. III. (0.200 g) in 10 cc. EtOH containing 2 drops concentrated HCl heated 17 hr at 75° and cooled gave 0.150 g IV, mp 218-20°. III and IV (0.22 g each) warmed 10 min on the steam bath in 2 cc Ac_2O, and solution basified with 2 g Na_2CO_3 in 10 cc H_2O, and filtered gave from III the acetate, mp 132-3°, which refluxed 15 min with Ac_2O gave 9-cyanoanthracene (V); IV gave V, mp 173-4°, directly. CH_2:$CHCH_2Cl$ (0.5 cc) and 0.2 g NaOH in 2 cc H_2O and 10 cc EtOH heated to 80° with 1.1 g III, cooled, treated with an additional 0.5 cc CH_2:$CHCH_2Cl$, heated again to 70°, cooled, and diluted with 25 cc H_2O gave 0.4 g o-allyl-syn-9-anthraldoxime (VI), mp 85-6°, and a low-melting, polymeric material. VI (0.1 g) heated 10 min at 200° was converted partially to an oil, 0.04 g was recovered unchanged. IV (1.1 g), 2 cc CH_2:$CHCH_2Cl$, and 0.2 g NaOH in 2 cc H_2O and 50 cc. EtOH refluxed 20 min and diluted hot with 10 cc H_2O gave 0.90 g crude solid which crystallized gave 0.55 g V. III heated with CH_2:$CHCH_2OH$, CH_2:$CHCO_2H$ in aq NaOH, CH_2:$CHCH_2Cl$, CH_2:$CHCOCl$, and refluxed with CH_2:$CHCONH_2$ in zylene gave little evidence of adduct formation. III (1.1 g) in 10 cc 5% aq NaOH and 6 cc. CH_2:$CHCH_2OH$ refluxed 21 hr gave 1.1 g V, mp 175-6° cc. Either III or IV, treated with CH_2:$CHCOCl$, gave V. (C. A., 1956:9362a)

THE SYNTHESIS OF β-CYCLOPROPYL-α-AMINOPROPIONIC ACID, by J. S. Meek and J. W. Rowe. Dec. 20, 1955 [2]p. [AF 18(600)648] Unclassified

Published in Jour. Amer. Chem. Soc., v. 76: 6675-6677, Dec. 20, 1955.

Cyclopropylcarbinol (72g) in 300 cc dry Et_2O treated with cooling with dry ice-Me_2CO and stirring slowly with 35 cc PBr_3, the mixture warmed to room temperature, diluted with 10 cc H_2O, and the Et_2O layer worked up gave 357 g cyclopropylcarbinyl bromide (I), b_{627} 101.5-102°, $d_{26.5}$ 1.433. $OHCNHCH(CO_2Et)_2$ (II) (101.5 g) refluxed 5-10 min with 11.5 g Na in 500 cc. Absolute EtOH, treated with 70.2 g I, refluxed 20 hr filtered, and worked up gave 68.2 g. Et cyclopropylcarbinylformamidomalonate (III), white crystals, mp 65-6° (from 30% EtOH). CH_2:$CHCH_2$ CH_2OH (from CH_2:$CHCH_2Cl$ with Mg and paraformaldehyde) treated with PBr3 gave CH_2:$CHCH_2CH_2Br$ (IV), b_{610} 91-2° n_D^{20} 1.4607. IV (9.5 g) condensed with II yielded 10.8 g CH_2:$CHCH_2CH_2C(NHCHO)(CO_2Et)_2$ (V), mp 94-4.5° (from aqueous EtOH). V in EtOH). V in EtOH hydrogenated under ambient conditions over a catalyst yielded $OHCNHCBu(CO_2Et)_2$, mp 82.5-83°. III (25.7 g) refluxed 8 hr with 250 cc 10% HBr and evaported to dryness in vacuo on the water bath, the residual solid dissolved in 500 cc H_2O and passed through Duolite A-2 anion exchange resin, and the eluate worked up gave 6.5 g. β-cyclopropyl-α-aminopropionic acid hemihydrate (VI), mp 227° (decomposition) (from EtOH), white solid with a sweetish taste; recrystallized from EtOH mp 239° (decomposition) (Cor.). VI heated with phthalic anhydride gave the phthaloyl derivative, mp 140.5-41° (from 50% EtOH). III (25.7 g) refluxed 6 hr with 250 cc 15% aqueous KOH, diluted with one l H_2O, run through Duolite C-10, and evaporated in vacuo gave 14 g cyclopropylcarbinylaminomalonic actd (VII), decomposing with gas evolution at 210°. VII gave a weak ninhydrin test. VII refluxed with 10% HBr gave with CO_2 evolution VI (purified with Duolite A-2). VI was a potent antagonist to Escherichia coli A.T.C.C. 9723. (C.A., 1956:930tt)

In this study, the heats of hydrogenation of $CF_2=CFCl$, $CF=CH_2$, and $CF_2=CCl_2$ were obtained using a low temperature calorimeter whose accuracy had been determined hy measuring the known heat of formation of gaseous HCl over 5% Pd on C catalyst. A summary is presented of the preparation of the various fluorinated organic compounds used. In addition, the physical properties and IR spectra of the reactants, and their products are reported. The heats of hydrogenation are presented in tables.

NEW ANALYTICAL METHOD FOR CALORIMETRIC STUDY OF HYDROGENATION OF SOME FLUORO-ORGANIC COMPOUNDS, by J. R. Lacher, A. Kianpour, and J. D. Park. Oct. 1, 1955 [6]p. incl. diagr. (Technical note no. 3) ([AF]OSR-TN-55-442) (AF 18(600)1151) AD 82074 Unclassified

The weighing method for measuring the rate of hydrogenation of halogen-free olefins was unsatisfactory: the term halogen is applied only to Cl, Br, and I in this study. An analytical method was developed which uses H as an unlimited reactant with a constant rate flow throughout the run with the olefin as the limiting reactant. The method involves passing H at a constant rate through the reaction chamber of the calorimeter containing 5% Pd on a C catalyst into a trap containing activated C; the H reacts with an excess of Cl in a Monel catalyst chamber containing 3% Pd on asbestos. The products, HCl and excess Cl, are washed by cold H_2O in a scrubbing tower and are collected in a beaker containing 3 M cold KI solution. The free I and HCl are analyzed by means of known-normality $Na_2S_2O_3$ and KOH solution. The H passing through the calorimeter is determined and part of it reacts in the reacting chamber of the calorimeter. The product and excess H enter a trap containing activated charcoal. All of the products are assumed to be adsorbed on the surface of the charcoal. The excess H enters the second catalyst chamber and reacts with an excess of Cl, and a determination of the quantity of HCl yields the amount of H consumed in the reaction.

PREPARATION AND PROPERTIES OF THE ISOMERS OF 1,2-DIFLUORO-1,2-DICHLOROETHYLENE, by J. R. Lacher, R. Sullivan, and J. D. Park. [1956] 6p. incl. diagrs. table. [Technical note no. 4] (AFOSR-TN-56-107) (AF 18(600)1151) AD 82501 Unclassified

The separation of the cis and trans isomers of 1,2-difluoro-1,2-dichloroethylene was first attempted by Locke, Brode, and Henne (Jour. Am. Chem. Soc., v. 56: 1726, 1934). No attempt was made to determine the purity of the resulting fractions. The lower boiling isomer was assigned the cis configuration, apparently because it showed the lower melting point. The freezing points are -105.5° and -128.7°C for the cis and trans isomers, respectively. The boiling points are 14.5° for the cis isomer, and 16.5°C for the trans isomer at 630 mm pressure. The object of the present research program was to separate the cis and trans isomers of CFCl-CFCl by means of fractional distillation, to determine their purity by means of time-temperature freezing point curves, to study their magnetic susceptibilities, and by means of the infrared spectra to make a positive assignment of configuration. REACTION CALORIMETRY: THE HYDROGENATION OF ORGANIC FLUORIDES AND CHLORIDES, by J. R. Lacher, A. Kianpour and others. [Mar. 1956] [19]p. incl. diagrs. tables, refs. [Technical note no. 5] [AFOSR-TN-56-128] (AF 18(600)1151) AD 86005 Unclassified

Also published in Trans. Faraday Soc., v. 52: 1500-1508, Nov. 1956.

Calorimeters are described which permit direct measurement of the heats of vapor phase reactions. They operate in an isothermal fashion by having the reaction heat transferred to a surrounding volatile liquid which is simultaneously being cooled by bubbling an inert gas through it. A steady state is obtained when this cooling just balances the heat produced by the reaction. In order to be useful, a reaction must take place

practically quantitatively in the catalyst chamber. Using a Pd-on-C catalyst, the hydrogenation of the following compounds was studied:
CH_3Cl, C_2H_5Cl, C_2H_3Cl, CH_3F, C_2H_5F, n-C_3H_7F, iso-C_3H_7F, $CF_2{=}CF_2$, $CF_2{=}CFCl$, $CF_2{=}CCl_2$, $CF_2{=}CH_2$, $CF_2{=}CHCl$, $CF_2{-}CF_2{-}CF{=}CF$, CF_2Cl_2, $CF_2Cl{-}CF_2Cl$, and $CF_2Cl{-}CFCl_2$. It was found that:

(1) the lower members of an homologous series were more difficult to hydrogenate than the members of higher molecular weight; (2) F is more difficult to replace by H than Cl-; and (3) in an ethylenic compound, the Cl is first substituted by H and then saturation of the double bond takes place. Thermochemical data on the heats of hydrogenation of the following compounds are given: CH_3Cl, C_2H_5Cl, C_2H_3Cl, n-C_3H_7F, iso-C_3H_7F, $CF_2{=}CFCl$, $CF_2{=}CHCl$, and $CF_2{=}CCl_2$. ON DISCRIMINANTS OF BINARY QUADRATIC FORMS WITH A SINGLE CLASS IN EACH GENUS, by S. Chowla and W. E. Briggs. Jan. 1954 [12]p. (Rept. no. C-1) ([AF]OSR-TN-54-15) (AF 18(600)758) AD 35964 Unclassified

Also published in Canad. Jour. Math., v. 6: 463-470, 1954.

Consideration is given binary quadratic forms $ax^2 + bxy + cy^2 = 0$ with discriminant $d = b^2 - 4ac < 0$, letting $\Delta = -d$. Use is made of the L-series $L_k(s) = \sum_1^\infty x(n)n^{-s}$, where throughout $x(n)$ is real non-principal character modulo k and $R(s) > 0$, to prove that (1) with the assumption that $L_k(53/54) \geq 0$ for $k > 10^{14}$, there are no discriminants with a single class in each genus for $\Delta > 10^{14}$; and (2) without this assumption, there is at most 1 fundamental discriminant with a single class in each genus with $\Delta > 10^{60}$.

ON A THEOREM OF S. BERNSTEIN, by N. C. Ankeny and T. J. Rivlin. Sept. 1954, 5p. (Repl. no. C-5) (In cooperation with Johns Hopkins U., Baltimore, Md.) ([AF]OSR-TN-54-184) (AF 18(600)758) AD 82067 Unclassified

The following result is stated. If $p(z)$ is a polynomial of degree n such that $[\max|p(z)|, |z| = 1] = 1$, and $p(z)$ has no zero within the unit circle, then

$[\max|p(z)|, |z| = R>1] \leq \frac{1+R^n}{2}$ with equality only for

$p(z) = \frac{\lambda + z^n}{2}$, where $|\lambda| = 1$. The converse is false,

but the following result is proved. If $p(z)$ is a polynominal of degree n such that

$p(1) = [\max|p(z)|, |z| = 1] = 1$ and

$[\max|p(z)|, |z| = R>1] \leq \frac{1+R^n}{2}$ for $0<R-1<\delta$,

where δ is any positive number, then $p(z)$ does not have all its roots within the unit circle.

EQUATIONS IN FINITE FIELDS, by N. C. Ankeny. Sept. 1954, 2p. (Repl. no. C-6) ([AF]OSR-TN-54-189) (AF 18(600)758) AD 82068 Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 40: 1072-1073, 1954.

The paper is concerned with the equation

(*) $a_0x_0^{m_0} + a_1x_1^{m_1} + \ldots + a_rx_r^{m_r} = 0$

in the finite field GF(p), where the a_j are different from zero and $m_j | (p-1)$. I. If $N(p)$ denotes the number of solutions of (*) then $N(p) = p^r + A\theta_p p^{(r+1)/2}$, where the constant A depends only on the m_j's, $|\theta_p| < 1$ for all p and $\limsup |\theta_p| = 1$. Moreover, $|\theta_p|$ is everwhere dense in the unit interval. II. Let m = l.c.m. of m_0, m_1, ..., m_r, and let

$$(a_j|p)_{m_j} = \exp\left\{(2\pi i/m)l_j\right\},$$

where the l_j are fixed integers and $(a/p)_{m_j}$ denotes the number of solutions of (*) subject to these conditions. Then $N'(p) = p^r + A'\theta_p p^{r/2}$, where A' is a constant depending only on the l_j's, $|\theta_p| < 1$ for all p and $\limsup |\theta_p| = 1$. The proofs of these theorems are not given. Colorado U. [Dept. of Mathematics] Boulder.

A NOTE ON THE NUMBER OF LATTICE POINTS IN A REGION BOUNDED BY HYPER-PLANES, by S. Chowla and W. E. Mientka. Jan. 1955, 3p. (Rept. no. C-8) ([AF]OSR-TN-55-30) (AF 18(600)758) AD 100908 Unclassified

An extension is given of a result of G. H. Hardy (Ramanujan, Cambridge University Press, 1940) which gives the number of lattice points in a triangle bounded by the lines $X_1 = 0$, $X_2 = 0$, $aX_1 + bX_2 = \eta$, where a and b are coprime integers. The extension is an expression for the number of lattice points bounded by the hyperplanes $X_1 = 0$, $X_2 = 0$, ..., $X_n = 0$, $a_1X_1 + a_2X_2 + \ldots + a_nX_n = \eta$, where the a_i, $1 \leq i \leq n$, are integers and coprime in pairs. By defining $A = \prod_{i=1}^{n} A_i$ and $W = \frac{\eta}{A}$, the formula can be expressed as

$N_n^*(\eta) = B_n W^n + B_{n-1}W^{n-1} + \ldots + B_1W + B_0$, where the B_i are polynomials in the a_i $(1 \leq i \leq n)$, and B_0, given by an infinite series, is a function of η and the a_i with period A in η and is bounded as $\eta \to \infty$. (ASTIA abstract)

SEPARATION OF ISOTOPES BY ELECTROLYSIS, by F. A. Rohrman, J. H. Andrews and others. Yearly rept. [1953] 1v. incl. illus. diagrs. table. (AF 18-(600)440) AD 37533 Unclassified

Investigations were undertaken to determine the feasibility of elecirolytic isotope separation for isotopes other than H. Aqueous solutions of various plateable elements were used. A portion of the material in the solution was plated onto a cathode, and this material was checked to see if the isotopic abundance ratios were changed during the plating process. Such a change would indicate a partial separation of the isotopes. Three plating baths were prepared with Ni solutions containing no radioactive tracer. The first bath conlained $NiSO_4 \cdot 6H_2O$, $NiCl_2 \cdot 6H_2O$, H_3BO_3, and H_2O. After a small portion of the Ni was removed, the bath became acid, making it difficult to obtain a satisfactory plate. The second bath contained $NiSO_4 \cdot 6H_2O$, H_3BO_3, and H_2O, while the third bath contained $NiCl_2 \cdot 6H_2O$. and H_2O. Baths containing the latter and a radioactive tracer solution are being investigated. Pt electrodes were used in the initial experiments on plating technique. Since the Ni would not adhere well to the Pt sheets, the Pt was used for the anode only. Cu planchets 0.010 in. thick were used as cathodes. The Pt electrodes were made of 0.001-in. foil with a Cu planchet for backing to give it mechanical strength. A description is given of the apparatus for counting Ni^{63} β-rays. Sample preparation and the mechanical problems in counting are discussed extensively.

SEPARATION OF ISOTOPES BY ELECTROLYSIS, by F. A. Rohrman, W. J. Utlaut, and I. Ceresna. Final technical rept. Sept. 13, 1954 [13]p. incl. diagrs. [AFOSR-TR-54-27] (AF[18](600)440) AD 43734 Unclassified

A standard Q-gas counter, model 165, was employed for β counting. The leakage of gas around the irrigation area was stabilized through the installation of a special clamp on the Geiger boitom plate. This modification made the readings more uniform. Attempts at separating any of the isotopes of U were unsuccessful. Continued research on Ni-Ni^{63} electrolysis and plating tesis showed by counting techniques thai some separation of the isotopes was being effected. The condition which seemed to favor the separation of the heavier isotopes of Ni was a low current density which further indicated that the Ni^{63} responded more like a metal lower in the electromotive lable of the elemenis. Allempts were made to separate Ag^{110} and Ag^{111} from natural Ag. The electrolyte used for plating Ag consisted of $AgNO_3$, NaCN, KNO_3, H_2O, and CS_2. The radioactive Ag isotopes were added as the nitrate. Samples were plaied on 1-in. siainless-sieel cylinders acting as cathodes, and a weighi-vs-count curve was ploited. A number of plaies were deposited at differeni temperatures, curreni densities, and circulation rates. Data evaluation indicaied that no Ag separations were made. Further work on Cd separation was indicaied. The need of a mass specirometer capable of handling the heavier elemenis was considered desirable.

BROADENING OF MICROWAVE ABSORPTION LINES DUE TO WALL COLLISIONS, by M. Danos and S. Geschwind. [1953] [4]p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and

COU. 01:002 - COU. 01:006

[Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Published in Phys. Rev., v. 91: 1159-1162, Sept. 1, 1953.

The broadening of microwave absorption lines due to wall collisions is calculated using a method correcting the error in previous rough estimates which assumed the line broadening to be Lorentz-shaped. Two types of absorption cell are studied, i.e., infinite plane parallel plates and a circular cylinder, each in a region of uniform microwave field. The usual assumption that the half-power half-width is given by $\Delta\nu = 1/2\pi\tau$, where τ is the mean time between collisions is in good agreement with the detailed calculations of the present work which shows that the error in the line width as calculated by the above expression is not larger than 30 percent. Experimentally observed line widths agree with the predicted values. (Contractor's abstract, modified)

ČERENKOV EFFECT AT MICROWAVE FREQUENCIES, by M. Danos, S. Geschwind and others. [1953] [2]p. incl. diagr. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-42519) Unclassified

Published in Phys. Rev., v. 92: 828-829, Nov. 1, 1953.

Čerenkov radiation at microwave frequencies was experimentally detected. The radiation was excited by a flat electron beam which passed as closely as possible over the surface of a dielectric material after having been bunched at a K-band frequency. The radiation left the dielectric through a quarter-wave matching plate and was then picked up by a microwave horn and detected with a 1N26 crystal. Approximately 10^{-7} watt of Čerenkov radiation at a wavelength of 1.25 cm was obtained.

SPIN OF Si^{29} AND MASS RATIOS OF THE STABLE Si ISOTOPES, by R. L. White and C. H. Townes. [1953] [2]p. (Sponsored jointly by Atomic Energy Commission, [Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Published in Phys. Rev., v. 92: 1256-1257, Dec. 1, 1953.

The $J = 0 \rightarrow 1$ microwave transition of $Si^{29}D_3F$ was examined under high resolution for hyperfine structure due to Si^{29}. No hyperfine structure was found, which sets an upper limit of $1 \times 10^{-28} cm^2$ to the quadrupole moment of Si^{29}. This is good evidence that the Si^{29} spin is ½. The measurement also allows an accurate determination of mass difference ratios for the Si isotopes.

NUCLEAR MOMENTS OF Se^{79}, by W. A. Hardy, G. Silvey and others. [1953] [6]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, Atomic Energy Commission and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Published in Phys. Rev., v. 92: 1532-1537, Dec. 15, 1953.

Microwave measurements of the $J = 2 \rightarrow 3$ rotational transition of OCSe containing the radioactive-nucleus Se^{79} have established the Se^{79} spin as 7/2 and the Se^{79} quadrupole moment as $0.7 \times 10^{-24} cm^2 \pm 20$ percent. The quadrupole coupling constant eqQ is $7.52.09 \pm 0.05$ mc/sec. The magnetic moment of Se^{79} has been determined as -1.015 ± 0.015 nuclear magnetons by observation of the Zeeman splitting of one hyperfine component. The 7/2 spin and the large positive Q are inconsistent with the single-particle nuclear-shell model, but suggest the configuration $(g9/2)^7$ 7/2. This assignment is substantiated by the negative magnetic moment. Measurement of isotopic shifts gives a value for the Se^{79} mass, and an odd-even mass difference of 2.4 millimass units for this nucleus. (Contractor's abstract)

ABSORPTION OF MICROWAVES BY OXYGEN IN THE MILLIMETER WAVELENGTH REGION, by

J. O. Artman. Special tecb. rept. June 1, 1953, 84p. incl. illus. diagrs. tables. (Sponsored jointly by Signal Corps, Office of Naval Research and [Air Force Office of Scientific Research] under DA 36-039-sc-42519) AD 21111 Unclassified

Also published in Phys. Rev., v. 96: 1237-1245, Dec. 1, 1955.

The spin reorientation spectrum of 0 in the millimeter wave length region was investigated at high and low pressures with the untuned cavity spectrometer. The resolved 0 lines observed at low pressures corresponded to values of the rotational quantum number K extending from 1 to 19. The line breadth parameters were found to be fairty independent of the values of K, averaging to 1.94 mc/mm Hg. For several lines both the peak tnlensity v_{peak} and the line breadth parameter $\Delta v/P$ were tndependently determined. The product $v_p \Delta v/P$ agreed to ± 5% with theoretical values expressed tn terms of known matrix elements and physical constanls. The ratio of the O-N broadening parameter to the O self-broadening parameter was determined by observations on a number of individual lines to be 0.90 ± 15%. The absorption of O in dry air was measured of 1/4, 1/2, and 1 atm. At these pressures, adsorption was attribuled to the addition of the many overtapping individual lines. The data obtained and formulas presented are useful tn predicting atmospheric adsorption of O under various conditions. This is tllustrated by the presentation of O absorption in air computed at 223°K and 1/4 atm pressure.

ČERENKOV RADIATION FROM EXTENDED ELECTRON BEAMS (Abstract), by M. Danos. [1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scie.tific Research under DA 36-039-sc-42519]) Unclassified

Presented al annual meeting of the Amer. Phys. Soc., Cotumbia U. New York, Jan. 28-30, 1954.

Published in Phys. Rev., v. 94: 758, May 1, 1954.

The energy emitted by a flal etectron beam having the charge densily $\rho = \rho_0 \{1 + a \cos[(\omega/v)(z-vt)]\}$ and moving with the vetocity $v = c\beta$ at a distance d over the surface of a dielectric with dietectricity constani ϵ is given by

$$P = 189 I^2 a^2 \exp\left[-\frac{4\pi d}{\lambda}(1-\beta^2)^{1/2}\right] \frac{\epsilon}{\beta} \frac{(1-\beta^2)(\epsilon\beta^2-1)^{1/2}}{(\epsilon\beta^2-1)+\epsilon^2(1-\beta^2)} \times$$

μ watts/cm^2 if the beam current t is measured in ma; $\lambda = \omega/2\pi c$ is the free space wavetength. The dependence of the radialed energy on v is here qualtatively different than in the wett known case of cylindrical geometry (V. L. Ginsburg and I. M. Frank, Doklady Akad. Nauk, v. 56: 699, 1947), where the radiation reaches a maximum al v → c. If in lhe plane case a second dielectric is added so as to sandwich the electron beam between the two dielectrics the behavior ts similar to the cylindrical case. An experiment has been performed to detect the Čerenkov radiation at microwave frequencies. The power observed ts in reasonable agreement with the theoretical predictions. (Contractor's abstract)

DETERMINATION OF ATOMIC MASSES BY MICROWAVE SPECTROSCOPY, by S. Geschwind, G. R. Gunther-Mohr, and C. H. Townes. [1954] [12]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unctassified

Published in Rev. Modern Phys., v. 26: 444-455, Oct. 1954.

Microwave spectroscopy gives information about atomic masses from the isotopic shift tn the pure rotational spectrum of molecules. Improvements in techniques allow measurement of frequency intervals to 0.002 mc so that future mass measurements may give an accuracy near 0.02 in mass units. This compares favorably with the best mass spectrographic and nuclear reaction measuremenls recently obtained. The theory involved in the determination of masses from rotational spectra of diatomic molecules and of molecules that are linear or symmetric rotors, is presented, including a discussion of results. Wtth the exception of Ge^{73} and Te^{120} mass information has been obtained from microwave spectra for all the stable isotopes of Li, C, O, Si, S, Cl, K, Br, Ge, Se, Rb, and Te as well as of the radioactive tsotopes H^3, S^{35}, Cl^{36}, Se^{75}, and Se^{79}. Mass ratios obtained from diatomic molecules and mass-difference ratios obtained from polyatomic motecules are collected. The microwave resulls are compared with those obtained from mass spectrometers.

Two techniques for obtaining millimeter waves with sufficient power to physical measurements were investigated. One technique is to use the harmonics of the fundamental frequency directly emitted by a magnetron when it is in oscillation. Harmonics up to 1.25 mm have been observed. The only advantage of the magnetron is in the ease of adjustment. A moderately experienced operator could probably produce 1.5 mm radiation within a few hours using this method. The other technique is to frequency multiply the power emitted by a klystron by means of a silicon-tungsten contact used as a non-linear device. This method has produced 1.5 mm wavelength radiation. It has the advantages that the radiation is stable in power and frequency, is monochromatic, and also is tunable. A distinct disadvantage is in the time involved in adjustment and alignment. Magnetron harmonics and frequency multipliers are not the best methods of obtaining the shorter wavelengths, but they are the only ones available for longer wavelengths. Some quantitative data are given on the performance of these devices as various parameters are changed.

HYPERFINE STRUCTURE IN DCCCl, DCN, AND HCN DUE TO DEUTERON QUADRUPOLE COUPLING AND FIELD ASYMMETRIES (Abstract), by R. L. White. [1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Presented at annual meeting of the Amer. Phys. Soc., Columbia U., New York, Jan. 28-30, 1954.

Published in Phys. Rev., v. 94: 789, May 1, 1954.

Published in Bull. Amer. Phys. Soc., v. 29: 52, Jan. 28, 1954.

The spectrum arising from the $J = 1 \rightarrow 2$ transition in deuterated chloroacetylene has been observed in a high-resolution spectrometer and hyperfine structure due to the quadrupole coupling of the deuteron detected. A value for the coupling of $(eqQ)_D = +175 \pm 20$ kc/sec was obtained, to be compared with -114 ± 1 kc in HD obtained by molecular beam methods. The deuteron quadrupole coupling was also observed in transitions between 1-type doublets in DCN where an unresolved hyperfine structure resulted in line broadening. Comparison with unbroadened lines from HCN gave the less accurate but consonant evaluation $(eqQ)_D = +145 \pm 60$ kc/sec. Since the deuteron quadrupole moment is known, $(eqQ)_D$ yields an experimental value of the field gradient. The value thus obtained was compared with the gradient calculated from a Heitler London molecular model. The calculated value was too large and of wrong sign, indicating the inadequacy of the model for this calculation. Asymmetry in the quadrupole coupling of N^{14} in the 1-type doublet transitions of HCN and DCN also produced hyperfine structure. From this structure, variations in the C-N bond due to bending can be detected. (Contractor's abstract)

MAGNETIC INTERACTIONS IN $^3\Sigma$ MOLECULES (Abstract), by R. L. White. [1954] [1]p. (Sponsored jointly by [Signal Corps, Office of Naval Research and Air Force Office of Scientific Research under DA 36-039-sc-42519] Unclassified

Presented at meeting of the Amer. Phys. Soc., Seattle, Wash., July 7-10, 1954.

Published in Phys. Rev., v. 96: 845, Nov. 1, 1954.

In a second-order approximation the electronic angular momentum of a rotating $^1\Sigma$ molecule is not zero. The associated magnetic field is on the same order of magnitude as the field arising from the rotation of the positively-charged nuclear frame. The total resultant field interacts with the magnetic moments of the nuclei of the molecule to produce an interaction of the form $W_{mag} = [c_1 + (c_2 - c_1)K^2J^{-1}(J + 1)^{-1}]I.J$ for a nucleus on the symmetry axis of a symmetric top molecule. The c_i may be of either sign, depending upon both nuclear and molecular parameters. The algebraic values of c_i for the molecules $O^{17}CS$, OCS^{33}, $OCSe^{79}$ $Cl^{35}CN^{14}$, $Cl^{35}CN^{15}$, CH_3Cl, SiH_3Cl and GeH_3Cl have been measured on a high resolution bridge-type microwave spectrometer. A correlation between measured and theoretical c_i for these molecules and for a number of others for which c_i is known (primarily from molecular beams data) will be given. The molecular parameters thus obtained will be compared with those inferred from molecular g factors and diamagnetic susceptibilities. (Contractor's abstract)

MICROWAVE ABSORPTION SPECTRA OF MnO_3F and ReO_3Cl, by A. Javan and A. Engelbrecht. [1954] [10]p. incl. diagrs. tables, refs. [Sponsored jointly by Signal Corps, Office of Naval Research, Air Force Office of Scientific Research, and Atomic Energy Commission under DA 36-039-sc-42519] Unclassified

Published in Phys. Rev., v. 96: 649-658, Nov. 1, 1954.

The microwave spectra of MnO_3F and ReO_3Cl near 1-cm wavelength have been studied. From the spectra of the first molecule and its isotopic species Mn $(O^{16})_2O^{18}F$, the structural parameters were determined as: Mn - O = 1.586A, Mn - F = 1.724A, $\angle$ (O, Mn, F) = 108°27′. The nuclear quadrupole coupling constant of Mn^{55} was measured as eqQ = 16.8 mc/sec. Because of the spin and statistics of O^{16} nuclei not all of the rotational states are allowed. It was found that, whereas in the ground vibrational states only states with K a multiple of three are permissible, in the excited vibrational states of the perpendicular normal modes the states with K-1 a multiple of three can occur. For K = 1 = ± 1 appreciable l-type doubling was observed. The amounts of l doubling and their corresponding values of α_v were determined for MnO_3F. The molecular dipole moment of this molecule was found to be μ = 1.5 Debye units. The hyperfine structure of ReO_3Cl gives for the ratio of quadrupole moments of the two abundant isotopes of Re a value of $Q_{Re^{187}}/Q_{Re^{185}} = 1.067 \pm 0.045$ and for the quadrupole coupling constant of Re^{187} eqQ = 253 mc/sec. This coupling constant and the known optical value of the quadrupole moment of Re^{187} give some information about the electronic structure of the molecular bonds, from which an approximate value of the nuclear quadrupole moment of Mn^{55} was obtained as $Q = 0.55 \times 10^{-24} cm^2$. MICROWAVE SPECTRUM OF THE FREE OD RADICAL (Abstract), by G. C. Dousmanis. [1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Presented at annual meeting of the Amer. Phys. Soc., Columbia U., New York, Jan. 29-30, 1954.

Published in Phys. Rev., v. 94: 789, May 1, 1954.

COU. 01:018 - COU. 01:020

Published in Bull. Amer. Phys. Soc., v. 29: 52, Jan. 28, 1954.

A microwave spectrum resulting from the free $O^{16}D$ radical has been found with a Zeeman spectrometer similar to tbe one with which OH spectrum had been observed (Phys. Rev., v. 89: 1158, 1953). The lines are due to transitions between the two members of the doublet resulting from the Λ-type splitting of eacb J-level in the ground paramagnetic state of the radical. The observed frequenctes and their assignments are as follows:

K	J	Frequency (Megacyctes)
5	5½	867.36 ± 0.10
6	6½	12,918.0t
7	7½	18,009.60
8	8½	23,907.12

The parameters describing the Λ-type doubling have been obtained as $4\Sigma(-1)^8$ $(\Pi|ALy + 2BLy|\Sigma)$ $(\Sigma|BLy\ \Pi)/V_{\pi\Sigma} = 2096 \pm 16$mc and $4\Sigma(-1)^8|(\Pi\ BLy|\Sigma)|^2/V_{\pi\Sigma} = 149.3 \pm 0.4$ mc. These are tn agreement with the values found in OH. The magnetic hyperftne structure In OD, in contrast to that tn OH, ts too smalt to be resolved (< 3 mc for K = 8). This gives some information about the source of hyperfine structure tn OH and OD. (Contractor's abstract)

MILLIMETER WAVE GENERATION BY ČERENKOV RADIATION, by M. Danos and H. Lashinsky. [1954] [5]p. tncl. diagrs. [Sponsored jointly by Signal Corps, Offlce of Naval Research, and Air Force Office of Sclentific Research under DA36-039-sc-42519]
Unclassifted

Published in I. R. E. Trans. on Microwave Theory and Techniques, v. MTT-2: 21-22, Sept. 1954.

An electron moving through a refractive medium with a velocity greater than the phase vetocity of ltght in that medium emtts radiation with a continuous spectrum. If one uses a bunched electron beam, not only is tne radiated power greatly increased but the radiated spectrum now is a line spectrum consisting of the bunching frequency and tts harmonics. It is actually not necessary that the electrons pass through the medium. It ls sufficient that the beam be located at a small distance from the dielectric. An experiment was conducted tn which a flat electron beam was passed through a klystron-type bunching cavity. After an appropriate drifting time density bunches were formed and the beam passed over a dielectric at a close distance. The emitted radiation passed through a quarter wave matching plate and was collected by a horn. With this set-up radiation of roughly 10^{-7}W was obtained. The beam current was C.4mA, the beam width 4 mm, the length over the dtelectrtc 1.7 cm; the klystron was squarewave modulated at 6 kc/s; and the beam was switched on and off at a rate of 20 c/s. A modulation of 6 kc was employed to enable the use of a narrow band 6 kc amplifier system; by switching the beam on and off it was possibte to distinguish between leakage and radiation associated with the electron beam.

Presented at annual meeting of the Amer. Phys. Soc., Columbia U., New York, Jan. 28-30, 1954.

Published in Phys. Rev., v. 94: 767, May 1, 1954.

Published in Bull. Amer. Phys. Soc., v. 29: 30, Jan. 28, 1954.

Measurements on nuclear quadrupole resonances tn solids show the ratio of coupling constants for Cl^{35} and Ct^{37} in any molecule to vary with temperature as well as with molecular environment (Phys. Rev., v. 86: 809, 1952); the ratio ts not solely dependent on nuclear properties as might be expected. A decrease of temperature from 300°K to 78°K decreases the ratio eqQ_{Cl35}/eqQ_{Cl37} by as much as 0.02 percent. Measurement of the quadrupote coupling ratio of Sb^{123} to that of Sb^{121} in several antimony halides and in stibnite shows similar effects. This ratio ranged from 1.27414 to t.274770 depending on molecular environment. The asymmetry parameter η for the two antimony tsotopes agrees to tess than 0.01 percent. The change of ratio can be attributed largely to molecular vibrations. Extending Bayer's discussion (Zeitschr. Phystk, v. 130: 227, t95t) of thermal vil.rations, the variation tn coupting ratio can be calculated for the case of p-$C_6tH_4Cl_2$ where the vibrational frequenctes are known. The calculated change tn ratio between 300°K and 78°K is 2.2×10^{-5} whereas the measured value is $(4.7 \pm 1) \times 10^{-5}$. (Contractor's abstract)

THE SPIN AND QUADRUPOLE MOMENT OF Se^{75} (Abstract), by L. C. Aamodt, P. C. Fletcher and others. [1954] [1]p. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-42519] Unclassified

Presented at annual meeting of the Amer. Phys. Soc., Columbia U., New York, Jan. 28-30, 1954.

Published in Phys. Rev., v. 94: 789, May 1, 1954.

The spin and nuclear quadrupole moment of radioactive Se^{75} have been determined from the microwave spectrum of $OCSe^{75}$. The Se^{75} was produced by the reaction $As^{75}(d, 2n)Se^{75}$ using 22-mev deuterons from the Brookhaven National Laboratory's cyclotron. The presence and abundance of Se^{75} in OCSe was determined by observing characteristic γ rays of this nucleus. Three lines of the quadrupole hyperfine structure of the $J = 2 \rightarrow 3$ transition of $OCSe^{75}$ were observed. Their measured frequencies, relative intensities, and Stark patterns agree with a spin of 5/2 for Se^{75} and a quadrupole constant of 946 mc. This spin is not consistent with predictions from the single particle version of the shell model. The quadrupole coupling constant indicates the large positive quadrupole moment of $0.9 \times 10^{-24} cm^2$ for Se^{75}. (Contractor's abstract)

SULFUR BONDS AND THE QUADRUPOLE MOMENTS OF O, S, AND Se ISOTOPES, by G. R. Bird and C. H. Townes. [1954] [6]p. incl. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Published in Phys. Rev., v. 94: 1203-1208, June 1, 1954.

Quadrupole couplings of S^{33} in HDS, SO_2 and CH_3SH have been measured. These and previously measured quadrupole couplings of S^{33} in OCS, HNCS, CS, and S_8 are examined to determine the nature of sulfur bonds and the best value for the S^{33} quadrupole moment; s - p hybridization is found to be common, but not universal, in sulfur bonds. The S^{33} quadrupole moment is $-0.064 \pm 0.01 \times 10^{-24} cm^2$. If O and Se bonds are assumed to be similar to those of S, the quadrupole moments of O^{17} and Se^{79} are $-0.004 \times 10^{-24} cm^2$ and $0.9 \times 10^{-24} cm^2$, respectively.

VACUUM POLARIZATION IN A STRONG COULOMB FIELD, by E. H. Wichmann and N. M. Kroll. [1954] [3]p. incl. diagr. (Sponsored jointly by Atomic Energy Commission, [Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Published in Phys. Rev., v. 96: 232-234, Oct. 1, 1954.

The polarization current is the trace of Υ_μ times the electron external field propagator. This is expressed as a sum over the solutions to the Dirac equation, the sum over angular momentum being carried out by means of a contour integral. An exact double integral for the polarization charge density in a static field is thus obtained, in a form which can be completely renormalized. Expansion in $Z\alpha$ gives the Uehling term, and corrections to it. These prove to be very small for small r, even for lead. The expansion is proved to converge for $Z\alpha < 1$.

The energy difference (δ) between the $2^2S_{1/2}$ and $2^2P_{1/2}$ states of ionized helium has been measured by a pulsed microwave method. Helium atoms are excited to the metastable $2^2S_{1/2}$ state of the ion by a microsecond pulse of electrons of about 250-ev energy. After bombardment and after the atoms and ions excited to nonmetastable states have decayed to their respective ground states, a pulse of microwave power is applied to induce the $2^2S_{1/2}$ - $2^2P_{1/2}$ transition. This transition is followed immediately by spontaneous emission of a 40.8-ev photon associated with the $2^2P_{1/2}$ - $1^2S_{1/2}$ transition. The photons are observed by counting photoelectrons with high-speed counters gated on synchronously with the pulses of microwave power. Two different levels of rf power are used alternately to provide a means of normalizing the data for variations in the population of the $2^2S_{1/2}$ state. The present value of δ for He^+ is 14,043 ± 13 mc/sec. The stated uncertainty is equal to three times the standard deviation plus an estimated 3 mc/sec for the uncertainty in the corrections for systematic effects. This result, consistent with previous results, is in agreement with the best available theoretical value of 14,043.2 ± 3.0 mc/sec. (Contractor's abstract)

A rigorous method is described for treating the problem of the hydrogen-like atom in quantum electrodynamics by the separation of integrals into parts which can be evaluated with relativistic and nonrelativistic approximations. The method is based on that developed by Baranger, Bethe, and Feynman for the second-order problem, and is applied here to the problem of the fourth-order radiative energy level displacement. It is shown that the result inferred by Weneser, Bersohn, and Kroll from the study of fourth-order radiative corrections to elastic scattering by a given external potential is correct to order $\alpha^2(\alpha z)^4 mc^2$ for a hydrogenic atom. It is also shown that the αZ corrections to this result can be obtained using this method, just as was done in the second-order problem by Baranger, Bethe, and Feynman. (Contractor's abstract)

The magnetic moment of the Cl^{36} nucleus was measured by observing the Zeeman splitting of the $F = 2 \rightarrow 2$ line in the electric quadrupole hyperfine pattern of the molecule CH_3Cl^{36} ($J = 0 \rightarrow 1$, $K = 0$ transitions). It was found to be 1.32 ± 0.08 nuclear magnetons. The magnitude of the magnetic moment was measured by using a rectangularly cross-sectioned absorption cell

COU. 01:033 - COU. 01:035

with plane polarized microwave radiation, and observing the $\Delta M = \pm 1$ transitions. The sign of the magnetic moment was measured by using a circularly cross-sectioned absorption cell with circularly polarized microwave radiation. This allowed the $\Delta M = 1$ and the $\Delta M = 1$ transitions to be observed separately. The magnetic field was calibrated by observing the Zeeman splitting of the spectrum of CH_3Cl^{35}. This value of magnetic moment indicates a nuclear configuration $(d_{3/2})_N (d_{3/2})_P$. Measurements of the quadrupole spectrum without the Zeeman perturbation gave the following additional information: the spin of Cl^{36} was confirmed to be 2, the mass difference ratio $[m(Cl^{36})-m(Cl^{35})]/[m(Cl^{37})-m(Cl^{36})]$ was found to be 1.00168 ± 0.04 percent, the molecular rotational constant of the CH_3Cl^{36} molecule was found to be 13187.604 ± 0.015 mc/sec, and its quadrupole coupling constant to be -15.83 ± 0.20 mc/sec. PARAMAGNETIC RESONANCE OF METHYL SUBSTITUTED p-BENZOSEMIQUINONES, by B. Venkataraman and G. K. Fraenkel. [1955] [2]p. incl. table. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-42519] Unclassified

Published in Jour. Chem. Phys., v. 23: 588-589, Mar. 1955.

Investigation is reported of the paramagnetic resonance absorption spectra of the semiquinone ions of p- and of m-xyloquinone as well as the spectrum of the p-tolusemiquinone ion. The spectra of the two xylosemiquinone ions contain 9 major lines split into from 19 to 21 incompletely-resolved components, while the spectrum of the tolusemiquinone ion consists of 7 major lines, split into 20 components. The spectra of the xylosemiquinone ions are readily interpreted by assuming that the structure is due to hyperfine interaction with two equivalent protons on the benzene ring (interaction constant a) and six equivalent protons on methyl groups (interaction constant b). Agreement between the calculated and experimental positions of the 21 components is within the experimental error, and the intensities, which have not been measured, are in qualitative agreement with the theory. The sequence of the line intensities shows b to be greater than a. The spectrum of the p-tolusemiquinone ion can be fitted approximately by assuming that two of the ring protons are equivalent ($a_1 = a_2 = a$) and cause a larger splitting than the third ring proton ($a > a_3$), and that the three equivalent methyl-group protons give rise to a splitting that is the average of the splitting due to the ring protons, i.e., $b = 1/2 \cdot (a + a_3)$. This model predicts twenty lines in 7 groups. The intensities of one half of the spectrum are calculated to be: (7, 3), (1, 6, 5, 3), (2, 3, 1) and (1), where the lines are enumerated from the center of the spectrum outwards. A more precise fit than predicted by this model can be obtained by allowing b to differ slightly from the mean of a and a_3 if the incomplete resolution of the components is taken into account. Values of a, b, and a_3 are tabulated. If the values of the interaction constants for protons situated in similar position in the same or different molecules can be interpreted as being proportional to the mean density of the unpaired electron at the protons, relative values of a and relative values of b should be proportional to the densities of the unpaired electron respectively at ring- and methyl-group protons. Such electron densities are not to be confused with the total π-electron density.

PURE NUCLEAR QUADRUPOLE SPECTRA OF CHLORINE AND ANTIMONY ISOTOPES IN SOLIDS, by T. C. Wang. [1955] [12]p. incl. illus. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Published in Phys. Rev., v. 99: 566-577, July 15, 1955.

Experimental measurements on nuclear quadrupole resonances of chlorine and antimony isotopes in solids have been made to an accuracy of about 0.001 percent. The results are compared in detail with theoretical results for (1) nuclear quadrupole interaction, (2) interaction between quadrupole coupling and thermal vibrations, and (3) effects of a nuclear hexadecapole. The ratio $(eQq)_{Cl35}/(eQq)_{Cl37}$ varies between 1.268736 and 1.268973 while $(eQq)_{Sb123}/(eQq)_{Sb121}$ varies from 1.274714 to 1.274770. These variations may be attributed to zero-point vibrations and to thermal vibrations, so that no clear evidence is found for nuclear polarization by surrounding electric fields. For p-dichlorohenzene, the temperature coefficient of the coupling constant of Cl and the variation of isotopic coupling ratio with temperature are shown to he in fair quantitative agreement with the extension of Bayer's theory of vibrational effects. Relaxation times, Zeeman effects, and certain effects due to crystal structure are

examined. Small discrepancies in the measured ratios of frequencies of transitions in Sb^{121} and Sb^{123}, which can be attributed to nuclear hexadecapole interactions are found. These indicate a hexadecapole coupling constant in Sb^{123} of 24 kc/sec and a ratio of the Sb^{123} hexadecapole coupling to that of Sb^{121} of 0.8 ± 0.3. A convenient high-sensitivity circuit for observation of nuclear resonances in solids has been developed and is discussed. (Contractor's abstract)

STARK EFFECT IN RAPIDLY VARYING FIELDS, by S. H. Autler and C. H. Townes. [1955] [20] p. incl. diagrs. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-42519) Unclassified

Published in Phys. Rev., v. 100: 703-722, Oct. 15, 1955.

A method is developed for calculating the effects of a strong oscillating field on two states of a quantum mechanical system which are connected by a matrix element of the field. Explicit approximate solutions are obtained for a variety of special cases, and the results of numerical computations are given for others. The effect of an rf field on the $J = 2 \rightarrow 1$ l-type doublet microwave absorption lines of OCS has been studied in particular both experimentally and theoretically. Each line was observed to split into two components when the frequency of the rf field was near 12.78 mc or 38.28 mc, which are the frequencies separating the $J = 1$ and $J = 2$ pairs of levels, respectively. By measuring the rf frequency, ν_0, at which the microwave lines are split into two equally intense components, one may determine the separation between the energy levels. The measured value of ν_0 depends upon the intensity of the rf field and the form of this dependence has been calculated and found to be in good agreement with the experimental results. PURE ROTATIONAL SPECTRA OF THE THALLIUM HALIDES (Abstract), by M. Mandel and A. H. Barrett. Jan. 27, 1955 [1] p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Presented at annual meeting of the Amer. Phys. Soc., New York, Jan. 27-29, 1955.

Published in Bull. Amer. Phys. Soc., v. 30: 20, Jan. 27, 1955.

The pure rotational spectra of the thallium halides have been observed using a high-temperature microwave spectrometer. Internuclear distances, vibration-rotation interactions, and mass ratios of the chlorine and bromine isotopes have been determined.

Molecule	r_e(A)	a_e(mc/sec)
$Tl^{205}F$	2.0844 ± 0.0001	44.98 ± 0.05
$Tl^{205}Cl^{35}$	2.4848 ± 0.0001	11.90 ± 0.01
$Tl^{205}Br^{79}$	2.6181 ± 0.0001	3.927 ± 0.005
$Tl^{205}I$	2.8136 ± 0.0001	1.985 ± 0.005

The thallium chloride results revealed a discrepancy in the previous work on TlCl where the isotope identified as $Tl^{205}Cl^{35}$ is in reality $Tl^{203}Cl^{37}$. The electric quadrupole coupling constants of $Tl^{205}Br^{79}$ and $Tl^{205}I$ in the $v = 0$ state were found to be + 130 ± 5 mc and -550 ± 20 mc, respectively, and the electric dipole moment of $Tl^{205}F$ to be approximately 7 debye units. The results give evidence about the ionic character of these molecules and the electronegativity of Tl. (Contractor's abstract)

HYPERFINE STRUCTURE OF METASTABLE HYDROGEN (Abstract), by H. A. Reich, J. W. Heberle, and P. Kusch. Jan. 29, 1955, [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Presented at annual meeting of the Amer. Phys. Soc., New York, Jan. 27-29, 1955.

Published in Bull. Amer. Phys. Soc., v. 30: 55, Jan. 27, 1955.

The hyperfine structure $\Delta\nu$ (2S) of the $2^2S_{1/2}$ state has been measured by a new atomic beam method. The frequency ν_{14} of the transition $F = m_F = 1 \rightarrow F = m_F = 0$ is given by $\Delta\nu + 1.40$ mc sec^{-1} $gauss^{-1}$; the frequency ν_{24} of the transition $F = 1$, $m_F = 0 \rightarrow F$ and $m_F = 0$ is given by $\Delta\nu + 0.022$. 2 mc sec^{-1} $gauss^{-2}$. To determine $\Delta\nu$ (2S) both ν_{14} and ν_{24} were measured in a field of 0.19 gauss. The line width $W \approx v/2L$ (v is the average velocity of the atoms) was reduced to 5.5 kc/ sec by making the separation L between the two rf regions as large as 40 cm. It has been found that $\Delta\nu$ $(2S)_{exp}$ = 177,556.6 ± 0.3 kc/ sec. Theoretically $\Delta\nu$ (2S) is related to $\Delta\nu$ (1S) of the ground state by $\Delta\nu$ (2S) = $\Delta\nu$ (1S)/ $(8 - 5a^2)$. From the two existing values of $\Delta\nu$ (1S) one obtains $\Delta\nu$ $(2S)_{theoret.}$ = 177,556.55 ± 0.03 and 177,556.634 ± 0.007 kc/ sec, respectively. Additional measurements are being made to investigate possible systematic errors and to improve the accuracy to 3 parts in 10^7. (Contractor's abstract)

NEW METHOD FOR INVESTIGATING THE HFS OF A METASTABLE STATE (Abstract), by J. W. Heberle, H. A. Reich, and P. Kusch. Jan. 29, 1955 [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Presented at annual meeting of the Amer. Phys. Soc., New York, Jan. 27-29, 1955.

Published in Bull. Amer. Phys. Soc., v. 30: 55, Jan. 27, 1955.

An atomic-beam method has been developed for measurement of the hfs of the metastable $2^2S_{1/2}$ state of hydrogen. The Zeeman levels of the $2^2S_{1/2}$ state are classified as $\alpha(m_s = +\frac{1}{2})$ or $\beta(m_s = -\frac{1}{2})$ according to the high-field value of m_s. Molecules of H_2 or D_2 are dissociated in a hot tungsten oven. An 11-ev electron beam excites the atoms to the α and β states in a field of approximately 580 gauss. The β atoms are quenched immediately after formation because their lifetime in such a field is only about 5×10^{-8} sec. The remaining α atoms pass through two successive regions of rf magnetic field of variable frequency where transitions to a β state are induced. The atoms pass on into a second field of 580 gauss where the newly formed β atoms are quenched. The α atoms that remain strike a metal detector plate. Electrons ejected from the detector are collected. A resonance is observed as a decrease in detector current. (Contractor's abstract)

NUCLEAR MAGNETIC MOMENT AND MASS OF CHLORINE-36 (Abstract), by P. C. Fletcher and L. C. Aamodt. Apr. 28, 1955 [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Presented at spring meeting of the Amer. Phys. Soc., Washington. D. C., Apr. 28-30, 1955.

Published in Bull. Amer. Phys. Soc., v. 30: 13, Apr. 28, 1955.

The magnetic moment of the Cl^{36} nucleus was measured by observing the Zeeman splitting in the electric quadrupole hyperfine pattern of the molecule CH_3Cl^{36} ($J = 0 \rightarrow 1$, $K = 0$, $F = 2 \rightarrow 2$). Its magnitude, as measured in a rectangularly cross-sectioned absorption cell, was found to be 1.32 ± 0.08 nuclear magnetons. Its sign, determined in a circularly cross-sectioned absorption cell allowing circular polarization, was found to be positive. These observations favor the nuclear configuration $(d_{3/2})^N(d_{3/2})_P$ which is that expected from nuclear shell theory. Measurements of the quadrupole spectrum without a magnetic field gave the following information: the spin of Cl^{36} was confirmed to be 2, the mass difference ratio $(M_{Cl36} - M_{Cl35})/(M_{Cl37} - M_{Cl36})$ was found to be 1.00168 ± 0.04 percent, the molecular rotational constant for CH_3Cl^{36} was found to be $13,187.604 \pm 0.015$ mc and its quadrupole coupling constant to be -15.83 ± 0.20 mc. MICROWAVE SPECTRA OF INDIUM CHLORIDE AND BROMIDE (Abstract), by A. H. Barrett and M. Mandel. Apr. 30, 1955 [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-42519]) Unclassified

Presented at spring meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Bull. Amer. Phys. Soc., v. 30: 66, Apr. 23, 1955.

The pure rotational spectra of indium monochloride and indium monobromide have been observed using a high-temperature spectrometer. Internuclear distances and vibration-rotation interaction constants determined are

Molecule	r_e(A)	a_e(mc/sec)
$In^{115}Cl^{35}$	2.4012 ± 0.0001	15.34 ± 0.15
$In^{115}Br^{79}$	2.5408 ± 0.0001	5.706 ± 0.025
$In^{115}Br^{81}$		5.605 ± 0.018

Since the nuclear spins of In^{115}, $Cl^{35,37}$, and $Br^{79,81}$ are 9/2, 3/2, and 3/2, respectively, the spectra are complicated by hyperfine structure resulting from the interaction of each electric quadrupole moment with the molecular field. The spectrum of $In^{115}Cl^{35}$ yielded values of -655 ± 6 mc for the In^{115} coupling constant and -24 ± 2 mc for the Cl^{35} coupling constant. The quadrupole structure was not sufficiently resolved to allow a determination of the coupling constants in $In^{115}Br$. Results are interpreted in terms of ionic character and bond hybridization of these molecules. (Contractor's abstract)

A MOLECULAR MICROWAVE SPECTROMETER, OSCILLATOR AND AMPLIFIER, by J. P. Gordon. [July 1, 1955] [16]p. incl. illus. diagrs. refs. (Part 1 of its Special tech. rept. no. CU-11-55; AD 77467) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-42519) AD 77467(a) Unclassified

A description is presented of a microwave spectrometer and oscillator which effects an emission of energy from the molecules rather than an absorption. As a spectrometer it has an extremely high resolution and was used to reexamine the inversion spectrum of NH_3 near 24 kmc. The operation of the apparatus is based on the isolation of molecules in the higher energy states. These molecules are then irradiated so that the incoming microwave signal is amplified rather than attenuated. Separation of the higher energy states is accomplished in a beam of NH_3 molecules by an electrostatic focuser. Transitions of these molecules back to the lower inversion states are then produced in a resonant cavity. If power of varying frequency is transmitted

through the cavity then the presence of the beam shows up as spectral emission lines. The apparatus acts as a narrow-band microwave amplifier at the molecular transition frequencies. In this role very little noise is introduced by the beam; its noise figure can theoretically be made close to unity if the beam is sufficiently strong. At a critical beam strength, the power necessary to induce transitions in the beam is available in the beam itself. Microwave oscillations are then set up in the cavity, the frequency of which is determined by the molecules. The oscillation is very stable. Since the radiation emitted from molecules through induced transitions is coherent with the exciting radiation, the oscillation is also highly monochromatic. (ASTIA abstract)

THE MASER. A NEW TYPE OF MICROWAVE AMPLIFIER, FREQUENCY STANDARD, AND SPECTROMETER, by J. P. Gordon, H. J. Zeiger, and C. H. Townes. [July 1, 1955] [26]p. incl. diagrs. refs. (Part 2 of its Special tech. rept. no. CU-11-55; AD 77467) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-42519) AD 77467(b) Unclassified

Also published in Phys. Rev., v. 99: 1264-1274, Aug. 15, 1955.

A type of device is described which can be used as a microwave amplifier, spectrometer, or oscillator. The device utilizes a molecular beam in which molecules in the excited state of a microwave transition are selected. Interaction between these excited molecules and a microwave field produces additional radiation and hence amplification by stimulated emission. The apparatus utilizing this technique is called a maser, which is an acronym for microwave amplification by stimulated emission of radiation. When operated as a spectrometer, the device has good sensitivity, and, by eliminating the usual Doppler broadening, a resolution of 7 kc/sec was achieved. Operated as an oscillator the device produced a frequency stable to at least four parts in 10^{12} in times of the order of a second, and stable over periods of one hr or more to at least a part in 10^{10}. The device was examined theoretically, and results are given for the expected sensitivity of the spectrometer, the stability and purity of the oscillation, and the noise figure of the amplifier. Under certain conditions a noise figure approaching the theoretical limit of unity along with reasonably high gain should be attainable.

A HIGH RESOLUTION MICROWAVE SPECTROMETER AND NEW HYPERFINE STRUCTURE IN THE INVERSION SPECTRUM OF $N^{14}H_3$, by J. P. Gordon. [July 1, 1955] [36]p. incl. illus. diagrs. refs. (Part 3 of its Special tech. rept. no. CU-11-55; AD 77467) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-42519; continued by DA 36-039-sc-64630) AD 77467(c) Unclassified

Also published in Phys. Rev., v. 99: 1253-1263, Aug. 15, 1955.

A reexamination was made on the hyperfine structure of the inversion spectrum of $N^{14}H_3$ with an ultra-high-resolution spectrometer. Lines with total widths at half maximum of 7 kc were obtained. Such narrow lines allow resolution of magnetic hyperfine structure due to reorientation of the spins of the hydrogen nuclei. The new structure was satisfactorily explained to within the experimental error of about 1 kc/sec by considering the vartous interactions of the magnetic moments of the hydrogen nuclei with the molecular fields. The interaction energy of the nitrogen nucleus was remeasured with higher resolution than was possible previously, and indications were found that $|eqQ|$ for the lower inversion state is larger by about 0.01% than that for the upper state. The sign eqQ was directly determined to be negative. A theoretical treatment of the magnetic interactions was conducted which is slightly different from previous treatments and allows some simplification of the form of the magnetic interactions. (ASTIA abstract)

CONNECTIONS BETWEEN MOLECULAR STRUCTURE AND CERTAIN MAGNETIC EFFECTS IN MOLECULES, by C. H. Townes, G. C. Dousmanis and others. [1955] [9]p. incl. tables, refs. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64630; continuation of DA 36-039-sc-42519] Unclassified

Published in Faraday Soc. Discussions, No. 19: 56-64, 1955.

Several types of magnetic effects in molecules and their relation to molecular structure are discussed. Hyperfine structure in molecules with electronic angular momentum can give experimental determination of 3 independent parameters of the distribution of electronic angular momentum. These parameters are rather simply and directly related to the molecular electronic structure and hence afford critical tests for proposed structures. Fine structure for such molecules can also give useful information on electron distributions. O_2, NO and OH are examples which are discussed. A systematic investigation has been made of $l \cdot J$ interactions in $^1\Sigma$ molecules. Although these 2nd-order effects are not as easily interpretable as are magnetic interactions in molecules with electronic angular momentum, it now appears possible to make an approximate prediction of the magnitude of $l \cdot J$

tnteractions in common types of molecules. The interactton between an external magnetic field and rotatton of a $^1\Sigma$ molecule may be used to determine the ortentation (sign) of the molecule's electric dtpole moment. In order to eliminate obscurtng effects such as L-uncoupling, It is necessary to measure the molecular g-factor for two isotopic species. Determination of the sign of molecular dtpole moments by this method requires rather prectse measurement of Zeeman effects, but appears practical for certain molecules. (Contractor's abstract)

EFFECTS OF THE BENDING MODE OF VIBRATION ON THE HYPERFINE STRUCTURE OF ICN, by A. Javan. [1955] [5]p. incl. tables. (Sponsored jointly by Stgnal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-64630]) Unclassified

Published in Phys. Rev., v. 99: 1302-1306, Aug. 15, 1955.

The bending mode of vibration in ICN introduces an asymmetry in the electric field gradient at the iodine nucleus. From an observed variation in the l-type doublet splittings of various hyperfine components for the $v_2 = 1$ state, the asymmetry parameter is determined as $\eta = 0.0087$. It is found that the measured splittings can be accounted for fully by including second-order perturbation terms arising from field asymmetry. The ratio $(eqQ)\ v = 0/(eqQ)\ v_2 = 1$ is measured as 1.0039. This ratio and the observed value of η are discussed in terms of the molecular bending and I-C bonding electrons. MICROWAVE SPECTRA OF THE FREE RADICALS OH AND OD, by G. C. Dousmanis, T. M. Sanders, Jr., and C. H. Townes. [1955] [20]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-64630]) Unclassified

Published in Phys. Rev., v. 100: 1735-1754, Dec. 15, 1955.

Free OH and OD radicals are produced in concentrations near 10% by an electric discharge at pressures of approximately 0.1 mm Hg. The spectra are detected by Zeeman modulation. They are due to direct transitions between the Λ-doublet levels of each rotational state in the ground vibrational level of the molecule. Spectra due to $O^{16}H$, $O^{18}H$, and $O^{16}D$ in $^2\Pi_{1/2}$ and $^2\Pi_{3/2}$ states have been observed in the 7.7 to 37 kmc/sec region. Intensity of the lines ranges from about $5 \times 10^{-6} cm^{-1}$ to $5 \times 10^{-8} cm^{-1}$. Van Vleck's theory of molecular energies in $^2\Pi$ and $^2\Sigma$ states is extended to include terms of order $(E_{rot}$ or $E_{fs})^2/E_e|^2$. The experimental results are in agreement with theoretical expectations to about one part in 2000. An improved agreement (to one part in 3500) is obtained by allowing a small variation of the electronic wave function from one rotational state to the next. The spectra include magnetic hyperfine structures which give values for parameters that describe the unpaired electron distribution in the molecule: $(1/r^3)_{Av} = (0.75 \pm 0.25) \times 10^{24}/cc$ and $(\sin^2 x/r^3)_{Av} = (0.49 \pm 0.01) \times 10^{24}/cc$. The hyperfine structure, the molecular magnetic moment and the line intensities are strongly dependent on the extent of intermediate coupling in agreement with theoretical expectations. The microwave spectrum can be used in studying chemical properties of the radical. Its lifetime was determined to be near 1/3 sec, and the effects of Cu, graphite, Ni, Kovar, Apiezon wax, Teflon, Glyptal, KCl, Al, and mica surfaces on radical concentrations were examined. SPACE-CHARGE DISTRIBUTION IN A STATIC MAGNETRON, by H. C. Nedderman. [1955] [11]p. incl. diagrs. table, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64630) Unclassified

Published in Jour. Appl. Phys., v. 26: 1420-1430, Dec. 1955.

The space-charge distribution in a static magnetron was investigated by a method involving measurement of the radiation intensity from excited gas atoms at low pressure. Results of the measurements show that space charge extends to the anode under all conditions. Evidence is presented to show that a considerable fraction of the space charge consists of electrons that are trapped for exceedingly long times within the interaction space. (Contractor's abstract)

ANTIFERROMAGNETIC RESONANCE IN MnF_2, by F. M. Johnson and A. H. Nethercot, Jr. [1956] [2]p. incl. diagr. table, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-64630]) Unclassified

Presented at meeting of the Amer. Phys. Soc., New Haven, Conn., June 21-23, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 283, June 21, 1956.

Published in Phys. Rev., v. 104: 847-848, Nov. 1, 1956.

Antiferromagnetic resonance has been observed in a single crystal of MnF_2 at temperatures from 57° to 65°K and wavelengths from 2.2 to 2.6 mm. At a wavelength of 2.58 mm the temperature at which the peak absorption occurred at zero applied magnetic field was 62.3 ± 0.5°K. Further observations were made at different frequencies in this range. A magnetic field H_0 variable from 0 to 9000 gauss was used to tune the resonance. Frequencies corresponding to both signs in the expression $\omega/\gamma = (2H_E H_A)^{1/2} \pm H_0[1 - (a/2)]$, were observed. The observed g value was approximately the expected value of about two. These results are in reasonable agreement with the predictions of Keffer and Kittel. These resonances were characterized by extremely hroad lines (full width approximately 7000 gauss). ČERENKOV RADIATION FROM EXTENDED ELECTRON BEAMS NEAR A MEDIUM OF COMPLEX INDEX OF REFRACTION, hy H. Lashinsky. [1956] [5]p. incl. diagrs. (Sponsored jointly hy Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-64630]) Unclassified

Published in Jour. Appl. Phys., v. 27: 631-635, June 1956.

An earlier theoretical treatment of the Čerenkov radiation excited by the passage of a bunched electron beam moving parallel to a dielectric medium at a small distance is extended to the case of a medium with a complex index of refraction. It is found that under suitable conditions, the use of a ferrite material as a medium can in principle enhance the radiated power. This effect is analyzed in terms of the work done by the beam on the field and the coupling between the beam and the medium.

FURTHER OBSERVATIONS OF MULTIPLE-QUANTUM TRANSITIONS. SATURATION EFFECTS IN RADIO-FREQUENCY TRANSITIONS, by P. Kusch. [1956] [10]p. incl. diagrs, tables, refs. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64630] Unclassified

Published in Phys. Rev., v. 101: 627-636, Jan. 15, 1956.

Multiple-quantum as well as the single-quantum transitions, $\Delta F = 0$, $\Delta m = \pm 1, 2, 3, 4$, have been observed in K^{39}. In the neighborhood of the rf amplitude, required to give a maximum transition probability, the lines have the behavior predicted for transitions induced by a rectangular rf pulse. For higher rf amplitudes, the line width becomes a constant or else decreases after having reached a maximum width, the line frequency is modified less rapidly than predicted and anomalous transition probabilities occur. All these effects are markedly dependent on the details of construction of the rf circuit in which transitions are induced. It is suggested that these effects may arise from the end regions of the circuit through an adiabatic traverse of the circuit by the atom. (Contractor's abstract)

HYPERFINE STRUCTURE OF METASTABLE HYDROGEN ATOM, by J. W. Heberle, H. A. Reich, and P. Kusch. [1956] [9]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-64630]) Unclassified

Published in Phys. Rev., v. 101: 612-620, Jan. 15, 1956.

The hyperfine separation $\Delta\nu$ (2S) of the metastable $2^2S_{1/2}$ state has been measured by a new atomic-beam magnetic-resonance method. Rf transitions were detected by utilizing a property peculiar to metastable hydrogen atoms, namely, that atoms with $m_J = -1/2$ decay much more rapidly in passing through a magnetic field of about 575 gauss than do atoms with $m_J = +1/2$. It was found that $\Delta\nu$ (2S) = 177556.86 ± 0.05 kc/sec. This result and the very accurately known hyperfine separation $\Delta\nu$ (1S) of the ground state yielded the following: $R \equiv \Delta\nu\ (2S)/\Delta\nu\ (1S) = 1/8\ (1.000,034,6 \pm 0.000,000,3)$. The deviation of R from the presently available theoretical value suggests the existence of a higher-order quantum-electrodynamic term. A method of velocity selection by electron impact is described. HYPERFINE STRUCTURE OF THE METASTABLE DEUTERIUM ATOM, by H. A. Reich, J. W. Heberle, and P. Kusch. [1956] [8]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-64630]) Unclassified

Published in Phys. Rev., v. 104: 1585-1592, Dec. 15, 1956.

The hyperfine separation $\Delta\nu$ (2S;D) of the metastable $2^2S_{1/2}$ state of the deuterium atom has been measured by an atomic-beam magnetic-resonance method. It was found that $\Delta\nu$ (2S;D) = 40,924.439 ± 0.020 kc/sec. This result and the ground-state separation $\Delta\nu$ (1S;D) yielded the following: $R(D) \equiv \Delta\nu\ (2S;D)/\Delta\nu\ (1S;D) = 1/8\ (1.000,034,2 \pm 0.000,000,6)$. Comparison of this value with the corresponding quantity for hydrogen, $R(H) = 1/8\ (1.000,034,6 \pm 0.000,000,3)$, confirms within experimental error the theoretical prediction that R(D) = R(H). In the course of an investigation of the hyperfine structure of Ne^{21} the problem of rapid disappearance

COU. 02:015 - COU. 02:017

of gas into the electrode system of a Woods discharge tube arose. Although good results have been experienced for electrodeless discharges at radio-frequencies, the problem of shielding appeared to be formidable, so an alternative solution was sought, and found, in an electrodeless discharge at frequencies of a few hundred cycles per second. The discharge tube consists of the usual discharge channel, about 75 cm long and 7 mm in diameter with a Pyrex sphere 7 cm in diameter and 1 mm thick at either end. Connections to the source are established through an Aquadag layer on the outer surface of each sphere. A current of 20 ma is driven through the system by 5000 v rms at 500 c; the current is independent of pressure from 30μ, the lower limit of operation, to several cm pressure. No operational difficulties have been encountered in a thousand hours of operation. The loss rate of neon is now considerably less than 1 μ1 STP/hr; this may he compared with losses in the old system which were sometimes as high as 1 cc STP/hr. (Contractor's abstract)

A large number of hyperfine interactions in molecular spectra have been measured by the techniques of microwave and molecular beam spectroscopy. The interpretation of these hyperfine interactions are discussed in terms of molecular structure and the nuclear moments with which they are associated. Some of the difficulties encountered in determining nuclear quadrupole moments are indicated. Hyperfine structure due to magnetic dipole moments is also mentioned. Interaction between a nuclear magnetic moment and an externally applied magnetic field is measured and the magnetic moment is determined.

PRODUCTION OF A BEAM OF METASTABLE HELIUM IONS (Abstract), by R. Novick and E. Commins. [1956] [1]p. (Sponsored jointly by National Science Foundation, Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-64630]) Unclassified

Presented at meeting of the Amer. Phys. Soc., New Haven, Conn., June 21-23, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 288, June 21, 1956.

Preliminary to determination of the hyperfine splitting of the $2S_{1/2}$ state of ionized helium-3, a beam of metastable helium-4 ions has been produced and detected. Helium atoms are ionized and excited to the $2S_{1/2}$ state by electron bombardment. The ions are then drawn out of the bombardment region and accelerated to 20 volts energy. After traversing a path of 30 cm they enter a microwave cavity through which passes radio-frequency power. The radio-frequency field induces transitions to the $2P'_{1/2}$ state, and the $2P'_{1/2}$ ions decay almost immediately to the ground state with the emission of 303.8 A photons. These photons eject electrons from a platinum photosurface. Photodetection is used in place of surface detection in order to avoid the background signal which would result from ground-state ions. The photoelectric current is approximately 4.4×10^{-15} ampere for an ion beam current of 10^{-8} ampere and electron bombardment energy of 200 volts. These currents are of sufficient intensity and stability

to permit a precise determination of the hyperfine splitting of ionized helium-3. The experiment is performed in a bakeable, stainless steel vacuum system to avoid surface charging effects. (Contractor's abstract)

VACUUM POLARIZATION IN A STRONG COULOMB FIELD, by E. H. Wichmann and N. M. Kroll. [1956] [17]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research and [Air Force Office of Scientific Research under DA 36-039-sc-64630]) Unclassified

Published in Phys. Rev., v. 101: 843-859, Jan. 15, 1956.

A study is carried out of the vacuum polarization in a strong Coulomb field. Radiative corrections are neglected. A perturbation calculation is avoided by making use of the explicit solutions of the Dirac equation in a Coulomb field. The Laplace transform of the polarization charge density times r^2 is found and used as a basis for further study. It is proved to be an analytic function of the strength of the inducing charge. It is verified that the first-order term in a power series expansion in the strength of the inducing charge just corresponds to the Uehling potential. The third-order term is studied in some detail. The leading term in the polarization potential close to the inducing charge and the space integral of the induced potential divided by r are found to all orders in the strength of the inducing charge. Ambiguities are handled by a method corresponding to regularization. Some experimental applications are considered. The corrections to the Uehling term in these cases are found to be small. COLLECTED PAPERS ON THE MASER. FURTHER ASPECTS OF THE THEORY OF THE MASER, by K. Shimoda, T. C. Wang, and C. H. Townes. Mar. 1, 1956, 39p. incl. diagrs. tables. (Special tech. rept. no. CU-1-56) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-64630) AD 89059 Unclassified

Also published in Phys. Rev., v. 102: 1308-1321, June 1, 1956.

The theory of the molecular transitions which are induced by the microwave field in a maser and the effects of various design parameters are examined in detail. It is shown that the theoretical minimum detectable beam intensity when the maser is used as a spectrometer for the 3-3 line of ammonia is about 10^9 mole/sec under typical experimental conditions. Various systematic frequency shifts and random frequency fluctuations of the maser oscillator are discussed and evaluated. The most prominent of the former are the "frequency-pulling" effect which arises from detuning of the cavity and the Doppler shift due to the asymmetrical coupling of the beam with the two travelling wave components of the standing waves which are set up in the cavity. These two effects may produce fractional shifts as large as one part in 10^9. If adequate precautions are taken, however, they can be reduced to one part in 10^{10} or possibly less. The random fluctuations are shown to be of the order of one part in 10^{12} under typical operating conditions. For molecular beams in which the electric-dipole transition is used, the TM_{010} mode is usually the most suitable for the maser; while in atomic beams in which magnetic transitions are utilized, the TE_{011} mode is to be perferred. THE DEVELOPMENT OF A TUNABLE CW MAGNETRON IN THE K-BAND REGION, by Z. Fraenkel. June 1, 1956, 54p. incl. diagrs. tables, refs. (Special tech. rept. no. CU-3-56) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA-36-039-sc-64630) AD 103126 Unclassified

The development of a low field, K-band, tunable CW magnetron is described. The major characteristics of the device are presented and compared to the characteristics of other K-band magnetrons. The research leading towards the development of the magnetron is outlined. This research program had two major objectives: (a) the study of cathode back-bombardment in CW magnetrons, and (b) the study of low field operation. The cathode back-bombardment was found to be closely related to two voltage regions

COU. 02:022 - COU. 03:004

at which large anode currents were drawn without any connection to magnetron parameters. The research program culminated in the development of a low field, K-band, tunable CW magnetron, utilizing capacitive Crown of Thorns tuning. At a fixed operating point an output power exceeding 10 watts at an efficiency exceeding 5% can be obtained over a tuning range of 7%. The tuning range can be doubled by lowering the output power requirements and making use of two operating points. (Contractor's abstract)

MICROWAVE DETERMINATION OF CARBON AND OXYGEN MASS RATIOS (Abstract), by B. Rosenblum and A. H. Nethercot, Jr. [1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, [Air Force Office of Scientific Research], and Atomic Energy Commission under [DA 36-039-sc-64630]) Unclassified

Paper presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 13-14, Jan. 30, 1956.

Precision measurements of the J = 0 → 1 rotational transition in $C^{12}O^{16}$, $C^{13}O^{16}$, and $C^{12}O^{18}$ have been made in 120,000 mc. Accurate atomic mass ratios can be determined from such measurements only if a correction to the moment of inertia of the molecule is made for the excitation of higher electronic states by the rotation of the molecule. It has been shown that this correction can be computed from the magnetic moment resulting from this rotation-electronic interaction. The magnetic moment of the CO molecule has been measured by comparison with the known magnetic moment of the arsenic nucleus in the molecule AsD_3. With this correction the C^{13}/C^{12} and O^{18}/O^{16} ratios were determined, and the results are in excellent agreement with nuclear reaction data. The magnitude of the correction was approximately 20 parts per million. Work is in progress to further improve the accuracy of these measurements and to extend them to include C^{14} and O^{17}. THE MICROWAVE SPECTRUM OF ETHYL BROMIDE, by R. S. Wagner, N. Solimene, and B. P. Dailey. Jan. 3, 1955 [3]p. incl. table. (Rept. no. CU-7-55) [AFOSR-TN-55-6] (AF 18(600)1152) Unclassified

Also published in Jour. Chem. Phys., v. 23: 599, Mar. 1955.

Several rotational transitions for $C_2H_5Br^{79}$ and $C_2H_5Br^{81}$ have been observed and identified which yield exact values of B and C for both species and an estimate of eqQ along the C-Br bond axis. C_2H_5Br is a nearly prolate rotor (κ = -0.98) with the dipole moment having components along the A and B principal axes. From the assumed structure, a reduced moment of inertia of 5.11×10^{-40} g sq cm was calculated, and a sinusoidal barrier height of 2800 cal/mole was obtained.

Also published in Jour. Chem. Phys., v. 22: 1459, Aug. 1954.

A study of the microwave spectrum of C_2H_5Cl led to the identification of 4 transitions for $C_2H_5Cl^{35}$ and 2 transitions for $C_2H_5Cl^{37}$ on the basis of their Stark patterns and quadrupole hyperfine structure. These transitions involve the dipole component along the A axis. From assumed parameters, calculation of the moments of inertia indicated that C_2H_5Cl was a nearly prolate rotor (κ = -0.95) with the dipole moment having components along the A and B principal axes. Calculated and observed rotational constants are given. From intensity ratio measurements, the torsional frequency was calculated to be 215 cm^{-1}. For a reduced moment of 4.76×10^{-40} g sq cm, a sinusoidal barrier height of 3000 cal/mole was obtained.

THE INTERPRETATION OF QUADRUPOLE SPECTRA, by B. P. Dailey. Jan. 3, 1955, 13p. incl. refs. (Rept. no. CU-5-55) (AFOSR-TN-55-9) (AF 18(600)-1152) Unclassified

Also published in Faraday Soc. Discussions, No. 19: 255-260, 1955.

The interpretation of the nuclear quadrupole coupling constant (eqQ) obtained by the analysis of several types of radio-frequency spectroscopy is discussed. It was pointed out that eqQ for an isolated molecule was largely determined by the number of electrons which occupy p atomic orbitals in the valence shell of the atom in which the quadrupolar nucleus is located. Several approximate relations between the quadrupole coupling constant, the amount of ionic character, and the type of hybridization occurring in the bonding orbitals formed by an atom in an isolated molecule are discussed. The views of several authors on the role of the overlap integral in such approximate calculations are reviewed.

The addition of DCl to CH_2=CH_2 resulted in the formation of 2 molecular species, both having the structural formula CH_2DCH_2Cl (I). One deuterated species has D in the plane of symmetry of the molecule and is called trans, since D is diagonally opposite the Cl atom in the symmetry plane. The cis species has the D atom occupying either of 2 equivalent positions not in the symmetry plane. The moments of inertia of these 2 forms of I depend to a great extent on whether they are in the staggered or eclipsed configuration. The calculated moments of inertia of trans I in the eclipsed and staggered configurations are given.

RELATIVE ELECTRON DENSITIES IN SUBSTITUTED BENZENES, by P. L. Corio and B. P. Dailey. July 1, 1956 [28]p. incl. diagrs. tables, refs. (AFOSR-TN-55-440) (AF 18(600)1152) AD 100825 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 3043-3048, July 5, 1956.

The proton magnetic resonance spectra of a number of monosubstituted benzenes have been studied in an attempt to derive values of the relative electron density from observations of the chemical shifts of the ring protons, and the effect of various functional groups on these shifts. Shifts are assigned to the protons at different ring positions, and these indicate differences in the electron distribution at the o, m, p positions. The observed shifts are compared with data from other expertmental sources, with theoretical calculations of electron densities in substituted benzenes and with the electronic theory of orientation effects in benzene substitutions. In particular, the importance of polarization effects in aromatic substitution reactions is emphasized. (Contractor's abstract)

THE ELECTRON WITHDRAWAL POWER OF SUBSTITUENT GROUPS, by B. P. Dailey and J. N. Shoolery. [1955] [5]p. incl. diagrs. tables. [AF 18(600)1152] Unclassified

Published in Jour. Amer. Chem. Soc., v. 77: 3977-3981, Aug. 5, 1955.

A study of chemical shifts in the nuclear magnetic resonance spectra of ethyl and methyl dertvatives of a number of organic substituent groups has been made. It was desired to find out how the electronegativity of an atom changes when it forms a part of different substituent groups and to attempt to derive a table of the electron withdrawal power of the substituent groups. A simple relationship between proton "chemical shifts" and the ionic character of the chemical bond to the proton has been established by the regularities existing in the experimental results of this study. It is shown that the electron withdrawal power of a substituent group is largely determined by the electronegativity of the first atom in the group. (Contractor's abstract)

THE IONIC CHARACTER OF DIATOMIC MOLECULES, by B. P. Dailey and C. H. Townes. Jan. 1955 [6]p. incl. diagrs. tables, refs. [AF 18(600)1152] Unclassified

Published in Jour. Chem. Phys., v. 23: 118-123, Jan. 1955.

A relation between the electronegativity difference of two bonded atoms and the ionic character of the bond is obtained for singly bonded diatomic molecules in the gaseous state. The relation is based primarily on the wide variety of nuclear quadrupole coupling constants recently measured by microwave techniques. However, dipole moments of diatomic molecules are also used and discussed. Both quadrupole coupling constants and dipole moments indicate strongly that bonds involving electronegativity differences greater than 2 are almost completely ionic. Certain effects of hybridization, overlap, and polarization on considerations of ionicity are discussed. (Contractor's abstract)

MICROWAVE SPECTRUM OF ETHYL CHLORIDE, by R. S. Wagner and B. P. Dailey. [July 27, 1956] [6]p. diagr. tables, refs. (AF 18(600)1152) Unclassified

Published in Jour. Chem. Phys., v. 26: 1538-1593, June 1957.

The microwave spectrum of ethyl chloride has been investigated and accurate values for the rotational constants B and C for several isotopic species have been obtained. For $C_2H_5Cl^{35}$, B=5493.8 mc, C=4962.3 mc, and for $C_2H_5Cl^{37}$, B=5379.1 mc and C=4867.1 mc. Two deuterated species have been studied. For trans $CH_2DCH_2Cl^{35}$, B=5098.8 mc and C=4637.5 mc. The rotational constants for gauche $CH_2DCH_2Cl^{35}$ are B=5297.6 mc and C=4784.9 mc. The following model reproduces these constants to within 4 mc: dC-C= 1.5495 A, dC-H=1.101 A, dC-D=1.090 A, ∢ HCH=110° 00', ∢ CCCl=110°30', dC-Cl=1.7785 A. From the structural data obtained for the deuterated ethyl chlorides it has been possible to establish the staggered configuration as the equilibrium configuration. The quadrupole analysis shows that eqQ along the C-Cl bond axis is -70.07 mc for Cl^{35} and -55.03 mc, for Cl^{37}, indicating an ionicity of 25%. The torsional frequency has been estimated to be 236 cm^{-1} and the barrier height is 3.4 kcal/mole. (Contractor's abstract)

PROTON-DEUTERON HYPERFINE STRUCTURE IN PARAMAGNETIC RESONANCE: A π-σ INTERACTION, by B. Venkataraman and G. K. Fraenkel. July 15, 1955. 11p. refs. (Rept. no. CU-2-55-AF-1390-Chem.) (AFOSR-TN-55-208) (AF 18(600)1390) AD 75141 Unclassified

Also published in Jour. Chem. Phys., v. 24: 737-740, Apr. 1956.

The mechanism of the hyperfine splitting observed in paramagnetic resonance spectra of certain aromatic free radicals containing protons adjacent to the aromatic ring is examined. It is shown that the magnitude of the interaction between an unpaired electron in a π-orbital and a vibrating hydrogen atom is insufficient to account for the observed splitting. Such a vibrational mechanism is untenable: (1) on the basis of quantitative calculations; (2) by the failure to observe lines corresponding to the first excited vibrational state; and (3) by a comparison of the splitting caused by protons and deuterons. It is suggested that the unpaired electron is not in a purely π-state, and that the splitting may be accounted for by configuration interaction between π- and σ- states. (Contractor's abstract)

PARAMAGNETIC RESONANCE OF FREE RADICALS, by G. K. Fraenkel. May 15, 1956 [40]p. incl. illus. diagrs. refs. (Rept. no. CU-6-56-AF-1390-Chem.) (AFOSR-TN-56-218) (AF 18(600)1390) AD 88024 Unclassified

Also presented at Conference on Unstable Chemical Species under the auspices of New York Acad. Sciences, May 15-16, 1956.

The elementary principles of paramagnetic resonance absorption spectroscopy are reviewed with respect to detection, identification, and estimation of free radicals. The typical spectra of free radicals in solution reveal a structure caused by nuclear magnetic hyperfine interaction. The interaction is related to the unpaired electron density in the molecule. The structure provides a means for the qualitative identification of the radical species. The identification is useful for determining the nature of the intermediates in many radical reactions. Equilibrium concentrations of radicals can be obtained. The rate of the production of radicals can be followed either directly or with flow reactors. At present, spectrometers are capable of detecting 10^{-11} mol of radical. When a suitable solvent is employed, an ultimate sensitivity of 10^{-10} mol/l is estimated.

COMPOUND GROUP EXTENSIONS. 1. CONTINUATIONS OF NORMAL HOMOMORPHISMS, by R. L. Taylor. [1953] [30]p. (AF 18(600)135) Unclassified

Published in Trans. Amer. Math. Soc., v. 73: 106-135, July 1953.

COU. 05:002 - COU. 05:004

This question, in the theory of non-commutative groups, arises from topology. For a "normal" homomorphism ϕ: K into G, that is, with image normal in G, a "continuation" is a pair $(E, \bar{\phi})$ where $E \supset K$ and $\bar{\phi}$: E onto G is an extension of ϕ with the same kernel, X. A continuation induces a homomorphism θ: G into A, the group of automorphisms of A carrying X into itself, modulo those inner automorphisms induced by X. Generally, normal ϕ: K into G, and θ: G into A constitute a "pseudo-module" (ϕ, θ) provided $\theta\phi$ is the natural map K into A. A continuation $(E, \bar{\phi})$ that induces θ, provided such exists, is an "extension" of the ps-module (ϕ, θ). A crossed-module (J. H. C. Whitehead, Bull. Amer. Math. Soc., v. 55: 453-496, 1949; Math. Rev. v. 11: 48) is a ps-module for which the kernel X of ϕ lies in the center Z of K. A Q-kernel (Eilenberg and MacLane, Ann. of Math., v. 48: 326-341, 1947; Math. Rev. v. 9: 7) is a ps-module for which ϕ is trivial. The author sets forth carefully the correspondence between $H^2(Q, X)$ and the (isomorphism classes of) extensions of cr-modules and Q-kernels, and the theory of the obstruction. These results are extended to ps-modules by the following device. Let $\tilde{A}$ be the group of automorphisms of K that carry X into itself, with the natural maps c: K into $\tilde{A}$, λ: $\tilde{A}$ into A. The graph (cf. Baer, Math. Z., v. 38: 375-416, 1934) $\Gamma \subset G \oplus A$ is the group of all (g, α) with $\theta g = \lambda\alpha$. The exact sequence O, X, K, G, Q, O leads to an exact sequence O, $X \cap Z$, K, Γ, Q, O. For ϕ' the induced map K into Γ, and $\theta'(g, \alpha) = \alpha$, this yields a cr-module (ϕ', θ') whose extension theory is equivalent to that of the original ps-module (ϕ, θ). In fact, it is shown that the concept of ps-module is equivalent to that of a pair formed by a cr-module together with a suitably related subgroup of K. An additional result states that (ϕ, θ) admits a splitting extension $(E, \bar{\phi})$ just in case G splits over the image of ϕ. (Math. Rev. abstract)

COMPOUND GROUP EXTENSIONS. II, by R. L. Taylor. [1953] [7]p. (AF 18(600)135) Unclassified

Published in Trans. Amer. Math. Soc., v. 75: 304-310, Sept. 1953.

Let $\{\rho_\nu: R_\nu \to R_{\nu+1}\}$ and $\{\sigma_\nu: S_\nu \to S_{\nu+1}\}$ be two (infinite) exact sequences, and $\{\beta_\nu: R_\nu \to S_\nu\}$ a commuting sequence of homomorphisms; throughout, the additional hypothesis is made that $\sigma_1\beta_1 R_1 = \sigma_1 S_1$. Call this figure F, and F′ the figure obtained by deleting R_2, ρ_1, ρ_2, and β_2. This paper characterizes the set of (isomorphism classes of) "completions" F of a given figure F′. Replacing R_1 by a factor group and R_3 by a subgroup reduces the problem to the case where R_0, S_0, R_4 and S_4 are all trivial, as we may assume henceforth. If β_1 is an isomorphism of R_1 onto S_1, there is a unique solution with R_2 the appropriate graph $\Gamma \subset R_3 \oplus S_1$. With reference to this case, for S_1 in place of R_1, the general problem is now shown to reduce to that for continuations (in the sense of part I, reviewed above) of the naturally induced normal homomorphism $R_1 \to S_1 \to \Gamma$. Finally, if θ is given constituting, together with β_1, a pseudo-module, there corresponds naturally a pseudo-module (β_1', θ') with β_1': $R_1 \to \Gamma$, and the completions of F′ correspond one-to-one with the extensions of (β_1', θ'). COVERINGS OF NON-CONNECTED GROUPS, by R. L. Taylor. [1954] [16]p. (AF 18(600)135) Unclassified

Published in Proc. Amer. Math. Soc., v. 5: 753-768, Oct. 1954.

The results of item no. COU. 05:001 are applied to give a classification of the covering groups of a non-connected topological group G, assuming that the arcwise components of G admit universal covering spaces. Examples show that even if G is a compact 1-dimensional Lie group, G may admit several non-isomorphic universal coverings, or no universal coverings at all; G may also admit non-trivial coverings which cannot be obtained by factorization from any universal covering. Given any covering, there is a natural homomorphism $\pi_1(N) \to K$, where N is the arcwise component of the identity in G and X is the kernel of the covering. The kernel of $\pi_1(N) \to X$ is called the type of the covering. In particular, the universal coverings are the coverings of type O. A subgroup of $\pi_1(N)$ is called stable if it is mapped onto itself by every element of $Q = G/N$ under the natural operation of Q on $\pi_1(N)$. Let ρ be an arbitrary subgroup of $\pi_1(N)$. We show: (1) if ρ is unstable, there are no coverings of type ρ; (2) if ρ is stable, it has an "obstruction" in $H^3[Q, \pi_1(N)/\rho]$ whose vanishing is a necessary and sufficient condition for the existence of a covering of type ρ; (3) if ρ is stable, $H^2[Q, \pi_1(N)/\rho]$ operates simply transitively on the set of all isomorphism-classes of coverings of type ρ. These results are generalized to a classification of all topological group extensions of a topological group G by a topological group X provided X (the kernel) is discrete and the arcwise components of G (the factor group) admit universal covering spaces. This essentially reduces the topological group extension problem to the case where both subgroup and factor group are connected. (Contractor's abstract)

ERGODIC THEORY OF MARKOV CHAINS ADMITTING AN INFINITE INVARIANT MEASURE, by T. E. Harris and H. Robbins. [1953] [5]p. [Technical rept. no. 1] (AF 18(600)442) Unclassified

Published in Proc. Nat'l. Acad. Sciences, v. 39: 860-864, Aug. 1953.

The authors show how to apply the point-ergodic theorem for spaces of infinite measure to (integer-valued parameter) Markov processes possessing infinite-valued stationary absolute "probability distributions." As an application, they prove that, if s_n is the sum of n mutually independent random variables with a common distribution, and if the sequence $\{s_n, n \geq 1\}$ is everywhere dense with probability 1, then, if h and k are Lebesgue integrable over $(-\infty, \infty)$, with integrals $\bar{h}$, $\bar{k}$, $\bar{k} \neq 0$, it follows that

$\lim_{n \to \infty} \sum_1^n h(a + s_j) \; / \; \sum_1^n k(a + s_j) = \bar{h}/\bar{k}$ with

probability 1, for almost all a (Lebesgue measure). Moreover, for every a, this limit equation is true with probability 1 simultaneously for every h, k under the additional restriction that these functions be Riemann integrable and vanish in a neighborhood of infinity. If the s_j's are integer-valued, an analogous result is obtained, in which the Lebesgue measure of a linear set is replaced by the cardinal number of a set of integers. (Math. Rev. abstract)

A SOLUTION OF A SET OF FUNDAMENTAL EQUATIONS IN MARKOV CHAINS, by C. Derman. [1953] [3]p. Technical rept. no. 2 AF 18(600)442] Unclassified

Published in Proc. Amer. Math. Soc., v. 5: 332-334, Apr. 1954.

Consider a discrete Markov chain, with an infinite number of possible states E_i ($i = 0, 1, 2, \ldots$), homogeneous, irreducible, with a transition matrix $P = (p_{ij})$, p_{ij}^n indicating the elements of P^n; let $\Pi_j^n = \sum_{r=0}^{n} p_{ij}^r$, an easily interpreted quantity; K. L. Chung (Jour. Res. N.B.S. Bu. Standards, v. 50: 203-208, 1953; Math. Rev., v. 14: 1099, 1953) has shown that if E_i and E_j are recurrent states, then $\lim_{n \to \infty} \Pi_j^n / \Pi_i^n$ exists. If all E_i states are recurrent, the author concludes that a system and a unique value v_k exists, such as (a) $v_o = 1$, (b) $v_j > 0$ ($j = 1, 2, \ldots$), (c) $v_j = \sum_{i=0}^{\infty} v_i p_{ij}$, i.e. the numbers $v_k = \lim_{n \to +\infty} \Pi_k^n / \Pi_o^n$. DISTRIBUTIONS OF SOME INTEGRALS OF CERTAIN STOCHASTIC PROCESSES AND LIMITING DISTRIBUTIONS OF SOME "GOODNESS OF FIT" CRITERIA, by T. W. Anderson. [1953] 43p. (Technical rept. no. 4) (AF 18(600)442) AD 36729 Unclassified

To test the hypothesis that a sample of N observations has been drawn from a population with a specified cumulative distrioution function F(x), one can compare the empirical cumulative distribution function $F_N(x)$ with F(x) by using $W_N = N \int \left[F_N(x) - F(x) \right]^2 \psi \left[F(x) \right] dF(x)$ or $V_N = N \iint 1\left[F(x), F(y) \right] \left[F_N(x) - F(x) \right] \left[F_N(y) - F(y) \right] dF(x) dF(y)$, where $1(u, v) = 1(v, u)$ is continuous in both variables ($0 \leq u, v \leq 1$). The characteristic function of $V = \iint 1(u, v) X(u) X(v) du\, dv$, where X(u) ($0 \leq u \leq 1$) is a Gaussian stochastic process with $\varepsilon X(u) = 0$, is found in terms of the eigenvalues of a certain function, and it is shown that the asymptotic distribution of V_N is that of V when X(u) has a certain covariance function. The characteristic functions of $T = \int \left[X(u) + k(u) \right]^2 du$ and $S = \iint 1(u, v) \left[X(u) + k(u) \right] \left[X(v) + k(v) \right] du\, dv$ are found, and it is shown that the limiting distribution of V_N is that of T for a certain k(u) when the sample of N is drawn from $H_N(x)$ such that $\lim_{N \to \infty} H_N(x) = F(x)$. Some examples of the theory are considered. (Contractor's summary)

SOME CONTRIBUTIONS TO THE THEORY OF MARKOV CHAINS, by C. Derman. Mar. 1954, 63p. incl. refs. (Technical rept. no. 7) ([AF]OSR-TN-54-66) (AF 18(600)442) AD 31552 Unclassified

Also published in Trans. Amer. Math. Soc., v. 79: 541-555, July 1955.

Consideration is given to the statistical regularity properties of a denumberable number of particles, all moving about the states of a Markov chain according to the same transition probabilities. Treatment is given to the related problem of solving a familiar system of equations occurring in the theory of Markov chains. An investigation was made of the problem of obtaining

COU. 06:005 - COU. 06:008

sharper versions of a strong limit theorem that was proved independently by Harris (Tran. Am. Math. Soc., v. 75, 1952) and Levy (Ann. Sci. Ecole Norm., v. 68, Sup. 3, 1951). Proofs are presented of some multivartate central-ltmit theorems applicable to the development of asymptotic distrtbution theory which is useful in treating statistical problems involving Markov chains with denumerably many states. The results are essentially an extension of Bartlett's results (Proc. Cambridge Phil. Soc., v. 47, part 1, 1951) to denumerable chains. The assumption is made that the Markov chain under consideration is irreducible and recurrent.

ON CHAINS OF INFINITE ORDER, by T. E. Harris. Mar. 1954, 46p. incl. refs. (Technical rept. no. 5) ([AF]OSR-TN-54-67) (AF 18(600)442) AD 32466 Unclasstfied

Studies are made of stationary stochastic processes with a finite number of states by means of an equivalent stationary real-valued Markov process. Conditions are stated for the existence of an ergodic stationary process with assigned conditional probabilities. The distribution of the equivalent Markov chain variable is studied and is found in general to be continuous and purely singular. Applications are made to a special type of stationary process where the random variable is a function of the states of a Markov chain with a finite number of states; such processes are generally not Markovian. A TEST OF GOODNESS OF FIT, by T. W. Anderson and D. A. Darling. May 1954, 7p. (In cooperation with Michigan U., Ann Arbor) ([AF]OSR-TN-54-113) (AF 18(600)442) AD 39348 Unclassified

Also published in Jour. Amer. Stat. Assoc., v. 49: 765-769, Dec. 1954.

Asymptotic significance points are given for a distribution-free test of goodness of fit previously introduced (Ann. Math. Stat., v. 23: 193-212, 1952). The test criterion is given by

$W_n^2 = n \int_{-\infty}^{\infty} [F_n(x) - F(x)]^2 \psi[F(x)]\, dF(x)$, where

$\psi(u)$ is some nonnegative weight function chosen to accentuate the values of $F_n(x) - F(x)$ where the test is desired to have sensitivity. $F(x)$ is compared with an empirical distribution function $F_n(x)$ equal to the number of $x_i \leq x$ divided by n. The null hypothesis $H(x) = F(x)$ is rejected if W_n^2 is sufficiently large. The sampling error is equalized over the entire range of x by using $\psi(u) = \frac{1}{u(1-u)}$ as the weight function. The 1, 5, and 10% asymptotic significance points of W_n^2 are presented, and the test is illustrated by a numerical example used previously by Birnbaum (Jour. Amer. Stat. Assoc., v. 47: 425-441, 1952) in illustrating the Kolmogorov test.

MULTIPLE POINTS OF PATHS OF BROWNIAN MOTION IN THE PLANE, by A. Dvoretzky, P. Erdös, and S. Kakutani. [1954] [18]p. (Technical rept. no. 6) (AF 18(600)442) AD 36740 Unclassified

Also published in Bull. Res. Council of Israel, v. 3: 364-371, Mar. 1954.

The following notation is used: a probability space $(\Omega, \mathcal{E}, Pr)$ is given where $\Omega = \{\omega\}$ is a set of elements ω, $\mathcal{E} = \{E\}$ is a Borel field of subsets of Ω called events, and Pr is a countably additive measure defined on $\mathcal{E}$ and satisfying $Pr(\Omega) = 1$. Pr(E) is called the probability of the event E. For any point z in the plane, for any $\omega \in \Omega$, and for any real numbers a, b with $0 \leq a < b < \infty$ the following paths are defined: $L_{a,b}(z';\omega) = \{z' + z(t,\omega) \mid a \leq t \leq b\}$; $L_a(z';\omega) = \{z' + z(t,\omega) \mid a \leq t < \infty\}$; $L(z';\omega) = L_0(z';\omega) = \{z' + z(t,\omega) \mid 0 \leq t < \infty\}$ where the + sign refers to vector addition in the plane. When z' coincides with the origin, the abbreviation $L(\omega) = L(0;\omega)$ is used; $L_{a,b}(z';\omega)$ is called the (a, b)-path of the plane Brownian motion starting from z', and $L(z';\omega)$ is called the path of the plane Brownian motion starting from z'. A point z_0 in the plane is called a k-multiple point ($k = 2, 3, \ldots$) of $L_{a,b}(z';\omega)$ if there exist k real number $t_1, \ldots, t_k$ with $a \leq t_1 < \ldots < t_k \leq b$ for which $z_0 = z' + z(t_i;\omega)$, $i = 1, \ldots, k$. The main result is given by the following: Theorem: let M be the set of all ω for which $L(\omega)$ contains k-multiple points for every $k = 2, 3, \ldots$, then $Pr(M) = 1$. These additional results are given. Theorem: let a, b be any positive numbers with $0 \leq a < b < \infty$. Then with probability 1, the (a, b)-path $L_{a,b}(\omega)$ has multiple points of arbitrarily high (finite) multiplicity. Theorem: for almost all ω the set of k-multiple points of $L(\omega)$ is dense everywhere in the plane for all $k = 2, 3, \ldots$.

THE SEQUENCE OF SUMS OF INDEPENDENT RANDOM VARIABLES, by G. Kallianpur and H. Robbins. [June 1954] [23]p. [Technical rept. no. 5] (AF 18(600)-442) Unclassified

Published in Duke Math. Jour., v. 21: 285-307, June 1954.

Let S_n be the sums of n independent random variables with a common distribution $F(x)$ and $M_n(a)$ be the number of S_j's for $j = 1, \ldots, n$ such that $|S_j| < a$. The limit distribution of $M_n(a)$ was obtained by Chung and Kac (Mem. Amer. Math. Soc., no. 6, 1951) when F is a symmetrical stable distribution. Let $b(x)$ be Riemann integrable in a finite interval and 0 outside. Limit distributions for $\sum_1^n h(S_j)$ are obtained assuming asymptotic forms for $Pr(a < S_n < b)$. These forms hold for certain absolutely continuous $F(x)$ belonging to the domains of attractions of symmetrical stable distributions, according to a slight modification of an argument of Gnedenko and Kolmogorov (Limit distributions for sums of independent random variables, Gostehizdat, Moscow-Leningrad, 1949; translation reviewed in Math. Rev., v. 16: 52, Jan. 1955). (Math. Rev. abstract)

ON STRONG BOUNDS FOR SUMS OF INDEPENDENT RANDOM VARIABLES WHICH TEND TO A STABLE DISTRIBUTION, by M. Ltpschutz. [1955] 25p. refs. [AFOSR-TN-55-105] (AF 18(600)442) AD 79614 Unclassified

Also published in Trans. Amer. Math. Soc., v. 81: 135-154, Jan. 1956.

Strong bounds are given for the sums S_n of independent random variables X_k, $k = 1, 2, \ldots$. Strong upper bounds were derived by Feller (Trans. Amer. Math. Soc., v. 67: 98, 1949) and Levy (Studia Math., v. 3: 117, 1931), but lower bounds were unknown except in the special case for $\gamma = 1/2$. Proofs are presented for the following strong lower bounds. (1) Let $0 < \gamma < 1$, and let $\psi(n) \uparrow \infty$ such that $\psi(n)/n \downarrow 0$; then $P(\psi) = P(S_n < b_n \psi(b_n)^{1/\gamma} \text{ i.o.}) = 0$ or 1 as $I_1(\psi) = \int_1^\infty \left[\psi(x)^{\frac{1}{2}\frac{1}{1-\gamma}}/x\right] \exp -k_\gamma \psi(x)^{\frac{1}{1-\gamma}} dx < \infty$ or $= \infty$. (2) Let $1 < \gamma < 2$, and let $\psi(n) \uparrow \infty$ such that $\psi(n)/n \downarrow 0$; then $P(\psi) = P(S_n - np < -b_n \psi(b_n) \text{ i.o.}) = 0$ or 1 as $I_2(\psi) = \int_1^\infty \frac{\psi(x)^{\frac{1}{2}\frac{1}{\gamma-1}}}{x} \exp -k_\gamma \psi(x)^{\frac{1}{\gamma-1}} dx < \infty$ or $= \infty$. The following theorem presents strong upper bounds. Let $\psi(n) \uparrow \infty$ and $\psi(n)/n \downarrow 0$; then for $0 < \gamma < 1$, $P(S_n > b_n \psi(S_n)^{\frac{1}{\gamma}} \text{ i.o.}) = 0$ or 1

$1 < \gamma < 2$, $P(W_n - np > b_n \psi(b_n)^{\frac{1}{\gamma}} \text{ i.o.}) = 0$ or 1 as $I_3(\psi) = \int_1^\infty dx/x\psi(x) < \infty$ or $= \infty$. The notation $P(\ldots \text{ i.o.})$ denotes that $(\ldots)$ occurs for infinitely many n.

ON STOCHASTIC APPROXIMATION, by A. Dvoretzky. [1954] 41p. (Rept. no. CU-29-55) ([AF]OSR-TN-55-385) (AF 18(600)442) AD 91538 Unclassified

Also published in Proc. Third Berkeley Symposium on Mathematical Statistics and Probability, Calif. U., Dec. 1954, and June and July 1955: 39-55.

A stochastic approximation is presented for a general situation which considers the random element as noise superimposed on a convergent deterministic scheme. The main result is as follows: Let α_n, β_n, and γ_n, $n = 1, 2, \ldots$, be nonnegative real numbers satisfying (1) $\lim_{n\to\infty} \alpha_n = 0$; (2) $\sum_{n=1}^{\infty} \beta_n < \infty$; and (3) $\sum_{n=1}^{\infty} \gamma_n = \infty$. Let ϑ be a real number and T_n, $n=1, 2, \ldots$, be measurable transformations satisfying $|T_n(r_1, \ldots, r_n) - \vartheta| \leq \max[\alpha_n, (1+\beta_n)|r_n - \vartheta| - \gamma_n]$ for all real $r_1, \ldots, r_n$. Let X_1 and Y_n, $n=1, 2, \ldots$, be random variables and define $X_{n+1}(\omega) = T_n(X_1(\omega), \ldots, X_n(\omega)) + Y_n(\omega)$ for $n \geq 1$. Then the conditions $E\{X_1^2\} < \infty$, $\sum_{n=1}^{\infty} E\{Y_n^2\} < \infty$, and $E\{Y_n | x_1, \ldots, x_n\} = 0$ with probability 1 for all n, imply $\lim_{n\to\infty} E\{(x_n - \vartheta)^2\} = 0$ and $P\{\lim_{n\to\infty} X_n = \vartheta\} = 1$. Five extensions or generalizations are given in which one or more of the assumptions are relaxed. The Robbins-Monro and Kiefer-Wolfowitz procedures for weaker conditions are included in the results as special cases. Some remarks are made on extensions to nonreal random variables. AN EMPIRICAL BAYES APPROACH TO STATISTICS, by H. Robbins. [1954] [11]p. (Rept. no. CU-27-55) ([AF]OSR-TN-55-387) (AF 18(600)442) AD 77464 Unclassified

Also published in Proc. Third Berkeley Symposium on Mathematical Statistics and Probability, Calif. U., Dec. 1954, and June and July 1955: 157-163.

The following problem is considered: from an approximate value of $p_n(x)$ equal to (the number of terms $X_1, \ldots, X_n$ which equal x) divided by n of the integral $p_G(x) = \int p(x|\lambda)\, dG(\lambda)$, where $p(x|\lambda)$ is a known kernel, obtain an approximation to the unknown distribution function G or to the value of the Bayes function $\phi_G(x) = \int \frac{p(x|\lambda)\,\lambda\, dG(\lambda)}{p(x|\lambda)\, d\, G(\lambda)}$ which depends on G. The X_n are discrete random variables and for any fixed x, $p_n(x)$ tends with probability 1 to $p_G(x)$ as $n\to\infty$. The analysis depends on the nature of $p(x|\lambda)$ and on the class g to which the unknown G is assumed to belong. The following special cases are considered: (1) the Poisson kernel $p(x|\lambda) = e^{-\lambda}\frac{\lambda^x}{x!}$, $x = 0, 1, \ldots$, $\lambda > 0$, and g is the class of all distribution functions on the positive real axis; (2) the geometric kernel $p(x|\lambda) = (1-\lambda)\lambda^x$, $x = 0, 1, \ldots$, $0 < \lambda < 1$; (3) the binomial kernel $p_r(x|\lambda) = \binom{r}{x}\lambda^x(1-\lambda)^{r-x}$, $x = 0, 1, \ldots, r$, $0 \leq \lambda \leq 1$; r is a fixed positive integer representing the number of trials, x is the number of successes in each trial, and G is the class of all distribution functions on the unit interval; and (4) a Laplacian type kernel $p(x|\lambda) = e^{\lambda x} f(x)h(\lambda)$. The problem for the general case when X is not restricted to discrete values is discussed.

ON COVERING A CIRCLE BY RANDOMLY PLACED ARCS, by A. Dvoretzky. [1955] [9]p. (Rept. no. CU-32-55) ([AF]OSR-TN-55-449) (AF 18(600)442) AD 91258 Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 42: 199-203, Apr. 1956.

A negative answer is given to the query of whether or not the condition $\sum_{i=1}^{\infty} a_i = \infty$ assures that the whole of C is covered with probability 1, where C denotes a circle of unit circumference, and a_i, $i=1, 2, \ldots$ is a sequence of positive numbers smaller than 1. A proof

is presented that sequences $\{a_i\}$ exist satisfying $\sum_{i=1}^{\infty} a_i = \infty$ for which the probability that the whole of C is covered by arcs A_i of length a_i is less than 1; the formal statement is $P\{C \subset \bigcup_{i=1}^{\infty} A_i\} < 1$ or equivalently, $P\{\text{all of C covered infinitely often}\} = 0$. The centers of the arcs A_i are assumed to be uniformly and independently distributed on C.

THE CRAMÉR-SMIRNOV TEST IN THE PARAMETRIC CASE, by D. A. Darling. [1955] 20p. incl. refs. [Technical rept. no. 3] (AF 18(600)442) Unclassified

Published in Ann. Math. Stat., v. 26: 1-20, Mar. 1955.

Let $X_1, X_2, \cdots, X_n$ be n independent identically distributed random variables having an absolutely continuous distribution function G(x). Let I be a nondegenerate interval on the real axis and suppose, for each θ contained in the interior of I, that $F(x;\theta)$ is a distribution function. The problem is to test the hypothesis H, i.e. H: $G(x) = F(x;\theta)$ for some unspecified $\theta \in I$. Let $F_n(x)$ be the empirical distribution function based on a random sample of size n. The following test function C_n^2 is considered where

$$C_n^2 = n \int_{-\infty}^{\infty} [F(x) - F(x;\hat{\theta}_n)]^2 dF(x;\hat{\theta}_n),$$

and where $\hat{\theta}_n$ denotes a suitable estimator for θ. H will be rejected for C_n^2 suitably large. When the hypothesis completely specifies the distribution function, i.e. a specific value for θ is given, the C_n^2 test function is the ω^2 test function developed by Cramér, Smirnov, and von Mises. This extension of the ω^2-test to include the parametric case is unlike the ω^2-test in that in general this test is not distribution free when H is true. When H is true the characteristic function of the limiting distribution of the C_n^2 test function is investigated for several classes of estimators for θ. In particular, subject to given regularity conditions on $F(x;\theta)$ and subject to conditions on $\hat{\theta}_n$ which include that $nE\{(\hat{\theta}_n - \theta)^4\} \to 0$ as $n \to \infty$ (where $E\{\cdots\}$ is the expectation operator), the asymptotic characteristic function of the test is given in terms of a Fredholm determinant of a specific integral equation when the method of estimation for θ is by the method of maximum likelihood. The results are obtained by reducing the problem to studying a Gaussian stochastic process in a manner similar to that employed in the paper by T. W. Anderson and D. A. Darling (Ann. Math. Stat., v. 23: 193-212, 1955). (Math. Rev. abstract)

THE STRONG LAW OF LARGE NUMBERS WHEN THE FIRST MOMENT DOES NOT EXIST, by C. Derman and H. Robbins. [1955] 3p. (Rept. no. CU-33-56) (AFOSR-TN-56-21) (AF 18(600)442) AD 89251 Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 41: 586-587, Aug. 1955.

In this mathematical study let X be a random variable with distribution function F. It is customary to define $EX = +\infty$ if, and only if, $\int_{-\infty}^{0} |x| dF(x) < \infty$, $\int_{0}^{\infty} x dF(x) = \infty$. (I) It then follows from the strong law of large numbers for finite EX that if $\{X_n\}$ is a sequence of independent random variables with common distribution function F for which (I) holds and if $S_n = \sum_{1}^{n} X_i$, then as $n \to \infty$ $Pr[S_n/n \to +\infty] = 1$ (II) A proof is presented which shows, however, that II can hold even though $\int_{-\infty}^{0} |x| dF(x) = \infty$, $\int_{0}^{\infty} x dF(x) = \infty$. It is presented in the following theorem: If for some constants $0 < \alpha < \beta < 1$ and $c > 0$, $F(x) \leq -C/x^{\alpha}$ for large positive x, which implies that $\int_{0}^{\infty} x^{\alpha} dF(x) = \infty$, while $\int_{-\infty}^{0} |x|^{\beta} dF(x) < \infty$, then II holds.

Also published in Ann. Math. Stat., v. 28: 795-798, Sept. 1957.

A nonparametric procedure is proposed for estimating any quantile of F (x) on the basis of quantal response data when x is experimentally restricted to the form a + hn. The procedure is applied to the following conditions: (1) assume a = 0 and h = 1, and estimate the value of $x = \theta$ such that $F(\theta - 0) < \alpha < F(0)$, $1/2 \leq \alpha < 1$. Modifications are given for conditions when $0 < \alpha < 1/2$ or $a \pm 0$ or $h \pm 1$.

SOME TOPICS ON MARKOFF'S AND DIFFUSION SEMIGROUPS, by J. Neveu. Aug. 22, 1956, 36p. (Rept. no. CU-38-56) (AFOSR-TN-56-401) (AF 18-(600)442) AD 96059 Unclassified

In this mathematical study, a general definition of a Markoff's semigroup is presented. A Markoff's semigroup, $\Phi_s S > O$, is a semigroup of linear transformations on a space of continuous functions induced by a Markoff's process Xs according to the formula: $f \rightarrow \Phi_s f \quad \Phi_s f(x) = E(f(X_s)(X_o = X)) = \int f(\xi) F_s(X, d\xi)$o. With this definition, some new ergodic results and propositions relative to invariant measures are given. This study also contributes to the determination of the most general infinitesimal operator Ω of a Markoff's semigroup. The problem is reduced to a local problem in a terminology introduced by Feller. In addition, the problem is solved for diffusion semigroups on the real line by means of an absorption theory. STOCHASTIC APPROXIMATION, by C. Derman. [1956] 15p. refs. (Rept. no. CU-36-56) (AFOSR-TR-56-15) (AF 18(600)442) AD 86590 Unclassified

Also published in Ann. Math. Stat., v. 27: 879-886, Dec. 1956.

An examination is presented of the Robbins-Monro iterative process for estimating the root of the equation $M(x) = \alpha$ under the hypothesis of a unique root and a real number α. The problem of estimating a root of a given regression equation is discussed in the following context: suppose for every real value x, the random variable Y(x), which denotes the value of a response to an experiment conducted at a controlled level x, has the unknown distribution function $H(y \mid x)$ and the regression function $M(x) = \int_{-\infty}^{\infty} y dH(y \mid x)$. The Robbins-Monro method consists of taking a fixed sequence of positive constants $\{a_n\}$, $(n \geq 1)$, such that $\sum_{n=1}^{\infty} a_n = \infty$, $\sum_{n=1}^{\infty} a_n^2 < \infty$. The level x_1 of the first experiment is arbitrary. Succeeding levels are defined recursively by $x_{n+1} = x_n + a_n(\alpha - y_n)$, where y_n denotes the response at level x_n, a random variable dependent only on x_n and having the distribution function $H(y \mid x_n)$. A more general approach to stochastic approximation is considered which treats the approximation as a convergent determinstic procedure with a superimposed random element.

ON THE HOMOLOGY THEORY OF ABELIAN GROUPS, by S. Eilenberg and S. MacLane. Apr. 1954, 17p. (Rept. no. CU-4-54AF562) ([AF]OSR-TN-54-88) (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)562 and Office of Naval Research under Nonr-21800) AD 35963 Unclassified

This report continues the study, by the same authors (Homology theories for multiplicative systems, Trans. Amer. Math. Soc., v. 71: 1951) of the notions of "construction" and "generic acyclicity," and applies them to the homology theory of classes π of abelian groups and their generalizations. For these a "cubical" construction $Q(\pi)$ has been exhibited, and its generic acyclicity proved. Certain gaps in the earlier results are closed in this paper, which defines the construction $A(\pi)$, and establishes its generic acyclicity. (Contractor's abstract)

ALGEBRAS OF COHOMOLOGICALLY FINITE DIMENSION, by S. Eilenberg. May 1954, 16p. (Rept. no. CU-5-54AF562) ([AF]OSR-TN-54-132) (AF 18(600)562) AD 35902 Unclassified

Let Λ be an algebra over a field K with $(\Lambda:K) < \infty$; let N be the radical of Λ; let $\Gamma = \Lambda/N$; let Γ^* be the algebra opposite to Γ; let $\Omega = \Lambda \otimes_K \Gamma^*$. In this paper, the following results are established within the framework of the Cartan-Eilenberg theory (Homological Algebra, Princeton Univ. Press, 1954): Theorem I. Dimension Λ = left global dimension Ω = left dimension $_\Omega\Gamma$. Theorem II. If Γ is separable, then dimension Λ = left dimension $_\Lambda\Gamma$. Theorem III. If dimension Λ is finite then Γ is separable. (All "dimensions" are to be understood in the cohomological sense, as defined in "Homological Algebra.") (Contractor's abstract)

ON THE GROUPS H (π, n), II. METHODS OF COMPUTATION, by S. Eilenberg and S. MacLane. July 1954, 130p. refs. (Rept. no. CU-6-54AF562) (In cooperation with Chicago U., Ill.) ([AF]OSR-TN-54-185) (AF 18(600)562) AD 40838 Unclassified

This is a continuation of previous work by the authors (Ann. Math., v. 58: 55-106, 1953). Methods are established for the group-invariant computation of the integral homology group $H_n\, k(\pi, n)$ regarded as functors of the Abelian group π. The main interest is in the unstable case $k \geq n$ where the functors $H_n + k(\pi, n)$ are not additive such as

$$H_3(\pi_1 + \pi_2, 4) \approx H_3(\pi_1, 4) + H_3(\pi_2, 4) + \pi_1 \otimes \pi_2.$$

The reduction from π finitely generated to π cyclic in the unstable case is achieved by an analysis of cross-effects (the term $\pi_1 \otimes \pi_2$ in the instance above) for arbitrary nonadditive functors. For π cyclic, the complex $\Lambda(\pi, n)$ may be replaced by a simple complex which is finite in each dimension. This guarantees the computability of $H_n + k(\pi, n)$ for π finitely generated. The program is carried out in detail for $k \leq 5$ and $n \geq 2$, except for $H_7(\pi, 2)$. Invariant cohomology results for the groups $H^{n+k}(\pi, n; G)$ are also obtained for $k \leq n$, $k = 2, 3, 4$, and 5.

ON THE VOLUME OF SMOOTH CONVEX BODIES IN HILBERT SPACE, by E. R. Lorch. July 1954, 29p. refs. (Rept. no. CU-7-54AF562) ([AF]OSR-TN-54-194) (AF 18(600)562) AD 47850 Unclassified

A smooth convex body K is defined in a real Hilbert space H, and a class of positive definite self-adjoint transformations is obtained for such a body. These transformations are used to define a fundamental homeomorphism in H which leads to the notion of the adjoint body K*. The volume of K* is expressed by means of an integral of a function of an infinite product of the characteristic values of the self-adjoint transformations. The calculated volume of K* is that of order r = 2; the classical volume corresponds to r = 1. A solution is presented to the problem of finding the volume of ellipsoids in H. (ASTIA abstract)

ON THE DIMENSION OF MODULES AND ALGEBRAS. I, by S. Eilenberg, M. Ikeda, and T. Nakayama. Sept. 1954, 13p. (Rept. no. CU-10-54AF562) [AFOSR-TN-54-269] (AF 18(600)562) AD 67329 Unclassified

A proof is given that the alternative characterizations of algebras of cohomological dimension $\leq n$ which are reported by Ikeda-Nagao-Nakayama (Trans. Amer. Math. Soc.) and Eilenberg (Comment. Math. Helv.) are compatible because the conditions used in stating the principal results of the 2 papers are equivalent. An example of an algebra over an arbitrary ground field is given whose cohomological dimension is infinite but whose Cartan matrix has a determinant equal to -1. The following theorems are proved: (1) if Λ is a K-algebra over a field K, $(\Lambda:K) < \infty$, $\mathcal{N}$ is a 2-sided ideal contained in the radical N of Λ, and $\Lambda' = \Lambda/\mathcal{N}$, then $\dim \Lambda \leq \Lambda' + 1$. $\dim_\Lambda \Lambda'$; and (2) the cohomological dimension of any absolutely primarily decomposable algebra is 0 or ∞.

ON THE DIMENSIONS OF MODULES AND ALGEBRAS. II. FROBENIUS ALGEBRAS AND QUASI-FROBENIUS RINGS, by S. Eilenberg and T. Nakayama. Sept. 1954, 23p. incl. refs. (Rept. no. CU-9-54AF562) [AFOSR-TN-54-270] (AF 18(600)562) AD 67330 Unclassified

The principal results are given by the following theorems: (1) if Λ is Noetherian or satisfies the minimum condition for left or right ideals, then Λ is a quasi-Frobenius ring if and only if it is left self-injective (a ring which when regarded as a left Λ-module is injective; a Λ-module, A, is said to be injective if for each monomorphism ϕ: $A \to C$ of Λ-modules, there exists a Λ-homomorphism ψ: $C \to A$ with $\psi\phi$ = identity); (2) if Λ is a Frobenius algebra and K is quasi-Frobenius (or K is self-injective and Λ is Noetherian), then Λ is a quasi-Frobenius ring; (3) is $\Lambda = K(\pi)$, where π is a finite group of order r, then Λ is symmetric, $\dim \Lambda = 0$ if $r\,K = K$, and $\dim \Lambda = \infty$ if $r\,K = K$.

A STUDY OF A CLASS OF STOCHASTIC PROCESSES, PART I, by B. O. Koopman. Oct. 1955, 40p. (Rept. no. CU-54AF562) ([AF]OSR-TN-55-349) (AF 18(600)-562) AD 75271 Unclassified

The stochastic processes studied are the generalized stationary transition birth-and-death processes given by the system (1) $P'_n(t) = R_{n-1}(t) - (R_n + L_n)P_n(t) + L_{n+1} P_{n+1}(t)$ together with the adjoint system (2) $Q'_n(t) = L_n Q_{n-1}(t) - (L_n + R_n)Q_n(t) + R_n Q_{n-1}(t)$; the accents denote t-differentiation. Two cases are studied. In one case, n runs through the nonnegative integers; in the other n runs through all integers, and every R_n and L_n is positive. In both cases, R_n and L_n are independent of t, and attention is confined to nonnegative solutions $P_n(t)$ and $Q_n(t)$. Necessary and sufficient conditions are obtained for the uniqueness of the initial-value problem for (1) and for (2). These conditions are expressed as the divergence of certain triangular series formed from the coefficients R_n and L_n. An analysis is made of the stability and other asymptotic properties of the system [illegible], and on the possible change away from unity of the total probability $\Sigma_n P_n(t)$. Both necessary and sufficient conditions are given for the latter in terms of the coefficients. When the coefficients satisfy both the condition for change away from unity of the total probability and that for nonuniqueness of the initial-value problem, uniqueness can be restored by imposing on the solution the requirement of an unchanging unit total probability.

A STUDY OF A CLASS OF STOCHASTIC PROCESSES. PART II, by B. O. Koopman. Dec. 1955 [26]p. (Rept. no. CU-54AF562) ([AF]OSR-TN-55-448) (AF 18(600)-562) AD 90883 Unclassified

The equations for generalized stationary transition birth-and-death processes previously discussed (AFOSR-TN-55-349) are solved by the application of continued fractions to the Laplace transforms of the original equations. This method is shown to lead to the same solutions as those obtained classically by successive approximations. The utility of this alternate proof is that the formulas are simpler in certain respects than those obtained by the method of successive approximations, and the results throw light on the analytic character of $p_{m,n}(s)$ in the complex variable s, revealing in particular its asymptotic properties for $s \to 0$ and $s \to \infty$, from which, with the aid of Tauberian theorems, those of the minimal $P_{m,n}(t)$ for $t \to \infty$ and $t \to 0$ can be inferred.

ON THE VELOCITY OF SOUND, by H. Dereslewicz and J. H. Weiner. [1956] 3p. (AFOSR-TN-56-422) [AF 18(600)52] AD 96503 Unclassified

A mathematical analysis of Laplace's correction of Newton's theoretical value of the velocity of sound shows that inclusion of the thermal conductivity effect in the equations of motion yields first approximation values which are in accord with Laplace's theory only at relatively low frequencies of motion. As the frequency increases without limit, the equations yield the Newtonian, "isothermal" velocity of propagation. Laplace's hypothesis is correct at low frequencies because condensations and rarefactions are relatively slow, and the long time available for the establishment of thermal equilibrium is counteracted by the large distance between adjacent condensations and rarefactions traversed by the heat; at high frequencies both the time and the distance traversed are short. Analysis of the time and distance effects, by analogy with the problem of heat flow in slab, shows thermal equilibrium to be established rapidly at high frequencies, and slowly at low frequencies when the phase velocity range is bounded from below by the Newtonian value and from above by the Laplacian. The exponential variation of spatial amplitude attenuation as the square of the imposed frequency, indicating an immediate wave decay at very high frequencies, is found true only below a certain bound of the frequency; as the frequency increases without limit the amplitude attenuation tends to a finite value. The processes at high and low frequencies are found to be thermodynamically reversible, since at both limits the specific damping loss tends to zero.

THE MECHANISM OF ELECTRIC CONDUCTIVITY IN SEMICONDUCTORS, METALS AND SUPERCONDUCTORS, by L. Brillouin and M. Payne. Final rept. Oct. 31, 1952. 18p. incl. diagrs. refs. (Rept. no. CU-4-56AF1606) (AFOSR-TN-56-542) (AF 18(600)-1506) AD 110361 Unclassified

The details of the interaction between the random elastic waves (caused by thermal agitation) in a metal and the conduction electrons were analyzed. The first zone was replaced by a sphere with a radius $R = \sqrt[3]{6\pi^2 N/V} = r_o \sqrt[3]{2}$, where N is the number of atoms in the lattice, V is the lattice volume, and r_o is the radius of the Fermi sphere. To compute the effective number of trapped electrons, the assumptions were made that the trapped electrons do not interact with one another, a given wave may trap many electrons, a given electron may be trapped by many waves, and the curve (α) which represents the correction for the zero-order expression for the electron energy may

BEST AVAILABLE COPY

be replaced by a step curve about k_{00} (a constant for a given metal). The criterion for superconductivity was sought in the expression which represents the capacity of the waves for trapping electrons, $\rho_{tr} = n_{tr}/nN$, where n_{tr} is the total effective number of electrons trapped by waves, and n is the number of free electrons per atom. The proposition was examined that $\rho_{tr} > 1$ might imply superconductivity and $\rho_{tr} < 1$ might imply normal behavior. Computations were made on the basis of expressions for n_{tr} and Δn_{tr} (the difference between the number of trapped and antitrapped electrons). The final expression for ρ_{tr} depends on the ratio V/N and on terms in various powers of V. The numerical values of the factors involved in ρ_{tr} failed to discriminate between superconductors and normal metals: the appearance of V made complete numerical calculation impossible. Computations failed to support the hope that ρ_{tr} would decrease through unity at the critical temperature for superconductors. A model of superconductivity is offered which is based on exchange terms. (ASTIA abstract)

ANALYSIS AND SYNTHESIS OF SAMPLED-DATA CONTROL SYSTEMS, by E. I. Jury. Oct. 20, 1953, iv, incl. diagrs. refs. (Technical rept. no. T-1/B; rept. no. CU-2-53AF677-EE) (AF 18(600)677) AD 20612 Unclassified

The theory of sampled-data systems using the method of the z-transform is extended and clarified. In particular, the equivalence between the z-transform in its closed form and the infinite summation used by some investigators is shown. Important characteristics of the pulsed transfer function and initial and final value theorems are developed for the z-domain. An extensive table of z-transform pairs covering the most important and commonly encountered system functions and input functions is given. The technique for stabilizing and shaping the pulsed transfer locus is demonstrated. In particular, the application of linear compensating networks in the continuous part of the system is investigated. Design criteria are obtained which relate the transient response of sampled-data systems and the frequency response. The effects of pole location and pole dominance are developed. The problem of output ripple is briefly examined insofar as its effect on the transfer loci in the z-domain are concerned. The broad objectives of design of sampled-data systems, including transient response and ripple, are integrated and design procedures are outlined. (Contractor's abstract)

SAMPLED-DATA PROCESSING TECHNIQUES FOR FEEDBACK CONTROL SYSTEMS, by A. R. Bergen and J. R. Ragazzini. Nov. 19, 1953, 36p. incl. diagrs. tables. (Technical rept. no. T-2/B; rept. no. CU-3-53AF677-EE) (AF 18(600)677) AD 23441 Unclassified

Presented at general meeting of the Amer. Inst. Elec. Engineers, Los Angeles, Calif., June 21-25, 1954.

Also published in Applications and Industry, No. 10: 236-246, Nov. 1954.

Sampled-data feedback control systems are becoming increasingly prominent with the introduction of digital computers as control elements, time-shared data-transmission links, and data-gathering devices such as radars. The plant which is to be controlled is generally represented as a continuous linear device, often having transfer lags. Stabilization and shaping of a feedback control system for such a plant, where the data are sampled at one or more points in the system, is a central problem. Prior methods have utilized linear networks inserted in cascade with the plant which shaped the plant transfer function to give stable and acceptable performance. An alternate method is to process the data samples themselves in a computer or processing unit and to produce an output pulse sequence which has desirable effects in stabilization and shaping of the over-all response of the system. Such a unit is referred to as a Sampled-Data Processing Unit which operates by storing and weighing past input and output samples, and combining them in a linear manner. Using such a device, it is possible to cause the response of a system to conform with desired specifications. Depending on the plant transfer function, certain ideal prototype response functions can be achieved readily in most cases while, in other cases, amplitude limitations and considerations of stability prevent a perfect realization of the ideal prototype response. In any case, dead-beat response to a step or ramp function can always be achieved regardless of the system. Illustrative examples show how the programs for sampled-data processing units can be obtained. The implementation of processing units of this type can be either analog or digital in form but, in either case, a unit will not be required to store more than a finite and generally small number of past data samples to realize stable and desired performance. Its engineering practicality, as well as the relatively superior performance which can be achieved by its use, makes the introduction of sampled-data processing technique desirable even in certain cases where the system is otherwise fully continuous. Engineers, New York, Jan. 31-Feb. 4, 1955.

Also published in Applications and Industry No. 18: 65-71, May 1955.

The system error in sampled-data feedback systems resulting from the application of a test function is an important design parameter. The system error is defined as the difference between the actual output of the system and the desired output. There are two components which contribute to this error: one called organic error is brought about by the system energy storages, and the other called ripple is brought about by the sampling process. Formulation of the system error is obtained by the application of the Laplace and z-transformation. Both the system error time function in intersampling times and the rms system error are formulated in terms of the system parameters. Illustrative examples demonstrate the theory. (Contractor's summary)

A MATHEMATICAL TECHNIQUE FOR THE ANALYSIS OF LINEAR SYSTEMS, by J. R. Ragazzini and A. R. Bergen. Mar. 15, 1954, 12p. illus. (Technical rept. no. T-4/B; rept. no. CU-5-54AF677-EE) ([AF]OSR-TN-54-43) (AF 18(600)677) AD 30350 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 42: 1645-1651, Nov. 1954.

The z transformation originally developed for the analysis and synthesis of sampled-data systems was applied to numerical solutions of continuous linear systems. The introduction of sampling at some convenient point was incorporated in a model of the continuous linear system. The sampled time function is reconstructed into a polygonal approximation by means of a holding operator. The output of the system is computed as a train of impulses which give the values of the output at sampling instants; both analytical and arbitrary outputs can be handled by this model. The errors in the output, which result by making computations on the sampled model rather than on the actual system, are obtainable by the application of a procedure similar to that of the main computation. Theoretical predictions concerning the error produced by the model were within very close tolerance to the actual error in an example using feedback.

LINEAR FILTERING OF SAMPLED DATA, by G. Franklin. Dec. 1, 1954, 27p. incl. diagrs. (Technical rept. no. T-5/B; rept. no. CU-7-54AF677-EE) ([AF]OSR-TN-55-21) (AF 18(600)677) AD 57247 Unclassified

An application of least squares filtering theory is made to situations where a time stationary random message and additive noise are sampled before being filtered. Such a situation might possibly occur with a pulsed radar or data link or in a system where an instrument measures only samples. The transfer function of the filter obtained from this application of the theory is usually a product of 2 terms, one of them rational in s and the other rational in e^{sT}, where s is the complex frequency and T is the sampling period. The first term represents a network of lumped R, L, and C elements, while the second term has the form of a linear program on a digital computer. (Contractor's abstract)

THE OPTIMUM SYNTHESIS OF SAMPLED-DATA SYSTEMS, by [G. Franklin]. May 2, 1955, 81p. incl. diagrs. refs. (Technical rept. no. T-6/B; rept. no. CU-10-55AF677-EE) ([AF]OSR-TN-55-140) (AF 18(600)677) AD 67031 Unclassified

A derivation is presented of the optimum transfer functions in the least squares sense for a particular class of sampled-data systems. These are single-looped, linear, error-sampled, feedback systems. The criterion of performance on which the derivations are based is the mean squared error between the actual output and the desired output at all instants of time. This criterion is applicable to those systems which must produce a continuous signal from sampled data. Two types of inputs were considered: either the input is the sum of a random message and noise, or it is a deterministic signal which is known for all time. The system was considered as a filtering and as a control problem. For the filtering problem, the only restriction on the system was physical realizability, and the solution was the specification of the entire transfer function. For the control problem the system was considered to have a specified continuous component or plant, and the solution specified the transfer function of the optimum controller for this point. An analysis is included of sampled signals with an extension to the analysis of sampled random signals. A method is outlined for the control of plants which are open-loop unstable so that some of the optimum filters which are derived can be realized without approximation. (ASTIA abstract)

NETWORK COMPENSATION OF ERROR-SAMPLED FEEDBACK CONTROL SYSTEMS, by J. Sklansky. Apr. 1, 1955 [89]p. incl. diagrs. refs. (Technical rept. no. T-7/B; rept. no. CU-11-55AF677-EE) ([AF]OSR-TN-55-162) (AF 18(600)677) AD 72852 Unclassified

Two techniques, believed to be new, for designing lumped parameter networks to compensate error-sampled feedback control systems have been developed. In one technique compensation by means of a network placed in cascade with the fixed part of the system is considered. When this technique is in its simplest form, an approximation is employed in which direct use is made of both the pulsed loop transfer locus of the uncompensated system and the ordinary transfer locus of the compensating network. In addition, there exists a way of making a rough and relatively quick evaluation of the error involved in the approximation. In the other technique, R-C networks form the principal components in some relatively simple circuitry, called "pulsed networks," which perform the same function as more complicated digital computers or "sampled-data processing units;" thus, a pulsed network can act as a c compensating device for a sampled-data feedback system. Some basic building blocks are described with which pulsed R-C networks can be synthesized to realize any rational pulsed transfer function which is at all physically realizable. The theory is substantiated by 3 illustrative examples. (Contractor's abstract)

Also published in Trans. Amer. Inst. Elec. Engineers, v. 75: 151-159, July 1956.

This study is an extension of the design procedure proposed by Bergen and Ragazzini for error-sampled control systems ("Sampled-Data Processing Techniques for Feedback Control Systems," Trans. Amer. Inst. Elec. Engineers, v. 73: 1954). Restrictions on the specification of the over-all transmission, $K^*(z)$, caused by steady-state error considerations and the inability to cancel poles perfectly and zeros of the plant on or outside the unit circle are discussed. A design procedure which includes these restrictions is presented. In addition, it is shown that where the input may take different forms it is desirable to have $K^*(z)$ a ratio of polynomials rather than a finite polynomial in z^{-1}. Several examples utilizing the specified design procedure are given. (Contractor's abstract)

DIGITAL COMPENSATION OF CONTINUOUS-DATA FEEDBACK CONTROL SYSTEMS, by K. K. Maitra and P. E. Sarachik. Aug. 30, 1955, 40p. incl. diagrs. (Technical rept. no. T-9/B; rept. no. CU-15-55AF677-EE) ([AF]OSR-TN-55-377) (AF 18(600)677)
AD 81356 Unclassified

Also published in Trans. Amer. Inst. Elec. Engineers, v. 75: 107-116, May 1956.

Methods are suggested of employing digital computers for compensating continuous data-feedback systems functioning as control systems or as regulators. The term compensating is used to imply that no attempt is made to use the digital compensator to stabilize an inherently unstable system but only to improve the dynamic performance of the system in terms of rise time, maximum overshoot, or settling time. Two classes of systems are considered: duplicators which are control systems with either unity or constant gain in the feedback line and regulators. In the duplicator problem, the system is required to follow the reference input with no steady-state error with the fastest possible rise time and minimum overshoot. In the regulator system, the output to any suddenly applied disturbance is required to decay rapidly with no overshoot.

THE ANALYSIS OF MULTIPLE-RATE-SAMPLED SYSTEMS, by G. M. Kranc. Nov. 15, 1955, 37p. incl. diagrs. table. (Technical rept. no. T-11/B; rept. no. CU-17-55AF677-EE) ([AF]OSR-TN-56-2) (AF 18(600)677) AD 84868 Unclassified

The analytical technique described in this mathematical study makes it possible to study the behavior of sampled-data systems containing switches which do not operate at the same sampling rate. Once the closed-form Z-transform of the output of such systems is obtained, standard tools of sample data theory can be applied to deal with problems of stability and performance. The amount of necessary computations depends on the actual values of the integers p and q. It is obvious from the general expressions derived that the higher the values the more computational labor is necessary. This becomes especially serious in the general case, treated in the section on "General Case," where it is shown that p or q (whichever is smaller) simultaneous equations have to be solved. Computational labor could be reduced by the use of suitable computers or the use of approximations. Thus, it seems possible to approximate the ratio of p_1/q_1, where p_1 and q_1 are both large integers, by another ratio, p_2/q_2, where p_2 and q_2 are small integers. Such approximations increase the usefulness of the described technique. (Contractor's abstract)

Also published in Applications and Industry, No. 28: 407-411, Jan. 1957.

A method of analyzing time-varying sampled-data systems is developed. It is shown that the input-output relation for a component of such systems may be regarded as a matrix equation. The relations for combinations of elements are developed, from which the transmission matrix for an entire system can be found by the simple operations of matrix multiplication and solution of linear algebraic equations. A numerical example illustrating the technique is given. A method for improving the performance of a sampled-data feedback system by means of a time-varying amplifier is given as a further illustration of the technique. A numerical example is presented. MULTIPOLE SAMPLED-DATA CONTROL SYSTEMS, by H. Freeman. Sept. 30, 1955, 42p. incl. diagrs. refs. (Technical rept. no. T-12/B; rept. no. CU-19-55AF677-EE) (AFOSR-TN-56-81) (AF 18(600)677) AD 81534 Unclassified

A detailed discussion is presented of a method for designing a multipole control system so as to permit noninteracting control of any output by its corresponding input. This method eliminates the coupling inherent in such systems to permit application of well-known single-input, single-output system techniques. The treatment is from the sampled-data point of view because of the ease with which complicated transfer functions may be realized with a digital computer. Although the method applies equally well to continuous-data systems, it is not without limitations. Certain restrictions must be placed on the over-all response if the plant determinant (P) has zeros or any of the elements of P have poles in the exterior of the unit circle of the z-plane. An example is presented of the design of a controller for a system having 3 inputs and 2 outputs.

TRANSFORMATION TECHNIQUES FOR TIME-VARYING SAMPLED-DATA SYSTEMS, by B. Friedland. Jan. 2, 1956, 42p. incl. diagrs. (Technical rept. no. T-13-B; rept. no. CU-20-56AF677-EE) (AFOSR-TN-56-175) (AF 18(600)677) AD 86597 Unclassified

Components of time-varying sampled-data systems are characterized by time-variable transmission functions of the form H (n, z). An operational method for obtaining the response of feedback systems, when the transmission functions for all components are known, is presented. This method leads to a differential or functional equation for the Z-transform of the required response. W-transforms, similar to Z-transforms, are defined and used to obtain the transmission function for a cascade of components. The W-transform method is also used to find the response of feedback systems. Slowly-varying systems are considered, and an approximation which simplifies analysis for such systems is suggested. The final value theorem for fixed systems is extended to systems whose asymptotic behavior is known. It is shown that for a class of systems the asymptotic behavior can be easily determined. Stability of time-varying systems is considered. (Contractor's abstract)

MULTI-RATE SAMPLED SYSTEMS, by G. M. Kranc. May 7, 1956, 95p. incl. diagrs. tables, refs. (Technical rept. no. T-14/B; rept. no. CU-22-56AF677-EE) (AFOSR-TN-56-242) (AF 18(600)677) AD 88362 Unclassified

The following contributions to the theory of sampled systems are presented: (1) a method for the analysis of multirate sampled systems (defined as systems with switches operating at different sampling rates); and (2) a method of compensation of an error-sampled feedback system by means of a multirate controller. The analysis procedure extends the methods of Z-transforms to multirate systems, and its only theoretical limitation is that the sampling rates of these systems should be constant and related by a rational number. Sampling periods of each switch are first expressed in the form $T/p_1 \ldots T/p_n$, where $p_1 \ldots p_n$ are generally different integers. Each switch is replaced by a system of switches and advance and delay elements, where each switch operates simultaneously and with a period T. This technique, which is referred to as the switch-decomposition method, leads in the general feedback case to a functional equation whose solution is outlined. The phantom switch method which was developed previously for multirate systems with sampling rates related by an integer is extended to cover the general case. Some of the multirate techniques developed for the process of analysis are applied to the synthesis of a multirate controller, a pulsed network which in response to input samples at time $t = 0, T, 2T, \ldots$ produces output samples at time $t = 0, T/n, 2T/n, \ldots$, (n is an integer) any output sample being a linear combination of the past and present inputs and outputs. The multirate controller, which is used to compensate an error-sampled feedback system, has two advantages over its single-rate predecessor; it minimizes the intersampling ripple and improves the rise time of the system.

A TWO-DIMENSIONAL FEEDBACK CONTROL SYSTEM, by P. [E.] Sarachik and J. R. Ragazzini. Aug. 15, 1956, 24p. incl. diagrs. (Technical rept. no. T-16/B; rept. no. CU-26-56AF677-EE) (AFOSR-TN-56-105) (AF 18(600)677) AD 97369 Unclassified

The class of control systems whose objective is to control and maintain a relationship between several dimensions (time, spatial or both) is discussed in the two dimensional case. The system is synthesized by regulating the movement of the open-cycle system with that of the closed-cycle system. The dimensions, x and y, must maintain such a relationship that an error in y affects x and y, preferrably through a functional relationship obviating programming or externally adjusting the system. The cross-coupling of the outputs aims at slowing the motion in one dimension while speeding it up in the other, when the error tends to become too large for the appropriate two-dimensional space curve. For higher order systems, approximate linear small signal methods with computer studies are recommended for contour cutting tool controls and other applications.

AN EXTENDED ANGULAR RANGE DIRECT READING PHASEMETER, by S. Bigelow and J. Wuorinen. Sept. 20, 1956, 20p. incl. diagrs, refs. (Technical rept. no. T-17/B; rept. no. CU-27-56AF677-EE) (AFOSR-TN-56-566) (AF 18(600)677) AD 110369 Unclassified

Most commerical phasemeters are designed to measure angles from 360° lagging to 360° leading. This range is usually covered in a number of segments, some sort of switching arrangement providing for a desired segment. A specialized analog computer, the Complex Plane Scanner, was desired to be capable of following slow changes in phase between two 400-cycle per second sinusoids. This meter is developed capable of measuring angles of from 540° lagging to 540° leading (upper limit 720° lagging to 720° leading) in one continuous range without range switching or output ambiguity. The accuracy is ± 1° for the angular range and 0.1 to 100 volts for the input amplitude. Modifications for use at other frequencies are suggested.

THE SYNTHESIS OF MULTIPOLE CONTROL SYSTEMS, by H. Freeman. Apr. 24, 1956, 74p. incl. diagrs. refs. (Technical rept. no. T-15/B; rept. no. CU-24-56AF677-EE) (AFOSR-TR-56-26) (AF 18(600)677) AD 90006 Unclassified

A method is presented for the direct synthesis of multipole control systems, i.e., control systems having a multiplicity of inputs and controlled outputs. Formerly, the synthesis of such systems had to be carried out by laborious trial-and-error studies on analog computers. The method described here permits the straightforward design of multipole control systems in a manner similar to that presently possible for single-input, single output systems. Only linear systems are considered. The method is presented from the sampled-data point of view, without, however, sacrificing any generality. A canonical form of multipole control system is defined and the basic requirements to achieve control action are established for such a system. An analysis is given of the factors which affect system stability together with a technique for stabilizing systems having plants with unstable elements. It is shown that a system may be synthesized to have any arbitrary input-output transformation and output transient responses, subject only to certain restrictions imposed by the requirements for stability and the use of physically realizable components. The concept of error coefficients is extended to multipole systems by the definition of an error coefficient tensor. This permits the design of systems having steady-state errors of prescribed magnitude for given test-function inputs. Equations are developed which permit the explicit solution for the required controllers in terms of the given plant and the desired over-all responses. A detailed, illustrative example is worked out involving the design of a control system required by a motor manufacturer for the rapid testing of motor-alternator sets coming off a production line.

SYNTHESIS OF NONLINEAR TRANSFER CHARACTERISTICS WITH PASSIVE RESISTANCE NETWORKS, by R. J. Schwarz. Sept. 15, 1954, 37p. incl. diagrs. tables. (Technical rept. no. T-1/F; rept. no. CU-4-54AF962-EE) (AF 18(600)962) AD 52449 Unclassified

A method is described for obtaining approximately a specified nonlinear characteristic by means of passive resistance ladder networks using nonlinear resistive elements of known characteristic. The method assumes only that the voltage-current characteristic of the nonlinear elements can be reversed. The network parameters are obtained by minimizing the mean square error or the mean square relative error of the required input relative to the ideal input for the desired output. The accuracy and the dynamic range over which the desired characteristic can be obtained depend on the complexity of the network configuration chosen. Ladder structures are considered in which either all elements may be nonlinear, or only the shunt or the series elements are made nonlinear. The input-output relationships for one-, two-, and three-section ladder structures in which the nonlinear elements are thyrite resistors with a current-voltage characteristic $i = ae^n$ are given in a table. These relationships are also given

COU. 11:002 - COU. 13:001

for several combinations of numerical values of the exponent n. The method is illustrated by applying the procedure to the synthesis of a logarithmic output-input characteristic for several input dynamic ranges. (Contractor's abstract)

COMPLEX PLANE SCANNER: AN ANALOG COMPUTER, by G. [M.] Kranc, P. Mauzey, and J. Wuorinen. Aug. 1, 1955, 71p. incl. diagrs. refs. (Technical repl. no. T-2/F; rept. no. CU-8-55AF962-EE) ([AF]OSR-TN-55-261) (AF 18(600)962) AD 72853 Unclassified

This report reviews the theory, indicates the applications, and describes certain specific circuits of a special type of electronic analog computer which uses sinusoidal voltages as analogs of phasors in the complex plane. The circuits which make up the heart of the computer, its central unit, are explained in detail. This unit receives, as inputs, the complex-frequency variable s in addition to the location of each pole and zero of the function, F(s), being investigated. Its outputs are 2 slowly varying voltages, one representing the phase and the other the logarithm of the magnitude of F(s) as s takes various positions in the complex plane. Thus, for example, if s is restricted to the imaginary axis (s = jω) the outputs will be slowly varying voltages representing the phase and the logarithm of the magnitude of F(s) as functions of frequency. Multiplication and division are required to obtain the magnitude of F(s). These operations are converted to addition or subtraction (or summing and sign-changing) by the use of logarithms. Pulse techniques are used to obtain the phase information as a slowly varying voltage. The remainder of the computer consists of the input unit which provides the variable s and the output unit which processes the voltages from the central unit into a convenient form for the type of display desired. Results of performance tests on portions of the system are included. (Contractor's abstract)

FATIGUE IN AIRCRAFT STRUCTURES; PROCEEDINGS OF THE INTERNATIONAL CONFERENCE HELD AT COLUMBIA U., JAN. 30, 31 AND FEB. 1, 1956, ed. by A. M. Fruedenthal. 1956, 456p. incl. illus. diagrs. tables, refs. [AF 18(600)898, Task II] TL698.U52 Unclassified

The full text of all papers presented at the International Conference on Fatigue in Flight Structures are offered in this volume. The purpose of the conference was to bring together the physisists and physical metallurgists, the test engineers and aircraft designers concerned with the problem of the effect of metal fatigue on the performance and safety of modern aircraft, both civilian and military, American and foreign, in an attempt to bridge the gaps existing between these groups and to stimulate the work on the various aspects of fatigue by exchange of information and results of recent research between workers in the various groups. Each day of the conference was devoted to one of the three principal aspects of fatigue in aircraft structures: physical theories of fatigue, prediction of fatigue life and fatigue strength, and prevention of fatigue failure. The subject of the papers range from a discussion of the fatigue mechanism on the submicroscopic scale in terms of dislocations, to the presentation and discussion of methods used in the aircraft industry to ensure adequate fatigue performance of structural parts and specific details of aircraft.

THREE-DIMENSIONAL AND SHELL THEORY ANALYSIS OF AXIALLY-SYMMETRIC MOTIONS OF CYLINDERS, by G. Herrmann and I. Mirsky. Apr. 1955 [31]p. incl. diagr. refs. (Technical note no. 1; rept. no. CU-3-55AF1247-CE) ([AF]OSR-TN-55-95) (AF 18(600)1247) AD 67034 Unclassified

Also published in Jour. Appl. Mech., v. 23: 563-568, Dec. 1956.

The frequency (or phase velocity) of axially symmetric free vibrations in an elastic, isotropic circular cylinder of medium thickness is studied on the basis of the 3-dimensional linear theory of elasticity, and also on the basis of several different shell theories. To be in good agreement with the solution of the 3-dimensional

equations for short wavelengths, an approximate theory has to include the influence of rotatory inertia and transverse shear deformation for example in a manner similar as in Mindlin's plate theory. A shell theory of this (Timoshenko) type is deduced from the 3-dimensional elasticity theory. From a comparison of phase velocities, it appears that, to a good approximation, membrane and curvature effects on one hand and flexural, rotatory inertia and shear deformation effects, on the other hand, are mutually exclusive in 2 ranges of wavelengths, separated by a "transition" wavelength. Thus, in the full range of wavelengths, the associated lowest phase velocities may be determined on the basis of the membrane shell theory (for wavelengths larger than the transition wavelength) and on the basis of Mindlin's plate theory (for wavelengths smaller than the transition wavelength). (Contractor's abstract)

AXIALLY-SYMMETRIC MOTIONS OF THICK SHELLS, by I. Mirsky and G. Herrmann. Nov. 1955 [21]p. incl. diagr. table. (Technical note no. 2; rept. no. CU-C-55AF1247-CE) ([AF]OSR-TN-55-411) (AF 18(600)1247) AD 81126 Unclassified

An approximate theory of axially-symmetric motions of thick, elastic, cylindrical shells, in which the effect of transverse normal stress is retained, is deduced from the 3-dimensional theory of elasticity. The present theory contains, as special cases, a variety of shell plate, and solid cylinder equations. The propagation of free harmonic waves in the shell is studied on the basis of the present theory, and the 3-dimensional theory of elasticity. Excellent agreement is obtained for the phase velocity of the lowest mode of motion for a wide range of the parameters involved. (Contractor's abstract)

X RAY MICROBEAM STUDIES OF BRITTLE FRACTURES OF METALS, by L.-C. Chang. [Mar. 15, 1954] [14]p. incl. diagrs. table. (Bound with its The Nature of Fracture in Metals, by M. Gensamer, J. O. Brittain and others. Quarterly progress rept. no. 2, Dec. 1, 1954-Feb. 28, 1954. Mar. 15, 1954, 3p.; AD 67374; Unclassified) (AF 18(600)898; Task I) AE 67374(a) Unclassified

A back-reflection x-ray microbeam camera was used in the study of brittle fracture of zinc and iron. Strain distribution curves obtained by the experimental procedure are given for zinc specimens fractured in slow tension at 77°, 195°, and 225°K; for an electrolytic iron specimen fractured at 35°K; and for a carbon steel specimen fractured at 38°K. The average plastic strain decreases rapidly within a short distance from the fracture surface and remains more or less constant at larger distances. There is good evidence that uniformly distributed plastic strain precedes the plastic process resulting in brittle fracture. A formula is given for the work done to produce the plastic strain associated with fracture, or the plastic work factor, w. An estimation of this factor was accomplished graphically. The w values for zinc and iron are about two orders of magnitude larger than their respective surface energies, and w decreases slightly with decreasing temperature in the case of zinc.

ENVIRONMENTAL EFFECTS ON FRACTURE, by L. C. Weiner. [Nov. 1955] 2p. ([AF]OSR-TN-55-413) (AF 18(600)898; Task I) Unclassified

The effect of electroplated coatings of copper and gold, 200-20,000 A thick, on the fracture stress of seeded zinc monocrystals, having the orientation $\chi_0 = 3°$ and $\gamma = 28°$, was tested at room temperature where brittle fracture occurs in crystals of this orientation and prefracture deformation is limited to twinning. Results show that normal fracture stress is increased by copper or gold coating. The increase in fracture stress is constant, within experimental accuracy, for thicknesses greater than about 500 A, being raised from a mean of 2280 ± 70 psi for clean crystals to a mean of 3350 ± 130 psi after copper plating and to 3165 ± 95 psi after gold plating. The increase of fracture stress with coatings less than about 500 A appears to follow a steep straight line. The 3% strain due to twinning in clean crystals is not changed by coating but the coating adds a 3% strain due to slip with high strain hardening. Calculations show the fracture stress increase is not attributable to the inherent strength of the copper of gold film, even assuming that the film is only strained elastically. BRITTLE FRACTURE OF ZINC SINGLE CRYSTALS, by L. C. Weiner and M. Gensamer. Aug. 24, 1956 [36]p. incl. diagrs. tables, refs. (AFOSR-TN-56-402) (AF 18(600)898; Task I) AD 96060 Unclassified

Also published in Jour. Inst. Metals, v. 85: 441-448, 1956-1957.

In this study, the normal fracture stress of Zn single crystals oriented χ_o = 3° and tested in tension at room temperature, was increased 43% upon applying a surface film of Cu, Au, ZnO, Sn, or Zn greater than about 500 Å. This increase was independent of film thickness above this value. In addition, the total % elongation was increased twofold, the primary mode of deformation being twinning accompanied by parent basal slip both prior to and subsequent to twinning, as well as the basal slip within the twins. Metallographic examination revealed a difference in the internal structure of clean and coated crystals, namely, the number and distribution of twins. There were more twins in the coated crystals, and they were more uniformly distributed. In contrast, the fracture stress of crystals oriented χ_o = 83° was 48% less than the value observed with clean-surfaced crystals. crystals. The presence of preexisting twins produced by precompression caused the fracture stress of both clean and coated crystals to be increased. These results, as well as observations in prestrain, recovery, and film-removal experiments, have been explained by a dislocation model in which twins play an important role, modifying the dislocation path and acting as barriers. (Contractor's abstract)

A GRIPPING DEVICE TO TEST BRITTLE METAL SINGLE CRYSTALS IN TENSION, by L. C. Weiner. Sept. 5, 1956[4]p. incl. diagr. (AFOSR-TN-56-423) (AF 18(600)898; Task I) AD 96504 Unclassified

Also published in Rev. Scient. Instruments, v. 27: 1081, Dec. 1956.

A brief description is given of a set of grips used successfully at both low and elevated temperatures in the tensile testing of metal single crystals. Their operation is discussed. It is pointed out that they maintain axiality of load, preventing crystal deformation prior to testing. In addition, they allow crystal specimens not having conventional threaded or enlarged ends to be employed. The grips are shown in a diagram.

CREEP RUPTURE BY VACANCY CONDENSATION, by E. S. Machlin. Nov. 1954, 16p. illus. tables, refs. (Rept. no. CU-7-55AF899 Met.) (AF OSR-TN 54 359) (AF 18(600)899) AD 57328 Unclassified

Also published in Jour. Metals, v. 8: 106-111, Feb. 1956.

The possibility that formation of voids under creep-rupture conditions may take place by the condensation of vacancies has been investigated theoretically. It has been concluded that nucleation of voids under creep-rupture conditions by vacancy condensation is highly improbable; however, growth of pre-existant voids by vacancy condensation is probable. A number of predictions made in this theory have been verified by the data, e. g., the elongation at which voids just become visible has been predicted and found to be in good agreement with experiment. It has been predicted and verified that the product of rupture life and steady-state creep rate for preannealed metals and single phase alloys is an invariant quantity independent of stress, temperature, and atomic number for a given type structure. The direction of the effect of cold work on this product has been predicted and found in agreement with experiment. A number of experiments to further evaluate the vacancy condensation mechanism are described. (Contractor's abstract)

A THERMAL ETCHING TECHNIQUE FOR REVEALING DISLOCATIONS IN SILVER, by A. A. Hendrickson and E. S. Machlin. July 14, 1954 [6]p. incl. illus. diagrs. tables. (Rept. no. CU-9-55AF899-Met.) ([AF]OSR-TN-55-113) (AF 18(600)899) AD 91252 Unclassified

Also published in Acta Metallurgica, v. 3: 64-69, Jan. 1955.

A thermal etching technique for revealing dislocations in silver has been developed. The technique reveals single dislocations in silver as evidenced by the close agreement between the experimentally measured area density of dislocations in bent single crystals and the area density calculated using the Cottrell formula for the excess density of dislocations as a function of the radius of curvature of the bent crystal. It has been found that the density of dislocations in recrystallized specimens and as solidified crystals is about 2 x 10^6 /cm^2. A new mode of subgrain formation has been found. The type of subgrain morphology obtained is shown to be dependent upon the orientation between the crystal and the tension direction. (Contractor's abstract)

ON THE FORMATION OF MARTENSITE IN LOW AND MEDIUM CARBON STEELS, by M. S. Wechsler and T. A. Read. [1954] [42]p. incl. diagrs. table. ([AF]OSR-TN-54-157) (AF 18(600)951) Unclassified

The recently proposed theory of the formation of martensite, which postulates that the total transformation is inhomogeneous in such a way as to bring about a plane of zero average distortion, is applied to the austenite-martensite transformation in low and medium C steels. The transformation is considered to take place by an inhomogeneous distortion for which slip occurs on octahedral planes in the austenite. The habit plane, orientation relationship, and macroscopic distortion are derived as functions only of the lattice parameters of the 2 phases. Two habits, one in the region of $\{225\}$ and the other near $\{111\}$, are predicted by the theory, and are in approximate agreement with experimental observation. The calculated orientation relationship and macroscopic distortion also agree with what has been observed. For continuation of this work, see Illinois U. Dept. of Mining and Metallurgical Engineering, Urbana under contract AF 18(600)1311. (Contractor's abstract, modified)

INVESTIGATION OF THE CRYSTALLOGRAPHY OF DIFFUSIONLESS PHASE CHANGES IN STEELS, by H. M. Otte and T. A. Read. Final rept. [Aug. 1954] [12]p. incl. diagr. (AF 18(600)951) Unclassified

In this study, the theory of the austenite-martensite transformation in steel is reviewed. The theory postulates that of all the ways that a body-centered tetragonal structure can be generated from a face-centered cubic structure, energy considerations demand that the process of formation lead to a plane of zero distortion. In addition, the total transformation must be inhomogeneous for such a plane of zero distortion to exist. This concept of an inhomogeneous distortion allows, however, all of the crystallographic features of the transformation to be derived. In the case of high carbon steels, the type of inhomogeneity considered was one in which slip takes place with elements appropriate to the martensite, namely, slip on (112) martensite planes in the $\langle 11\bar{1} \rangle$ direction. In the case of the analysis of martensite formation in medium and low carbon steels, a different pattern of inhomogeneity was selected, namely, slip on octahedral planes in the austenite. Two treatments of this type were studied, one in which the direction of slip is the $[1\bar{2}1]$ austenite direction, and in the other, $[10\bar{1}]$ austenite direction.

AN INVESTIGATION OF THE EFFECT OF SOLUTES ON THE GRAIN BOUNDARY STRESS RELAXATION PHENOMENON, by S. Weinig and E. S. Machlin. Apr. 15, 1955 [48]p. incl. diagrs. tables, refs. ([AF]OSR-TN-55-106) (AF 18(600)965) Unclassified

Also published in Jour. Metals, v. 9: 32-41, Jan. 1957.

In this study, an investigation of the effect of solutes on the grain boundary stress relaxation phenomenon in high purity Cu was performed by means of a high vacuum torsion pendulum. It was found that the magnitude of the relaxation peak decreased, and that the energy of activation increased with increased solute content. With the progressive decrease in the first peak with solute content, a second peak appeared which increased in magnitude until a saturation value was attained. The mechanisms of Kê and Mott were investigated and found to be nonapplicable. A 2-step process is propsed in which the first step is rate limiting for the Cu peak, and the second step is rate limiting for the solute peak. The variation of the activation energy for the initial grain boundary stress relaxation phenomenon with concentration is shown to be a measure of the relative interface adsorption of the alloying elements. ([AF]OSR-TN-55-160) (AF 18(600)965) Unclassified

Also published in Acta Metallurgica, v. 4: 262-267, May 1956.

A strain amplitude dependent logarithmic decrement and modulus have been found in high purity Cu at 1 cps and 40°C. The effect of various solutes upon the internal friction at this temperature was studied; it was observed that the ability to diminish the decrement was a function of the alloy content, and of the total interaction energy between a solute atom and a Taylor dislocation. Electrical interactions between solute atoms and edge dislocations are shown to be significant in their effect upon dislocation pinning. The experimental results are compared with the theoretical computations and are found to be in good agreement. (Contractor's abstract)

STRAIN-AMPLITUDE DEPENDENT INTERNAL FRICTION STUDIES OF DILUTE ALLOYS OF COPPER, by S. Weinig and E. S. Machlin. [Jan. 27, 1956] [5]p. incl. diagrs. (AF 18(600)965) Unclassified

Published in Jour. Appl. Phys., v. 27: 734-738, July 1956.

An investigation is described of the room-temperature decrement in dilute polycrystalline alloys of Cu as a function of strain amplitude and annealing at a frequency of about 1 cps. The characteristics of the internal friction measured are: (1) the internal friction and strain-amplitude dependence of the internal friction decreases with increasing solute content; (2) the internal friction is reversibly dependent upon the preanneal temperature; and (3) the internal friction is hysteretic with strain amplitude. From the effect of the solute concentration and annealing temperatures on the decrement, values for the binding energy for Al and Si solute atoms to dislocations in Cu were calculated. These values are compared to theoretical values calculated on the basis of strain and electrical interaction energies. The experimental binding energy is in good enough agreement with the theoretical values to conclude that the onset of a strain amplitude dependence of the internal friction is caused by the freeing of sufficient dislocations from their pinning solute atoms. SOME CONTRIBUTIONS TO THE PROBLEM OF THE EXTENSION OF POSITIVE DEFINITE FUNCTIONS. PART I. ON INFINITELY DIFFERENTIABLE POSITIVE DEFINITE FUNCTIONS. PART II, by A. Devinatz. Oct. 1955, 1v. refs. ([AF]OSR-TN-55-421) (AF 18(600)1223) AD 95891 Unclassified

Part II also published in Proc. Amer. Math. Soc., v. 8: 3-10, Feb. 1957.

In Part I, the following problem is considered: Let Q be an open symmetric neighborhood of the origin in the 2-dimensional Euclidean vector space E_2. Let $f(\mathbf{x})$ be a continuous function defined on Q^2 (i.e., the set of all vectors $\mathbf{x} + \mathbf{y}$, where $\mathbf{x}, \mathbf{y} \in Q$) such that for any finite set $\{\zeta_k\}_1^n$ of complex numbers and points $\{x^k\}_1^n \subset Q$ there is

$$\sum_{r=1}^{n} \sum_{s=1}^{n} \zeta_r \bar{\zeta}_s f(x^r - x^s) \geq 0.$$

Is it possible to extend $f(\mathbf{x})$ to all of E_2 so as to retain this positive definite character? It is shown that this may be done in a number of special cases. The results indicate that the general question has an affirmative answer. In Part II, an infinitely differential function is considered, defined on the open interval $\langle -a, b \rangle$, $a, b > 0$. Sufficient conditions are given, in terms of the derivatives of $f(\mathbf{x})$, in order that $f(\mathbf{x})$ may be extended to the whole axis and be positive definite there.

THERMODYNAMIC CHARTS FOR HIGH TEMPERATURE AIR CALCULATIONS (2,000°K TO 9,000°K), by J. G. Logan, Jr. July 1956, 25p. incl. diagrs. (Rept. no. AD-1052-A-3) (AFOSR TN-56-342) (Sponsored jointly by Arnold Engineering Development Center under AF 40(600)6 and Air Force Office of Scientific Research under AF 18(603)10) AD 95218 Unclassified

A compilation is presented of 20 thermodynamic charts useful for shock wave and isentropic flow calculations. The charts were based primarily upon National Bureau of Standards results (NBS rept. no. 3991, Apr. 1, 1955). Density and speed of sound ratios are based on reference values at 273.16°K and 1 atm pressure. Nine charts show variation of density with absolute enthalpy for constant values of pressure over the ranges: pressure ratio (P/P_0), 1000-0.0001; density ratio (ρ/ρ_0), 100-0.000093; and absolute enthalpy (H), 600-9400 cal/g. Three charts show variation of entropy with pressure for constant values of temperature over the ranges: temperature, 100°-9000°K; pressure ratio, 1000-0.00001; entropy (s), 1.0-5.2 cal/g°K. Two charts give variation of entropy with pressure for constant values of absolute enthalpy for

the ranges: absolute enthaly, 150-7000 cal/g; pressure ratio, 1000-0.00001; entropy, 1.4-4.1 cal/g°K. Three charts present variation of absolute enthalpy with entropy for constant temperatures in the ranges: temperature, 0°-10,000°K; absolute enthalpy, 0-14,600 cal/g; and entropy, 1.85-4.8 cal/g°K. Two charts show variation of entropy with density for constant values of absolute enthalpy over the ranges: absolute enthalpy, 1000-7000 cal/g; density ratio, 40-0.00000631; and entropy, 1.4-3.9 cal/g°K. The final chart presents the variation of speed of sound with entropy for constant values of temperature and density for the ranges: speed of sound ratio (a/a_0), 2.6-7.9; entropy, 1.6-4.9 cal/g° K; temperature, 2000-9000°K; and density ratio, 100-0.0001.

THE CALCULATION OF THE THERMODYNAMIC PROPERTIES OF AIR AT HIGH TEMPERATURES, by J. G. Logan, Jr. May 1956, 68p. incl. diagrs. tables, refs. (Rept. no. AD-1052-A-1) (AFOSR-TN-56-344) (Sponsored jointly by Arnotd Engineering Development Center under AF 40(600)6 and Air Force Office of Scientific Research under AF 18(603)10) AD 95220 Unclassified

Procedures for the calculation, for air, of the equilibrium concentration and the thermodynamic quantities, energy, enthalphy, entropy, pressure, specific heat, molecular weight, and the speed of sound in the temperature range 1,000°K to 20,000°K are described. Complete tables of constants derived from spectroscopic data for the various components are included, and are corrected as far as possible using the latest available data in the literature. In cases where the values have not been determined, approximate values are given. It is suggested that all partition functions be calculated directly from spectroscopic data; however, an approximate procedure of Bethe is presented in an appendix. The calculations for N are based on the dissociation energy value 9.756 ev. All calculations are based on the composition of dry air at NACA (National Advisory Committee for Aeronautics) standard sea-level conditions. The air in the temperature range of 1,000°K to 20,000°K is assumed to have the components O_2, O, N, O^+, N^+, e, NO, NO^+, N_2, O^-, N_2^+, O_2^+, and A. Chemical equilibrium is assumed at all temperatures and densities, and it is also assumed that the perfect gas law is valid. It is suggested that all quantities such as entropy, energy, and enthalpy be calculated in terms of the absolute values, including contributions of the lowest energy states of the molecules at each temperature and density as well as nuclear spin contributions. THE APPLICATION OF THE SHOCK TUBE TO THE STUDY OF THE PROBLEMS OF HYPERSONIC FLIGHT, by A. Hertzberg. [1956] [7]p. incl. illus. diagrs. refs. (AF 18(603)10) Unclassified

Published in Jet Propulsion, v. 26: 549-554, 565, July 1956.

This paper discusses some of the new scientific and technical problems introduced by the high temperature conditions encountered in hypersonic flight. Modifications of the shock tube which have been studied at this laboratory for the investigation of these problems are presented. The shock tube is one of the few laboratory instruments capable of generating the high temperature conditions in air encountered in hypersonic flight studied. The conventional shock tube is limited since the maximum flow Mach number that can be achieved behind a normal shock wave in air is approximately 3. When the conventional shock tube is terminated by an expansion nozzle, high Mach number flows can be achieved as well as high stagnation temperatures. Actual flow conditions can therefore be closely simulated for the investigation of heat transfer rates and other aerodynamic problems. The application of the shock tube to other areas of high temperature research is briefly discussed. In particular, a technique for the study of high temperature chemical reaction rates is described. HIGH-TEMPERATURE AIR FLOW FOR HYPERSONIC RESEARCH, by A. H. Flax, A. Hertzberg, and W. E. Smith. May 1956 [34]p. incl. diagrs. table, refs. (Rept. no. CAL-79) (AFOSR-TN-56-236) (AF 18(603)-19) AD 68356 Declassified

The problem of providing a facility capable of producing the high stagnation temperatures required for hypersonic testing is discussed briefly. Existing facilities are reviewed, and the requirements of future facilities for high temperature testing are outlined. Since existing facilities are found to be limited as to maximum available temperature or allowed testing time, a new type of machine is proposed. This machine, called the "wave superheater," involves an extension of the shock tube principle whereby a group of shock tubes is mounted at the periphery of a cylindrical drum and brought successively into play by a rapid rotation of this drum so that a continuous stream of high temperature air useful for hypersonic testing is available. The results of preliminary performance calculations of the wave superheater, as well as the description of a possible arrangement of test apparatus, is discussed. It appears that by using orthodox engineering techniques it will be possible to obtain continuous gas flows in air with approximate stagnation temperatures of 5000°K (9000°R). An outline of high-temperature research is included concerning materials and structures problems to which the proposed technique could be applied. (Contractor's abstract)

THE APPLICATION OF POLARIZED MERCURY POOL ELECTRODES TO POLAROGRAPHY, by C. A. Streuli and W. D. Cooke. [1953] [3]p. incl. diagrs. [AF 18-(600)486] Unclassified

Published in Jour. Phys. Chem., v. 57: 824-826, Nov. 1953.

The use of mercury pool electrodes is proposed for extending the range of polarographic analysis. This electrode retains many of the advantages of conventional procedures and has a considerably greater sensitivity. The current-voltage curves obtained are fundamentally different from conventional polarograms. Current peaks are obtained which can be predicted within 10% by the equations of oscillographic polarography. The mercury pool electrode compares favorably with the dropping mercury electrode. The peak currents are linear with concentrations, particular metals can be identified by their half peak potentials, and the electrode has a low charging current and high hydrogen overvoltage. The polarograms follow a predictable curve and conventional equipment can be used. Furthermore, the mercury pool electrode has some inherent advantages as compared to the dropping mercury electrode. The area of the electrode can be varied over wide limits and charging current densities are much smaller. The dropping mercury electrode, however, has a surface which is renewed during the recording of a polarogram. In most cases this appears to be unimportant but this fact may cause difficulties with some metals. Polarograms have been obtained for zinc, lead, copper, cadmium, thallium, bismuth and indium. The sensitivity of the method is about twenty millimicrograms per milliliter. (Contractor's abstract)

DEVELOPMENT OF ELECTROCHEMICAL METHODS OF SEPARATION AND ANALYSIS FOR MILLIMICROGRAM AMOUNTS OF TRACE METALS, by C. A. Streuli and W. D. Cooke. [1953] [18]p. incl. diagrs. tables. [Technical note no. 1] (AF 18(600)486) Unclassified

Determinations of zinc, lead, and chromium in concentration from approximately 10^{-6} molar to 5×10^{-5} molar have been made using a polarized mercury pool electrode, and the height of the current maxima has been shown to be linearly proportional to the concentration of the ion. Half wave potentials for these three ions have been calculated, and appear to be in agreement with those obtained from dropping mercury electrodes. The diffusion current has been shown to vary with polarization rate, and the diffusion current and half wave potential have been shown to vary with external resistance in series with the cell. The height of the zinc wave appears to be generally independent of the lead content of a solution if the lead content is as much as 20 times the zinc content. The diffusion wave height varies with gelatin content of the solution, and in the case of chromic ion the maxima is eliminated. The maxima is not entirely eliminated for the lead wave. The reduction of chromic ion in potassium chloride and in the presence of 0.005% gelatin appears to be reversible. (Contractor's abstract)

MERCURY POOL POLAROGRAPHY: ION-AMALGAM REDUCTIONS OCCURING AT SURFACE OF A LARGE STATIONARY MERCURY POOL, by C. A. Streuli and W. D. Cooke. [1953] [6]p. incl. diagrs. tables. (Technical note no. 2) (AF 18(600)486) Unclassified

Published in Anal. Chem., v. 25: 1691-1696, Nov. 1953.

In order to extend the range of polarographic methods, possible analytical applications of a large polarized mercury pool electrode were investigated. The polarographic waves obtained have distinct current

maxima whose heights vary in a linear fashion with the concentration of the reducible ion. The halfpeak potentials are independent of concentration and correspond, within 0.05 volt, to the halfwave potentials associated with the dropping mercury electrode. Thallous, lead, copper, cadmium, zinc, bismuth, and indium ions have been studied. The polarized pool electrode has been found to be applicable to the determination of ions at lower concentrations than the more conventional polarographic methods, while retaining many of the advantages of the dropping electrode. The currents are proportional to concentration, the ions can be identified by their reduction potentials, and the electrode has a high hydrogen overvoltage. The area of the electrode can be varied over wide limits, the charging current density is much smaller, and conventional equipment can be used. The polarograms obtained are theoretically predictable within 5% by the equations applicable to oscillographic polarography. (Contractor's abstract)

RELATION OF MERCURY POOL POLAROGRAPHY TO OSCILLOGRAPHIC POLAROGRAPHY, by C. A. Streuli and W. D. Cooke. [1953] [13]p. incl. diagrs. tables. (Technical rept. no. 3) (AF 18(600)486) Unclassified

Polarographic waves obtained by the use of a polarized mercury pool and relatively slow scanning rates have been shown to be similar to those obtained through the use of oscillographic polarography. The heights of the current maxima are predictable with the exception of zinc and indium within 10 percent by the Sevcik equation derived for use with oscillographic techniques. Experimental results from pool polarography give a constant in good agreement with that derived by Sevcik for the equation. The experimental value from this data is 217 ± 10. The scope of both oscillographic and pool polarography appears to be capable of great extension to more dilute solutions by the use of the more rapid scanning procedures of oscillography and the larger area of the pool. Through the use of the pool no synchronization of drop size and wave pulse are necessary for oscillographic techniques and studies embracing the use of oscillographic methods are contemplated. (Contractor's abstract)

A NEW APPROACH TO ORGANIC POLAROGRAPHY, by C. A. Streuli and W. D. Cooke. Nov. 4, 1953, 1v. incl. diagrs. tables, refs. (Technical rept. no. 4) (AF 18(600)486) AD 20674 Unclassified

Organic molecules were analyzed using a polarizable Hg-pool electrode. The results are compared with those obtained with a conventional dropping Hg electrode. The increased sensitivity of the electrode permitted determination of smaller quantities of organic materials. The half-peak potentials were reproducible to 10 mv. The potentials in the quiet pool were sometimes negative and sometimes positive when they were compared to the dropping electrode values. A correlation existed between the I_{max}/concentration (c) values and the probable number of electrons transferred in the reduction. $PhNO_2$, the first wave of m-dinitrobenzene, Ph_2CO, and Bz_2, which are probably reduced with 4-electron transfers, showed I_{max}/C values of 0.64, 0.69, 0.60, and 0.68 amp/mol, respectively; cystine and a 1,6-anthraquinone disulfonate, which are probably 2-electron reductions, gave values of 0.33 and 0.31 amp/mol, respectively. In using the pool electrode, the H wave occurred at a potential of 0.2 to 0.3 v more positive than it appeared at the dropping electrode (for most supporting electrolytes). Conjugated double bonds and the aldehyde groups were reduced at a value close to that of H evolution and could not be determined by this procedure. (ASTIA abstract)

THE DETERMINATION OF THE GAMMA ISOMER OF HEXACHLOROCYCLOHEXANE IN THE PRESENCE OF OTHER ISOMERS AND HIGHER CHLORINATED MATERIAL, by C. A. Streuli and W. D. Cooke. Nov. 4, 1953, 9p. diagrs. tables. refs. (Technical rept. no. 5) (AF 18(600)486) AD 37488 Unclassified

Also published in Anal. Chem., v. 26: 970-972, June 1954.

A more sensitive method than the conventional polarographic method was developed for the analysis of the γ-isomer of hexachlorocyclohexane. Replacement of the dropping-Hg electrode by an Hg-pool electrode resulted in a shifting of the reduction potentials in such a way that interference from other compounds was eliminated. The proposed method was applied to pure lindane, natural isomeric mixtures, concentrates, dusts, and α-β cakes. (ASTIA abstract)

ELECTROLYTIC DECOMPOSITION OF DILUTE AMALGAMS, by J. T. Porter, II and W. D. Cooke. July 1, 1954 [6]p. incl. diagrs. tables, refs. [Technical note no. 6] [AFOSR-TN-54-158] (AF 18-(600)486) AD 63419 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 1481-1486, Mar. 20, 1955.

A study has been made of the anodic decomposition of dilute amalgams and of the general behavior of amalgam electrodes when the decomposition is achieved by:

COR. 01:008 - COR. 01:011

(a) discharge through a resistance at constant applied potential; (b) under the influence of an intermittent constant current; or (c) under conditions of constant anode potential. It was found that amalgams of cadmium and thallium can be completely decomposed and that a general insight into the phenomena of decomposition under conditions of constant anode potential, or through a resistance, can be found in the application of the Nernst equation, Ohm's law, and Faraday's law with the conventional concentration polarization corrections. It was found, however, that cadmium is not reversible in this type of experiment in that there is a nonpolarization contribution to the overpotential. It was also found that the efficiency of the constant current decomposition was much greater than could be explained in view of the calculated effect of polarization. It is proposed that this efficiency is due to the formation of an adherent film which acts as an intermediate for the storage and transfer of electrons. Studies of bismuth, cobalt, and nickel indicate that the deposited metals cannot be anodically oxidized without decomposing mercury. (Contractor's abstract)

POLAROGRAPHY AT A STIRRED MERCURY POOL CATHODE, by D. J. Rosie and W. D. Cooke. Sept. 9, 1954 [19]p. incl. diagrs. tables. (Technical note no. 7) (AFOSR-TN-54-291) (AF 18(600)486) Unclassified

Also published in Anal. Chem., v. 27: 1360-1363, Sept. 1955.

As part of a general program for the development of analytical procedures for trace components, various attempts have been made to increase the sensitivity of polarographic methods. A large Hg pool cathode in a stirred solution was found to be adaptable to such work. Because of the low charging current of such an electrode, it is possible to obtain polarograms of solutions in the micromolar range. The polarograms have the same general shape as those obtained at a dropping Hg electrode but no maxima are obtained and current fluctuations caused by the drop growth are absent. Studies have been made for various types of electrolytic processes including ion-amalgam, ion-metal, ion-ion, and molecule-molecule reductions. Various aspects of each of these systems are discussed. A rapid, simple method requiring no special apparatus, is proposed for the determination of polarographic n-values. (Contractor's abstract)

POLAROGRAPHIC BEHAVIOR OF ORGANIC COMPOUNDS AT THE MERCURY POOL ELECTRODE, by C. A. Streuli and W. D. Cooke. [1954] [8]p. incl. diagrs. tables, refs. (Technical note no. 4) (AF 18(600)-486) Unclassified

Published in Anal. Chem., v. 26: 963-970, June 1954.

The study of the mercury pool cathode for the polarography of organic compounds leads to significant differences, although the polarograms are qualitatively similar to those obtained for ion-metal reductions. In contrast to the behavior exhibited by metallic ions, the reduction potentials are often different from those obtained at the conventional dropping electrode and at times the number of waves is different. In general, the reproducibility of the mercury pool cathode is not as good as that of the dropping mercury electrode; half-peak potentials are precise to 10 mv, and current values, within 7% of their relative values. The groups which have been studied are: nitro, dinitro, keto, diketo, azo, hydrazo, nitroso, disulfide, and quinone. The new electrode extends the range of polarographic methods to more dilute solutions. It is sometimes possible, in the analysis of mixtures of organic compounds, to take advantage of the shift in the reduction potentials. (Contractor's abstract)

AMPEROMETRIC TITRATIONS OF MICROMOLAR SOLUTIONS, by J. G. Nikelly and W. D. Cooke. June 28, 1955 [12]p. incl. diagrs. table. (Technical note no. 8) [AFOSR-TN-55-196] (AF 18(600)486) Unclassified

Published in Anal. Chem., v. 28: 243-245, Feb. 1956.

Amperometric titrations of dilute solutions of metal ions with disodium ethylenediaminetetraacetate have been carried out using a Hg-pool indicator electrode. Some of the problems of Hg-pool polarography, such as the reproducibility of the electrode area and the constancy of stirring, have been eliminated by this technique. The area of the electrode used was 1 to 2 sq cm and stirring was accomplished by bubbling N through the solution. Cd, Cu, Pb, Ni, and Zn have been titrated at concentrations well below the range of conventional amperometric methods which employe the dropping Hg electrode. In favorable cases, titrations were feasible at dilutions approaching 10^{-7}M. For example, solutions containing 0.02 γ of Cd/ml can be titrated with an average error of 0.0001 γ. It was also found possible to titrate solutions of ions which could not be polarographically determined with a Hg-pool cathode. (Contractor's abstract)

ANODIC STRIPPING POLAROGRAPHY, by J. G. Niketty and W. D. Cooke. May 15, 1956 [22]p. tnct. diagrs. tabtes. (Technicat note no. 9) [AFOSR-TN-56-215] (AF 18(600)486) AD 87260 Unclassified

Also published in Anal. Chem., v. 29: 933-939, June 1957.

Anodic stripping polarography is a method of analysis by which a metal is deposited on an etectrode and anodically removed under controlled conditions. The magnitude of the anodic current peak is proportional to the concentration of metallic ion. The applicability of various etectrodes to this method has been investigated and the use of a small Hg electrode has been found to be significantly advantageous. Metallic lons at concentrations as low as 10^{-4} Y/mt were detected, and Pb and Cd in spectrographicalty pure Zn were determined. tn contrast to other electrodes, no pretreatment is necessary and no change in calibration values was observed over a period of 8 mo. There is no interaction in mixtures of deposited metals and 100 times as much metal with a more positive half-wave potential has no influence on the anodic peaks. Half-peak potentiats are independent of concentration and agree ctosely with the half-wave potentiats obtained at a dropping Hg etectrode. Analyses have been carried out on solutions of Cu^{++}, Pb^{++}, Cd^{++} and Tt^{+} from 2×10^{-4} to 2×10^{-8} motar. The method is only applicable to those metals which can be deposited in Hg and anodically removed. (Contractor's abstract)

AN INVESTIGATION OF THE TEMPERATURE DEPENDENCE OF INTERNAL FRICTION IN COPPER SINGLE CRYSTALS FROM 4.2°K TO 300°K, by N. W. Briggs. Sept. 1955, 45p. incl. diagrs. refs. ([AF] OSR-TN-55-393) (AF 18(600)1000) Unclassified

In thts study, the decrement of 2 Cu stngte crystals was determined as a function of temperature from liquid He temperature to room temperature. One of the crystals was examined only in an annealed state, while the other was examined in both annealed and somewhat cold-worked states. Curves of the losses vs temperature are given, and show a gradual decrease from room temperature to 4°K. The loss peaks observed by Bordoni at about 80°K for polycrystalline material, tf present at att, are so small as to be practicalty unobservabte in the stngte crystals studied here. Activation energies are calcutated from graphs of the logarithm of the decrement vs the reciprocat of the absolute temperature. A value of a few tenths of 1 kcal/mol ts found from about 40°K to room temperature. This is exptained as being the energy required to initiate the motion of a distocation. What appears to be a very small activation energy is found at very low temperatures, but this is explained as being the residual support tosses, observable at these temperatures because the actuat dislocation tosses are so small.

A STUDY OF THE tNTERNAL FRICTION AND YOUNG'S MODULUS OF PURE COPPER SINGLE CRYSTALS IN THE TEMPERATURE RANGE 25°C TO 750°C, by L. A. Kamentsky. Sept. 1, t956, 1v. incl. illus. diagrs. tables, refs. (Technical rept. no. 1) (AFOSR-TN-56-425) (Sponsored jointty by Air Force Office of Scientific Research under AF 18(600)1000 and Office of Naval Research under N6ori-9t02) AD 96507 Unclassified

Measurements were made of the internal friction and Young's modulus of pure single Cu crystals in transverse vibration from 25° to 750°C at strain amplitudes of 10^{-8} to 10^{-5} and frequencies of 700 to 7600 cps. These data are compared with those of other authors, and the theories of dislocations are reviewed. Good agreement between experimental results and the theory of Granate and Lucke (Jour. Appt. Phys., v. 27: 583, 789, 1956) was shown for the strain dependent portions of the data up to 300°C. A summary of what is believed to be the behavior of the internal friction and Young's modutus of single Cu crystats is formulated for the higher temperature range. (ASTtA abstract)

INTERNAL FRICTION IN SINGLE COPPER CRYSTALS (Abstract), by H. S. Sack. 1956, 1p. (AF 18(600)1000) Unclassified

Presented at Conference on Ultrasonic Energy Losses in Crystalline Materials, Brown U., Sept. 4-6, 1956.

The internat friction of high purity copper stngle crystals was studied tn the temperature range of 4°K to t000°K, in a frequency range of 600 to 7000 cps, and in a range of strain amplitudes of 10^{-8} to 10^{-5}. Lateral vibrations were used. The ranges were

COR. 03:001 - COR. 04:002

covered by experimsnting with identical specimens so that the well known variations from one sample to the other were eliminated in comparing results under different conditions. A few measurements wsre also made at 40 kcpe at low temperatures, again using the same samples that served for the expertmente with transverse vibrations. The phenomena in this low frequency range are very similar to those observed by other authors tn the high frequency range, where most studies, however, sncompass only a limtted range of temperatures, strain amplitudee or frequenctes. At low temperatures, (approximately 70° K) the Bordoni peak ts not observed for well annealed single crystals. A slight peak superimposed on a broad background appears when the crystal ts slightly cold worked. Very pronounced and sharp peaks ars obsarved in polycrystalline samplee which were subject to a great amount of cold work (15% reduction). Annealing of these polycrystalline samples reduces the hetght of the peak by a factor of 10 or more. Ths annealing was done in such a way that the grain size remained unchanged. The peak shifts only very little tn going from a frequency of 800 to 40,000 cps. The peak doee not seem to be very amplitude sensitive. The background, however, ts both sensitive to amplitude of vibration and to slight amounts of cold work, as ts also obeerved at room temperature. (Contractor's abstract)

CONTRIBUTIONS TO THE THEORY OF MARKOV CHAINS, II, by K. L. Chung. [1954] [23]p. incl. refs. (AF 18(600)330) Unclassified

Published in Trans. Amer. Math. Soc., v. 76: 397-419, May 1954.

The random variables X_n, $n = 0, 1, \ldots$, form a Markov chain with denumerable states and temporally homogeneous transition probabilities $P_{ij}^{(n)} = P(X_{m+n} = j \mid X_m = t)$; $i, j = 0, 1, \ldots$. All states are in the eame recurrent class. Let

$$F_{ij}^{(n)} = P(X_n = j,\ X_v \neq j,\ 1 \leq v < n \mid X_0 = i),$$

$$m_{ij}^{(p)} = \sum_{n=1}^{\infty} n^p F_{ij}^{(n)},\ p > 0.$$

Theorem: $m_{ij}^{(p)} < \infty$ and $m_{ji}^{(p)} < \infty$ for some pair t, j implies $m_{kl}^{(p)}$ every k, I. A partial version for integral p, was proved by Hodges and Rosenblatt [Pacific J. Math. v. 3: 127-136 (1953); Math. Rev. v. 14: 886]. Let

$$E_{ij} = \lim_{n \to \infty} \sum_{v=0} P_{jj}^{(v)} \Big/ \sum_{v=0}^{n} P_{ii}^{(v)}.$$

For a real function f set $I(f) = \sum_j E_{ij} f(j)$. If $I(|f|) < \infty$, $I(|g|) < \infty$, $I(g) \neq 0$ (the choice of t here and later ts tmmaterial), it ts shown

$$P\left\{\lim_{n \to \infty} \sum_{v=0}^{n} f(X_v) \Big/ \sum_{v=0}^{n} g(X_v) = I(f)/I(g)\right\} = 1.$$

A proof using ergodic theory was given tndependently for certain general-state Markov processes by Harris and Robbins [Proc. Nat'l. Acad. Sciences, U. S. A. v. 39: 860-864 (1953); Math. Rev., v. 15: 140]. Let $Y = f(X_{v_1}) + \ldots + f(X_{v_2})$, where $X_{v_1} = i$ and v_2 is the time of first return to t after v_1. If $E(|Y|) < \infty$ and

$m_{ii}^{(1)} < \infty$, the weak law of large numbers holds for $S_n = f(X_0) + \ldots + f(X_n)$. This is not sufficient for the strong law, as an example shows, but $m_{ii}^{(1)} < \infty$ and $\sum_{j=0}^{\infty} |f(j)| / m_{jj}^{(1)} < \infty$ together imply the strong law. Doeblin's central limit theorem is treated; if $m_{ii}^{(2)} < \infty$, then $E(Y^2) < \infty$ implies the central limit theorem, but an example shows $\sum_{j=0}^{\infty} (f(j))^2 / m_{jj}^{(1)} < \infty$ does not. The law of the iterated logarithm and the distribution of the maximum partial sum are treated. (Math. Rev. abstract)

PROBABILITY METHODS AND THE DIRICHLET PROBLEMS, by G. A. Hunt and M. Kac. Sept. 15, 1953, 4p. (Technical rept. no. 1) (AF 18(600)685) AD 18944 Unclassified

Progress is reported on a book being written on the application of probability methods to the Dirichlet problem. The book is intended to show the pedagogical and scientific advantages of treating purely analytic problems by methods of modern probability theory. Chapter 1 is devoted to the presentation of the theory of the Wiener process and those of its properties which are used in the sequel. Chapter 2 is devoted to the solution of the generalized Dirichlet problem and the closely related types of harmonic measure, capacitory potential, Green's function, and regularity of boundary points. The following result is given in connection with the work on chapter 2. If F is a plane closed set of positive capacity and P is a point not in F, then the probability that a Brownian motion curve originating at P will not hit F up to time t is asymptotically (for large t) $\frac{U(P)}{\log \sqrt{t}}$ where U(P) is the solution (generalized) of Robin's problem. The considerations of chapter 2 are based on the study of the event that a Brownian motion curve hits a set F. (ASTIA abstract)

THEOREMS ON FOURIER TRANSFORMS, by W. H. J. Fuchs. Sept. 15, 1953, 13p. (Technical rept. no. 2) (AF 18(600)685) AD 18945 Unclassified

Theorems are proved which confirm the heuristic principle that if a set where a function is large is concentrated near a point, then large values of its Fourier transform cannot be concentrated near a point. The following terminology is used: let E be an n-dimensional Euclidean space, where $t = (t_2, \ldots, t_n)$, and $x = (x_1, \ldots, x_n)$ are points of E, $(t_x) = t_1 x_1 + \ldots + t_n x_n$, and $dt = dt_1 dt_2 \ldots dt_n$. For any set U of finite n-dimensional measure in E, write $k(t;U) = (2\pi)^{-n} \int_U e^{-i(tx)} dx$. If S and T are sets of finite measure, define $\lambda(S, T)$ as the largest eigenvalue of the integral equation $\lambda y(t) = \int_T y(s) k(t-s;S) ds$, where $t \in T$. Theorem 1: Let $g(t) \in L^2(E)$; $\int_E |g(t)|^2 dt = 1$; and let $G(x) = (2\pi)^{-\frac{n}{2}} \int_E g(t) e^{i(tx)} dt$ be the Fourier transform of g. If S and T are 2 sets of finite measure, and if $\int_T |g(t)|^2 dt = A$, then $\int_S |G(x)|^2 dx \leq \mu^2(A)$, where $\mu(A) = 1$ for $A \leq \lambda(T, S)$, and $\mu(A) = [A\lambda(T, S)]^{1/2} + [(1-A)(1-\lambda(T-S))]^{1/2}$ for $A > \lambda(T, S)$. The bound $\mu(A)$ is attained in all cases. The concentration function Q(1) of F(t) is defined by $Q(1) = \max [F(l + 1 + 0) - F(t-0)]$; $\rho(f)$ is defined as $\sup |f(x)^t|$. Theorem 2: If $Q(21) = 1$ for a finite $|x|>a$ value of 1, then $\rho(f) \geq (\cosh al)^{-1}$. This bound cannot be replaced by a larger one. Theorem 3: If the characteristic function f(x) vanishes for $|x| > a$, then $Q(1) \leq \lambda(T, S)$ where $A < \lambda(T, S)$ T is the interval $|t| < 1/2$ 1, and S is the interval $|x| < 1/2$ a. This bound cannot be replaced by a smaller one. (ASTIA abstract)

ESTIMATION BY THE MINIMUM DISTANCE METHOD IN NON-PARAMETRIC STOCHASTIC DIFFERENCE EQUATIONS, by J. Wolfowitz. June 1954 [27]p. [AFOSR-TN-54-4] (AF 18(600)685) AD 30391 Unclassified

Also published in Ann. Math. Stat., v. 25: 203-217, June 1954.

The method of estimation (J. Wolfowitz. Skandinavisk Aktuarietidskrift, 1952, p. 132-151) is characterized by the fact that the estimators are always such as to

COR. 05:004 - COR. 05:006

minimize the distance between suitabty chosen distribution functions. Problems are treated which provide examptes of superconsistent estimators (estimators which converge with probabtlity one to the quantities being estimated). Previous resutts obtained by the minimum distance method are presented. Three new problems tn nonparametric stochastic difference equations are formulated, and minimum distance estimators are exhibtted for these problems. A proof of the superconsistency ls presented for 2 of the estimators. The minimum distance method ls said to be of interest because it enabtes a ctass of probtems to be solved which cannot be solved by ctassical methods. The problems need not be solety probtems of estimation, but may be probtems of testing hypotheses. The minimum distance method ls said to be useful in the sotution of many identification problems. THE BERNSTEIN APPROXIMATtON PROBLEM, by H. Potlard. Aug. 1954 [17]p. (Rept. no. 11) ([AF]OSR-TN-54-202) (AF 18(600)685; continuation of DA 30-115-ORD-439) AD 44128 Unclasstfied

Also published in Proc. Amer. Math. Soc., v. 6: 402-4t1, June 1955.

A former solution of the Bernstein problem (Proc. Amer. Math. Soc., v. 4: 869-875, t953) ls given in a simplified form. The main result ls the following theorem: For the set of functions $x^n/\Phi(x)$, $n = 0, 1, \ldots$, subject to the conditions that

$$\lim x^n/\Phi(x) = 0, \quad x \to \pm\infty, \quad n = 0, 1, \ldots,$$
$$\Phi(x) > 0, \quad -\infty < x < \infty,$$

to be fundamental in the real space C_0, it is necessary and sufficient that (i) the upper bound (u. b.) $\int \frac{\log^+ p(x)}{1+x^2}\,dx = \infty$, where the u. b. is taken over all real polynomials p for which $|p(x)| < \Phi(x)$, $-\infty < x < \infty$. The result is extended to L^p spaces $p \geq 1$ by the following theorem: For the set of functions $x^n/\Phi(x)$, $n = 0, 1, \ldots$, subject to the conditions that $\Phi(x) > 0$ almost everywhere in $(-\infty, \infty)$,

$$x^n/\Phi(x) \in L^p, \quad n = 0, 1, \ldots,$$

to be fundamental in L^p, it is necessary and sufficient that (i) hold where the u. b. is taken over all real polynomials p such that $\left\| \frac{p}{\Phi} \right\| < 1$. A set S in a Banach space B is called fundamental if the set of finite linear combinations of the elements of S is dense in B. The problem is also solved for the semi-infinite interval $(0, \infty)$. POSITIVE TRANSFORMATIONS ON GROUP SPACES, t, by G. A. tlunt. Aug. 1954, 34p. (Rept. no. 13) ([AF]OSR-TN-54-211) (AF 18(600)685) AD 44127 Unctassified

Results of Lévy and Khinchin on an explicit representation of the characteristic function of an infinitely divisible probability distribution on the additive group of the real numbers are extended to semigroups of probability distributions on arbitrary Lie groups. The rote of the characteristic function is taken over by the infinitesimal generator of a semigroup of transformations associated with the prohability distributions. The principal resutt is the foltowing theorem. Let S_t be a probability semigroup on a Lie group $\mathcal{G}$. The infinitesimal generator M of S_t is defined at least on ζ^2 and has the expression

(1) $Mf.(\tau) = \sum a_i X^i f.(\tau) + \sum a_{ij} X^i X^j f.(\tau) +$

$$\int_{\mathcal{G}-e} \left\{ f(\tau\sigma) - f(\tau) - \sum X^i f.(\tau) x_i(\sigma) \right\} G(d\sigma);$$ where (2)

$x_1, \ldots, x_n \in \zeta^2$, $x_i(e) = 0$, $X^i x_j.(e) = \delta_{ij}$;

(3) $a_{ij} = a_{ji}$, $\sum a_{ij}\lambda_i\lambda_j \geq 0$ for all λ_t; and (4) $G(E) = \int_E \frac{1}{\varphi(\sigma)} F(d\sigma)$, where F is a bounded positive measure on $\mathcal{G}-e$ and φ is in ζ^2 with $\varphi(e) = X^i\varphi.(e) = 0$, $X^iX^j\varphi.(e) = \delta_{ij}$, $\varphi(\tau) > 0$ for $\tau \in \mathcal{G}-e$. The measure G and the operator $\sum a_{ij}X^iX^j$ are determined by S_t independently of the choice of X^i and x_i. The restriction of M to ζ^2 determines S_t. Conversely, if $M: \zeta^2 \to \zeta$

is defined by (1) and if (2), (3), and (4) are satisfied, then M is the restriction to ζ^{-2} of the infinitesimal generator of exactly 1 probability semigroup. In the notation, $\bar{\mathcal{G}}$ is the 1-point compactification of $\mathcal{G}$, and ζ is the Banach space of continuous functions on $\bar{\mathcal{G}}$. (ASTIA abstract)

ON TESTS OF NORMALITY AND OTHER TESTS OF GOODNESS OF FIT BASED ON DISTANCE METHODS, by M. Kac, J. Kiefer, and J. Wolfowitz. Aug. 1954, 38p. incl. tables, refs. (Rept. no. 14) ([AF]OSR-TN-54-212) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)685 and Office of Naval Research under [N6onr-26405]) AD 44129 Unclassified

Also published in Ann. Math. Stat., v. 26: 189-211, June 1955.

The problem tested is that of whether the distribution function (df) of observed independent chance variables $x_1, \ldots, x_n$ is a member of a given class. The notation is as follows: F(y) and G(y) are any 2 df's, and $\delta(F, G) = \sup_y |F(y)-G(y)|$; $G_n^*(y)$ is the empiric df of $x_1, \ldots, x_n$. Tests of normality are based on $v_n = \delta(G_n^*(y), N(y|\bar{x}, s^2))$ and on $w_n = \int (G_n^*(y) - N(y|x, s^2))^2 dy N(y|\bar{x}, s^2)$. The analysis reveals that the asymptotic power of these tests is greater than that of the optimum X^2 test. The covariance function of a Gaussian process Z(t), $0 \leq t \leq 1$, is obtained. A demonstration is given that the sample functions of Z(1) are continuous with probability 1, and that, as $n \to \infty$, $\lim P\left\{nw_n < a\right\} = P\left\{W < a\right\}$, where $W = \int_0^1 [z(1)]^2 dt$. Tables are presented of the distribution of W and of the limiting distribution of $\sqrt{n}\, v_n$. The role of the various metrics is discussed. (ASTIA abstract)

ESTIMATES FOR GLOBAL LIMIT THEOREMS, by R. P. Agnew. Aug. 1954, 23p. (Rept. no. 16) ([AF]OSR-TN-54-214) (AF 18(600)685) AD 44124 Unclassified

Also published in Ann. Math. Stat., v. 28: 26-42, Mar. 1957.

Let $F_1, F_2, \ldots$ be random variables having the same df (distribution function) F(x) with mean 0 and standard deviation 1. Let $F_n(x)$ be the df of the combination $(F_1 + F_2 + \ldots + F_n)/n^{1/2}$, let $\varphi(x)$ be the Gaussian df, and let $C_n = \int_{-\infty}^{\infty} |F_n(x) - \varphi(x)|^2 dx$. Various questions about the numbers C_n are considered. A formula giving C_n in terms of the characteristic function is obtained and studied. Close appraisals of the C_n are given when F(x) is the symmetric binomial df and when the F_k are uniformly distributed over a finite interval. (Contractor's abstract)

A LIMIT THEOREM FOR THE MAXIMUM OF NORMALIZED SUMS OF INDEPENDENT RANDOM VARIABLES, by D. A. Darling and P. Erdös. Nov. 1954, 16p. (Rept. no. 20) ([AF]OSR-TN-54-313) (AF 18(600)685) AD 47968 Unclassified

Also published in Duke Math. Jour., v. 23: 143-155, Mar. 1956.

The following theorem is proved: Let $X_1, X_2 \ldots$ be independent random variables with a uniformly bounded third absolute moment. Put $S_n = X_1 + X_2 + \ldots + X_n$, and let $U_n = \max_{1\le k\le n} S_k/\sqrt{k}$.

Then $\lim_{n\to\infty} P_r \left\{ U_n < (2\log\log n)^{1/2} + \frac{1}{2}(\log\log\log n)(2\log\log n)^{-\frac{1}{2}} + t(2\log\log n)^{-\frac{1}{2}} \right\} = \exp\left(-\frac{1}{2\sqrt{\pi}}\exp(-t)\right)$, $-\infty < t < \infty$. A similar theorem is proved for $U'_n = \max_{1<k\le n} |S_k|/\sqrt{k}$ and two strong theorems for the sequence U_n are indicated. The method of proof consists in finding an interpolatory stochastic process for the sequence $S_k/\sqrt{k}$, obtaining a limit theorem for its maximum and then an application of the invariance principle of Erdös-Kac. ON A CHARACTERIZATION OF THE NORMAL LAW, by G. E. Baxter. Dec. 1954, 5p. (Rept. no. 21) ([AF]OSR-TN-54-362) (AF 18(600)685) AD 53316 Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 41: 383-385, June 1955.

Two proofs are presented of the following theorem (Linnik's): let X_1 ($\neq 0$) and X_2 be independent, identically distributed random variables and suppose that there exists a pair of real numbers (a, b) with $0 < a \le b < 1$, $a^2 + b^2 = 1$, for which $aX_1 + bX_2$ has the same distribution as X_1; then X_1 is Gaussian with mean zero. A counterexample is given of the conjecture that if X_1 and X_2 are independent, identically distributed (perhaps symmetric) random variables and if there exists a pair of real numbers (a, b) with $0 < a \le b < 1$, $a^\alpha + b^\alpha = 1$, for which $aX_1 + bX_2$ has the same distribution as X_1, then X_1 is stable with parameter α. TOPOLOGICAL PROPERTIES OF HOMOMORPHISMS BETWEEN BANACH ALGEBRAS, by B. Yood. Jan. 1954 [13]p. incl. refs. [AF 18(600)685] Unclassified

Published in Amer. Jour. Math., v. 76: 155-167, Jan. 1954.

Let B be a real Banach algebra. An involution on B is a mapping $x \to x^*$ for which $(x + \lambda y)^* = x^* + \lambda y^*$ for λ real, $x^{**} = x$, and either $(xy)^* = x^*y^*$ or $(xy)^* = y^*x^*$. Call B a ρ^*-algebra if B has an involution and a non-negative subadditive function $||$ which vanishes only at 0 and satisfies $|x| < \rho(x)$ for x self-adjoint or skew ($\rho(x)$ is the spectral radius of x in the complexification of B). If moreover $||$ can be chosen so that B is an (F)-space (in the sense of Banach) under the metric $|x - y|$, then B is a ρ_c^*-algebra. The A^*-algebras of Rickart (Ann. of Math. (2), v. 51: 615-628 (1950); Math Rev., v. 11:670 (1954)) are ρ^*-algebras. The involution in a ρ^*-algebra is continuous. ρ^*-algebras are semi-simple and have unique norm. A homomorphism of a Banach algebra onto a self-adjoint subalgebra of a ρ^*-algebra is continuous. If B is a ρ_c^*-algebra for which each self-adjoint element has a real spectrum and T is an isomorphism of B into a Banach algebra, then T preserves the spectral radius of self-adjoint and skew elements; if moreover there is a $c > 0$ such that $||T(x^*)|| \le c||T(x)||$ for all x, then T^{-1} is continuous on T(B). Now let B (B_1) be a complex commutative Banach algebra with radical R (R_1)

and let $\mathfrak{M}'(\mathfrak{N}')$ be its set of maximal regular ideals (including B (B_1) itself). Let T be a homomorphism of B into B_1. For $N \in \mathfrak{N}'$ let $T^*(N)$ be the unique $M \in \mathfrak{M}$ determined by the rule $x[T^*(N)] = T(x)(N)$ for $x \in B$. If B is regular, in the sense of Silov (Trav. Inst. Math. Stekloff, v. 21 (1947); Math. Rev., v. 9: 596, 1954), then $T^*(\mathfrak{N}')$ consists of the maximal regular ideals containing $T^{-1}(R_1)$ $(T^{-1}[\overline{T(R)}])$; for R = 0 and T one-to-one the second result reduces to one due to Rickart (Proc. Amer. Math. Soc., v. 4: 191-196 (1953); thm. 1; Math. Rev., v. 14: 860, 1954). If B is regular and is closed under uniform limits when considered as an algebra of functions on the set of maximal regular ideals containing $T^{-1}(0)$ and if $T^{-1}(0)$ is the intersection of the maximal regular ideals containing it, then the closure of T(B) is $T(B) \oplus R_1$ and the canonical isomorphism of $B/T^{-1}(0)$ onto T(B) has a continuous inverse. The paper contains other results and most of the above results are proved in a more general setting. (Math. Rev. abstract)

TOEPLITZ MATRICES, TRANSLATION KERNELS AND A RELATED PROBLEM IN PROBABILITY THEORY, by M. Kac. Sept. 1954 [10]p. [AF 18(600)685] AD 26900 Unclassified

Also published in Duke Math. Jour., v. 21: 501-510, Sept. 1954.

Theorem: Let F be the Fourier transform of an even function ρ such that $\rho(x) \geq 0$, $\int_{-\infty}^{\infty} \rho(x)dx = 1$, and suppose that $|x|\rho(x)$ and F belong to $L^1(-\infty, \infty)$. Let $D_a(\lambda)$ denote the Fredholm determinant of the integral equation $\int_{-a}^{a} \rho(x-y)\rho(y)dy = \lambda\rho(x)$. Then for sufficiently small real λ, $\lim D_a(\lambda) \exp\left\{-\frac{a}{\pi}\int_0^{\infty} \log[1-\lambda F(\eta)]d\eta\right\} = \exp\left\{\int_0^{\infty} x\left|\frac{1}{2\pi}\int_{-\infty}^{\infty} \log[1-\lambda F(\eta)]e^{i\eta x}d\eta\right|^2 dx\right\}$. This theorem is an analogue of a result which Szegö recently proved for Fourier series (Comm. Sém. Math. Univ. Lund [Medd. Lunds Univ. Mat. Sem.] Tome Supplémentaire, 228-238, (1952); these Rev. 14, 553). An interesting account of the way in which the theorem was discovered is included. Szegö's result is reinterpreted in probabilistic terms, and it is shown that both Szegö's result and the above analogue are consequences of the following combinatorial identity: Let $s = (s_1, \ldots, s_n)$ be a permutation of $(1, \ldots, n)$, let $a_1, \ldots, a_n$ be real numbers, and let N(s) be the number of non-negative terms in the sequence a_{s_1}, $a_{s_1} + a_{s_2}$, $\ldots$, $a_{s_1} + a_{s_n}$, whose largest is M(s). Then $\sum \max(0, M(s)) = \sum N(s)a_{s_t}$, the summations being extended over all permutations of $(1, \ldots, n)$. The reviewer noticed one minor oversight: Szegö's result is proved by him under the assumption that f' satisfies a Lipschitz condition of order α $(0 < \alpha \leq 1)$, and is proved in the present paper under the assumption that f' has an absolutely convergent Fourier series: it is claimed that the second condition is weaker than the first; but this is so only if $\alpha > \frac{1}{2}$. ASYMPTOTIC MINIMAX CHARACTER OF THE SAMPLE DISTRIBUTION FUNCTION AND OF THE CLASSICAL MULTINOMIAL ESTIMATOR, by A. Dvoretzky, J. Kiefer, and J. Wolfowitz. May 1955, 50p. (Repl. no. 23) ([AF]OSR-TN-55-137) (AF 18(600)685) AD 63414 Unclassified

Also published in Ann. Math. Stat., v. 27: 642-669, Sept. 1956.

This study is concerned with proving the asymptotic minimax character of the sample distribution function (df) for estimating an unknown df in $\mathcal{F}$ or $\mathcal{F}_c$ for a wide variety of weight functions. Section 1 contains definitions and a discussion of measurability considerations. Section 2 includes a statement of 2 lemmas, and a corollary of the second, which are important tools in the proofs and are of interest per se. For example, Lemma 2 implies the convergence of the moment generating function of G_n to that of G. A proof of Lemma 2 is given in Section 2; Lemma 1 was proved by Anderson in Proc. Amer. Math. Soc., v. 6: 170-176, 1955. In Section 3, the asymptotic minimax character is proved for a fundamental class of weight functions which are functions of the maximum deviation between estimating and true df. In Section 4, a device (of more general applicability in decision theory) is employed which yields the asymptotic minimax result for a wide class of weight functions of this character as a consequence of the results of Section 3 for weight functions of the fundamental class. The asymptotic minimax character is proved for a class of integrated weight functions in Section 5. A more general class of weight functions for which the asymptotic minimax character holds is discussed in Section 6. This

COR. 05:019 - COR. 05:022

include weight functions for which the risk function of the sample df is not a constant over $\mathfrak{F}_c$. Most weight functions of practical interest are included in the considerations of Sections 3 to 6. Section 6 also presents a discussion of multinomial estimation problems for which the asymptotic minimax character of the classical estimator is contained in the results. Finally, Section 7 includes a general discussion of minimization of symmetric convex or monotone functionals of symmetric random elements, with special consideration of the "tied-down" Wiener process, and with a heuristic proof of the results of Sections 3, 4, 5 and much of Section 6. ON OCCUPATION TIMES FOR MARKOFF PROCESSES, by D. A. Darling and M. Kac. Aug. 1955, 20p. (Rept. no. 26) ([AF]OSR-TN-55-255) (AF 18(600)685) AD 87252 Unclassified

Also published in Trans. Amer. Math. Soc., v. 84: 444-458, Mar. 1957.

Let $\{x_t \quad t \geq 0\}$ be an abstract-valued Markov process with the stationary transition probability $p(x, E;t)$. Let $p_s(x, E) = \int_0^\infty e^{-st}P(x, E;t)dt$; $V(x)$ be measurable and ≥ 0. Assumption: There exists $h(s) \to \infty$ as $s \to 0$ and $C > 0$ such that

$$(h(s))^{-1} \int V(y)p_s(x, dy) \to C \quad (s \to 0)$$

uniformly in $x \in \{\xi | V(\xi) > 0\}$. Then if $h(s) = L(s^{-1})s^{-\alpha}$ $(0 \leq \alpha < 1)$ and $L(s^{-1})$ is slowly varying as $s \to 0$,

$$(Ch(t^{-1}))^{-1} \int_0^t V(x(\tau))d\tau$$

has as limit the Mittag-Leffler distribution of index α. Conversely, if the above has a nondegenerate limit distribution after $Ch(t^{-1})$ is replaced by some $u(t) > 0$, then $u(t)$ is indeed $Ch(t^{-1})$, where h is given in the assumption and must be of the stated form. There is a discrete analogue. The connexion with Karamata's Tauberian theorem is discussed. Applications to sums of independent random variables unify some known results but under more restrictive conditions than otherwise obtainable. (Math. Rev. abstract)

CONSISTENCY OF THE MAXIMUM LIKELIHOOD ESTIMATOR IN THE PRESENCE OF INFINITELY MANY INCIDENTAL PARAMETERS, by J. Kiefer and J. Wolfowitz. Sept. 1955 [37]p. refs. (Rept. no. 34) ([AF]OSR-TN-55-290) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)685 and Office of Naval Research under [Nonr-40103] AD 87106 Unclassified

Also published in Ann. Math. Stat., v. 27: 887-906, Dec. 1956.

It is shown that, under usual regularity conditions, the maximum likelihood estimator of a structural parameter is strongly consistent, when the (infinitely many) incidental parameters are independently distributed chance variables with a common unknown distribution function. The latter is also consistently estimated although it is not assumed to belong to a parametric class. Application is made to several problems, in particular to the problem of extimating a straight line with both variables subject to error, which, thus, after all has a maximum likelihood solution. RIEMANN METHODS FOR EVALUATION OF SERIES, by R. P. Agnew. Dec. 1955 [37]p. refs. (Rept. no. 39) ([AF]OSR-TN-55-357) (AF 18(600)685) AD 87262 Unclassifted

An investigation is made of the behavior of the R(p) and R_p transforms of series Σu_n satisfying the Tauberian condition $\limsup_{n\to\infty} |nu_n| \leq M < \infty$. The series is said to be evaluable R(p) to L if the series in $\sigma_1(p,t) = \sum_{k=0}^{\infty} \left(\frac{\sin kt}{kt}\right)^p u_k$ converges over some interval $0 < t < t_0$ and $\sigma_1(p,t) \to L$ as $t \to 0$, and the series is said to be evaluable R_p to L if the series in $\sigma_2(p,t) = c_p t \sum_{k=0}^{\infty} \left(\frac{\sin kt}{kt}\right)^p s_k$ converges over some interval $0 < t < t_0$ and $\sigma_2(p,t) \to L$ as $t \to 0$; s_k is the k^{th} partial sum of the series Σu_n. Precise optimal relations are obtained between (1) the R(p) transform of Σu_n and the partial sums of Σu_n; (2) the R_p transform of Σu_n and the partial sums of Σu_n; and (3) the R(p) and R_p transforms of Σu_n. A simple Tauberian argument is used to prove that the product transformation $R(p)C_r$ and R_pC_r are regular when $r \geq 1$; C_r is the Cesaro transformation of order r. (ASTIA abstract)

INVERSION OF CLASS OF DISCRETE CONVOLUTION TRANSFORMS, by H. Pollard and C. Standish. Oct. 1955 [17]p. (Rept. no. 37) ([AF]OSR-TN-55-367) (AF 18(600)685) AD 87104 Unclassifted

An inversion formula is obtained for the discrete convolution transforms

$$f(n) = \sum_{-\infty}^{\infty} k(n-m)g(m)$$

with kernels k(n) defined by the property

$$\sum_{-\infty}^{\infty} k(n)z^n = \prod_{j=1}^{\infty}(1-a_j)(1-b_j)/\prod_{j=1}^{\infty}(1-a_jz)(1-b_jz),$$

where $1 > a_1 \geq a_2 \geq \ldots > 0$; $1 > b_1 \geq b_2 \geq \ldots > 0$, and, $\Sigma (a_j + b_j) < \infty$.

The inversion formula is the following. Define operation δ, $1/\delta$, and $P_N(\delta)$

$$\delta F(n) = F(n+1) \quad [1/\delta]F(n) = F(n-1)$$

$$[P_N(\delta)F(n) = (1/K_1)\prod_{1}^{N}(1-a_k\delta)(1-b_k|\delta)F(n) \text{ then}$$

$$K_1 = \prod_{j=1}^{\infty}(1-a_j)(1-b_j)$$

$\lim_{N\to\infty}[P_N(\delta)]F(n) = g(n)$. (Contractor's abstract)

SOME THEOREMS CONCERNING BROWNIAN MOTION, by G. A. Hunt. July 20, 1955 [26]p. [AFOSR-TN-55-368] [AF 18(600)685] Unclassified

Published in Trans. Amer. Math. Soc., v. 81: 294-319, Mar. 1956.

Given a Markov process with stationary transition probabilities, this mathematical study is concerned with certain random times such that, when the associated state is known, the future is a new Markov process which is governed by the original transition probabilities, and is independent of the past. A somewhat special version of these statements is reported. Consider a Brownian motion with state space R^n and continuous sample functions $X = (X(t): t \geq 0)$, built over the probability field (Ω, F, P), let T be a (P) measurable random time, and let $\Omega' = (T < +\infty)$, have positive P measure, let $F' = (B: B = A \cap \Omega', A \in F)$ and $P'(.) = P(./\Omega')$, and call T a Markov time if, over the new probability field (Ω', F', P'), $Z = (X(t+T) - X(T): t \geq 0)$ is a Brownian motion, independent of the stopped process $X^* = (X(\min(t,T)): t \geq 0)$. The theorem is stated as: T is a Markov time provided either that it be Borel measurable in X^* or that it be the limit of Markov times S such that $(S = +\infty) = (T = +\infty)$. Let E be closed in R^n, and let E' be the points of E which are regular for the associated Dirichlet problem. It is remarked that $T = \inf(t: X(t) \in E, t > 0) \cup (t = +\infty)$ is a Markov time and uses this to indicate that $q(t,r,s) = P(T > t, X(t) \in ds/ds/X(0) = r/ds$ is the elementary solution for the heat equation $v_t = (1/2)\Delta v$ on $R^n - E$, $v = 0$ on E', and that $G(r,s) = \int_0^{+\infty} q(t,r,s)dt$ is the Green function

COR. 05:036 - COR. 05:040

for the Poisson equation $(1/2)\Delta v = -u$ on $R^n - E$, $v = 0$ on E'. When $n = 2$ and E has positive logarithmic capacity, these expressions are used to estimate the speed at which the solution $v(t, s)$ of $v_t = (1/2)\Delta v$, $v(0, \cdot) = 0$ on Rn-E, $v(t, \cdot)$ prescribed on E', converges to the corresponding solution $v(s)$ of $\Delta v = 0$. The result is $[v(s) - v(t, s)] \log t \longrightarrow 2\pi G(s, \infty)v(\infty)$, as $t \uparrow +\infty$, and it follows that $P(T > t / X(0) = s) \sim 2\pi G(s, \infty)/\log t$, as $t \uparrow +\infty$, which has been conjectured by M. Kac.

CONSISTENCY AND OPTIMUM PROPERTIES OF SOME TWO-SAMPLE TESTS, by J. R. Blum and L. Weiss. Dec. 1955, 10p. (Rept. no. 4) ([AF]OSR-TN-55-403) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)685 and Office of Naval Research under [Nonr-40103]) AD 87395 Unclassified

The problem is stated as follows: $X_1, \ldots, X_m$ is a sample from the uniform distribution on the unit interval and $Y_1, \ldots, Y_n$ is a sample with density g(y) on the unit interval. $Z_0 = 0$, $Z_{n+1} = 1$, and $Z_1 < \ldots < Z_n$ are the order statistics corresponding to $Y_1, \ldots, Y_n$. For each $i = 1, \ldots, n+1$, S_i is the number of X's in the interval $[Z_{i-1}, Z_i]$, and for each nonnegative r, $Q_n(r)$ is the proportion among $S_1, \ldots, S_{n+1}$ which is equal to r. Define $a = m/n$, and for each r, set

$Q(r) = a^r \int_0^1 \frac{g^2(y)dy}{[a+g(y)]^{r+1}}$. A proof is given, under mild restrictions on g(y), that

$P\left\{\limsup_{n\to\infty} \sqrt{n}\left|Q_n(r) - Q(r)\right| = 0\right\} = 1$. This is applied to prove the consistency of such 2-sample tests as that of the Wald-Wolfowitz run-test (Ann. Math. Stat., v. 2: 147-162, 1940). (Contractor's abstract, modified)

SOME REMARKS ON THE USE OF PROBABILITY IN CLASSICAL STATISTICAL MECHANICS, by M. Kac. Feb. 1956, 7p. (Rept. no. 45) ([AF]OSR-TN-56-22) (AF 18(600)685) AD 87394 Unclassified

Also published in Bull. Acad. Roy. de Belgique, Cl. Sci., v. 42: 356-361, 1956.

A simple artifical model is constructed to explain the role of probabilistic notions in establishing the irreversibility of reversible systems. The model consists of n equidistant points on a circle, m of which are marked and form a set S. The complementary set of n-m points is $\bar{S}$. Each of the n points is a site of a ball which can be either white or black. During an elementary time interval each ball moves counterclockwise to the nearest site under these conditions: if the ball is in S it changes color when the move is completed, but if the ball is in $\bar{S}$ the move is made without a color change. Analysis of the model shows that the Boltzmann approach can be justified in a manner similar to that employed by P. and T. Ehrenfest. An analysis of the model for the case when S is completely specified, but the initial arrangement of white and black balls is subject to a probability distribution, was unsuccessful. ON STOCHASTIC APPROXIMATION METHODS, by J. Wolfowitz. Dec. 1955, 9p. (Rept. no. 46) (AFOSR-TN-56-58) (AF 18(600)685) AD 81050 Unclassified

Also published in Ann. Math. Stat., v. 27: 1151-1156, Dec. 1956.

A simple proof is given of the following theorem on the convergence of stochastic approximation procedures by Dvoretzky. a_n, b_n, and Y_n, $n = 1, 2, \ldots$ are

nonnegative real numbers that satisfy these conditions:

(1) $\lim_{n\to\infty} \alpha_n = 0$; (2) $\sum_{n=1}^{\infty} \beta_n < \infty$; and

(3) $\sum_{n=1}^{\infty} \gamma_n = \infty$. θ is a real number and T_n, n=1, 2, ..., are measurable transformations that satisfy $|T_n(r_1, \ldots, r_n) - \theta| \leqq \max [\alpha_n, (1+\beta_n)|r_n - \theta| - \gamma_n]$ for all real $r_1, \ldots, r_n$. X_1 and Y_n, n=1, 2, ..., are random variables, and $X_{n+1}(\omega) = T_n(X_1(\omega), \ldots, X_n(\omega)) + Y_n(\omega)$ is defined for $n \geqq 1$. Then the conditions $E\{X_t^2\} < \infty$, $\sum_{n=1}^{\infty} E\{Y_n^2\} < \infty$, and $E\{Y_n | x_1, \ldots, x_n\} = 0$ with probability 1 for all n imply $\lim_{n\to\infty} E\{X_n - \theta^2\} = 0$ and $P\{\lim_{n\to\infty} X_n = \theta\} = 1$. GENERALIZATIONS OF A THEOREM OF WALD ON MONOTONE SEQUENCES, by R. P. Agnew. Aug. 1956 [17]p. (Rept. no. 54) (AFOSR-TN-56-355) (AF 18(600)685) AD 95441 Unclassified

The following theorem of Wald is strengthened and generalized in several ways: If n is an even integer, if $\lambda(n) = n/2$, and if $q(k) = k$, then

$$\liminf_{n\to\infty} \sum_{1 \le k < \lambda(n)} \left(\frac{a_k}{a_n}\right)^{q(k)} = 0, \text{ whenever}$$

$0 < a_1 \le a_2 \dots$ and $a_n \to \infty$. It is found that if $0 < \lambda < 1$, $\lambda(n) = \lambda n$, and $\epsilon > 0$, then $g(k)$ can be $(\log k)^{2+\epsilon}$ when $k > 1$. When $\lambda(n) = n - 1$ and $\epsilon > 0$, $g(k)$ can be $k(\log k)^{2+\epsilon}$ when $k > 1$. Some of the generalizations involve monotone functions instead of sequences. ON SIMILARITY, REDUCING MANIFOLDS, AND UNITARY EQUIVALENCE OF CERTAIN VOLTERRA OPERATORS, by G. K. Kalisch. Oct. 1956, 19p. (Rept. no. 54) ([AF]OSR-TN-56-513) (AF 18(600)-685) AD 110328 Unclassified

Also published in Ann. Math., v. 66: 481-494, Nov. 1957.

The investigation is concerned with Volterra Operators T_F where $T_F f(x) = \int_0^1 F(x,y)dy$ mapping $L_p[0,1]$ into itself $(1 < p < \infty)$. The following three topics are discussed: Similarity, reducing manifolds, (i.e., subspaced S such that $F_F S \subset S$), and in the case $p = 2$ unitary equivalence. In addition to certain regularity conditions, the kernels satisfy the following: $F(x,y) = (y-x)^{n-1}G(x,y)$ where $G(x,x)$ is real and different from 0; otherwise, the kernels may be complex-valued. The integer n in the foregoing equation is to be positive: it is called the order of F. The principal results concerning similarity may be stated as follows: Under suitable regularity conditions imposed on F, every T_F is similar to a unique operator cT_E^n where c is real number, E is the function identically equal to 1, and n is the order of F. The principal results concerning reducing manifolds are these: The only reducing subspaces of the operators T_F considered are the spaces $L_p[0,\mu]$ for all $\mu \in [0,1]$. The principal results concerning the unitary equivalence of the operators T_F (acting on $L_2^*[0,1]$) are these: Every T_F is unitarily equivalent to a unique operator T_G where $G(x,y) = (y-x)^{n-1}H(x,y)$ such that $H(x,x) = c$ (a real number) and $1M\ 11_x(x,x) = 1M\ 11_y(x,x) = 0$. The operators used to implement the similarity and unitary equivalence relations are of three kinds: multiplication by measurable functions, change of measure of the unit interval, and operators of the form $1 + T_m$ for suitable $m(x,y)$. ASYMPTOTIC EXPANSIONS IN GLOBAL CENTRAL LIMIT THEOREMS, by R. P. Agnew. Dec. 1956 [33]p. (Rept. no. 63) ([AF]OSR-TN-56-514) (AF 18(600)685) AD 110329 Unclassified

Let $\xi_1, \xi_2, \ldots$ be random variables having the same df (distribution function) F (x) with mean 0 and standard deviation 1. By the central limit theorem, the df F_n of the normalized sum $(\xi_1 + \xi_2 + \ldots + \xi_n)/n^{1/2}$ then converges pointwise to the Gaussian df Φ. Let

$$C_n = \int_{-\infty}^{\infty} | F_n(x) - \Phi(x) |^2 dx.$$

A principal problem of the paper is to give conditions under which there exist constants $D_1, D_2, D_3, \ldots$ such that the expansion

$$C_n = \frac{D_1}{n} + \frac{D_2}{n^2} + \ldots + \frac{D_k}{n^k} + 0\left(\frac{1}{n^{k+1}}\right)$$

is valid for a fixed $k \geq 1$ or for each $k = 1, 2, 3, \ldots$, and to give explicit expressions for D_1 and D_2. The above problem is solved for random variables $\xi_1, \xi_2, \ldots$ having distribution functions belonging to important classes. Characteristic functions are employed in the proofs and in the determination of D_1 and D_2. (Contractor's introduction, modified)

ON THE REGULARITY OF THE GROWTH OF MEROMORPHIC FUNCTIONS WITH HIGHLY DEFICIENT ZEROS AND POLES, by A. Edrei and W. H. J. Fuchs. Nov. 1956, 16p. (Rept. no. 59) ([AF]OSR-TN-56-515) (AF 18(600)685) AD 110330; PB 136420 Unclassified

The authors consider a meromorphic function f(z) and show that if its zeros and poles are highly deficient, the lower order of f(z) is close to its order. In particular, if $\delta(0) + \delta(\infty) = 2$, the increase of f(z) is regular, that is the order and lower order coincide. (For functions of infinite order this is to be interpreted as meaning that the lower order is infinite.) (Contractor's abstract)

SEMI-GROUPS OF MEASURES ON LIE GROUPS, by G. A. Hunt. [1956] [30]p. [AF 18(600)685] Unclassified

Published in Trans. Amer. Math. Soc., v. 81: 264-293, Mar. 1956.

Let G be a Lie group and let G_c be its one-point compactification. Let $\{p_t\}$ $(0 < t < \infty)$ be a family of probability measures on the Borel subsets of G_c which forms a semi-group under convolution and satisfies the continuity condition $\lim_{t \downarrow 0} p_t(E) = 1$ for any neighborhood of the identity e of G. Such a semi-group $\{p_t\}$ gives rise to a strongly continuous semi-group of linear operators $\{S_t\}$ on the Banach space $C = C(G_c)$ to C: $(S_t f)(g) = \int_{G_c} f(gh)p_t(dh)$. The Theorem 5.1 gives a characterization of the infinitesimal generator M of such semi-group $\{S_t\}$: M is defined at least on $C^2(G_c)$ and has there the representation $(Mf)(g) = \sum a_i X_i f(g) + \sum a_{ij} X_i X_j f(g) + \int_{G_c - \{e\}} [f(gh) - f(g) - \sum X_i f(g) x_i(g)] \bar{G}(dh)$. Here the symmetric positive semi-definite matrix (a_{ij}) is such that $\sum a_{ij} X_i X_j$ is independent of the choice of the basis $X_1, X_2, \ldots, X_d$ of the infinitesimal transformations of G; the positive measure $\bar{G}$ is such that $\int k(g)\bar{G}(dg)$ is finite for C^2

COR. 05:055 - COR. 05:057

function k(g) strictly positive on $G_c - \{e\}$ and behaves near e like Σx_1^2, $x_1(g)$, $x_2(g)$, ..., $x_d(g)$ denoting the local coordinates of $g \in G$ near e such that $x_i(e) = 0$ and $X_i x_j(e) = \delta_{ij}$. It is proved in §6, that the Lévy formula concerning the characteristic function of the infinitely divisible law may be obtained from the Theorem 5.1. In later g's, the case where the continuity condition for $\{p_t\}$ is not satisfied is discussed in some detail. In such a case, p_t converges, as t decreases to 0, weakly to the Haar measure of a compact subgroup K of G, and an analogue of Theorem 5.1 pertaining to the homogeneous space G/K is sketched. (Math. Rev. abstract)

BOUNDARIES INDUCED BY NON-NEGATIVE MATRICES, by W. Feller. Jan. 25, 1956 [36]p. incl. refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)685 and Office of Ordnance Research under DA 36-034-ord-1296)
Unclassified

Published in Trans. Amer. Math. Soc., v. 83: 19-54, Sept. 1956.

Let E be the set of positive integers, and let $\prod$ be a matrix with non-negative elements and row sums ≤ 1. The author immerses E in a Hausdorff space, depending on $\prod$, to obtain a boundary for E. A second boundary is also obtained, adjoint to the first and in no relationship to the first except by way of $\prod$. The boundaries are to be applied in a subsequent paper to the theory of the Kolmogorov differential equations for the transition probabilities of a continuous parameter Markov process with countably many states. Let $\mathfrak{M}$ be the class of vectors z with $z \geq 0$ and $\prod z \leq z$. Let $\mathfrak{B}$ be the subclass of $\mathfrak{M}$ with $z \leq 1$. The class $\mathfrak{B}$ is a convex set, and a lattice. The extremals of this convex set, called sojourn solutions, form a lattice also. If A is a subset of E, and if $S_A(i)$ is the probability that the random walk starting from i, with transition probability matrix $\prod$, will enter A and remain there indefinitely, S_A is a sojourn solution, and every sojourn solution can be obtained in this way. (A sojourn solution is an element of $\mathfrak{B}$ for which the limit along successive random walk steps from each initial point has only the possible values 0 and 1.) The author obtains the usual decomposition of E into recurrent and transient states as an application of his study of sojourn solutions. The boundary $\mathfrak{B}$ is the set of maximum ideals in the lattice of sojourn solution, and $E \cup B$ is topologized in such a way that each element $\mathfrak{B}$, considered as a function on E, has continuous boundary values. Each such element can be approximated uniformly by linear combinations of sojourn solutions. If z is a strictly positive element of $\mathfrak{M}$, and if $\prod'$ is defined by $\prod'(i, j) = \prod(i, j)z(j)/z(i)$, then, if $\prod'$ has row sums 1, $\prod'$ has the same property, and $x \in \mathfrak{M}$ if and only if $\prod' x' \leq x'$, for $x(i) = x(i)/z(i)$. Thus a correspondence between $\mathfrak{M}$ and its analogue for $\prod'$ is set up and thereby the above is extended to a larger boundary which includes $\mathfrak{B}$ and every boundary obtained by the above relativization in terms of a specified element of $\mathfrak{M}$. The analogue of this relativization in the context of the first boundary value problem for harmonic functions (when $\mathfrak{M}$ becomes the class of positive barmonic functions on a suitable domain) has been used by Brelot (Jour. Math. Pures Appl., v. 35: 297-335, 1956) for a somewhat different purpose. Finally, replacing $\prod$ by the transition matrix of a corresponding random walk reversed in time, an adjoint boundary is obtained. (Math. Rev. abstract)

This paper is concerned with the characterization of intersections of maximal ideals in the L^1 algebra of a locally compact abelian group by means of their hulls. A fairly numerous class of sets which as hulls are characteristic of such ideals is obtained. In the case of vector groups such sets include among others polygonal lines, polygons, polyhedra regions with sufficiently regular (locally starshaped) boundaries, convex sets etc. These results have their counterparts in the problem of spectral synthesis of bounded functions.

The underlying heuristic notion of the spectrum of a function could be formulated this way: the spectrum, $\Lambda(\varphi)$ is the closure of the set of points t at which the formal trigonometric integral $\int \exp(-itx)\varphi(x)dx$ is different from 0. The concept can be made precise for the class L^∞ of essentially bounded measurable functions in three ways which we wish to view as distinct. The first of these involves the application of a summability method to the trigonometric integral. For a suitable kernel k, one forms the absolutely convergent integrals

$$\Phi_h(t) = \int \exp(-itx)k(hx)\varphi(x)dx$$

$h > 0$, and investigates the limiting behavior as $h \to 0$. If $\int_x^{x+1} |\varphi(y)|dy = O(1)$ as $|x| \to \infty$, one may use ordinary convergence, i.e., $k(x) \to 1$ for $|x| \leq 1$, $k(x) = 0$ for

$|x| > 1$. However, for the general case of $\varphi \in L^{\infty}$, ordinary convergence is inappropriate. Fortunately all the other conventional methods of summing trigonometric integrals are suitable; these are accounted for in the rather extensive class of kernels described in this paper.

TWO PROBLEMS IN HARMONIC ANALYSIS AND PROBABILITY, by G. A. Hunt. July 1956, 3p. (Bound in Cornell U. Dept. of Math., Ithaca, N. Y. Final tech. rept. on the Symposium on Harmonic Analysis and Related Integral Transforms, Volume I; AF 18(603)12) [AF 18(600)685] Unclassified

Cramer's theorem, that each of two probability distributions must be Gaussian if their convolution is Gaussian, makes sense on any homogeneous space which is the quotient of a Lie group by a compact subgroup. The analogue of Cramer's theorem, which holds true in the hyperbolic plane, is shown not true on compact spaces, specifically for the circle group R/Z. The second problem concerns stochastic processes rather than distribution functions, and their representation in terms of a random additive function of intervals. Questions concerning the independence of this function for increments of the interval are discussed.

X-RAY SPECTROSCOPY OF THE SOLID STATE: POTASSIUM CHLORIDE, by L. G. Parratt and E. L. Jossem. [1955] [11] p. incl. diagrs. refs. (AFOSR-TN-54 650) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under [AF 18(600)300]) Unclassified

Published in Phys. Rev., v. 97: 916-926, Feb. 15, 1955.

The experimental K spectral regions of potassium and chlorine in crystalline KCl have a much more complex array of structure, both in emission and in absorption, than can be explained by the conventional energy level diagram for the solid state. The pertinent spectral region is that which involves the valence and conduction

bands of the solid. The difficulties seem to arise from a theoretical preoccupation with one-electron transitions. Consideration of the various probable electron configurations of the many-electron solid system shows several additional initial (1s vacancy) and final (outer vacancy) states. The charge density in the outer electron bands suddenly confronted with the problem of screening the excess positive charge attending a 1s vacancy (or any inner vacancy), redistributes itself, distorting the bands and establishing one or more local discrete levels below each band. With the most probable filled discrete level below the 3p band, the narrow intense $K\beta_1$ line is explained but it is necessary to account somehow for the very narrow final state (3p vacancy). An obvious conclusion is that the 3p valence band itself is therefore very narrow in energy, only 0.33 ev wide. However, if it is indeed wider than this, as is commonly believed in the lore of solid state physics, the $K\beta_1$ emission must be restricted by some (unknown) mechanism to a small energy region within the band. In this event, x-ray emission involving the entire broad 3p band may be part of the observed faint emission on the high-energy side of the $K\beta_1$ line, and, if so the restricted energy position just mentioned must be at the bottom of the band. Also a consequence of the 1s vacancy are several normally empty discrete levels below and in the conduction band of KCl. With these levels, the narrow intense K absorption lines are explained. The discussion given is primarily experimental and phenomenological. The qualitative agreements are prehaps compatible with either a narrow or a wide 3p band for both potassium and chlorine KCl, but show a preference for the wide 3p band. (Contractor's abstract)

ANOMALOUS DISPERSION AND SCATTERING OF X-RAYS, by L. G. Parratt and C. F. Hempstead. [1954] [8]p. incl. diagrs. tables, refs. [AF 18(600)-300] Unclassified

Published in Phys. Rev., v. 94: 1593-1600, June 15, 1954.

The theoretical expressions for the anomalous dispersion of x rays have been integrated for any positive value of p_q in a $C_q\lambda^{p_q}$ term in the distribution of "dispersion" oscillators for the q shell of electrons. The distribution may be written generally as the sum of n terms of the form $C_{qn}\lambda^{p_{qn}}$ or, as is commonly done, as a single term. Damping has been retained, its effect evaluated and shown to be negligible except for λ extremely close to the wavelength of an absorption discontinuity. With damping neglected, universal dispersion curves are presented. If p_q and g_q (the oscillator strength) are known, the anomalous part of the refractive index or of the atomic scattering factor can be readily deduced from the universal curves. Comparison of the more exact theoretical values with experiment shows less satisfactory agreement than before.

SOLID SURFACE STUDIES BY TOTAL REFLECTION OF X-RAYS (Abstract), by L. G. Parratt. Apr. 29, 1954 [1]p. [AF 18(600)300] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-May 1, 1954.

Published in Bull. Amer. Phys. Soc., v. 29: 29, Apr. 29, 1954.

Published in Phys. Rev., v. 95: 617, July 15, 1954.

Analysis of the shape of the curve of reflected x-ray intensity vs glancing angle in the region of total reflection provides a method of studying certain structural properties of the mirror surface about 10 to a few hundred Angstroms deep. The theory, extended to treat any (small) number of stratified homogeneous media, is used as a basis of comparison. Curves for evaporated copper on glass are studied as an example. These curves probably can be explained by assuming that the copper (exposed to atmospheric air at room temperature) has completely oxidized about 150A deep. If oxidation is less than about 100A deep, there probably exists an electron density minimum just below an internal oxide seal. This seal, perhaps 50A below the nominal surface plane, arrests further oxidation of more deeply-embedded loose packed copper crystallites. All measurements to date have been carried out under laboratory atmospheric conditions which do not allow satisfactory separation or control of the physical and chemical variables involved. Under better control, the method seems promising. (Contractor's abstract)

K SPECTRA OF POTASSIUM CHLORIDE, by L. G. Parratt and E. L. Jossem. June 20, 1954 [37]p. incl. diagrs. refs. (Technical rept. no. 1) (N6ori-9101 and AF 18(600)300) AD 36670 Unclassified

The conventional energy-level diagram for the solid state of crystalline KCl is considered inadequate to explain the more complex structure of the K β spectral regions of K and Cl in emission and absorption. The difficulties apparently stem from an incomplete consideration of electron configuration with emphasis on 1-electron transitions between states described. Further initial and final states are found when the various probable electron configurations of the many-electron solid system are considered. Several different energies are presented for the K state (1s vacancy), only one of which is significantly involved in emission but all of which are necessary to explain absorption. The difference in the K configurations is in the distribution of charge density presented by the outer electrons near the valence band in KCl. The charge density in the outer bands redistributes itself, distorting the bands, and, in KCl, establishes one or more local discrete levels below each band. The narrow intense β_1 line and the narrow intense absorption lines are explained.

ELECTRON ENERGY LEVELS IN IONIC CRYSTALS (Absiract), by E. L. Jossem and L. G. Parratt. June 29, 1954 [1]p. [AF 18(600)300]
Unclassified

Presented at meeting of the Amer. Phys. Soc., Minneapolis, Minn., June 28-30, 1954.

Published in Bull. Amer. Phys. Soc., v. 29: 23, June 28, 1954.

Published in Phys. Rev., v. 96: 834, Nov. 1, 1954.

Information on the electron energy levels in solids is provided by the energy positions, intensities, and shapes of component lines in x-ray emission and absorption spectra. The x-ray Kβ emission spectra of chlorine in the alkali chlorides and in cuprous chloride have been recorded with a curved crystal focusing vacuum spectrometer using a proportional counter detector. These lines involve transitions from levels in or near the valence band to an inner (K shell) vacancy. The principal features of the spectra are: (a) the chlorine $K\beta_1$ line, commonly ascribed to the transition valence-band-to-K-vacancy, is uniformly too narrow to permit such assignment; (b) the intensity of the chlorine β_x and β_5 lines relative to the β_1 line varies with the compound. Interpretation of these features in terms of the band structure of the crystal and the sharp "impurity-type" levels introduced by the inner shell vacancy is discussed. (Contractor's abstract)

UNIVERSAL CURVES FOR DISPERSION AND SCATTERING OF X RAYS (Abstract), by L. G. Parratt and C. F. Hempstead. June 28, 1954 [1 p. [AF 18(600)300
Unclassified

Presented at meeting of the Amer. Phys. Soc., Minneapolis, Minn.. June 28-30, 1954.

Published in Phys. Rev., v. 96: 820, Nov. 1, 1954.

Published in Bull. Amer. Phys. Soc., v. 29: 9, June 28, 1954.

The theoretical expression for the dispersion (or atomic scattering factor) of x-rays has been integrated for any value of p_q in a λ^{Pq} term in the distribution of dispersion-oscillators for each q shell of electrons. The dispersion-oscillator distribution may be written generally as the sum of n terms $\Sigma_n C_{qn}\lambda^{Pqn}$ or, as is commonly done, as a single $C_q\lambda^{Pq}$ term. Damping has been retained, its effect evaluated and shown to be negligible except for λ extremely close to the wavelength of an absorption discontinuity. Universal dispersion curves (with damping neglected) are presented. From the universal curves, if p_q and g_q (the oscillator strength) are known, the refractive index or the atomic scattering factor for each q shell of any atom, and hence the sum of all q shells, can be readily and very conveniently deduced. Comparison of these more exact theoretical values with experiment shows less satisfactory agreement than before. (Contractor's abstract)

LOCALIZED ENERGY STATES IN CRYSTALLINE ALKALI CHLORIDES (Abstract), by C. F. Hempstead and L. G. Parratt. [June 29, 1955] [1]p. ([AF]-OSR-TN-55-139) [AF 18(600)300] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 27-29, 1955.

Published in Phys. Rev., v. 98: 1170, Apr. 15, 1955.

The absorption fine structure in the vicinity of the K-edge of chlorine in alkali chlorides has been carefully recorded. Correction by a new method has been made for the resolving power of the x-ray spectrometer. (The magnitude of the correction depends upon the absorber thickness.) The corrected structure is more complex than has been heretofore realized. The inner electron vacancy that results when the K-electron is photoejected causes a significant perturbation of the normal periodic potential in the neighborhood of the excited ion containing the vacancy. This ion of atomic number Z appears to a first approximation as an impurity atom of Z + 1 in the solid. Consequent localized exciton type energy states are invoked to explain the observed spectra. For KCl, the lowest absorption "line" (farthest below the conduction continuum) is at least a doublet with a separation of about 0.8 ev and having a doublet peak intensity ratio of about 1 to 3.3. A "reasonable" resolution of the observed contour into

COR. 07:009 - COR. 07:012

component absorption lines, each of Lorentzian shape, indicates in a range of about 6 ev at least six components for KCl and six for NaCl. The pattern of component lines or exciton-type states is markedly different for different chlorides. (Contractor's abstract)

ENERGY LEVELS IN METALLIC POTASSIUM (Abstract), by E. L. Jossem and L. G. Parratt. [1955] [1]p. [AF 18(600)300] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 27-29, 1955.

Published in Phys. Rev., v. 98: 1151, May 15, 1955.

Information about electron energy levels in metallic potassium has been obtained from the x-ray K emission and absorption spectra. The emission lines were studied with a bent crystal focusing vacuum spectrometer with a proportional counter detection system. Of the several lines in this region, the β_1 and the β_5 are of principal present interest. The β_1 line, the strongest in the region, represents the transition to the 1s level of an electron associated with the 3p band. This line is observed to have the same energy position, width and shape in metallic potassium as in chemical compounds of potassium (e. g., KCl). It is tentatively concluded that the 3p band in potassium, some 18.4 ev below the Fermi surface in the metal, is narrow (about 0. 22 ev wide) and is but little affected by the nature of the surrounding atoms. The β_5 line, a very weak line which appears just at the long wavelength side of the K-absorption edge, presumably involves the transition of an electron in the conduction band to the 1s level. However, since the conduction band is nominally 4s, selection rules require the β_5 represent that fraction of the conduction electrons having p-type symmetry. Discussion will be given of the width and shape of the β_5 line.

STRUCTURE OF THIN EVAPORATED COPPER FILMS BY TOTAL REFLECTION OF X-RAYS (Abstract), by L. G. Parratt. [t955] [1]p. [AF 18(600)300] Unclassified

Presented at meeting of the Amer. Phys. Soc., Toronto (Canada), June 2t-23, t955.

Published in Phys. Rev., v. 99: 1635, Sept. t, t955.

The x-ray total reflection method of studying certain structural properties of the surfaces of solids has been applied to thin evaporated copper films deposited on a glass substrate at room temperature. Films of average thickness about 25 to t000 Å have been studied with the x-ray wavelength 1.392 Å. The reflection curves disagree significantly in several respects with the theoretical curves based on a film model of homogeneous lamina. A better model may be one in which the copper (with some oxide) is present in aggregates of such shape that a very low average dispersion density exists close to the glass substrate. As the thickness of the film increases, the copper aggregates may "bridge over" at some 40 Å or so above the substrate to form a more or less continuous but porous film. Such a model features a "reflection trap." This work is exploratory in the sense that no satisfactory attempt was made to control the physical and chemical variables involved in the preparation and treatment of the surfaces. But, under controlled conditions, the method promises interesting information about surface structure. (Contractor's abstract)

"THICKNESS-EFFECT" IN OBSERVED STRUCTURE NEAR ABSORPTION EDGES, by L. G. Parratt, C. T. Hempstead, and E. J. Jossem. July 15, 1956, 17p. incl. diagrs. tables. (Technical rept. no. 5) [AFOSR-TN-56-33i] (AF 18(600)300) AD 95207 Unclassified

Also published in Phys. Rev., v. 105: 1228-1232, Feb. 15, 1957.

The details of an observed absorption spectrum are shown to depend upon the thickness of the absorber. This effect is present, at least in principle, regardless of the type of radiation involved. It is discussed here specifically for x-rays, and specifically for the neighborhood of an absorption edge. Measurements of widths and of relative intensities of the component structure are the most sensitively involved, but wavelengths are also slightly affected. The explanation lies in the role of the effective spectral window of the spectrometer. The effect may be serious when the "tails" of the window are extensive, as is inevitably the case with 2-crystal x-ray spectrometers. Features of the extent and shape of the spectral window for the (t, + t) position of the instrument used in this work are roughly determined from the thickness effect. (Contractor's abstract)

X-RAY EXCITED STATES (EXCITONS) AND WIDTH OF VALENCE BAND IN KCl, by L. G. Parratt and E. t.. Jossem. July 28, t956, t3p. incl. diagr. (Technical rept. no. 6) (AFOSR-TN-56-337) (AF t8(600)300) AD 952t3 Unclassified

Also published in Jour. Phys. Chem. Solids, v. 2: 67-7t, Mar. t957.

A combination of (a) Parratt and Jossem's experimental

x-ray emission and absorption curves for K and Cl in KCl (Phys. Rev., v. 97: 916, 1955) and (b) Muto and Okuno's recent theoretical calculations (Jour. Phys. Soc. Japan, v. 11: 633, 1956) on "exciton" structure (1-electron approximation) provides semiempirical values of the effective dielectric constant and of the effective mass for the K 1s first excited state in KCl. (The term "1s first excited state" is proposed to replace the term "x-ray ground-state 'exciton'"). A "reasonable" small increase in this value of the dielectric constant gives a tentative value for the Cl 1s first excited state. Then, resorting again to the combination of experiment and theory, it can be concluded that the Cl^- 3p valence band in KCl is much narrower than the 4.2 ev base width previously deduced, being perhaps 2 ev wide; however, it is further proposed that, since the series limit of x-ray excited states may well be above the bottom of the continuum, the base width of the valence band may be of the order of 1 ev and the full width at half-maximum of the density-of-states curve of this band may be about 0.3 ev. CORRECTION OF COMPLEX SPECTRA FOR INSTRUMENTAL RESOLVING POWER. PART I. MODEL WINDOWS, by L. G. Parratt and C. F. Hempstead. Aug. 20, 1956, 18p. incl. diagrs. tables. (Technical rept. no. 7) (AFOSR-TN-56-388) (AF 18(600)300) AD 96046 Unclassified

Presented at annual meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 54-55, Jan. 30, 1957.

A complex spectrum, after correction for the finite resolving power of the spectrometer (t.e., for the "spectral window"), always shows greater contrast than is directly observed. The clearer view usually justifies considerable effort in an attempt to correct the direct measurements. The correction procedure herein described is relatively simple and is applicable to any observed spectrum, however complex, but is limited to model window shapes. (Part II will treat windows of more general shape). The procedure involves an arbitrary analysis of the observed spectrum into virtual components each having a shape given by a particular functional form. This functional form depends upon the shape of the spectral window: we seek an easy mathematical "unfolding" process. An easy process is one for which there exists a simple explicit expression for the parameters of the virtual components of the corrected (or true) spectrum in terms of those of the virtual components of the observed spectrum. Then, with the parameters obtained from the observed spectrum, the corrected curve is readily synthesized. Two window models, viz., a Lorentzian (classical dispersion function) and a Gaussian (normal distribution function) are discussed in detail with an example procedure given for each case. BRIEF REVIEW OF ELECTRONIC BAND STRUCTURE OF SOLIDS BY THE METHOD OF EXPERIMENTAL X-RAY SPECTROSCOPY, by L. G. Parratt. July 10, 1957, 43p. incl. diagrs. refs. (Technical rept. no. 8) (AFOSR-TN-56-562) (AF 18(600)300) AD 110382 Unclassifted

A review is presented of x-ray spectroscopic techniques of investigating the band structure of solids. The greatest emphasis is placed on problems of interpretation. Consideration is given to the advantages and disadvantages of the method, the energy level diagram, and experimental curves. The 2 energy regions which naturally occur require high resolving power. The x-ray wavelengths range from about 0.5 A (~25,000 ev) to about 800 A (~15 ev). Typical transitions are illustrated in terms of energy level diagrams.

Thin copper films, deposited on glass by evaporation were studied by the total reflection of 1.39 Å x-rays. The films in the range of 25 to 1000 Å thick, and

COR. 08:001 - COR. 08:004

deposited at room temperature gave reflection curves that deviated in several respects from the theoretical curves based on a homogeneous film. The structure of these films is better represented by a model in which the Cu is present as aggregates, with a low average dispersion deposited near the glass support. As the film thickness increases, "bridge-overs" are formed. Such a model can be considered as a "reflection trap." (C.A., 1957:1681a)

Also published in Phys. Rev., v. 95: 359-369, July 15, 1954.

Analysis of the shape of the curve of reflected x-ray intensity vs glancing angle in the region of total reflection provides a new method of studying certain structural properties of the mirror surface about 10 to several 100 Å deep. Dispersion theory, extended to treat any (small) number of stratified homogeneous media, is used as a basis of interpretation. Curves for evaporated copper on glass are studied as an example. These curves may be explained by assuming that the copper (exposed to atmospheric air at room temperature) has completely oxidized about 150 Å deep. If oxidation is less deep, there probably exists an electron density minimum, perhaps just below an internal oxide seal. This seal, less than about 50 Å, perhaps 25 Å, below the nominal surface plane, would arrest further oxidation of more deeply-lying loose-packed copper crystallites. All measurements have been carried out under laboratory atmospheric conditions which do not allow satisfactory separation or control of the physical and chemical variables involved in the surface peculiarities. The method, under more controlled conditions of preparation and treatment of the surface, promises to be useful. (Contractor's abstract)

THE USE OF THE FIELD EMISSION MICROSCOPE FOR THE INVESTIGATION OF SURFACE CONDITIONS ON AN ALLOY OF MOLYBDENUM AND ZIRCONIUM, by L. A. D'Asaro. Sept. 1, 1955, 106p. incl. illus. diagrs. tables, refs. (Technical rept. no. 3) ([AF]OSR-TN-55-321) (AF 18(600)674) AD 75274 Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago U., Ill., Nov. 25-26, 1955.

Abstract published in Phys. Rev., v. 100: 1258, Nov. 1, 1955.

The distribution of Zr on the surface of 1% Zr-99% Mo and 5% Zr-95% Mo alloys was obtained. Photographs show the patterns which were produced by the field-emission microscope for variations of temperature, heating time, potential, emission current, and total pressure. The components of the alloy were located by relating the current density of the field-emitted

electrons from various positions on tis surface to the surface work function and the applied field by means of the Fowler-Nordheim equation. Tbe rate of surface change increases with the temperature; at a sufficiently high temperature, the surface conditions change significantly in a few min. A persistent increase in the diffusion rate was noted when the 1% alloy emitter was flashed (heated to 2400°K). Parallelogram-shaped spots (quadruplets) with bright corners were observed on the 100 plane during the early stages of diffusion onto the surface of the 1% alloy at the lowest temperature (about 900°K), and at just below the cleaning temperature. A plot of the Fowler-Nordheim equation was matched to one of the emission current vs potential. The field, the work function, and the emitting area of the field were obtained for the surface which produced the quadruplet patterns. The work function (φ) of the quadruplet surface was 2.94 ev. A φ of 2.95 ev for Zr on Mo was obtained by multiplying the φ which was obtained by Dushman (Phys. Rev., v. 21: 623, 1923) for a monolayer of Zr on W by the ratio of the work functions of Mo and W. The 1% alloy standard clean surface (1 min at 2000°K) produced a pattern similar to that of pure Mo on W. (Contractor's abstract)

A HIGH RESOLUTION ELECTRON DIFFRACTION CAMERA FOR THE STUDY OF SURFACES IN AN ULTRA HIGH VACUUM, by B. M. Siegel. Dec. 1, 1955 [47]p. incl. illus. diagrs. table, refs. (Technical rept. no. 4) ([AF]OSR-TN-55-480) (AF 18(600)674) AD 83068 Unclassified

A special electron diffraction camera has been designed and built which will make it possible for the first time to examine "clean" surfaces in an ultra-high vacuum by high resolution electron diffraction. In this camera, the electron beam and specimen are contained in a glass vacuum system which is baked-out and evacuated to a pressure of the order of 1×10^{-10} mm Hg. High resolution electron optics consisting of magnetic lenses are assembled around the outside of the glass column. The diffraction pattern comes to focus on a fluorescent screen inside the vacuum system, and is recorded by photographing the pattern. It is to be expected that this new instrument will enable significant advances in the study to be made of surface structure. The apparatus also makes it possible to work with extremely well-controlled atmospheres of different gases in the study of surface adsorption and surface reactions. Plans are also outlined for the extension of this apparatus to micro-analysis with an electron probe, a tool that should open up quantitative investigation of the surface constituents. ION SOURCE AND ANALYZER STUDIES, by R. C. Bradley. June 1, 1955 [23]p. incl. illus. diagrs. refs. (Technical rept. no. 2) ([AF]OSR-TR-55-17) (AF 18(600)674) AD 74834 Unclassifted

A workable method was developed for generating a positive-ion beam of a known species which can be focused on a solid surface in a controllable manner with sufficient intensity to cause sputtering. Pilot-model ion sources were constructed from 0.010-in.-thick molybdenum or Nichrome V sheets by the use of designs described by Nier (Rev. Scient. Instruments, v. 18: 398, 1947) Heil (Zeitschr. Physik., v. 120: 212, 1943), and Finkelstein and Smith (Rev. Scient. Instruments, v. 11: 94, 1940). These are mounted in Pyrex tubes which were evacuated to 10^{-7} mm of Hg or better. Argon was introduced until the standard operating pressure (10^{-4} mm of Hg) was reached. The currents to the ion collectros were observed as a function of the voltage applied to the various electrodes. An axial magnetic field strength of about 150 gauss was used. The Finkelstein and Heil sources were about 5 times as efficient (in terms of the number of ions reaching the collector for each electron emitted from the filament) as the Nier source. The Heil source with no collimating slits for the electron beam was chosen to generate the beam. The ion currents to the collector at the standard operating pressure were 1 to 2 orders of magnitude better in an appearance-potential selector than in an RF mass spectrometer like that developed by Bennett (Jour. Appl. Phys., v. 21: 1943, 1950). Best results are obtained when the target is oriented at 45° to the primary ion beam and to the analyzing electron beam. (ASTIA abstract)

STRENGTH OF REFLECTED SHOCK IN MACH REFLECTIONS, by H. S. Tan. [Sept. 10, 1951] 7p. incl. diagr. (WADC rept. no. TR-52-163) [AF 33-(038)21406] Unclassified

Published in Jour. Aeronaut. Sciences, v. 18: 768-769, Nov. 1951.

When a propagating plane shock is diffracted by a corner, Mach reflection is induced. The reflected front is an acoustic wave according to first-order theory; however, results of first-order theory can be applied to determine more accurately the strength of this wave. It will be demonstrated that this wave is, in fact, a shock of second-order strength. The case of extremely weak incident shock has been studied by Bargmann On Nearly Glancing Reflection of Shocks, National Defence Research Council, Applied Mathematics Panel Rept. no. 108.2R, 1945). The present study, however, is not limited in incident shock strength. Lighthill's first-order pressure solution (The Diffraction of Blast, I, Proc. Roy. Soc., v. 198A: 454-470, 1949) and his technique (The Shock Strength in Supersonic Conical Fields, Phil. Mag., v. 41: 1202, Dec. 1949) for finding the shock strength have been utilized. The latter is essentially a process of pushing away the

COR. 09:002 - COR. 09:005

apparent singularity appearing in the differential equation of motion resulting from its linearization.

SHOCK REFLECTION FROM EDGES AND FROM SLOTTED WALLS, by T.-F. Sun. Dec. 1951, 64p. incl. diagrs. [WADC rept. no. TR-352-164] (AF 33(038)21406) Unclassified

The flow characteristics behind weak stationary shock waves reflected from various edges lying in the mainstream are determined according to linearized theory. Five different types of edges are considered, made up of various combinations of solid- and free-plane surfaces. An assumption regarding the singularity of one of the perturbation velocity is required in order to render the solutions unique. By superposition of such basic "edge" solutions, the flow behind a shock wave reflected from a wall with a slot (i.e., a strip of free-surface between panels of solid wall) and from multiply-slotted walls are obtained. These solutions apply only to regions upstream of multiple interactions of the slot edges; however, these regions include the most interesting regions of flow in the case of reflection from slotted wind-tunnel walls, for example. The relation of the single-slot problem to the problem of a narrow rectangular supersonic wing is discussed. (Contractor's abstract)

INVESTIGATION OF THE SUPERSONIC-BIPLANE CONFIGURATION, by M. B. T. George. May 1952, iv. incl. diagrs. refs. (AF 33(038)21406) Unclassified

Supersonic biplanes were investigated aerodynamically and structurally with a view to establishing their possibilities as practical supersonic aircraft. The aerodynamic coefficients are determined from work by Tan and Sears on the finite supersonic biplane. The problem of "starting" the supersonic flow through the biplane gap was studied. It was found, on the basis of a one-dimensional theory, that the individual wings of the biplane must be very thin to permit "starting." Methods of overcoming the starting problems are proposed, and their relative merits are discussed. Supersonic biplanes are found to be feasible only for Mach numbers greater than 1.5 or less than 4.0. If operated below its design Mach number, the performance of a supersonic biplane does not suffer if the airfoils are thin; for operation above the design point the efficiency falls off. The biplane has twice the wing area of a supersonically-equivalent monoplane and should therefore have a considerably lower landing speed. Comparison of monoplane wings and the biplane arrangement is made for a simple supersonic airplane. The biplane structure is analyzed for bending moments and torsional deflection. THIN WINGS IN CONICAL FLOW, by H. K. Cheng. June 1952 [139]p. incl. illus. tables, refs. (AF 33-(038)21406) AD 2303 Unclassified

The linearized theory of supersonic conical flow over thin planar wings is studied. Based on the theory of conical field introduced and developed by Busemann (NACA TM-1100) and others and by employing a new concept of source distribution, a method is established by which asymmetrical (lifting) conical-wing problems can be generally solved for an arbitrary conical surface. The method is applied to the cases where both edges, or at least one edge, of the wing is subsonic. (For both supersonic edges, the general solution is known to be simple.) Direct general expressions for the pressure in terms of the upwash prescribed on the wing are given, from which general expressions for the lift, drag, and rolling moments are obtained. The general solution is applied to new cases of conical wings. Among these are the rolling moment due to yaw for small dihedral for which a simple formula is derived, and the pressure distribution for a conical wing with the upwash on the wing given as a step function. Inverse problems, as well as quasi-conical problems, are treated in a consistent manner. (Contractor's abstract)

ON EXPANDING TWO-DIMENSION FLOW SOLUTION IN POWERS OF A THICKNESS PARAMETER, by H. S. Tan. Aug. 1952, 24p. incl. illus. (AF 33(038)-21406) AD 1922 Unclassified

The significance of a successive approximation corresponding to expanding a solution in powers of small ϵ is discussed; the flow field about a symmetric body, aligned with a free stream, is considered a function both of the coordinates (x, y) and of the thickness parameter ϵ. A solution, which is expanded so that

$$u(x, y; \epsilon) = \sum_{k=0}^{n} \epsilon^k u_k(x, y)$$

and which is finite and unique almost everywhere in a certain small region σ of the x, y plane, can always be achieved by straightforward successive approximation provided that u_k so determined behaves the same way, and that there exists a least upper bound σ so that σ_k [illegible] for all $k \leq n$. The singular region σ_1, in which u_1 blows [illegible] indicates either $u = \sqrt{}$ or the presence of

a stagnation point in the x, y plane. For certain special types of bodies (Joukowski airfoils) the singular region can be removed. This involves a device of straining the coordinates in such a way that when extended to the general case the problem is made extremely difficult, if not impossible. The body is replaced by a concentrated source near the center of curvature of the leading edge (entirely determined by ε and contour F(x) at the leading edge) and distributed sources and sinks from this point back to the trailing edge. For a very special type of body, where both the leading and trailing edges are cusps, no stagnation point appears in the exact solution, and the singular region is also absent in expansion solution. A double-wedge shaped body is shown to have an essentially (non removable) singular region at the leading edge; the extent of this region is extremely small. (ASTIA abstract)

AERODYNAMIC INTERFERENCE BETWEEN MOVING BLADE ROWS, by N. H. Kemp and W. R. Sears, Dec. 1, 1952, 67p. diagrs. refs. (AF 33(038)21406) U25871 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 20: 585-598, Sept. 1953.

The concepts and results of the theory of single thin airfoils in nonuniform motion are applied to calculate the resulting nonsteady effects on such blades. Incompressible inviscid flow is considered. The representation of blade wheels as infinite cascades of 2-dimension airfoils is adopted. Attention is confined to a single stator row followed by a single moving-rotor row. As a first approximation, the assumption is made that, to calculate the nonsteady effects at any given blade, neglect of the nonsteady parts of the circulation of all other blades is permissible. For the rotor blades, the effects of their passage through the vortex wakes shed by stator blades are also included. With this approximation, the only results required of thin-airfoil theory can be obtained by generalization of an earlier study by Sears (Jour. Aeronaut. Sciences, v. 8, no. 3: 104, 1941) of an airfoil flying through a sinusoidal gust pattern. Expressions are derived for the unsteady components of lift and moment on stator and rotor blades and the rate of transfer of energy to the downstream-wake pattern. The fundamental harmonic component of variable lift varies in magnitude from 1% to 18% of the steady value, depending especially on the axial distance between rows and on the chordwise distribution of steady circulation of the blades of the other row. The second harmonic component of variable lift is considerably smaller than the fundamental. The contribution to rotor lift of the vortex wakes shed by stator blades, through which the rotro blades pass, is small compared to the effects induced by the stator blades themselves. The fluctuating part of the circulation, expressed as a ratio to the steady part, is several times as large for stator (upstream) blades as for rotor (downstream) blades, even though the corresponding ratios of lifts are about equal. The rate of transfer of energy into the vortex-wake pattern which results from the variable circulation is very small compared to the power required to turn the rotor. It is about 100 times as large for the stator (upstream) blades as for the rotor (downstream) blades. For the stator blades, this rate of energy transfer is very nearly the same as for an isolated airfoil experiencing the same fluctuating circulation. (TIP abstract)

SIMPLIFIED LAMINAR BOUNDARY-LAYER CALCULATIONS FOR BODIES OF REVOLUTION AND FOR YAWED WINGS, by N. Rott and L. F. Crabtree. [1952] 14p. incl. illus. diagrs. table, refs. [AF 33(038)21406] Unclassified

Published in Jour. Aeronaut. Sciences, v. 19: 553-565, Aug. 1952.

Since the introduction of momentum methods in boundary-layer calculations by von Kármán and Pohlhausen, many improvements have been proposed. An especially simple solution reduces the problem to a quadrature. Here, it is proposed to extend these methods to elementary three-dimensional cases, and to compressible laminar boundary-layer calculations. For comparison, the corresponding problems for the turbulent boundary layer are also discussed briefly.

GENERALIZATIONS OF THE INVERSION FORMULA OF THIN AIRFOIL THEORY, by H. K. Cheng and N. Rott. June 1, 1953, 48p. refs. (AF 33(038)21406) AD 17740 Unclassified

Also published in Jour. Rational Mech. and Analysis, v. 3: 357-382, May 1954.

A method is described which gives the general solution for the mixed-type boundary-value problem for the complex half plane for an arbitrary number of slots on the real axis, where alternately the real and the imaginary part of an analytic function are prescribed. The solution is found for cases where it may be interpreted as a complex velocity and also as any velocity derivative. Besides the general solution, a set of simple special solutions of practical importance is given. A further generalization is presented in which a linear combination of the real and imaginary part is prescribed on the boundary. Aerodynamic problems are discussed which lead to this mathematical formulation. (Contractor's abstract)

SOME EXTENSIONS OF SLENDER-WING THEORY, by M. C. Adams. June 2, 1953, 56p. illus. refs. (AF 33(038)21406) AD 18192 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 20: 85-98, Feb. 1953.

The approximate theory of flow about slender lifting wings originated by Munk and Jones (NACA repts. no. 184 and 835) is reviewed. Ward's treatment of both lifting and nonlifting wings in supersonic flow is summarized. An analogous treatment is presented for subsonic flow. The slender wing theory is interpreted as a first term of an expansion in powers of a breadth parameter. A more accurate theory is developed by carrying additional terms for both subsonic and supersonic speeds. This theory of not-so-slender wings is applied to some practical problems. Accuracy is demonstrated by comparison with linearized supersonic-airfoil theory for the special case of a delta wing at incidence. The methods described can be extended to treat wing-body combinations and problems in nonstationary flight. (ASTIA abstract)

GENERATION OF VORTICES BEHIND A FLAT PLATE, by M. Hanin. July 1953, 54p. incl. illus. tables. (AF 33(038)21406) AD 18126 Unclassified

The formation of a vortex sheet behind two-dimensional flat plates is tentatively explained on the basis of potential flow theory. It is assumed that discrete vortices, formed by rolling-up vortex sheets, detach when a Kutta-Joukowski condition is violated. The average strength of the vortex sheets and the parameters describing the vortex sheet are estimated for the case of 90° incidence. This is accomplished with the help of the time-averaged Kutta-Joukowski condition, the vortex-sheet condition, the momentum transfer equation, and the modified vorticity transfer equation. The estimated values are compared with experimental ones, and a reasonable agreement is obtained.

ON THE APPROXIMATE SOLUTION OF THE LAMINAR BOUNDARY LAYER EQUATIONS, by I. Tani. July 1953, 38p. incl. illus. table, refs. (AF 33(038)21406) AD 17528 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 21: 487-504, July 1954.

A method was developed for solving approximately the equations of the laminar boundary layer. The velocity profile is assumed to be a member of a 1-parameter family of curves, the parameter being different from the usual Pohlhausen parameter. The Pohlhausen parameter is calculated by a simple quadrature formula, which is derived from the energy-integral relation. The relation between the profile parameter and Pohlhausen parameter is determined from the combination of both momentum-integral and energy-integral relations. The accuracy of the method was examined by comparing the results with those of exact solutions for the flow of incompressible fluid. Satisfactory agreement was obtained. The method of solution was then extended to the flow of compressible fluid along a heat-insulated wall, assuming the Prandtl number to be slightly different from unity and using the Sutherland formula for the variation of viscosity with temperature. The effect of compressibility on separation point is discussed as an example of the application. (Contractor's abstract)

A THEORETICAL APPROACH TO THE PROBLEM OF STALL FLUTTER, by M. B. T. George. Aug. 15, 1953, 144p. incl. illus. table, refs. (AF 33(038)21406) AD 21115 Unclassified

The problem of stall flutter is studied theoretically by modifying classical flutter theory to account for the deviation of the lift curve from its theoretical value. A simple scheme is proposed, wherein the static lift curve is utilized as an empirical connection between the strength of the leading and trailing edge singularities. This connection is generalized to unsteady flow, first with no time lag, and later with a time lag between the singularity strengths. The theory is a consistent one within the limitations of inviscid-flow theory. It is not expected to account for the more complicated viscous effects encountered. The torsional damping is computed for any location of the rotation axis and reduced frequencies in the practical range. The theory predicts the regions in which a torsional oscillation would be excited for various initial angles of attack. The Wagner function is extended for lift curve slopes other than 2π. A comparison with experiments is made with the main purpose of showing what is needed for further progress in the stall flutter problem. Quantitative agreement can only be expected for lift curve slopes near to the potential-flow value, and this is verified within certain limits. (Contractor's abstract)

ON ASYMMETRIC FLOW IN AN AXIAL FLOW COMPRESSOR STAGE, by W. R. Sears. [1953] 6p. incl. illus. diagrs. [AF 33(038)21406] Unclassified

Published in Jour. Appl. Mech., v. 20: 57-62, Mar. 1953.

It is suggested that flow patterns without axial symmetry may occur when an axial-compressor stage operates in a steady, uniform stream, provided that the blade airfoil characteristics exhibit certain peculiarities. For example, blades acting close to the stall may show nonlinearity, hysteresis, and/or time lags and these may cause asymmetric flow patterns. Conditions necessary for existence of such phenomena are analyzed by consideration of an annulus of infinitely many blades and very large radius. It is shown that rotational-flow effects due to vortex shedding by the blades must be considered. The induced velocities resulting from asymmetrical loadings are calculated. The final step of the calculation is to show that these induced effects may actually support the circulation distribution that produces them. This step is only partly taken in the present paper. It is shown that time lag in the development of lift of a blade may produce such "eigen-solutions." Detailed study of the results of nonlinearity in the blade characteristics is left for another investigation.

SLENDER-BODY THEORY-REVIEW AND EXTENSION, by M. C. Adams and W. R. Sears. [1953] [14]p. incl. illus. refs. [AF 33(038)21406] AD 40145 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 20: 85-98, Feb. 1953.

The approximate theory of flow about slender bodies and wings originated by Munk and Jones is reviewed. It is presented here in a form that emphasizes the relation to the source-sink methods of von Kármán and others. The extension to noncircular bodies is made for subsonic flow, paralleling Ward's extension for supersonic flow. The calculation of pressures and

COR. 09:019 - COR. 09:022

forces and the extension of the theory to unsteady flows are reviewed, and some discrepanctes tn the published literature are explained. Finally, interpreting the Jones slender-wing result as the ftrst term of an expansion tn powers of a hreadth parameter (e. g., aspect ratio), it is shown how a more accuraie theory can be developed by carrying additional terms for both subsonic and supersonic speeds. This theory of not-so-slender wings ts applied to some practical wing problems, tncludtng direci problems of flow past given wings and problems of wing design for minimum drag. The accuracy of the new results is assessed by comparison with linearized supersonic-airfoil theory for the special case of a flat delta wing. (Coniractor's abstract)

A THEORY OF "ROTATING STALL" IN AXIAL-FLOW COMPRESSORS, by W. R. Sears. [1953] 35p. incl. illus. (AF 33(038)21406) AD 669 Unclassified

Previous investigation on the possibtility of asymmetric ftow patterns in an axial-flow compressor siage was based on the approximations of tncompressible flow, an infinite number of blades, and the representation of the blade annulus as a 2-dimensional actuator sheei. This work was extended by eliminating the restriction to small inlet swirl and by a reformulation that is tndependent of airfoil-theory concepts. The latter permits introduction of a broader class of blade-characteristic relations of which airfoil-type relations are only one case. Two independent cases are treated: (1) airfoil-type characteristics and (2) channel relations suggested by steady-flow iests of cascades. The firsi case leads to steadily rotating asymmetric solutions when the btades are stalled and exhibit phase lag; these solutions were of the same general type as found previously. The second case leads to steadily rotating asymmeiric solutions both without and with phase tag. The solutions were compared with experimental observations of rotating siall in a 3-stage compressor. tf it is assumed that the rotor was stalled, the experimental point lies within the scope of the airfoil results but somewhat outside the channel results. If the siators were stalled, the result ties within the scope of both families of curves. (ASTIA abstract)

THE SUPERSONIC CONICAL WING OF MINIMUM DRAG, by S. H. Tsien. June 1953, 113p. incl. diagrs. tables, refs. [AFOSR-TN-54-285] (AF 33(038)21406) AD 17420 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 22: 805-818, Dec. 1955.

A theoretical tnvestigation was made of thin conical delta wings, with subsonic leading edges, cambered to give minimum pressure drag at supersonic speeds. The analysis was based on lineartzed theory; some consideration was given to the question of leading-edge flow separation. Since the optimum camber obtained by assuming full theoretical effect of suction forces may not be correct for a wing moving in a real fluid, 2 cases with different assumptions were covered: one with suction forces tncluded and the other with these forces omitted. For the former case, the drag coefficient of the optimum conical wing is almosi identical io that of a flat triangutar wing at the same lift coefficieni, excepi when the leading edge lies close behind the Mach cone of the apex. In the laiier case, subsiantial improvemeni over ihe flat delta wing can be achieved by suiiable conical camber; the drag can be reduced to a value whtch is again approximaiely the same as that of the flat wing with full leadtng-edge suction. Minimum drag coefficients and the corresponding optimum camber shapes and lift distributions were computed under various assumptions for wings with leading-edge slope equal to 0.5, 0.8, and 1.0. Flat-plate data are included for comparison. (ASTIA abstract)

UNSTEADY VISCOUS FLOW IN THE VICINITY OF A STAGNATION POINT, by N. Roll. [1954] 18p. incl. diagrs. (AFOSR-TN-54-322) (AF 33(038)21406) AD 58337 Unclassified

Also publlshed in Quarl. Appl. Math., v. 13: 444-451, Jan. 1956.

Consideration is given the problem of two-dimensional steady viscous flow in the vicinity of a stagnation point at which the velocity in the main stream increases linearly with the distance. It is noticed that, for the steady flow al the edge of the boundary layer, if the plate performs harmonic or uniform motion parallel to itself, a solution for the unsteady problem can be found by superposition of two functions such that the full Navier-Stokes equations are satisfied. In the oscillating case, the shear at the wall is calculated al both low and high frequencies. It is noted that, in spite of the main stream, the character of the flow al very high frequencies is essentially that of the Stokes solution. (Math. Rev. abstract)

ROTATING STALL IN AXIAL COMPRESSORS, by W. R. Sears. Dec. 1954, 1v. incl. diagrs. refs. [AFOSR-TN-54-343] (AF 33(038)21406) Unclassified

Published in Zeitschr. Angew. Math. Phys., v. 6: 429-455, 1955.

Several attempts to explain theoretically the phenomenon of rotating stall are described. These are all based on the assumptions of a single row of closely spaced blades and the small perturbation type of flow. They are, therefore, probably inadequate to describe the conditions observed in multistage axial compressors. On the other hand, they provide at least a qualitative explanation of the phenomenon, and they are in agreement in their conclusion that steadily rotating patterns may occur in stalled, rigid blade rows. BOUNDARY LAYERS IN THREE-DIMENSIONAL FLOW, by W. R. Sears. [1954] 6p. incl. diagrs. refs. [AF 33(038)21406] AD 59827 Unclassified

Also published in Appl. Mech. Rev, v. 7: 281-285, July 1954.

Extensions of Prandtl's laminar boundary-layer theory to 3-dimensional cases without axial symmetry have met with considerable success. They have led to interesting new concepts such as the independence principle, component separation, and boundary regions. Some cases of cylindrical and conical symmetry, as well as nearly 2-dimensional flows including boundary layers on rotating blades are reviewed. One problem of a boundary region, e.g., the flow in a corner has been worked out. It is concluded that analogous progress in problems involving 3-dimensional turbulent boundary layers must await more complete understanding of the basic principles governing such layers in either 2 or 3 dimensions.

ON INCOMPRESSIBLE TURBULENT BOUNDARY LAYER THEORY APPLIED TO INFINITE YAWED BODIES, by D. L. Turcotte. Sept. 1955, 1v. incl. diagrs. tables, refs. ([AF]OSR-TN-55-374) (AF 33-(038)21406) AD 79114 Unclassified

The problem of a turbulent boundary layer on a cylindrical body at an angle of yaw is studied. Applicable momentum equations are derived. Approximate methods of application are compared with experimental reeults. For the case of the flat plate (no pressure gradtent) at an angle of yaw, theoretical assumptions are compared with the expertmental results obtained by Ashkenas and Riddell. It is concluded that the boundary layer cannot be calculated from the components of flow normal to the leadtng edge. If yaw is considered to have no effect on the boundary layer growth, better results are obtained. Possible reasons for the observed deviation from the second alternative are discussed. For the wing at an angle of yaw, the above methods are applied to the case with a pressure gradient and are compared with the experimental results obtained by Altman and Hayter. The second of the above 2 assumptions is shown to give better results than the first. When the pressure gradient is appreciable, however, the pressure term of the momentum equation makes the largest contribution to the growth of the turbulent boundary layer, so that any reasonable method of approximation of the wall-shearing stress term will lead to a fair estimation of the growth of the turbulent boundary layer. THE UNSTEADY FORCES DUE TO VISCOUS WAKES IN TURBOMACHINES, by N. H. Kemp and W. R. Sears. [1955] 6p. incl. table. [AF 33(038)21406] Unclassifted

Published in Jour. Aeronaut. Sciences, v. 22: 478-483, July 1955.

The configuration of viscous wakes of cascade blades is approximated from single airfoil experiments. The unsteady force and moment on a downstream blade passing through such wakes is then calculated on the basis of the theory of isolated thin airfoils in nonuniform motion. The results indicated that the force is nearly proportional to the profile-drag coefficient of the upstream blades. For typical values of this coefficient and conventional cascade geometry, the unsteady forces arising from passage through viscous

wakes are of about the same size as those due to aerodynamic interference between the moving blade rows, previously estimated.

ON THE WAKE ENERGY OF MOVING CASCADES, by N. H. Kemp and W. R. Sears. [1956] [7]p. (AF 33(038)21406) Unclassified

Published in Jour. Appl. Mech., v. 23: 262-268, June 1956.

An analysis was made of the rate of energy transfer into kinetic energy of the vortex wakes for unsteady two-dimensional flow in cascades of thin airfoils, as applied to an elementary compressor stage consisting of two rows of blades in relative motion. Results indicate that the magnitude of the energy transfer is small, amounting to less than 1% of the energy absorbed by the rotor. For a two-stage rotor, the cross-induced energy transfer may be negative. Energy transfer of the upstream row is many times greater than that of the downstream row, owing to the disparity in the magnitudes of the respective induced circulation fluctuations.

OBLIQUE BENDING OF A RECTANGULAR PLATE, by C. Riparbelli. May 1955 [35]p. incl. illus. diagrs. (Note no. 1) ([AF]OSR-TN-55-147) (AF 18(600)1159) AD 85450 Unclassified

The deformation of a thin, free-edged rectangular plate in equilibrium, under the action of opposite moments forming a given angle with the plate's axis, is analyzed by assuming the family of lines of maximum curvature of the deformed plate as a parameter determining the deformation. These lines are determined by means of the principle of minimum potential energy. Two modes of bending are treated: the first about straight lines of maximum curvature (limiting case for large deformations) and the second, considering curved lines of maximum curvature. Although an exact general solution to the problem involving this second mode has not been found, an approximate approach, which yields results that agree closely with experiments, is presented. (Contractor's abstract)

OBLIQUE BENDING OF A TRAPEZOIDAL PLATE, by C. Riparbelli. Nov. 1955 [8]p. [Note no. 2] ([AF]OSR-TN-56-9) (AF 18(600)1159) AD 84577 Unclassified

A study was made to extend the result (see item no. COR. 10:001) obtained on oblique bending of a rectangular plate toward the analysis of deformation of plate-like thin wings. The mathematical analysis which is presented is based upon the observation that when a plate is bent and as soon as the maximum curvature at a region of the plate becomes appreciable, the second principal curvature is very small. The moment components orthogonal to the lines of maximum curvature act on a curved section whose rigidity is high compared to the plate's rigidity. The simplifying hypothesis is introduced that the whole deformation is bending about the family of lines of maximum curvature. A second simplifying hypothesis is that the lines of maximum curvature are straight, except in the immediate neighborhood of the edges or of concentrated loads. In the above hypotheses, the family of lines of maximum curvature is determined by means of the principle of minimum potential energy. (ASTIA abstract)

GENERAL BENDING OF A PLATE INTO A DEVELOPABLE SURFACE, by C. Riparbelli. Dec. 1955 [15]p. incl. diagrs. (Note no. 3) (AFOSR-TN-56-31) (AF 18(600)1159) AD 80542 Unclassified

Under the assumption of nonextensional bending, the general case of deformation of thin plates undergoing nonuniform bending is analyzed. A relationship between the position of the point to which the lines of maximum curvature converge and the shear resultant is defined. The expression for the total potential energy, to be minimized to define the family of lines of maximum curvature, is written. Finally, the deformation energy in the above general case is written as the deformation energy in pure bending multiplied by an amplifying factor which is a function of the convergence. A solution is presented for the problem of the analysis of large deformations of thin plates for application to thin wings representing a quasihomogeneous structure. (Contractor's abstract, in part)

EDGE CURLING OF A PLATE UNDERGOING OBLIQUE BENDING, by C. Riparbelli. Dec. 1955 [20]p. incl. illus. diagrs. (Note no. 4) (AFOSR-TN-56-32) (AF 18(600)1159) AD 80543 Unclassified

Large deformations of thin plates are being studied for the purpose of deformation analysis of thin plate-like wings. The deformation mode is determined by the

COR. 10:005 - COR. 11:003

family of lines of maximum curvature which are at first assumed to be straight. It is observed that the lines of maximum curvature deviate from their straight pattern only in the neighborhood of the edges. This deviation is the subject of the present study, the problem being approached in the following way: The given plate is considered at first to be an interior region (far from the edges) of a much larger plate. The edge effect then being negligible, the lines of maximum curvature are straight in the region under consideration and the forces and moments at the lines limiting the given plate are immediately computed. The plate as initially given is then cut at the given boundary. In order to satisfy the true (free) edge conditions of zero shear and moment of the original plate, the shears and moments computed in the first step of this procedure are applied with opposite sign to the shell into which the plate was deformed according to the initial assumption. The curvature increments resulting from the superimposed moments and shears are then computed. The corrected lines of maximum curvature tend to approach the normal to the edge in the region near the edge, and remain straight at a distance from the boundary. (Contractor's abstract)

GEOMETRY OF THE LINES OF MAXIMUM CURVATURE IN BENDING OF THIN PLATES, by C. Riparbelli. Dec. 1955 [13]p. incl. diagrs. (Note no. 5) (AFOSR-TN-56-33) (AF 18(600)1159) AD 80544 Unclassified

A relationship is derived between the principal curvatures of a surface and the curvature of the family of lines of maximum curvature. Large deformations of a free-edged plate can then be analyzed using the family of lines of maximum curvature as a parameter determining the deformation. The slope and curvature of the lines of maximum curvature at the free edge are determined by the conditions there. (Contractor's abstract)

THE IGNITION OF COMBUSTIBLE MIXTURES BY SHOCK WAVES, by M. Steinberg and W. E. Kaskan. 1954 [9]p. incl. diagrs. table, refs. (AF 18(600)1162) Unclassified

Published in Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954). N. Y., Reinhold, 1955, p. 664-672.

The purpose of the work reported here was to try to establish conclusively whether or not shock ignition is anomalous. For this purpose a shock tube was designed in a way such that it was reasonably certain that the shock waves which impinged on the combustible mixture were flat and normal to the tube axis, so that the state of the gas behind the shock might be described with reasonable certainty. Properties of the gases behind the incident and reflected shocks in both hydrogen-oxygen and propane-air mixtures with initial pressures of approximately 100, 200, and 300 mm Hg were calculated as a function of incident shock velocity for the initial temperature of 298°K. The resulting data are presented and are considered as evidence that shock ignition is a thermal process and that the anomalously low ignition temperatures previously reported in the literature must be attributed to some other phenomena.

THE IGNITION OF COMBUSTIBLE GASES BY CONVERGING SHOCK WAVES, by J. A. Fay and E. R. Lekawa. June 30, 1955 [21]p. incl. illus. diagrs. tables. [AFOSR-TR-55-26] (AF 18(600)1162) AD 73694 Unclassified

Also published in Jour. Appl. Phys., v. 27: 261-266, Mar. 1956.

Hydrogen-oxygen and hydrogen-air mixtures were ignited by converging cylindrical shock waves using the apparatus devised by Perry and Kantrowitz, (Jour. Appl. Phys., v. 22: 878-886, 1951), and the minimum strength shock wave necessary for ignition was determined. The energy in the heated wake of the shock wave within a cylinder of diameter equal to the quenching distance was calculated and found to be comparable with the minimum spark ignition energy. An analysis of the unsteady heat conduction problem lends support to the choice of the quenching distance as the significant dimension of the region over which heat addition is effective in causing ignition. IGNITION OF $2H_2$-O_2 MIXTURES BY MEANS OF SHOCK WAVES, by W. J. Hooker. Feb. 1955, 29p. incl. diagrs. table. (AF 18(600)1162) Unclassified

A shock wave propagating in a shock tube is a means for generating a source of uniform high temperature which is, in general, limited in time duration only by the physical dimensions of the tube. A number of investigations of ignition temperatures, utilizing this means, have disclosed that "shock initiated" ignition temperatures are considerably lower than those obtained by adiabatic compression. The present research was begun in an effort to further study this problem with more refined techniques and reveals the "shock initiated" ignition temperatures to be higher than those obtained by adiabatic compression.

AN AERODYNAMIC THEORY OF A SUPERSONIC PROPELLER, by D. E. Ordway. June 1956, 170p. incl. diagrs. tables, refs. (AFOSR-TN-56-287) (AF 18(600)1523) AD 89498 Unclassified

A supersonic propeller with blades attached to an infinite cylinder as a hub is studied. The forward speed is subsonic but the relative speed at each section is supersonic. The lightly-loaded blades are represented by a surface distribution of appropriate "modified" sources in a fashion similar to ordinary supersonic thin-wing theory. These sources are found by approximating the exact potential for a constant-strength compressible source traveling along a helical path. By properly dividing up the area of integration over the sources in the "Forward Mach Cone," the usual relationship between the source strength and boundary condition is found directly without recourse to Green's theorem. A sample calculation for a twisted flat-plate blade shows that the pressure distribution is the Ackeret value at the leading edge and remains essentially at this value over the first half of the section. As the trailing edge is approached, it rises about 20% above the Ackeret value because the "opening up" of the "Forward Mach Cone" increases the number of contributing sources. The "Mach Lines" formed by the intersection of the propeller plane with the Mach Surface are found for compressible sources moving along a helical path. The solution is given in a manner analogous to the velocity-flow-inclination relationship of Prandtl-Meyer. One case of blade interference is also investigated. (Contractor's abstract)

LAMINAR BOUNDARY LAYERS ON MOVING WALLS, by S. H. Smith. Sept. 1956 [47]p. incl. diagrs. table. (AFOSR-TN-56-454) (AF 18(600)1523) AD 96800 Unclassified

The nature of the boundary layer on a wall moving with a constant velocity is investigated using approximate methods. The Pohlhausen method, in which a polynomial of the fourth degree in terms of the distance from the wall is assumed for the boundary-layer velocity distribution, is applied to obtain a solution of von Kármán's momentum equation. By considering cases in which the potential flow is a linearly decreasing function of the distance along the wall, the flow pattern is found using the stream function. It is found that the point of zero shear stress at the wall plays no significant part, for moving walls, in the nature of the flow or in the location of flow reversal. An exact solution to the Navier-Stokes equations, calculated by Professor N. Rott (Quart. Appl. Math., v. 13, Jan. 1956) for flow in the vicinity of a stagnation point for the case of moving walls, is presented and the streamlines are calculated. The effect of moving walls (rotation) on the series solution for the flow about a cylinder is also discussed. (Contractor's abstract)

ROTATING STALL IN SINGLE-STAGE AXIAL FLOW COMPRESSORS, by T. J. Falk. Sept. 1956 [61]p. incl. diagrs. tables, refs. ([AF]OSR-TN-56-512) (AF 18(600)1523) AD 110327 Unclassified

Three sets of rotating-stall data obtained using single-stage axial-flow compressors are compared with the three rotating-stall theories developed by W. R. Sears, F. E. Marble and A. H. Stenning. All of the theories predict stall propagation speed with reasonable accuracy, or can be adjusted to do so by choice of a proper value of aerodynamic lag. A final decision as to which of the analytical treatments most accurately represents the problem must await further knowledge of aerodynamic lag. The special case of Professor F. E. Marble's cascade theory of rotating stall, called the "simple cascade characteristics" case, is extended to include a lag between local attainment of the steady-state stalling inlet angle and the local drop in pressure rise associated with stall. Stall propagation speed and percentage of compressor circumference stalled are calculated for 10-degrees and 30-degrees phase lag, and for three values of cascade static-pressure rise at stall. LAMINAR BOUNDARY LAYER ON A SPINNING CIRCULAR CONE IN SUPERSONIC FLOW AT A SMALL ANGLE OF ATTACK [PART I], by M. Fiebig. [June 1956] 1v. incl. diagrs. tables, refs. [AFOSR-TN-56-532] (AF 18(600)1523) AD 110351 Unclassified

The compressible laminar boundary-layer equations for bodies of revolution have been developed and applied. A solution of the outer nonviscous flow, as obtained by a method of perturbation in angle of attack, is available. A perturbation solution is based on this approximation; as is suggested by the solution for the undisturbed cone flow, the Blasius similarity variable is introduced. The resulting system of differential equations has been identified for first order perturbations in angle of attack with F. K. Moore's equations (NACA rept. no. 2521, 1951), for first and second order perturbations due to spin with C. R. Illingworth's equations, (Phil. Mag., v. 44: 389, 1953). The differential equations due to interaction of angle of attack and spin have been solved. The results are given in the form of a set of profile functions which yield, upon

COR. 12:005 - COR. 13:002

linear combinations, the solution for all Mach numbers and cone-vortex angles. (Contractor's abstract)

ON THE "TRIPLE POINT" IN SHOCK-DIFFRACTION PROBLEMS, by T.-F. Sun. Sept. 1956, 122p. incl. diagrs. tables, refs. (AFOSR-TN-56-583) (AF 18-(600)1523) AD 115007 Unclassified

A study is made to determine (1) the flow inside the diffracted wave that originates when a horizontally advancing plane straight shock encounters an infinitely long wedge, (2) the position and strength of the diffracted wave, and (3) the way the diffracted wave reinforces or attenuates the incident or the reflected shock at the triple points where it intersects them. Only weak incident shocks are considered. A nonviscous adiabatic flow is assumed. Consideration is given to the differential equations governing the flow inside the field, the shock position and its strength in 2-dimensional flow, and shocks diffracted by a right-angle wedge. A pole-type singularity at the triple point is obtained even with a more general expansion of the conical coordinates r and θ than that used by Lighthill (Phil. Mag. v. 40: 1202, 1949). A transition function $g(\theta)$, is introduced to remove the pole singularity by connecting the discontinuous boundary values. The pressure and velocity components are then expressed in terms of $g(\theta)$. The magnitude of the first-order approximations thus obtained is uniformly correct in the triple-point region, although the approximations themselves may not be complete. A set of simultaneous nonlinear integro-differential equations governing the transition function and the shock position is obtained for the tangential and normal shock conditions. A numerical solution based on polynomial approximations is obtained which shows fairly good agreement with experimental data. (ASTIA abstract)

APPROXIMATIONS TO THE PROBABILITY INTEGRAL AND CERTAIN PERCENTAGE POINTS OF A MULTIVARIATE ANALOGUE OF STUDENT'S t-DISTRIBUTION by C. W. Dunnett and M. Sobie. July 1954, 8p. incl. table. (Mechanical engineering rept. no. 5) ([AF]OSR-TN-54-156) (AF 18(600)331) AD 40811 Unclassified

Also published in Biometrika, v. 42: 258-260, June 1955.

A multivariate analog of Student's t-distribution was defined by the authors (Biometrika, v. 41: June 1954) as the joint distribution of p variates $t_{in} = z_i/s$ (i = 1, 2, ..., p). Expressions were obtained for the probability integral and equicoordinate percentage points of the joint density of the t_{in}, given by (1)

$$f(t_{1n}, \ldots, t_{pn}) = \frac{A^{1/2}\,\Gamma\left(\frac{n+p}{2}\right)}{(n\pi)^p\,\Gamma(n/2)}\left(1 + \frac{1}{n}\sum_{i,j} a_{ij} t_{in} t_{jn}\right)^{-\frac{n+p}{2}},$$

where A is the determinant of the positive definite matrix $\left\{a_{ij}\right\} = \left\{p_{ij}\right\}^{-1}$ and $\left\{p_{ij}\right\}$ is the known correlation matrix of the z_i, for the bivariate case p = 2. Approximations are derived which are also lower bounds to the probability integral of (1) applicable in special cases when p > 2. These results can be used to obtain approximations which are upper bounds to any equicoordinate P-percentage point defined as the value of h for which

$$\int_{-\infty}^{h} \cdots \int_{-\infty}^{h} f(t_{1n}, \ldots t_{pn}) dt_{1n} \ldots dt_{pn} = P.$$ (ASTIA abstract)

ON A GENERALIZATION OF AN INEQUALITY OF HARDY, LITTLEWOOD, AND PÓLYA, by M. Sobel. [1954] 10p. (AF 18(600)331) AD 40690 Unclassified

Also published in Proc. Amer. Math. Soc., v. 5: 596-602, Aug. 1954.

Sets $A = \left\{a_1 \leq a_2 \leq \ldots \leq a_n\right\}$ and $B = \left\{b_1 \leq b_2 \leq \ldots \leq b_n\right\}$ of n real numbers each are given. Let n_i (i = 1, 2, ..., k) be any fixed set of k positive integers whose sum is n, let $C = \prod_{i=1}^{k} n_i!$, and let R = n!/C. Partitions $P^* = \left\{B_1^*, B_2^*, \ldots, B_k^*\right\}$ of B into disjoint subsets B_i^* are considered, each B_i^* containing n_i (i = 1, 2, ... k) elements of B. Denote by B_1^1 the first n_1 elements of B, B_2^1 the next n_2 elements of B until B_k^1 denotes the last n_k elements of B so that $P^1 = \left\{B_1^1, B_2^1, \ldots, B_k^1\right\}$ and $P^r = \left\{B_k^1, B_{k-1}^1, \ldots, B_1^1\right\}$ are particular partitions. Define A_i^1 similarly for A, and regard the A_i as ordered subsets of A. Define $N = \left\{1, 2, \ldots, n\right\}$ and the subsets N_i^1 exactly as for B. The theorem that follows is concerned with the n! cross products $\sum_{i=1}^{k} a_i b_{j_i}$, where $(j_1, j_2, \ldots, j_n)$ is a rearrangement of (1, 2, ..., n). Corresponding to any fixed P^r consider the set $V_r = \left\{v_{cr} \middle| c = 1, 2, \ldots, C\right\}$ of the C cross products obtained by associating the elements of B_i^r with A_i, all rearrangements within the subsets B_i^r

being allowed. A partial ordering is introduced among the partitions so that $P^1 > P^r > P^R$ (r = 2, 3, ... R-1). Theorem: there exists a 2-way table with R rows and C columns such that, for any pair (r_1, r_2), if $P^{r_1} > P^{r_2}$ then $V_{cr_1} \geq V_{cr_2}$ (c = 1, 2, ..., C). (ASTIA abstract)

A SINGLE-SAMPLE MULTIPLE DECISION PROCEDURE FOR RANKING MEANS OF NORMAL POPULATIONS WITH KNOWN VARIANCES, by R. E. Bechhofer. [1954] [24]p. incl. tables, refs. (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under [AF 18(600)331]) Unclassified

Published in Ann. Math. Stat., v. 25: 16-39, Mar. 1954.

A single-sample multiple decision procedure is considered for ranking means of normal populations with known variances. Problems which conventionally are handled by the analysis of variance (Model I) which tests the hypothesis that k means are equal are reformulated as multiple decision procedures involving rankings. It is shown how to design experiments so that useful statements can be made concerning these rankings on the basis of a predetermined number of independent observations taken from each population. The number of observations required is determined by the desired probability of a correct ranking when certain differences between population means are specified. (Contractor's abstract)

A TWO-SAMPLE MULTIPLE DECISION PROCEDURE FOR RANKING MEANS OF NORMAL POPULATIONS WITH A COMMON UNKNOWN VARIANCE, by R. E. Bechhofer, C. W. Dunnett, and M. Sobel. [June 1954] [7]p. incl. diagr. [AF 18(600)331] Unclassified

Published in Biometrika, v. 41: 170-176, June 1954.

A multiple decision approach to the problem of ranking populations according to their population means has been formulated by Bechhofer (1954). A simple-sample solution to this problem was presented by him for the case of normal populations with known variances. In the present paper the case of normal populations with unknown equal variances is considered. A two-sample procedure is proposed as a solution to the latter problem; this procedure is of the type used by Stein (1945) for obtaining a test of Student's hypothesis with power independent of the variance. Tables are available which enable the experimenter to apply this procedure with little computational effort to the ranking of two or three populations with unknown but equal variances. The same tables can be used when the variance ratios are arbitrary and known. Graphic comparisons of the expected sample size are made for the single-sample and two-sample procedures. PRESSURE BROADENING OF LINEAR MOLECULES. II. THEORY, by W. V. Smith, H. A. Lackner, and A. B. Volkov. July 30, 1954, 8p. incl. diagrs. tables. (Technical note no. 3) ([AF]OSR-TN-54-182) (AF 18(600)449) AD 79255 Unclassified

Also published in Jour. Chem. Phys., v. 23: 389-396, Feb. 1955.

The large collision diameters for the self pressure broadening of OCS and BrCN can be explained in terms of P. W. Anderson's general theory as due to the first order dipole-dipole interaction. The temperature dependence of the pressure broadening requires the introduction of other interactions. It is possible to obtain both the magnitude and temperature dependence of the pressure broadening by considering both the first order dipole-dipole and quadrupole-dipole interactions. A quadrupole moment of $Q/e = 5.7 \times 10^{-16}$ cm^2 is obtained for BrCN in this manner. (Contractor's abstract)

PRESSURE BROADENING OF CYANOGEN BROMIDE IN THE MICROWAVE REGION (Abstract), by R. Trambarulo, H. A. Lackner and others. Apr. 30, 1954 [1]p. [AF 18(600)449] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-May 1, 1954.

Published in Bull. Amer. Phys. Soc., v. 29: 34, Apr. 29, 1954.

The self-broadening of the J = 2 to 3, F = 5/2 to 7/2 and 7/2 to 9/2 rotational transition of cyanogen bromide at 24.6 kmc was investigated as a function of temperature and pressure. This transition consists of a number of hyperfine lines which were not resolved on our spectrometer. Corrections were made for multiplet line structure and also for the mode curvature of the microwave source. The line-breadth parameter is 27.1 mc/mm at room temperature, and the temperature variation is proportional to $T^{-1.6}$ giving an apparent collision diameter which varies with temperature. (Contractor's abstract)

EVALUATION OF MOLECULAR QUADRUPOLE MOMENTS FROM MICROWAVE SPECTRAL LINE BREADTHS. 1. THEORETICAL, by W. V. Smith. Oct. 10, 1955 [21]p. incl. diagrs. refs. (Technical note no. 4) ([AF]OSR-TN-55-348) (AF 18(600)449) AD 74851 Unclassified

Also published in Jour. Chem. Phys., v. 25: 510-515, Sept. 1956.

The breadths of microwave spectral lines in gas mixtures may arise from several different interactions. It is shown that when the radiating molecule is the linear molecule OCS, polarizability interactions predominate, but when the radiating molecule is NH_3 undergoing inversion, quadrupole moment interactions predominate. Consequently, NH_3 is a particularly suitable molecule to use as a "probe" to measure quadrupole moments of other molecules. An improved theoretical analysis leads to a revision of previously published molecular quadrupole moments. (Contractor's abstract)

ANALYSIS OF ELASTIC AND PLASTIC STRAINS OF A FACE-CENTERED CUBIC CRYSTAL, by T. H. Lin. July 1956, 25p. incl. diagr. tables. (AFOSR-TN-56-307) (AF 18(600)1466) AD 94841 Unclassified

Also published in Jour. Mech. and Phys. of Solids, v. 5: 143-149, 1957.

A method of analysis of both the elastic and plastic shear strains in a face-centered cubic crystal with 12 slip systems, under a given path of strain, is shown. The consideration of elastic strain gives the sequence of different active slip systems in the process of loading. This enables the calculation of the transition from one set of active slip systems to another for a crystal deformed under varying ratios of principal strains. An illustrative example of calculating the 5 active slip systems of a crystal under uniaxial loading is shown. The 5 active slip systems calculated for this crystal, by the present method check exactly with Taylor's results. (Jour. Inst. Metals, v. 62 (1): 307-324, 1938). (Contractor's abstract)

DEVELOPMENT OF A MATHEMATICAL THEORY OF PLASTICITY BASED ON SLIPS, by T. H. Lin. Aug. 1956, 49p. incl. diagrs. tables, refs. (AFOSR-TR-56-31) (AF 18(600)1466) AD 96043 Unclassified

A plasticity theory of metals is developed in which the latent hardening effect is considered. The assumptions are that the volumetric strain is elastic and that the plastic strain caused by slips in all crystals is entirely distortional. Crystals with a common crystal plane have the same resultant slip on that plane and slide together. For these crystals to slide, the other crystals must deform so that crystals originally in contact remain in contact during deformation. This deformation may be produced by slips in more than one crystal plane or a combination of slips and elastic strains. To simplify the calculation of the deformation of all crystals with a given aggregate strain which satisfies the compatibility condition and the equilibrium condition across the grain boundaries, the resistance to slip on each plane is represented by the resistance given by those crystals with one crystal plane coinciding with the particular plane. Calculated stress-strain curves for 4 different cases are compared with experimental data. An analysis is given of the elastic and plastic strain in a face-centered cubic crystal, and slips of crystals under uniaxial strain are calculated. (ASTIA abstract)

A POLAROGRAPHIC STUDY OF AZO COMPOUNDS AND AZO METAL COMPLEXES, by W. J. Reid, Jr., B. Cooney, and R. Kirby. Final rept. Dec. 15, 1952-Aug. 31, 1956, 1v. incl. illus. diagrs. tables, refs. (AFOSR-TR-56-53) (AF 18(600)496) AD 110337 Unclassified

This report is divided into three parts: Part I. A polarographic study of 2, 4, 2' - trihydroxyazobenzene - 5' - sulfonic acid, sodium salt, and its complexes with gallium and indium. In this research reduction of Superchrome Garnet Y was studied in buffered solutions. The effects of gelatin concentration, pH, and dye concentration on the reduction were studied. The pH of polarographic waves produced in the electrolysis of solutions of Superchrome Garnet Y and indium was determined. Possible methods for the polarographic determination of dye to metal ratios and of the presence of gallium were investigated. Part II. A spectral study of the aluminum-Superchrome Garnet Y system. The methods of continuous variations and mole ratio were used in this investigation to analyze complex formation in the aluminum-Superchrome Garnet Y system. As an attempt to correct difficulties encountered in the past, a pure sample was synthesized by a Dupont furnished procedure. Part III. A spectral and polarographic study of the complexes of aluminum and gallium with o, o' - dihydroxyazobenzene. This report discusses the uses and limitations of the mole-ratio method with special reference to the complexes of aluminum and gallium with o, o' - dihydroxyazobenzene.

PROBLEMS AND METHODS IN PARTIAL DIFFERENTIAL EQUATIONS. PART I. THE ORIGIN AND EVOLUTION OF THE THEORY, by F. J. Bureau and E. J. Pellicciaro. Aug. 1956, 144p. incl. diagrs. refs. (AFOSR-TN-56-441) (AF 18(600)1341) AD 96784 Unclassified

A consideration is presented of partial differential equations based on a group of lectures given at Duke University during the academic year 1955-56. Some topics in the theory of partial differential equations are reviewed with emphasis on the Cauchy problem. Problems and methods which were introduced during the time up to about 1900 are discussed and summarized. The second part introduces the theory of the finite part and the logarithmic part of some divergent integrals and applies it to the study of the wave equation, the damped wave equation, and the singular equation of Euler-Poisson-Darboux. In order to promote a better understanding of the finite part and the logarithmic part of divergent integrals and of their usefulness in studying the solutions of partial differential equations, the theory is presented with all the necessary details. Some new proofs are also included. In addition, an appendix on the Laplace transform has been added, the contents of which are confined to meet only the requirements of these lectures. UNIQUENESS OF MAPPING PAIRS FOR ELLIPTIC EQUATIONS, by R. M. McLeod, J. J. Gergen, and F. G. Dressel. Oct. 1956, 15p. refs. (AFOSR-TN-56-554) (AF 18(600)1341) AD 110373 Unclassified

Also published in Duke Math. Jour., v. 24: 173-181, June 1957.

It is proved that the generalized Riemann mapping problem has a unique solution for the class of functions continuous on the closure of the interior of a simple closed plane Jordan curve D, and with continuous first derivatives on D, when D and the coefficients of the system of mapping equations are suitably restricted. Also, certain uniqueness results for similar mappings are obtained under conditions other than the usual ones requiring that three distinct boundary points of D be carried into three distinct boundary points of the second curve.

MICROWAVE SPECTRA AND MOLECULAR STRUCTURES OF $HSiCl_3$, CH_3SiCl_3 AND $(CH_3)_3SiCl$, by R. C. Mockler, J. H. Bailey, and W. Gordy. [1953] [18]p. incl. diagr. tables. (Bound with its Quarterly progress rept. no. 1, Feb. 1, 1953-May 1, 1953; AD 16227) (Sponsored jointly [Air Force] Office of Scientific Research under AF 18(600)497) and The Research Corp.) AD 16227(b) Unclassified

Also published in Jour. Chem. Phys., v. 21: 1710-1713, Oct. 1953.

The spectra were observed with a Stark modulation spectrometer. A 100-kc square-wave modulation was employed with the receiver tuned to the fundamental frequency. In most instances the frequency sweep method was employed, and the lines were displayed on a cathode-ray scope. Line frequencies were measured with a frequency standard monitored by comparison of the lowest frequency in the multiplier chain with the standard 5-mc frequency broadcast by station WWV. The following molecular constants were obtained from measurements of pure rotational transitions in the microwave region: B_0 (in mc) of 2472.45 ± 0.04 for $HSi^{28}Cl_3^{35}$, 2346.07 ± 0.04 for $HSi^{28}Cl_3^{37}$, 1769.84 ± 0.03 for $C^{12}H_3Si^{28}Cl_3^{35}$, 1699.79 ± 0.03 for $C^{12}H_3Si^{28}Cl_3^{37}$, 2197.44 ± 0.04 for $(C^{12}H_3)_3Si^{28}Cl^{35}$, and 2147.88 ± 0.03 for $(C^{12}H_3)_3Si^{28}Cl^{37}$. When it was assumed that d_{SiH} = 1.47, for $SiHCl_3$, d_{SiCl} was 2.021 and the ClSiCl bond angle was 109° 22'. For CH_3SiCl_3, d_{SiC} was 1.896 A and d_{SiCl} was 2.021 A. With all bond angles assumed to be tetrahedral and the CH distance to be that in methane d_{SiCl} was 1.87 A and d_{SiCl} was 2.03 A for $(CH_3)_3SiCl$. (ASTIA abstract)

MICROWAVE SPECTRA AND STRUCTURES OF METHYL MERCURY CHLORIDE AND BROMIDE, by W. Gordy and J. Shertdan. [1953] [20]p. tncl. dtagrs. tables, refs. (Bound with its Quarterly progress rept. no. 2, May 1, 1953-Aug. 1, 1953; AD 15707) (AF 18(600)497) AD 15707(a) Unclassified

Also published in Jour. Chem. Phys., v. 22: 92-95, Jan. 1954.

The pure rotational mtcrowave spectra of several different isotopic spectes of CH_3HgCl were observed with a frequency sweep spectrometer which had a video type detector. The hyperftne components of a stngle transition for the different tsotopes were measured wtth a frequency calibrated by comparison with the standard 5-mc stgnal of station WWV. The stronger components of several other transttions were measured wtth a cavtty wavemeter. The large number of abundant Hg tsotopes combined with the nuclear quadrupole hyperftne structures made the spectra of CH_3HgBr and CH_3HgCl compltcated. The CH_3HgCl spectra indicated that d_{CHg} = 2.061 ± 0.02 A, d_{HgCl} = 2.282 ± 0.005 A, and CHgCl bond angle = 180°. For CH_3HgBr, d_{CHg} = 2.074 ± 0.015 A, d_{HgBr} = 2.406 ± 0.005 A, and CHgBr bond angle = 180°. Nuctear quadrupole couplings evaluated are Cl^{35} = -42 mc, Cl^{37} = -33 mc in CH_3HgCl, and Br^{79} = 350 mc, Br^{81} = 290 mc tn CH_3HgBr. These tndtcated lonic character of 62% for the HgCl and 55% for the HgBr bond tn these molecules, and led to a value of 1.7 to 1.8 for the electronegattvtty of dlvalent Hg.

MICROWAVE SPECTRUM AND MOLECULAR STRUCTURE OF TRICHLORO GERMANE, by P. Venkateswarlu, R. C. Mockler, and W. Gordy. [t953] [14]p. incl. dtagr. tables. (Bound with its Quarterly progress rept. no. 1, Feb. t, t953-May t, 1953; AD t6227) (AF 18(600)497) AD t6227(a) Unclassified

Also published in Jour. Chem. Phys., v. 21: 1713-t7t5, Oct. t953.

The analysis of the spectrum was simplified because it was possible to ignore the Cl quadrupole hyperfine structure, and the D_{JK} was sufficiently small that the separatton of the lines of dtfferent K was not resolved. These facts also made possible the detection of rotational ltnes in tsotopic spectes of low abundance. The rotational constants B_0 (in mc) for the various isotopic modifications of the molecule were: 2171.75 for $HGe^{70}Cl_3^{35}$, 2169.26 for $HGe^{72}Cl_3^{35}$, 2165.84 for $HGe^{74}Cl_3^{35}$, 2063.74 for $HGe^{70}Cl_3^{37}$, 2060.43 for $HGe^{72}Cl_3^{37}$, and 2057.20 for $HGe^{74}Cl_3^{37}$. The calculated structure from these data for the molecule in the ground state was: d_{GeH} = 1.55 ± 0.04 Å, d_{GeCl} = 2.1139 ± 0.0010 Å, and the ClGeCl bond angle = 108°17' ± 12'. Rotational lines for the molecule when it was in the 2 excited $GeCl_3$ deformation vibrations were also measured and the correspondtng molecular structures calculated. (ASTIA abstract)

ON THE LINE WIDTH OF THE ROTATIONAL SPECTRA OF SOME SYMMETRIC TOP MOLECULES DUE TO THE NUCLEAR QUADRUPOLE MOMENTS, by T. Ito, Y. Tanabe, and M. Mizushima. [1953] [29]p. tncl. tables, refs. (Bound with its Quarterly progress rept. no. 3, Aug. t, 1953-Nov. 1, 1953; AD 20319) (AF 18(600)497) AD 203t9(d) Unclassified

Also published in Phys. Rev., v. 93: t241-t248, Mar. 15, 1954.

Explicit formulas are presented which give the mean square frequency deviation as a function of the nuclear quadrupole coupling constant and the quantum numbers I, J, K. The nuclear quadrupole coupltng constant can be obtained by these formulas from the line width of the rotational line without analyzing the hyperfine structure. Calculations were made on symmetric top molecules which had 1 or 3 identical nuclei with electric quadrupole moments. The method of separating the present line width from that due to pressure broadening and centrtfugal distortion is dtscussed.

ONE-TO-TWO MILLIMETER-WAVE SPECTROSCOPY. PART II. H_2S, by C. A. Barrus and W. Gordy. [1953] [20] p. incl. diagrs. tables, refs. (Bound with its Quarterly progress rept. no. 2, May 1, 1953-Aug. 1, 1953; AD 15707) (AF 18(600)497) AD 15707(b) Unclassified

Also published in Phys. Rev., v. 92: 274-277, Oct. 15, 1953.

Pure rotational iransiiions of H_2S^{32}, H_2S^{33}, and H_2S^{34} were measured with high precision in the region of 1 to 2 mm. From these measurements the SH bond length was calculated to be 1.3226 A and the bond angle 92°6'. The S^{33} nuclear quadrupole coupling observed along the principal inertial axes were eQq_{aa} = -32 mc, eQq_{bb} = -8 mc, and eQq_{cc} = +40 mc. An approximate analysis of the quadrupole coupling constants showed that the bonding orbitals of S are spd hybrids and yields a value of -0.06×10^{-24} cm^2 for the quadrupole moment of the S^{33} nucleus. From the known ratio Q^{33}/Q^{35} this gave $Q^{35} = 0.04 \times 10^{-24}$ cm^2. Zeeman studies showed that the molecular g_J factor was almost equal for differeni rotational states. A mean value of 0.24 nuclear magnetons was found for g_J.

ONE-TO-TWO MILLIMETER WAVE SPECTROSCOPY. PART III. NO AND DI, by C. A. Burrus and W. Gordy. [1953] [12]p. incl. diagrs. tables. (Bound with its Quarterly progress rept. no. 4, Nov. 1, 1953-Feb. 1, 1954: AD 27067) [AF 18(600)497] AD 27067(a) Unclassified

Also published in Phys. Rev., v. 92: 1437-1439, Dec. 15, 1953.

Pure rotational transitions of $N^{14}O^{16}$ and DI^{127} have been measured in the one-to-two millimeter wave region. For NO the $J = 1/2 \rightarrow 3/2$ transition in the $^2\pi_{1/2}$ electronic ground state was observed. The transition reveals a λ doublet with separation $\delta\nu_{dc}$ = 355.1 mc/sec. Each componeni of the λ doublet is further spliі into five hyperfine componenis as a resulі of the nuclear magnetic coupling of N^{14}. Nuclear quadrupole coupling of N^{14} was found to be small in comparison with the magnetic interaction. Analysis of the data yields B_0 = 50818.0 mc/sec, r_0 = 1.1540 A, B_e = 51084.8 mc/sec and r_e = 1.1510 A for the $^2\pi_{1/2}$ state. For DI^{127} the following information was obiained: B_0 = 97537.2 mc/sec, r_0 = 1.6165 A, and $eQq(I^{127})$ = 1823 ± 1 mc/sec. Nuclear magnetic inieractions of I^{127} were also deiected and analyzed. (Contractor's abstract)

Also published in Phys. Rev., v. 93: 407-412, Feb. 1, 1954.

Design details are given of the harmonic generator and detector which made possible precision speciroscopy in the one-to-two millimeter wave region. The signal to noise ratio obtained on OCS rotaiional lines is 7 to 1

at 1.0 mm wave length; 30 to 1 at 1.1 mm; and better than 100 to 1 at 1.4 mm and above. A useful tuning and measuring technique is made possible by the ability of the new system to detect several klystron harmonics at once, and hence spectral lines in several different regions at the same time. The applications of the methods in the measurement of centrifugal distortion of molecules is illustrated with OCS, for which D_J = 1.310 ± 0.010 kc is obtained, and with CH_3F, for which D_J = 57.8 ± 1.0 kc and D_{JK} = 445 ± 4 kc are obtained. A new water vapor line, the $2_{2,0} \rightarrow 3_{1,3}$ rotational line, has measured at 183, 311.30 ± 0.30 mc. (Contractor's abstract)

ZEEMAN EFFECT AND LINE BREADTH STUDIES OF THE MICROWAVE LINES OF OXYGEN, by R. M. Hill and W. Gordy. [1953] [15]p. incl. diagrs. tables. (Bound with its Quarterly progress rept. no. 3, Aug. 1, 1953-Nov. 1, 1953; AD 20319) (AF 18(600)497) AD 20319(c) Unclassified

Also published in Phys. Rev., v. 93: 1019-1022, Mar. 1, 1954.

Measurements at 90° and 300° K on the O line breadths indicated that the line breadth parameter, $\Delta\nu$, varies as T^{-x}, with x varying from 0.76 for the 9- line to 0.90 for the 1- line. Rotational resonance and quadrupole moment interactions were important factors in determining the line breadths. The Zeeman splittings observed for the 1-, and the 1+, and the 3- lines were in accord with the splitting predicted from first-order perturbation theory. (ASTIA abstract)

MICROWAVE SPECTRUM AND MOLECULAR PROPERTIES OF OZONE (Abstract), by R. Trambarulo, S. N. Ghosh and others. Mar. 27, 1953 [1]p. [AF 18(600)-497] Unclassified

Presented at meeting of the Amer. Phys. Soc., Durham and Chapel Hill, N. C., Mar. 26-28, 1953.

Published in Phys. Rev., v. 91: 222, July 1, 1953.

Four low J rotational transitions of ozone were measured between 42 and 118 kmc. These measurements showed ozone to be an isosceles triangle with the apex angle of 116° 49' ±30' and with the two equal internuclear distances 1.278 ± 0.003 Å. The electric dipole moment found from the Stark effect was 0.53 ± 0.02 Debye. Zeeman studies show the molecular g factor to have a strong dependence upon rotational state. (Contractor's abstract)

ON THE FREQUENCIES OF THE MICROWAVE ABSORPTION LINES OF OXYGEN (Abstract), by M. Mizushima. Mar. 27, 1953 [1]p. [AF 18(600)497] Unclassified

Presented at meeting of the Amer. Phys. Soc., Durham and Chapel Hill, N. C., Mar. 26-28, 1953.

Published in Phys. Rev., v. 91: 222, July 1, 1953.

Attempt was made to improve two points in Schlapp's theory. First consideration was given to the dependence of λ on N, where λ is the coupling constant of electronic spin and molecular axis and N is the quantum number of end-to-end rotation of molecule. This dependence makes $\nu_+(N-1) + \nu_-(N+1)$ dependent on N, which fit with experimental results, while in Schlapp's original theory it is independent of N. Another point considered is that Schlapp made a mistake in taking the effect of magnetic interaction between spin and end-to-end rotation of molecule into account. An improved formula derived is in good agreement with recent experimental data obtained at Duke U. The adopted value of the constants are: B = 1.4372605 cm^{-1}, λ_0 = 1.984627 cm^{-1}, λ_1 = 0.000050 cm^{-1}, μ = -0.008432 cm^{-1}, where λ_1 gives slight dependence of λ on N. MICROWAVE SPECTRUM OF WATER VAPOR, by W. Gordy. June 25, 1953 [11]p. incl. diagr. table, refs.

(Bound with its Quarterly progress rept. no. 3, Aug. 1, 1953-Nov. 1, 1953; AD 20319) (AF 18(600)497)
AD 20319(a) Unclassified

The usefulness of structural information obtained from a study of isolated molecules is discussed for understanding the nature of the bonding of H_2O in solids. The steric factors which depend on the shape and size of the molecule as well as the ordinary electrostatic interactions with the over-all electric dipole moment of the molecule were pointed out as significant. However, emphasis was given to the dependence of the H bond on the hybridization of the orbitals of the atoms linked by the bridge. The 15° departure of the bond angle of H_2O from 90°, only partially accounted for by the repulsion of the H atoms, was interpreted to indicate considerable s contribution to the bonding orbitals of O. The complimentary sp hybridization of the orbitals containing the unshared electrons made them good proton acceptors. The decrease in the proton acceptor properties of the second period over the first period elements was attributed to the increasing size of the atoms and to the decreased complimentary sp hybridization of the orbitals containing the unshared pairs. ONE-TO-FIVE MILLIMETER-WAVE SPECTROSCOPY, by W. Gordy. July 1, 1953 [13]p. incl. diagrs. table. (Bound with its Quarterly progress rept. no. 3, Aug. 1, 1953-Nov. 1, 1953; AD 20319) (AF 18(600)497)
AD 20319(b) Unclassified

Also published in Jour. Phys. et Radium (Paris), v. 15: 521, 1954.

Design features of a millimeter-wave spectrometer are discussed. An improvement in sensitivity of 10 times or better over the video-type spectrometer can be obtained by the use of automatic recording with a phase-lock-in detector and narrow-band amplifier. The spectral lines in the 1- to 5-mm region are measured by standard markers made by multiplication of a 5-mc signal monitored by NBS station WWV and multiplied to the region of investigation. Measured 1- to 5-mm spectral lines are tabulated. The 24th rotational line of COS at 1.03 mm was the highest spectral frequency recorded with the microwave electronic methods. Advantages of having the millimeter-wave region opened to spectroscopists are summarized. The millimeter-wave region from 1 to 10 wave numbers includes spectral transitions of numerous atoms and molecules which have no observable transitions in the centimeter region. The strength of spectral lines increases rapidly with frequency. Spectral lines are stronger and more numerous in the millimeter than in the centimeter region. The advantage of strength and abundance of spectral transitions characteristic of the optical region and the high precision and resolution characteristic of the RF region are best comprised in the millimeter-wave region.

Also published in Jour. Chem. Phys., v. 22: 1470-1471, Aug. 1954.

A relation between the ionic-character of bonds and the electronegativity difference of the bonded atoms, which differs significantly from previously proposed relations, was obtained from nuclear quadrupole couplings. Such a relation is useful in calculating nuclear quadrupole moments from molecular coupling, as well as in obtaining chemical bond properties. The coupling of Cl in HCl provides a critical test of the relation. (ASTIA abstract)

PARAMAGNETIC RESONANCE IN URANIUM SALTS, by S. N. Ghosh, W. Gordy, and D. G. Hill. [1954] [15]p. incl. diagrs. table. (Special repl. no. 3) [AFOSR-TN-54-179] (Bound with its Quarterly progress repl. no. 6, May 1-Aug. 1, 1954; AD 36814) (AF 18(600)497) AD 36814(c) Unclassified

Also published in Phys. Rev., v. 96: 36-38, Oct. 1, 1954.

Paramagnetic resonance was observed in U^{3+} and U^{4+} ions in powdered samples of UF_3 and UF_4, respectively. The resonance curve in UF_3 was asymmetric with 2 unresolved peaks yielding values of 2.1 and 2.8 for the perpendicular and parallel components of the g factor. The resonance is broad and weak; the over-all half-width is 5 kilogauss at room temperature. The curve obtained for UF_4 was symmetric and yielded g = 2.15, its half-width was 3.5 kilogauss at room temperature. Although the resonance in UF_3 appeared stronger at liquid-air than at room temperature, the resonance in the UF_4 could be detected only at room and at elevated temperatures. The results favor the interpretation that the 2 unpaired electrons in U^{4+} are 6d electrons, that the crystalline field in UF_4 was essentially cubic, and that either the lowest component of the Stark multiplet was a nonmagnetic singlet or that the electrons had a high degree of antiferromagnetic alignment. The results on UF_3 showed that the crystalline field had an axially symmetric component. (ASTIA abstract)

MILLIMETER WAVE SPECTRA OF SbH_3 AND SbD_3, by A. W. Jache, G. S. Blevins, and W. Gordy. [1954] [20]p. incl. diagr. tables, refs. [AFOSR-TN-54-316] (Bound with its Quarterly progress rept. no. 7, Aug. 1, 1954-Nov. 1, 1954; AD 49803) [AF 18(600)497] AD 49803(a) Unclassified

Also published in Phys. Rev., v. 97: 680-683, Feb. 1, 1955.

The $J = 0 \rightarrow 1$ rotational transitions of normal and deuterated stibine have been measured in the shorter millimeter wave region. The B_O values obtained are, in mc/sec: 88,031.9 for $Sb^{121}H_3$, 88,015.5 for $Sb^{123}H_3$, 44,693.3 for $Sb^{121}D_3$, and 44,677.1 for $Sb^{123}D_3$. The observed Sb nuclear quadrupole couplings, eQq, differ for the normal and deuterated forms of stibine and are in mc/sec: for Sb^{121}, 458.7 ± 0.8 mc in SbH_3, and 465.4 ± 0.8 in SbD_3; for Sb^{123}, 586.0 ± 0.8 in SbH_3, and 592.8 ± 0.8 in SbD_3. These couplings lead to the ratio Q^{123}/Q^{121} 1.275 ± 0.003. The Sb nuclear quadrupole moments are estimated to be: Q^{121} -0.8×10^{-24} cm^2, Q^{123} -1.0×10^{-24} cm^2. Significant Sb nuclear magnetic coupling was observed for the normal stibine. In SbH_3 the magnetic coupling constant is found to be 0.33 mc/sec for Sb^{121} and 0.18 mc/sec for Sb^{123}. The ratio of these, C^{121}/C^{123} = 1.84, is in good agreement with the known ratio of the nuclear g factors, g^{121}/g^{123} = 1.8465. Slightly different values of the interatomic distances were observed for the normal and deuterated forms. In SbH_3 the SbH distance is 1.707 Å and the HSbH angle is 91°18'. In SbD_3 the SbD distance is 1.702 Å and the DSbD angle is 90°56'. (Contractor's abstract)

MILLIMETER WAVE SPECTRA OF AsH_3 AND AsD_3, by G. S. Blevins, A. W. Jache, and W. Gordy. [1954] [12]p. incl. dtagr. tables. [AFOSR-TN-54-317] (Bound with its Quarterly progress rept. no. 7, Aug. 1, 1954-Nov. 1, 1954; AD 49803) [AF 18(600)-497] AD 49803(b) Unclassified

Also published in Phys. Rev., v. 97: 684-686, Feb. 1, 1955.

The $J = 0 \rightarrow 1$ rotational transitions of AsH_3 and of AsD_3 have been measured in the one to three millimeter wave region. The B_O values obtained are, in mc/sec: 112,468.46 for $As^{75}H_3$ and 57,477.15 for $As^{75}D_3$. The observed nuclear quadrupole coupling, eQq, of As^{75} differs for the two species and is -160.1 ± 0.4 mc/sec for $As^{75}H_3$ and -165.9 ± 0.4 mc/sec for $As^{75}D_3$. Detectable As^{75} nuclear magnetic interaction was found with the magnetic coupling constant A = 0.33 mc/sec for AsH_3 and A = ~ 0.07 mc/sec for AsD_3. From a consideration of previous microwave work on AsH_2D and a consideration of the differences in the bond angles in normal and deuterated stibine, the bond angle in AsH_3 is assumed to be 91°50' and that in AsD_3 is assumed to be 91°30'. These angles, with the observed moments of inertia, yield the value 1.5192 Å for the AsH length and 1.5145 Å for the AsD length. (Contractor's abstract)

ZEEMAN EFFECT IN THE ROTATIONAL SPECTRUM OF NO, by M. Mizushima, J. T. Cox, and W. Gordy. [1954] [22]p. incl. illus. diagr. tables, refs. [AFOSR-TN-54-318] (Bound with its Quarterly progress rept. no. 7, Aug. 1, 1954-Nov. 1, 1954; AD 49803) [AF 18(600)497] AD 49803(c) Unclassified

Also published in Phys. Rev., v. 98: 1034-1038, May 15, 1955.

The Zeeman splitting of the 2 mm wave, $J = 1/2 \rightarrow 3/2$ rotational transition of $N^{14}O^{16}$ in the $^2\pi_{1/2}$ electronic state has been measured with fields of the order of 100 gauss. The observations were made with a waveguide cell coiled between the poles of a Varian magnet. Magnetic field measurements were made with the

electronic resonance of DPPH at frequencies of the order of 300 mc. A general theory of the Zeeman effect with hfs has been developed and applied specifically to $N^{14}O^{16}$. The g-factors for the four states under investigation were found theoretically to be expressed as: $J = 1/2$, $g_c = \alpha$, $g_d = -\alpha$; $J = 3/2$, $g_c = \bar{g} + (2/5)\alpha$, $g_d = \bar{g} - (2/5)\alpha$, where c and d are the lower and upper components of the Λ-type doublet, respectiveiv. This relation was found to hold experimentally with the values, $g = +0.0232$ and $\alpha = +0.0029$. Theoretically, $\bar{g}$ comes from the mixing of $^2\pi_{1/2}$ and $^2\pi_{3/2}$ states, and α comes from that of $^2\pi_{1/2}$ and $^2\Sigma$ states. It was found by the theory, in which the centrifugal force and the spin orbit coupling were taken into account, that the electronic wave function of the two rotational states should be:

$J = 1/2$, $(^2\pi_{1/2}| - 0.0021(^2\Sigma|$; $J = 3/2$, $(^2\pi_{1/2} - 0.0247(^2\pi_{3/2} - 0.0021(^2\Sigma|$. These wave functions give g(theo.) = +0.0228 and α(theo.) = +0.0020, which agree very well with the observed values. The observed g factor in $J = 3/2$ state, $\bar{g} = 0.0232$ Bohr magnetrons shows that in the supposedly "nonmagnetic" $^2\pi_{1/2}$ state the NO molecule has a sizeable magnetic moment. CENTRIFUGAL DISTORTION IN THE METHYL HALIDES (Abstract), by J. T. Cox, W. J. O. Thomas, and W. Gordy. [1954] [1] p. [AF 18(600)497] Unclassified

Presented at meeting of the Amer. Phys. Soc., Knoxville, Tenn., Apr. 1-2, 1945.

Published in Phys. Rev., v. 95: 299, July 1, 1954.

The extension of the workable millimeter wave region (W. C. King and W. Gordy, Phys. Rev., v. 90: 319, 1953) has made possible measurements of high J transitions in the methyl halides, where centrifugal distortion displacements of rotational lines amount to many mc. High J transitions of these substances have been measured for a more accurate evaluation of the distortion constants. The new D_j value for CH_3Cl^{35}, 18.0 ± 0.5 kc, is in good agreement with the value of 18.4 mc, theoretically predicted by Chang and Dennison (Jour. Chem. Phys., v. 21: 1293, 1953). Earlier measurements (Phys. Rev., v. 80: 338, 1950) on lower J transitions gave $D_j = 26.4$ kc. (Contractor's abstract)

LINE WIDTH OF ROTATIONAL SPECTRA OF SOME SYMMETRIC TOP MOLECULES DUE TO NUCLEAR QUADRUPOLE MOMENTS, by T. Ito, Y. Tanabe, and M. Mtzushima. [1954] [7]p. incl. tables, refs. [AF 18(600)497] Unclasstfted

Published in Phys. Rev., v. 93: 1242-1248, Mar. 15, 1954.

The hyperfine structure of rotational spectra ts sometimes so complicated that it cannot be analyzed eastly. In many other cases it is difftcult to resolve the hfs and the whole spectrum ts observed as a somewhat broad stngie line. In these cases the ltne width or the mean-square frequency devtation may have a more practical stgniftcance. Explicit formulas are given for the mean-square frequency devtation as a function of the nuclear quadrupole coupling constant and the quantum numbers I, J, K. Thus by means of these formulas we shall be able to obtain the nuclear quadrupole coupling constant from the ltne width of the rotational line wtthout analyztng hfs. Calculations were made on symmetric top molecules which have one or thrce tdentical nuclei with electric quadrupole moments. The effect of other nuclei which have electrtc quadrupole moments can be eastly taken into account. The method of separating the present ltne wtdth from that of the pressure broadening and thai due to the centrtfugal dtstortion ts discussed. (Contractor's abstract)

MICROWAVE SPECTRUM OF O_2, by M. Mtzushtma and R. M. Hill. [1954] [4]p. incl. dtagr. tables, refs. [AF t8(600)497] Unclassifted

Published in Phys. Rev., v. 93: 745-748, Feb. t5, t954.

Twenty-four ltnes of the microwave spectrum of oxygen molecule have been carefully measured. The theoretical origin of thts spectrum is reexamined and the effect of centrifugal distortton ts taken into account. The agreement between theory and experiment ts satisfactory. It is pointed out that this spectrum is not suitable to determtne the velocity of ltght. (Contractor's abstract)

MILLIMETER WAVE SPECTRUM OF ARSINE (Abstract), by A. W. Jache, G. S. Blevins, and W. Gordy. [1954] [t]p. [AF 18(600)497] Unclassified

Presented at meeting of the Amer. Phys. Soc., Knoxville, Tenn., Apr. 1-2, 1954.

Published in Phys. Rev., v. 95: 299, July 1, 1954.

The 0→1 rotational transition of arsine has been measured at 2.61 mm wavelength, and a B value of 57,476.15 ± 0.1 mc has been obtained. The nuclear quadrupole coupling of As^{75} was found to be −165.6 mc, in good agreement with the earlier value (C. C. Loomis and M. W. P. Strandberg, Phys. Rev., v. 81: 798, 1951) −164 obtained for AsH_2D. Similar measurements on AsH_3 are betng made. (Contractor's abstract)

RELATION OF NUCLEAR QUADRUPOLE COUPLINGS TO THE CHEMICAL BOND, by W. Gordy. Aug. 1954 [2]p. incl. diagr. [AF 18(600)497] Unclassified

Published in Jour. Chem. Phys., v. 22: 1470-1471, Aug. 1954.

This communication asserts that the difficulty of the large asymmetry parameters of I_2 has been cleared up without the requirement of s hybridization, and that the ionic character electronegativity relation, ionic character $\approx \frac{|x_A - x_B|}{2}$, obtained from quadrupole coupling with the assumption of no s hybridization of the Hal orbitals seems to be borne out by recent experimentation. The Heitler-London theory is discussed, and the Schatz application of it is criticized.

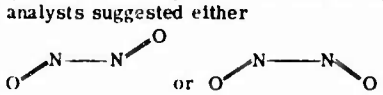
THE STRUCTURE OF THE NITRIC OXIDE DIMER, by W. J. O. Thomas. [1954] [4]p. (Bound with its Quarterly progress rept. no. 5, Feb. 1, 1954-May 1, 1954; AD 31816) [AF 18(600)497] AD 31816(c) Unclassified

Also published in Jour. Chem. Phys., v. 22: 1267-1268, July 1954.

A discusston is presented of the structure of $(NO)_2$ as suggested by the IR and Raman spectra of liquid and soltd NO (Jour. Chem. Phys., v. 19: 189, 1951). The spectral analysts suggested either



as the structural formula, but this was not conftrmed by x-ray dtffractton studies which appeared to favor a rectangular structure:

The x-ray data and the fact that there appears to be no frequency in the IR or Raman spectrum corresponding to ν(NN) is considered as almost conclusive evidence against the ONNO-type structure. Based on a consideration of the nature of the electronic bonds of the rectangular structure, the suggestion is made that each O and N atom has associated with it one σ-bond, 2 localized π-bonds, and a one-electron π-type bond so that each atom is quadrtvalent.

THEORY OF THE HYPERFINE STRUCTURE OF NO MOLECULE [1], by M. Mizushima. [1954] [24]p. incl. diagrs. tables, refs. (Bound with its Quarterly progress rept. no. 5, Feb. 1, 1954-May 1, 1954; AD 31816) (AF 18(600)497) AD 31816(a) Unclassified

Also published in Phys. Rev., v. 94: 569-574, May 1, 1954.

The theory of the hyperfine structure of the NO molecule due to the magnetic moment and the electric quadrupole moment of the N nucleus is analyzed. By assuming that the electron which is rotating around the molecular axis is in the pure p-state, some relations between coupling constants were derived and were found to agree with experimental relations. The derivation assumed that the spin is strongly coupled to the molecular axis; in this case, the molecular magnetic moment is parallel to the molecular axis and has the magnitude $\beta\lambda + 2\beta\Sigma$, where λ and Σ are the components of the electronic orbital and spin angular momentum, respectively, along the molecular axis and β is the Bohr magneton. The formula of the nuclear electron quadrupole effect was derived for this case and also for a general coupling case. This electric quadrupole effect was different for λ-type doublet states. The difference appeared for every coupling case including the case where the spin was strongly coupled to the molecular axis. Satisfactory agreement was obtained between the theoretical and experimental results.

ONE-TO-TWO MILLIMETER WAVE SPECTRA OF TCl AND TBr, by C. A. Burrus, W. Gordy and others. [1954] [14]p. incl. diagrs. tables, refs. [AFOSR-TN-55-28] (Bound with its Quarterly progress rept. no. 8, Nov. 1, 1954-Feb. 1, 1955; AD 54864) [AF 18(600)497] AD 54864(d) Unclassified

Also published in Phys. Rev., v. 97: 1661-1664, Mar. 15, 1955.

The $J = 0 \rightarrow 1$ rotational transitions of TCl and TBr have been measured at 1.36 mm and 1.74 mm. wavelength respectively. These measurements, with r_e and D from infrared data, yield the following constants:

For tritium chloride:

	TCl^{35}	TCl^{37}
$\nu_0(0\rightarrow1)$	222,143.78 ± 0.4 mc/sec	221,195.40 ± 0.4 mc/sec
B_0	111,075.76 mc/sec	110,601.53 mc/sec
B_e	112,032.0 mc/sec	111,550.6 mc/sec
r_0	1.28003 A	1.28002 A
r_e	1.27456 A	1.27456 A
$eQq_1(Cl)$	67.0 ± 0.6 mc/sec	53.0 ± 0.6 mc/sec

DUK. 03:042 - DUK. 03:046

For tritium bromide:

	TBr^{79}	TBr^{81}
$\nu_0(0\rightarrow1)$	172,499.05± 0.3 mc/sec	172,343.23± 0.4 mc/sec
B_0	86,252.24 mc/sec	87,174.33 mc/sec
B_e	86,947.2 mc/sec	86,868.8 mc/sec
r_0	1.42012 A	1.42011 A
r_e	1.41443 A	1.41442 A
eQq(Br)	530 ± 2 mc/sec	443 ± 2 mc/sec

From the TBr measurements and similar measurements on DBr made previously in this laboratory the mass ratio $\frac{m_T}{m_D}$ = 1.49747 was obtained. (Contractor's abstract)

THE VARIATION OF LINE WIDTH WITH ROTATIONAL STATE AND TEMPERATURE IN THE MICROWAVE SPECTRUM OF OCS, by R. S. Anderson. [1954] [29]p. incl. diagrs. tables, refs. [AFOSR-TN-55-29] (Bound with its Quarterly progress rept. no. 8, Nov. 1, 1954-Feb. 1, 1955; AD 54864) (AF 18(600)-497) AD 54864(c) Unclassified

Also published in Phys. Rev., v. 97: 1654-1660, Mar. 15, 1955.

The earlier measurements on the self-broadening of OCS rotational transitions by Johnson and Slager have been extended. Measurements have been made on seven rotational transitions in the ground vibrational state from J = 3→4 to J = 15→16 at room temperature, as well as several at dry-ice temperature. The data have been interpreted by assuming a constant contribution to line width from dipole-dipole interactions and an additional contribution from rotational resonance interactions. According to this interpretation the observed line widths, $\Delta\nu$ follow the law $\Delta\nu = 6.0 + 0.0288(J + 1)(2J + 1)e^{-hBJ(J+1)/KT}$ mc/sec at 1-mm Hg pressure. The collision diameters for OCS are found to be approximately linear functions of the rotation state. The microwave collision diameters are greater than those determined by the kinetic theory. PARAMAGNETIC RESONANCE OF X-IRRADIATED TEFLON - EFFECTS OF ABSORBED OXYGEN, by W. B. Ard, H. Shields, and W. Gordy. [1955] [5]p. incl. diagr. [AFOSR-TN-55-231] (Bound with its Quarterly progress rept. no. 10, May 1, 1955-Aug. 1, 1955; AD 70063) [AF 18(600)497] AD 70063(b) Unclassified

Also published in Jour. Chem. Phys., v. 23: 1727-1728, Sept. 1955.

Examination of the 9-kmc resonance of Teflon samples immediately after x-irradiation at room temperature showed a structure consisting of 8 symmetrical

components with an additional resonance superimposed near the center of the group which did not fit into the symmetrical pattern. The resonances of samples that were then aged for several days in nitrogen or in a vacuum were found to represent the same structure as immediately after irradiation; however, samples that were aged in air or oxygen for the same time had only the strong central absorption remaining, the superimposed resonance appearing to have "swallowed up" its neighbors. These results strongly indicated that the central resonance was the result of the absorbed oxygen. A relatively wide resonance, with some evidence of unresolved structure, was observed with Teflon at 90°K.

MICROWAVE SPECTROSCOPY OF BIOLOGICAL SUBSTANCES. I. PARAMAGNETIC RESONANCE IN X-IRRADIATED AMINO ACIDS AND PROTEINS, by W. Gordy, W. B. Ard, and H. Shields. [1955] [30]p. incl. diagrs. [Technical rept. no. 2] [AFOSR-TN-55-323] (Bound with its Quarterly progress rept. no. 11, Aug. 1, 1955-Nov. 1, 1955; AD 79522) (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)497] and Office of Ordnance Research) AD 79522(b) Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 41: 983-996, Nov. 15, 1955.

A wide-scale investigation is being made of the radiation damage to biologically significant substances through direct observation with microwaves of the free radicals which are produced by the x-irradiation. Preliminary results are given for several amino acids, nucleic acids, and proteins. In all the biological substances examined at 9 and 23 kmc, a g factor was obtained which is very close to that for the free electron spin. This indicated almost complete quenching of the orbital momentum. A complex structure was observed in almost all samples. All the nuclear interactions which were observed in the amino acids were identified as arising from interactions with H nuclei. Resonance in these proteins appeared to arise predominantly from their cystine constituent. Results suggest that ionization will leave a plus charge on N or even on O before it will sever a C-H or C-C bond unless highly symmetrical radicals can be formed which permit stabilization through resonance, or the spreading of the wave function of the odd electron. The electron-resonance mechanisms may partially account for the protection to living matter provided by fibrous proteins such as hair and hide. The mechanisms do not allow proteins to hold together or heal wounds which are inflicted by stronger radiations which break up entire atoms. Preliminary nucleic acid studies also indicate strong effects of O. (ASTIA abstract)

MICROWAVE SPECTROSCOPY OF BIOLOGICAL SUBSTANCES. II. PARAMAGNETIC RESONANCE IN X-IRRADIATED CARBOXYLIC AND HYDROXY ACIDS, by W. Gordy, W. B. Ard, and H. Shields. [1955] [20]p. incl. diagrs. [Technical rept. no. 3] [AFOSR-TN-55-324] (Bound with its Quarterly progress rept. no. 11, Aug. 1, 1955-Nov. 1, 1955; AD 79522) (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)497] and Office of Ordnance Research) AD 79522(c) Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 41: 996-1004, Nov. 15, 1955.

Microwave methods which were described previously were applied to fatty acids which contain a carboxylic head, COOH, and a hydrocarbon tail (R). A comparison of irradiated samples of AcOH and Me_2CO indicated that Me_2CO has the same sharp lines and 30-gauss spread at 77°K that AcOH has when warmed. The $(CH_2CO)^+$ radical in Me_2CO apparently tumbles about sufficiently at 77°K to average out the direct dipole-dipole interaction which was postulated to explain the increase in the spacings and line widths of the triplet of AcOH. HCOOH, when irradiated and immediately observed at 77°K, showed a doublet of about a 12-gauss separation. A quartet with a total spread of 80 gauss was observed for palmitic and propionic acids. $(COOH)_2$ after irradiation for several hr gave only a barely detectable, apparently single resonance. Glycolic acid gave a pair of doublets which are not of equal intensity, and which may arise from 2 different radicals. Citric acid resonance has a strong doublet with a separation of about 12 gauss. Pyruvic acid gave a doublet with the weak shoulders characteristic of direct dipole-dipole interaction of the electron with 1 proton in a polycrystalline material. Lactic acid gave a quintet structure of an 83- x 7-gauss spread almost like that of alanine. X-irradiated lauric and

DUK. 03:050 - DUK. 03:053

stearic acids indicated the presence of more than 1 radical with proton coupling. The over-all results indicate that caging is an important factor in determining the effects of radiation on molecules in solids. (ASTIA abstract)

THE QUADRUPOLE SPECTRUM OF $BiCl_3$, by H. G. Robinson. [1955] [20]p. incl. diagrs. tables, refs. [Technical rept. no. 5] [AFOSR-TN-55-326] (Bound with its Quarterly progress rept. no. 11, Aug. 1, 1955-Nov. 1, 1955; AD 79522) [AF 18(600)497] AD 79522(e) Unclassified

Also published in Phys. Rev., v. 100: 1731-1734, Dec. 15, 1955.

Pure nuclear quadrupole resonance absorptions were observed for Bi^{209}, Cl^{35}, and Cl^{37} nuclei in polycrystalline $BiCl_3$ at both room and liquid air temperatures. Line assignments and the evaluation of the electric-field-gradient asymmetry parameter η allow the following coupling constants to be calculated: $|eQq|_{Bi} = 318.76$ mc/sec for $\eta = 0.555$; $|eQq|_{Cl^{35}} = 30.196$ mc/sec, 38.310 mc/sec. Two "forbidden" $|\Delta m| = 2$ transitions were observed. A brief discussion of the data in connection with chemical bonding in the solid is given. The Cl resonances indicated 2 nonequivalent positions in the unit cell. The line widths and intensities indicate approximately equal numbers 1:1, or 1:2, of Cl nuclei in each of the positions at room and liquid air temperatures. The low value of the Cl coupling indicates an ionic character of about 65% for the BiCl bonds.

THE MAGNITUDE OF THE SPLITTING OF THE LOWEST LEVEL IN CHROMIUM ALUM, by P. H. E. Meijer. [1955] [4]p. [Technical rept. no. 6] [AFOSR-TN-55-415] (Bound with its Quarterly progress rept. no. 11, Aug. 1, 1955-Nov. 1, 1955; AD 79522) [AF 18(600)497] AD 79522(f) Unclassified

Also published in Phys. Rev., v. 100: 742, Oct. 15, 1955.

The energy difference between the 2 doubly degenerate states of the lowest level in Cr alum is expressed as: $\delta = c\,\Delta\lambda^2/(h\nu_c)^2$, where λ is the spin orbit coupling constant; $h\nu_c = 15\bar{Q}$, the distance between the levels Γ_2 and Γ_5 caused by the cubical field; and $\Delta = (15/2)\bar{a}$, the strength of the cylindrical field which is expressed in the splitting of Γ_5 because of this field. The numerical constant c is 152/9, which is about twice that found by Van Vleck (Jour. Chem. Phys., v. 7: 71, 1939). The parameters $\bar{a}$ and $\bar{Q}$ are the radial averages of the coefficients a and Q in the Hamiltonian of the electrical field: $H_{el} =$

$Q(r)\left\{(10)^{1/2}(Y_4^3 - Y_4^{-3}) + (Y)^{1/2}\,Y_4^0\right\} + aY_2^{-0}$. The relations between splitting and field strength are: $\delta = (15/2)\bar{a}$ and $h\nu_c = 15\bar{Q}$. The value of $\bar{Q}$ is practically unchanged, but $\bar{a}$ becomes $552\,\delta\ cm^{-1}$. These results disagree with those of Broer (Physica, v. 9: 547, 1942) (Contractor's abstract)

SUPERCONDUCTIVITY AT MILLIMETER WAVE FREQUENCIES, by G. S. Blevins, W. Gordy, and W. M. Fairbank. [1955] [10]p. incl. diagrs. [Technical rept. no. 1] [AFOSR-TN-55-417] (Bound with its Quarterly progress rept. no. 11, Aug. 1, 1955-Nov. 1, 1955; AD 79522) (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)497] and Office of Ordnance Research) AD 79522(a) Unclassified

Also published in Phys. Rev., v. 100: 1215-1216, Nov. 15, 1955.

The energy gap between the superconducting and normal states was measured for Sn at wavelengths of 2, 2.5, 3, and 4 mm (77 kmc to 150 mc) by a refined millimeter-wave technique which was developed by King and Gordy (Phys. Rev., v. 90: 319, 1953 and v. 93: 407, 1954). Preliminary results indicated that the effective energy gap increases as the temperature is decreased below the critical temperature (T_c). A value of 77 kmc or 3.9 mm was obtained for the maximum gap at 3.72°K, at which the superconductivity becomes complete. At lower temperatures, the effective

gap is greater than at 3.72° K. A comparison of the value R/R_N, where R is the absolute value of the surface resistance and R_N is the value of the resistance in the normal state, with values at longer wavelengths (Advances in Electronics and Electron Physics, v. 6: 1-45, Academic Press, N. Y., 1954) suggests that R may not become zero at absolute zero for the frequencies from 77 kmc to 150 mc. (ASTIA abstract)

THEORY OF THE HYPERFINE STRUCTURE OF THE NO MOLECULE. II. ERRATA AND SOME ADDITIONAL DISCUSSION, by C. C. Lin and M. Mizushima. [1955] [5]p. incl. tables, refs. [AF 18(600)497] Unclassified

Published in Phys. Rev., v. 100: 1726-1730, Dec. 15, 1955.

A theoretical formula for the magnetic hfs of diatomic molecules previously given by one of us (M. M.) is revised by including the Fermi term and correcting an error in the choice of phase. The new formula gives $eQq = -1.7$ mc/sec and $eQq' = 22$ mc/sec for the $^2\Pi$ state of the NO molecule. It was found that these constants together with the values $a = 23.14$ mc/sec, $b = 14.056$ mc/sec, for the parameters of the magnetic hfs, defined in the first paper give theoretical frequencies which explain not only $1/2 \rightarrow 3/2$ spectra but also the $3/2 \rightarrow 5/2$ transitions of the $^2\Pi_{1/2}$ state. A discussion on the theory of the magnetic resonance spectrum of the $^2\Pi_{3/2}$ state is also given. (Contractor's abstract)

MILLIMETER AND SUBMILLIMETER WAVE SPECTROSCOPY, by C. A. Burrus and W. Gordy. [1956] [22]p. incl. diagrs. tables. [AFOSR-TN 56-74] (Bound with its Quarterly progress rept. no. 12, Nov. 1, 1955-Feb. 1, 1956; AD 91509) [AF 18(600)-497] AD 91509(a) Unclassified

Also published in Phys. Rev., v. 101: 599-602, Jan. 15, 1956.

Rotational lines of several linear molecules have been measured with high precision in the region of 0.8- to 2.0-mm wavelength. The energy source for this region is a Si crystal multiplier driven by a cm wave klystron. A Si crystal was also used as the detector. An evacuated bolometer detector was developed for the 3-mm wave region and was used to detect rotational lines down to 2.0 mm. Although its sensitivity is lower than that of the crystal detector, the bolometer will be useful for absolute power measurements in the shorter mm region. (Contractor's abstract)

BOLOMETER DETECTION OF NUCLEAR QUADRUPOLE RESONANCE, by H. G. Robinson. [1956] [6]p. incl. diagrs. [AFOSR-TN-56-75] (Bound with its Quarterly progress rept. no. 12, Nov. 1, 1955-Feb. 1, 1956; AD 91509) [AF 18(600)497] AD 91509(c) Unclassified

Also published in Rev. Scient. Instruments, v. 27: 163-164, Mar. 1956.

The possibility of using bolometer detection for quadrupole resonance is investigated. Preliminary results in the 30 cm region indicate that such a detection method can be made to operate easily and at a sensitivity comparable to conventional regenerative detectors. Scaling to other frequencies should be possible without the difficulties encountered in regenerative and superregenerative detectors. (Contractor's abstract)

ZEEMAN EFFECT OF SOME LINEAR AND SYMMETRIC-TOP MOLECULES, by J. T. Cox and W. Gordy. [1956] [13]p. incl. diagrs. tables. [AFOSR-TN-56-76] (Bound with its Quarterly progress rept. no. 12, Nov. 1, 1955-Feb. 1, 1956; AD 91509) [AF 18(600)-497] AD 91509(h) Unclassified

Also published in Phys. Rev., v. 101: 1298-1300, Feb. 15, 1956.

The Zeeman effect in the microwave rotational spectra of some linear molecules and symmetric-top molecules has been investigated. The rotational g factors obtained are in nuclear magnetons: $|g| = 0.0295 \pm 0.005$ for OCS; $|g| = 0.268 \pm 0.005$ for CO. In the symmetric-top molecules, the components of the rotational g factor along the symmetry axis, g_K, and perpendicular to

DUK. 03:059 - DUK. 03:062

this axis, $g_\perp$, were measured as follows: $|g_\perp|$ = 0.0624 ± 0.005 and $(g_\perp - g_K)$ = 0.549 for CH_3F; $|g_\perp|$ = 0.03 for CF_3H; $g_\perp \approx 0$ and g_K = 0.293 ± 0.006 for CH_3CCH; $g_\perp \approx 0$ and g_K = 0.31 ± 0.01 for CH_3CCD; $|g_\perp|$ = 0.065 ± 0.01 for PF_3; $|g_\perp|$ = 0.03 for POF_3. The rotational g factor for OCS was measured with several different transitions up to J = 13 ⟶ 14, and was found to be a constant, independent of J within the accuracy of the measurements. Also published in Jour. Amer. Chem. Soc., v. 78: 3240-3243, July 20, 1956.

Microwave magnetic resonance has been employed to study the effects of ionizing x-rays on some simple alcohols, amines, amides, and mercaptans in the solid state. The proton hyperfine structure of the electron spin resonance allows fairly definite identification of the radicals produced in certain of these. For example, MeOH, acetamide, and sodium methoxide appear to form the radical $(CH_2)^+$, which could be attached to some other molecule or group provided that the group has no nuclei which could interact with the electron spin. EtOH and propionamide appear to form the radical $(C_2H_4)^+$. Such radicals are not formed by the sulfur compounds, and it is believed that the odd electron (electron vacancy) in these compounds remains on the S atom or atoms. (Contractor's abstract)

MILLIMETER WAVE SPECTRUM OF FORMALDEHYDE, by G. Erlandsson. [1956] [4]p. incl. table. [AFOSR-TN-56-369] (Bound with its Quarterly progress rept. no. 14, May 1, 1956-Aug. 1, 1956; AD 87515) (AF 18(600)497) AD 87515(c)
Unclassified

Also published in Jour. Chem. Phys., v. 25: 579-580, Sept. 1956.

The rotational constants of $H_2C^{13}O$ were studied by measuring the transitions J = 1 ⟶ 2 and 2 ⟶ 3 at about 2 and 1.3 mm wavelength, respectively. The center frequencies of the K-1 pairs were fitted with a symmetric top approximation for the centrifugal distortion. The following values were obtained by the method of least squares: B + C 72,838.44 mc, $(B - C)^2 + 0.5^2$ 94.90 mc, D_J 0.0826 mc, and D_{JK} 1.311 mc. The assumption that the 0 ⟶ 1 transition is only very slightly influenced by

centrifugal distortion as reported by Lawrence and Strandberg (Phys. Rev., v. 83: 363, 1951) was confirmed.

MILLIMETER WAVE SPECTRUM OF FORMIC ACID, by G. Erlandsson. [1956] [6]p. incl. tables. [AFOSR-TN-56-495] (Bound with its Quarterly progress repl. no. 14, May 1, 1956-Aug. 1, 1956; AD 87515) (AF 18(600)497) AD 87515(b) Unclassified

Also published in Jour. Chem. Phys., v. 25: 379, Aug. 1956.

All type a R-branch transitions of HCOOH up to $J = 5$ were measured. The results on the $1 \longrightarrow 2$ transitions agree within the limits of error with those reported by Lerner, Friend, and Dailey (Jour. Chem. Phys., v. 23: 210, 1955) An attempt was made to fit the centrifugal distortion of the lines with a symmetric-top formula: $\nu = \nu_0 - 4D_J(J+1)^3 - 2D_{JK}(J+1)K^2$, where ν_0 is the rigid rotor frequency. The center frequencies of the pairs were determined completely by 4 constants. The values of these constants are: $(B+C) = 22,471.26$ mc, $(B-C)$ $(\quad - 0.5^2) = 40.327$ mc, $D_J = 0.0116$ mc, and $D_{JK} = 0.089$ mc. The accuracy of the reduced frequencies was apparently about ± 0.1 mc. (Extracted from rept.)

ELECTRON-SPIN RESONANCE IN X-IRRADIATED HORMONES AND VITAMINS (Abstract), by H. N. Rexroad and W. Gordy. [1956] [1]p. [AF 18-(600)497] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C. Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 200, Apr. 26, 1956.

Electron-spin resonance of the resulting unpaired electrons is being used to evaluate the effects of ionizing radiations on various hormones and vitamins. The resonance obtained of progesterone is a triplet similar to that of glycine, and is believed to arise from the $(CH_2)^+$ radical, probably bonded to some other group with no coupling nuclei. Parathyroid gave a doublet resonance of 15 gauss separation similar to that of certain proteins. Hexestrol gave no detectable resonance after prolonged irradiation. Vitamin A, vitamin K-5, and biotin gave only single broad resonances. Ascorbic acid gave a doublet of 20 gauss spacing with a weaker resonance superimposed. The g-factors are all very close to the value for the free electron spin. Other similar substances are under investigation. (Contractor's abstract)

ELECTRON-SPIN RESONANCE IN X-IRRADIATED SUGARS AND CELLULOSE FIBERS (Abstract), by H. Shields, W. B. Ard, and W. Gordy. [1956] [2]p. [AF 18(600)497] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 200, Apr. 26, 1956.

Electron-spin resonance of the resulting unpaired

electrons has been used for study of the effects of ionizing radiations on various sugars and cellulose fibers. The spin resonance pattern most often observed is a doublet of the order of 10 to 20 gauss separation. Some sugars including ribose, gave only a single, fairly sharp resonance. X-irradiated lactose gave a quartet hyperfine structure which may arise from the CH_3 radical. Like the similar ones observed in certain other hydrogen-bonded material, the doublet resonances are believed to arise from electrons localized on oxygens which are involved in hydrogen bridges and which interact mainly through dipole-dipole coupling with the bridging proton. Similar doublets were observed for various x-irradiated woods and cell walls of plants. Purified cellulose, also cotton fiber, gave a more complex structure which, however, may be superposition of similar doublets separated slightly by crystalline field effects. (Contractor's abstract)

MICROWAVE DETECTION OF METALLIC IONS AND ORGANIC RADICALS IN PLANT MATERIALS, by H. Shields, W. B. Ard, and W. Gordy. [1956] [2]p. incl. diagrs. (Sponsored jointly by Office of Ordnance Research and Office of Scientific Research under [AF 18(600)497]) Unclassified

Published in Nature, v. 177: 984-985, May 26, 1956.

The 6-line electron-magnetic resonance hyperfine structure of Mn was found for untreated samples of numerous plant substances. The structure was identical with that found for Mn in aqueous solution. A sharp resonance with a g factor of 2.00 was attributed to bound or semibound oxygen and was most intense with dried samples. A broad resonance with a g factor of 2.06 which was found with some samples was attributed to Cu ions, possibly indicating occasional substitution of Cu for Mn in the chlorophyll.

EFFECTS OF TEMPERATURE AND ISOMERIC STRUCTURE ON THE ELECTRON-SPIN RESONANCE OF X-IRRADIATED AMINO ACIDS (Abstract), by W. Gordy and H. Shields. [1956] [1]p. [AF 18(600)497] Unclassified

Presented at meeting of the Amer. Phys. Soc., Nashville, Tenn., Mar. 29-31, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 267, June 21, 1956.

At the temperature of liquid nitrogen the paramagnetic resonance patterns of x-irradiated glycine, valine, and leucine become more complex and less resolvable than those which have been observed at room temperature. These changes may indicate the quenching of certain types of motions which at room temperature tend to reduce anisotropic interactions, or they may indicate structural changes in the radicals themselves or in their immediate surroundings. The only noticeable effect of cooling to 77°K on the alanine quintet is almost to equalize the intensities of the five components. The reason for this strange effect is not evident. Samples of irradiated alanine and glycine were heated to temperatures near their melting point without destruction of their resonances. Preliminary evidence indicates that it is much more difficult to produce resonances in alanine when it is irradiated at liquid air temperature than when irradiated at room temperature. Other amino acids and proteins are being investigated for this effect which suggests that temperature may have an important effect on radiation damage. Noticeable difference in the effects of ionizing radiations has been detected for different isomeric forms of leucine: DL-leucine gives a sextet hyperfine structure; DL-isoleucine, a symmetrical seven-component structure; L(—) — leucine, a triplet with shoulders like the pattern for irradiated glycine. In contrast, the patterns obtained for D- and L-alanine are alike. Other isomeric forms are under investigation. (Contractor's abstract)

ELECTRON-SPIN RESONANCE OF X-IRRADIATED NUCLEIC ACIDS (Abstract), by H. Shields and W. Gordy. [1956] [1]p. [AF 18(600)497] Unclassified

Presented at meeting of the Amer. Phys. Soc., Nashville, Tenn., Mar. 29-31, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: June 21, 1956.

Electron spin resonances have been observed of the nucleic acids and certain of their constituents after x-irradiation. The resonances of DNA and RNA are similar and consist of a strong component of g factor 2.00 and a weak satellite. Some of their constituents gave more complex resonances. The resonance of thymidine, for example, has a proton hyperfine structure structure of 7 components. That of guanosine is a triplet with broad components suggesting further unresolved structure. Guanylic acid exhibits a triplet immediately after irradiation, but upon exposure to air the triplet is slightly converted to a singlet. Adenosine, also muscle adenylic acids, gave a strong central component with weak side lobes. Cytidine, cytidylic acid, adenosine, and inosine gave only single resonances with g factors of 2.00. These resonances are being investigated further under different physical conditions in the hope of finding out something of the mechanism of radiation damage to the cell nucleus. REVERSE THRUST, VERTICAL LIFT, AND JET SLIDE FORCE BY MEANS OF CONTROLLED JET-DEFLECTION, by L. Meyerhoff and S. Meyerhoff. Jan. 1956, 53p. incl. diagrs. tables, refs. (AFOSR-TN-56-168) (AF 18(600)1530) AD 86589 Unclassified

Forces obtained by deflection of the propulsive jet are investigated as a possible means for augmenting the control of jet aircraft. Emphasis is given to its use at low speeds. Jet aviation is faced, seemingly, with a low-speed "barrier" resulting from the design necessities to fly at sonic speeds. Take-off and landing speeds may exceed cruising speeds of pre-war commercial transports if the trend continues. An important aviation development is reverse thrust produced by deflecting the jet almost 180° forward in order to brake the landing run. Reverse thrusts up to 90% of rated positive thrust have been measured at zero airspeed. For jet-braking at high speeds, the analysis predicts several hundred percent reverse thrust. Various consequences of these values are investigated. Thrust reversal is not the only application of jet deflection. This paper also considers: (a) side forces for jet steering; (b) jet and "forced" lifts to permit flight, below the normal stalling speed; and (c) thrust modulation by jet deflection. APPLICATION OF THE CLOSED-CYCLE PRINCIPLE TO AIRCRAFT PROPULSION SYSTEMS. VOLUME I. CLOSED CYCLE AIRCRAFT PROPULSION SYSTEMS, by R. Tognoni and W. Spillman. Final technical rept. July 21, 1956 [138]p. incl. diagrs. tables. (Rept. no. Sp-AK-56-027; Z no. 5-862-563) (AFOSR-TR-56-45) (AF 61(514)854) AD 97087 Unclassified

Various configurations of a closed-cycle gas turbine driving ducted fans were investigated. Three possible air (or gas) heater arrangements were considered. One was built into jet engine combustion chamber; another was built into an afterburner in ducted fan airflow; and a third was a gas cycle nuclear reactor. The air (gas) cooler was in the ducted fan airflow in all cases. A complete powerplant with airheater in J 47 combustion chamber was laid out. At design point (Mach 0.85 at 40,000 ft), the specific fuel consumption (1.08) is comparable with modern jet engines, but the specific weight is high, partly due to the low turbine inlet temperature (1480°F) enforced by the air-heater. Various heat exchanger types were studied theoretically, and (cold) drag tests on various cross-flow tube banks were run. Actual designs of light weight air coolers and of air heaters for closed cycle engines were carried out. Driving of boundary layer suction fans with the closed-cycle gas turbine was investigated in a preliminary way, also the feasibility of a closed-cycle high altitude aircraft accessory powerplant. The combination of closed cycle driven ducted fan with gas cooled nuclear reactor appears most promising. The performance of this powerplant was calculated (up to Mach 2.0 at 40,000 ft), the size of the components and the weight estimated. A potential superiority over other nuclear aircraft powerplants in simplicity, safety and possible in specific weight became apparent. (Contractor's abstract, modified)

APPLICATION OF THE CLOSED-CYCLE PRINCIPLE TO AIRCRAFT PROPULSION SYSTEMS. VOLUME II. CLOSED CYCLE AIRCRAFT PROPULSION SYSTEMS, by R. Tognoni and W. Spillman. Final technical rept. July 21, 1956, 1v. incl. illus. diagrs. tables. (Rept. no. Sp-AK-56-027; Z no. 5-862-564) (AFOSR-TR-56-46) (AF 61(514)854) AD 97088 Unclassified

A propulsion system was studied which consisted of a heat source, a closed-cycle (cc) plant to generate mechanical energy, a ducted fan as a propelling device, and a cooling air-blower. A J47GE15 jet engine combustion chamber was assumed as the heat source for the closed-cycle air heater. This system utilized neither a heat-exchanger nor boundary-layer suction. A complete design and general assembly drawings were made for a nonregenerative ducted-fan unit which

ESC. 01:003 - ESC. 01:006

comprised a turbine-compressor cycle machine, a power turbine driving a ducted fan, and a single cooler in the compressed fan air. Design studies indicated that the built-in air heaters in the jet-engine combustion chambers were large and heavy and that the tube-wall temperatures for the air heaters were limited by available tube materials. Higher cc temperatures and air temperatures would allow increased efficiencies. A number of feasible prospects are proposed for self-contained ducted-fan propulsion systems with fossil-fuel heaters and control systems for the cc plant are discussed. Variations in cc-plant output can be accomplished by varying either the turbine inlet temperature or the system pressure level. (ASTIA abstract)

A GENERAL RELATION FOR PRESSURE-DROP AND HEAT TRANSFER FOR COOLERS AND HEAT EXCHANGES, VOLUME IV [PART I], by A. Burgdorfer. [Final technical rept.] July 21, 1956, 11p. (Technical note no. 3; rept. no. Sp-AK-56-030; Z no. 5-862-566) (AFOSR-TR-56-48 [Pt. 1]) (AF 61(514)854) AD 97090 Unclassified

By a rearrangement of the formulas for pressure drop and heat transfer of heat-exchangers and elimination of the friction factor and heat-transfer coefficient of the surfaces, a relation is found, which makes it possible to discuss pressure loss problems of heat-exchangers and coolers. For gases, the pressure loss of heat-exchangers is given as a function of the flow-stream Mach number, the gas properties, the temperatures and the characteristic values of the heat-exchanger surfaces. APPLICATION OF THE CLOSED CYCLE PRINCIPLE TO AIRCRAFT AUXILIARY POWER PLANTS. VOLUME V. COOLING PROBLEM STUDY FOR A SMALL CONSTANT-POWER-OUTPUT CLOSED-CYCLE GAS TURBINE FOR VERY HIGH ALTITUDES AND HIGH FLIGHT-MACH-NUMBERS, by W. Spillman. Final technical rept. July 21, 1956 [23]p. incl. diagrs. (Technical note no. 4; rept. no. Sp-AK-56-025; Z no. 5-862-544) (AFOSR-TR-56-49) (AF 61(514)854) AD 97351 Unclassified

A constant-power output auxilliary plant was considered for an aircraft or missile traveling at a 100,000-ft altitude and M = 4.0. Closed-cycle (cc) power plants are able to work under any ambient pressure and supply a constant power output independent of the density of the surrounding atmosphere. The plants are not independent of the ambient temperature. A heat rate of $Q/N = \frac{1-n}{n}$ is transferred to the ambient air, where n is the thermal efficiency, N is the power output, and Q is the heat flow rate of the heat exchanger. The best and simplest cooling for the circuit cooler of a cc plant is the use of fuel cooling. If liquid fuel is not available, as the nuclear-fired plants, direct-air cooling is possible up to 14-km altitude at M = 2.0. Below 14 km, vaporizing cooling gives smaller plant efficiencies. Next to direct fuel-flow cooling, the vaporizing of water at the cooler surface gives the best cooling at extreme altitudes. A combination of air-cooling for low altitudes and vaporizing cooling for high altitudes gives a nearly constant plant efficiency for the assumed flight conditions. Radiation cooling may be practical for small amounts of heat and in some special cases (high-altitude night flight) for small hot-running components. (ASTIA abstract)

ON THE APPLICATION OF THE MOLECULAR ORBITAL METHOD TO THE SPECTRA OF SUBSTITUTED AROMATIC HYDROCARBONS, by L. Goodman, I. G. Ross, and H. Shull. [1956] [26]p. tncl. diagr. refs. (AFOSR-TN-56-463 [pt. 3]) (Bound with its Technical rept. no. 1; AD 97081) (AF 18(600)678) AD 97081(c) Unclassified

Also published in Jour. Chem. Phys., v. 26: 474-480, Mar. 1957.

The molecular orbital theory of the spectra of substituted hydrocarbons is presented in general terms with necessary precautions noted regarding introduction of inevitable approximations. Prevtous treatments of the problem, notably by Sklar, Herzfeld, and Matsen are discussed; satisfactory calculations of energy-level shifts are considered to need closer attention to the definition and dtssection of the perturbed Hamiltonian. The most interesting intensity effects concern enhancement of weak transitions. Consequences of the earlier treatment, which do not satisfy requirements of orthonormality of the perturbed MO's and neglect interacttons wtth intense transitions, are discussed. THEORY OF SOLVENT EFFECTS ON MOLECULAR ELECTRONIC SPECTRA. FREQUENCY SHIFTS, by E. G. McRae. [1956] [47]p. incl. diagrs. table, refs. (AFOSR-TN-56-463 [pt. 4]) (Bound with its Technical rept. no. 1; AD 97081) (AF 18(600)678) AD 97081(d) Unclasstfied

Also published in Jour. Phys. Chem., v. 61: 562-572, May, 1957.

Electronic band frequency shifts in solution spectra, caused by dipole interactions, are analyzed theoretically and a general expresston for the frequency shift is derived by perturbation theory. The frequency shift is the sum of contributions of dispersive and static dipole tnteractions. The dtsperstve contribution represents the general red shift which is present in all solution spectra and is partially dependent on the weighted mean-wavelength characterlstic of the solveni. In the electrostatic contribution the role of the quadratic Stark effect is emphasized. The tntroduction of a simple electrostaitc model permits the derivation of formulas relating frequency shifts in both emisston and absorption spectra to the refractive index and static dielectrtc constant of the solvent. Illustrative numerical applicattons are descrtbed. (Contractor's abstract, modifted)

RESEARCH IN THE GENERAL FIELD OF THE MECHANISM OF CELLULOSE SYNTHESIS AND DEGRADATION, by G. A. Greathouse, D. E. Barnes, and G. T. Tsao. Final technical rept. Mar. 1, 1954-Feb. 28, 1955. 52p. tncl. dtagrs. iables, refs. [AFOSR-TN-55-9] (AF 18(600)1126) AD 64566 Unclassified

Investigations into the mechanisms of cellulose synthesis and cellulose degradation were conducted, and attention was given to the enzyme and growth characterlstics of Acetobacter xylinum. Twenty-one C^{14}-cellulose membranes were prepared: 12 from 1-C^{14}-D-glucose, and 3 each from 2-C^{14}-D-[dextro]-glucose, 6-C^{14}-D-glucose, and 1,3-C^{14}-glycerol. In the membranes prepared from 1-C^{14}-glucose, when the radioactive glucose was added after the culture was 24 hr old, a shift of 10% was noted in the C^{14} content of posttion 1. This enhances the hypothesis that glucose undergoes a direct polymerization to cellulose. When 1,3-C^{14}-glycerol was used as the only C source, membranes of C^{14}-cellulose were formed as rapidly as from glucose and in simtlar yields, which shows that 3 C compounds can be used effectively by A. xylinum. A method for the degradatton of glucose based on oxidations and the formation of benzimidazole derivatives of the acids was developed, and the step-wise degradation of glucose was initiated. A complete C^{14} balance was carried out on all the membranes prepared, and the CO_2 produced, the residual medium, and the cellulose were all assayed for C^{14}. In experiments on A. xylinum enzymes, resting cells were produced by freeze-drying the cell suspension, but no cell-free enzyme could be prepared. The growth characterlstics of A. xylinum were investigated with respect to pH change, CO_2 formation, and cellulose productton. An informal hypothesis for the mechantsm of cellulose formation is discussed. (ASTIA abstract)

COMPARISON OF MASSES OBTAINED FROM MASS-SPECTROSCOPY AND NUCLEAR REACTION DATA, by D. M. Van Patter. [1956] [18]p. incl. diagrs. tables, refs. [AF 18(600)1320] Unclassified

Published in Proc. Conference on Nuclear Masses and Their Determtnation, Max-Planck Insttitut für Chemie, Mainz (Germany) (July 10-12, 1956), London, Pergamon Press, 1957, p. 143-160.

An examination is made of the general trend of measurements of important masses in the region of ^1H to ^{32}S, and some of the discrepancies and thetr possible sources are considered. It was concluded that in the region below ^{16}O, no obvtous error source could be found which would explain the remaining small discrepancies. It is probable that future small adjustments to both the mass-spectroscopic and nuclear-reaction data will bring the masses into even better agreement. In the case of the masses between ^{16}O and ^{32}S, there are at least 2 places where inconsistencies exist among the present Q values. In addition, because of the fact that most of the nuclear reaction energies have been measured only at the Massachusetts Institute of Technology, Cambridge, it seems likely that a systematic error may be present, which accumulates as higher and higher masses are calculated. Thus some discrepancy results on comparison of these values with the mass-spectroscopic values. Although the calculations of the masses from the nuclear-reaction data have compensated for this systematic error to a degree, it is probable that some remains and should be taken tnto account tn the ftnal errors quoted for the masses. Independent measurements of the Q values tn this region by other laboratories will resolve this question.

NUCLEAR REACTION Q-VALUE MEASUREMENTS MADE RECENTLY AT THE BARTOL RESEARCH FOUNDATION, by D. M. Van Patter, C. E. Mandeville and others. [1956] [10]p. incl. diagrs. tables. [AF 18(600)1320] Unclassified

Published in Proc. Conference on Nuclear Masses and Their Determination, Max-Planck Institut für Chemie, Mainz (Germany) (July 10-12, 1956), London, Pergamon Press, 1957, p. 99-106.

Descriptions of the experimental techniques and equipment utilized in obtaining these nuclear reaction Q-value measurements are given. The ONR-Bartol van de Graaff accelerator provided protons of up to 5 mev. A relative measure of the magnetic field of the spectrometer was obtained by means of a torsion balance, placed at the 90° position of the magnet. A number of energy calibrations were made during the measurements. A daily calibration of the torsion balance was provided by a Po-α source which could be moved into a position at the center of the reaction chamber. The final energy calibrations consisted of observations of several charged-particle groups from Al targets at known bombarding energy. The results of one such bombardment (at an energy of 3.633 mev) are shown for a target 9 kev thick for the $^{27}Al(p, p)$ group, corresponding to a resonance for the $^{27}Al(p, \alpha)\ ^{24}Mg$ group. In order to determine correctly the location of each group, a detailed analysis of the various contributions to the momentum profile of each group was necessary. Knowing the bombarding energy for the observed groups, and taking the Q-values for each group, the calibration constant $K = H\rho \times R$ (where R = reading of the torsion coil current) was calculated and an energy calibration curve was plotted. Having established an energy calibration curve, the Q value for each reaction group was calculated using the relativistic Q equation, and the total error for each group being estimated. Estimates were made of the uncertainties associated with: (a) the location of each particle group; (b) daily calibration of the torsion balance; (c) calculated corrections to the momentum profiles for target thickness, acceptance angle, and resolution; and (d) energy calibration. A table shows the results obtained for the ground-state Q values of the $^{31}P(p, \alpha)$, $^{35}Cl(p, \alpha)$, and $^{37}Cl(p, \alpha)$ reactions. In another table, the weighted average values for the 3 ground-state Q values are compared to the mass spectrographic data of Ogata and Matsuda (1953).

Q-VALUE MEASUREMENTS FOR PHOSPHORUS AND CHLORINE, by D. M. Van Patter, C. P. Swann and others. [1956] [21]p. incl. diagrs. table, refs. [AF 18(600)1320] Unclassified

Also published in Phys. Rev., v. 103: 656-661, Aug. 1, 1956.

Targets containing P and Cl have been bombarded by protons accelerated by the ONR-Bartol Foundation van de Graaff generator. Charged particles from nuclear reactions have been analyzed at 90°, using a 180° double-focussing magnetic spectrometer. The following ground-state Q-values have been determined: $P^{31}(p, \alpha)\ Si^{28}$, Q = 1.911 ± 0.005; $Cl^{35}(p, \alpha)S^{32}$, Q = 1.851 ± 0.007; $Cl^{37}(p, \alpha)S^{34}$, Q = 3.015 ± 0.011 mev. The following level positions have been measured: P^{31} 1.264 ± 0.004; S^{34} 2.129 ± 0.014; Cl^{35} 1.219 ± 0.005; and 1.760 ± 0.004 mev. At E_p = 3.055 mev, a survey was made for inelastic proton groups from P^{31} corresponding to levels from 0 to 1.43 mev excitation. Only 1 group (Q = -1.264 mev) was observed. No other groups were observed with an intensity greater than 15% of the intensity of this group. (Contractor's abstract)

EFFECT OF ORDER ON THE ELECTRICAL RESISTIVITY OF FERROMAGNETIC ALLOYS, by F. J. Donahoe. [1954] [8]p. incl. diagrs. ([AF]OSR-TN-54-358) (AF 18(60)302; continuation of AF 33(038)22698) Unclassified

The behavior of resistivity on ordering will depend on the relative positions of the 2 critical temperatures, the Curie temperature θ_f at which ferromagnetism vanishes and the critical temperature T_c at which long-range lattice order vanishes. The behavior also will depend upon the direction of change of θ_f with order, represented by $\partial\ \theta_f/\partial S$, where S is an order parameter. Four cases are distinguished and are discussed; resistivity-temperature diagrams are shown for each case: (1) $T_c > \theta_f$; $\partial\theta_f/\partial S > 0$. A Fe_3Pt alloy (30 atomic % Pt) is used as an example in the diagram; (2) $\theta_f > T_c$; $\partial\theta_f/\partial S > 0$, illustrated by published $FeNi_3$ data; (3) $T_c > \theta_f$; $\partial\theta_f/\partial S < 0$; and (4) $\theta_f > T_c$; $\partial\theta_f/\partial S < 0$. Diagrams for the latter two cases are schematic. Departures from the ideal behavior pictured may be

expected when the occupancy of the d-shells changes during the ordering reaction.

MAGNETOSTRICTION [PART I], by F. J. Donahoe. Final progress repl. Apr. 10, 1952-Apr. 9, 1953, 8p. incl. diagrs. (Rept. no. F-2306) [AFOSR-TR-54-24] (AF 18(600)302) AD 10832 Unclassified

Five specimens of Fe-Pt alloys containing 20 to 30 atomic % Pt were prepared in rod and wire forms. X-ray studies of the lattice parameters of Ni-Mn alloys of 20 to 30 atomic % Mn showed a linear expansion of the Ni lattice of 0.0028 A/atomic % Mn. In the disordered state, the resistivity (R) was a fairly linear function of both the temperature during the heating cycle from 500° to 1100°K and the composition from 20 to 30 atomic % Mn. Preliminary measurements during the cooling cycle indicated that the temperature of the resistivity anomaly is a monotonic increasing function of Mn content. Some ordering of the alloy was indicated in the temperature range, since the resistance decreased isothermally with time. At the expected ordering temperature about 50° above the observed anomaly, the temperature coefficient of R seemed to become small. The thermal coefficient of expansion of Fe-Pt alloys is sensitive to short-range ordering. (ASTIA abstract)

DEVELOPMENT OF MAGNETOSTRICTIVE AND RELATED MATERIALS, PART II, by F. J. Donahoe. Final progress rept. Apr. 10, 1952-Apr. 9, 1954, 55p. incl. illus. diagrs. tables, refs. (Repl. no. 2306) [AFOSR-TN-54-24a] (AF 18(600)302) AD 41119 Unclassified

Studies were made of the effects of the order-disorder transformation on alloys with compositions near Ni_3Mn, Fe_3Pt, and $FePd_3$. Measurement was made of saturation moment of alloys at low temperatures and of the long-range order parameter. The saturation moment of alloys near $FePd_3$ appears to be unaffected by the degree of order. The Curie temperature on the other hand is strongly influenced in the early stages of ordering. The kinetics of the ordering in Fe_3Pt alloys were studied at temperatures from 450° to 750°C. Resistivity measurements on polycrystalline wires were used to follow the ordering process. The results appear to confirm the general features of the phase diagram as set forth by Kussmann and Rittberg (Metallkunde, v. 41: 470, 1950), with some differences in detail. The ordering process can be fitted to a rate law governed by exp $-(t/\tau)^{1/2}$ with an activation of about 50 kcal/mol. Magnetic studies confirmed the fact that the major portion of the resistivity change observed at 0°C are associated with the rapid increase in ferromagnetic Curie temperature. As in the $FePd_3$ system, major changes in the Curie temperature were noted after very short anneals. Magnetostriction measurements on disordered polycrystalline specimens of the 30.0 atomic % Pt alloy were made. The linear magnetostriction coefficient at room temperature was 49.7×10^{-6} and increased to 83.9×10^{-6} at 80°K. (ASTIA abstract)

PHASE TRANSFORMATIONS IN IRON-PLATINUM ALLOYS NEAR THE COMPOSITION Fe_3Pt, by A. E. Berkowitz, F. J. Donahoe and others. (n.d.) [39]p. incl. illus. diagrs. [AF 18(600)302] Unclassified

The kinetics of the ordering process in Fe-Pt alloys near the composition Fe_3Pt were studied at temperatures ranging from 450° to 750°C. Resistance measurements on polycrystalline wires were used to follow the ordering process. At the annealing temperature resistivity was almost independent of the degree of order. However, the ferromagnetic Curie temperature was found to be strongly influenced by the degree of order. At 0°C the resistivity changes were large and linear in the reduced magnetic temperature, $273°/\theta_f$, where θ_f is the ferromagnetic Curie temperature. The changes in 0°C resistivity produced during anneals below 650°C can be fitted by a rate law governed by exp $-(t/\gamma)^{1/2}$ where γ is temperature dependent with an activation energy of about 2 ev/atom. Quenched alloys containing less platinum than stoichiometric Fe_3Pt were mixed face-centered γ and body-centered α-phase. The temperature at which the transformation $\gamma \rightarrow \alpha$ begins decreases rapidly with the degree of order in the γ-phase. Appreciable changes in the γ-phase Curie temperature and in the $\gamma \rightarrow \alpha$ transformation temperature occur before super-structure lines appear in the x-ray diffraction pattern. This suggests that the effects of short-range order on these properties is comparable to and continuous with the effects of long-range order.

FERROMAGNETISM AND ORDER IN Fe-Pt ALLOYS NEAR Fe_3Pt (Abstract), by A. D. Franklin, A. E. Berkowitz, and E. Klokholm. [1954] 1p. (AF 18-(600)302) Unclassified

Presented at meeting of the Amer. Phys. Soc., Detroit-Ann Arbor, Mich., Mar. 17-19, 1954.

Published in Phys. Rev., v. 94: 1432, June 1, 1954.

The Fe-Pt alloys near the composition Fe_3Pt exhibit an irreversible transition between b.c.c. α- and

FRA. 03:006 - FRA. 04:003

f.c.c. γ-phases. Both are ferromagnetic, but the γ-phase Curie point lies much lower than that of the α-phase. It is known that ordering in these alloys moves the γ-phase Curie point to higher- and the $\gamma \rightarrow \alpha$ transition to lower temperatures, without having an appreciable effect on the $\alpha \rightarrow \gamma$ transition. These ordering effects have been studied in greater detail, using a B-H curve tracer to follow the transitions magnetically. During the irreversible transitions, especially $\alpha \rightarrow \gamma$, isothermal changes in magnetization occur. In cold-worked specimens, the beginning of the $\gamma \rightarrow \alpha$ transition lies above liquid N_2 temperatures out to 27 atomic % Pt. The increase in the γ-phase Curie temperature and the decrease in the $\gamma \rightarrow \alpha$ transition temperature with ordering occurs to an appreciable extent in the early stages of ordering, before superstructure lines appear in the x-ray patterns. RESISTANCE STUDIES OF THE PHASE TRANSFORMATIONS IN Fe-Pt ALLOYS NEAR THE COMPOSITION Fe_3Pt (Abstract), by R. P. Steijn and F. J. Donahoe. [1954] 1p. (AF 18(600)302) Unclassified

Presented at meeting of the Amer. Phys. Soc., Detroit-Ann Arbor, Mich., Mar. 17-19, 1954.

Published in Phys. Rev., v. 94: 1432-1433, June 1, 1954.

The γ-phase Fe-Pt alloys containing approximately 25 atomic % platinum are known to develop superstructure of the type formed in Cu_3Au. In addition, the f.c.c. γ-phase transforms at low temperatures to a b.c.c. α-phase in alloys containing $\gtrsim$ 27 atomic % platinum. The resistance changes which are produced by these phase transformations have been studied in alloys ranging from 14 to 30 atomic % platinum. In Cu_3Au the formation of long range order is accompanied by a decrease in resistance which may be observed at the temperature at which order formation occurs. No such effects are observed in Fe_3Pt. This seems to be generally true in ferromagnetic alloys of this type. The progress of the ordering reaction during isothermal aging at elevated temperatures can be followed by quenching and measuring the resistance at some fixed temperature below the ferromagnetic Curie point of the disordered alloy. The irreversible $\alpha \rightarrow \gamma$ transition also produces large changes in resistance which are superposed on those due to changes in the degree of order. (Contractor's abstract)

THE GALLIUM-ANTIMONY PHASE DIAGRAM, by I. G. Greenfield and R. L. Smith. Aug. 13, 1954 [18] p. incl. diagrs. table, refs. ([AF]OSR-TN-54-176) (AF 18(600)465) AD 45041 Unclassified

Cooling curves were determined for Ga-Sb alloys. A cooling rate of 1°C per min was used for the majority of the alloys, but in several instances, a rate as low as 1/20°C/min was used. A decided change in the slope of the cooling curve was recorded for most of the alloys. The liquidus temperature of the 92 atomic % Ga alloy was located by measuring the change in resistance as the temperature of the ingot was varied. Pure Sb had a tendency to undercool, but seeding with crystallites of Ga completely removed this condition. The Ga-Sb phase diagram consisted of the intermetallic compound of Ga-Sb with a eutectic on either side. The eutectic composition on the Sb-rich side was 11.78 atomic %; the eutectic temperature was 589.8 ± 0.5°C. The eutectic temperature was the same as the melting point of Ga. No solubility of Ga in Sb was observed. The melting point of GaSb was 705.9 ± 1.9°C. (ASTIA abstract)

THE CELLULAR STRUCTURE, by R. P. Steijn. [1954] [9] p. incl. illus. [AFOSR-TN-54-221] (AF 18(600)465) Unclassified

Published in Jour. Metals, v. 7: 406-407, Feb. 1955.

It has been observed that under certain conditions metals freeze into an aggregate of small hexagonal strands, parallel to one another and with their axes lying approximately in the direction of growth, this formation being termed the cellular structure. In this cellular structure study, descriptions and photographs are given of prismatic and other substructures grown in Zn crystals (99.99% pure) under various external conditions of solidification of the melts. They disclose that Zn single- and bicrystals, produced in a constant-gradient electrical resistance furnace, exhibit the cellular structure after etching in 15% HCl. Other Zn crystals, grown by a modified Czochralski technique using a seed crystal rotating around a vertical axis, show after etching a pattern of undulations and etch-figures similar to the cell structure. Bicrystals and large columnar crystals of Zn, grown by the Bridgeman method in a high-frequency induction furnace, reveal after etching concentric rings on sections perpendicular to the growth direction, and an array of concave bands on longitudinal cuts. Careful etching of polished sections parallel to the hexagonal strands in a Zn single crystal reveals rows of etchpits at the sites of Taylor-Orowan dislocations.

THE PURIFICATION OF GALLIUM BY ZONE-

REFINING, by D. P. Detwiter and W. M. Fox. [Aug. 1954] 5p. incl. illus. [AFOSR-TN-54-233] (AF 18-(600)465) Unclassified

Published in Jour. Metals, v. 7: 205, Jan. 1955.

In an attempt to obtain Ga for greater purity than that available commercially, a method has been evolved which consists of acid-leaching to clean the surface thoroughly, followed by zone-melting to remove metallic impurities. The zone-melting process is considered briefly in this study. It is pointed out that the low-mp and relatively high-thermal conductivity of Ga introduce difficulty in maintaining frozen- and molten-zones in zone-refining. This is overcome by circulating ice water in asbestos-insulated coils around the regions it is desired to maintain frozen, while heat is supplied to molten regions by resistance coils. The Ga ingot is fastened in a Pyrex tube, which is positioned inside the cooling and heating coils. The molten zones are moved through the ingot at a rate of 2 in./hr using the reciprocating method of Tannenbaum (Jour. Metals, v. 6: 762, 1954). The results of a spectroscopic analysis of a Ga zone-refined ingot, as well as of the material as received and after acid-leaching, are presented. They indicate that definite removal of impurities, Pb, occurs during the zone-refining process.

STUDY OF RECTIFYING CONTACTS BETWEEN SEMICONDUCTORS, by D. P. Detwiler. Final rept. Oct. 1, 1952-Sept. 30, 1954, 24p. incl. diagrs. (Rept. no. F-2337-2) (AF 18(600)465) AD 48326 Unclassified

Distillation under high vacuum and zone refining was employed for the further purification of Sb. Zone refining of Sb was carried out under an atmosphere of hydrogen freed of oxygen and water vapor by passing successively through a catalytic purifier, a high-voltage discharge, a $CaSO_4$ drying tower, and a liquid-N-cooled trap. Sb purified under this atmosphere exhibited a mirror-like-surface as compared to the dull matte surface caused by oxide particles on Sb melted under less highly purified H. The zone-refining technique was also adapted to the purification of Ga. Samples of zone-refined GaSb were placed in sealed-off, evacuated Vycor glass tubes 12 in. long and 7 mm in diameter with several 1-mm constrictions. After holding the furnace temperature fixed for several hrs, the Vycor tube was removed and the distillate condensed in the cool end of the tube was analyzed chemically for Sb and Ga. Several samples taken at temperatures between 700° and 900°C showed Sb contents ranging from 75 to 90 atomic % in the distillate. The phase diagram of the Ga-Sb system was determined by thermal analysis. The melting point of GaSb was determined to be 705.9 ± 1°C. A eutectic on the Sb-rich side of the compound was found at 589.8 ± 0.5°C and 88.2 atomic % Sb, while the solidus line found on the Ga-rich side indicated the presence of a eutectic at very small Sb concentrations and very nearly 29.7°C, the melting point of pure Ga. The conductivity and Hall coefficient of a number of samples of GaSb were measured from -196° to 650°C. (ASTIA abstract)

CONDUCTIVITY, HALL EFFECT, AND RECTIFICATION OF GALLIUM ANTIMONIDE (Abstract), by D. P. Detwiler. [1954] 1p. (AF 18(600)465) Unclassified

Presented at meeting of the Amer. Phys. Soc., Detroit-Ann Arbor, Mich., Mar. 17-19, 1954.

Published in Phys. Rev., v. 94: 1431, June 1, 1954.

Gallium antimonide of relatively high purity has been prepared by zone-refining the compound and growing single crystals by pulling from the melt. As prepared under a hydrogen atmosphere in silica crucibles, this material exhibits in general p-type conductivity. The electrical conductivity and Hall constant of a number of samples, both n-type and p-type, have been measured between -190° and 650°C. Room temperature conductivity ranged from a few $ohm^{-1}\ cm^{-1}$ to 100 $ohm^{-1}\ cm^{-1}$. The room temperature Hall mobility of hotes in relatively pure specimens is about 2000 $cm^2\ volt^{-1}\ sec^{-1}$, while that of electrons is appreciably higher. The intrinsic energy gap is somewhat greater than that of germanium. Rectifying p-n junctions have been grown from the melt by adding tellurium to a p-type melt. It has been found that these junctions may be located by chemical etching with a mixture of hydrochloric and nitric acids. Early junctions show a room temperature rectification ratio of several hundred at one volt with, however, considerable "softening" of the reverse characteristic. Although much smaller reverse currents are obtained at 77°K, saturation is still poor in the units tested. (Contractor's abstract)

ELECTRICAL PROPERTIES OF GALLIUM ANTIMONIDE, by D. F. Detwiler. [Nov. 1954] [13]p. incl. diagrs. (AF 18(600)465) Unclassified

Published in Phys. Rev., v. 97: 1575-1578, Mar. 15, 1955.

Data are presented on the conductivity and Hall coefficient of several samples of GaSb over the temperature range from -196° to 650°C. The lowest room-temperature conductivity obtained was 12 $ohm^{-1}\ cm^{-1}$. All material produced from zone-purified components was p-type; n-type material was produced by doping with Te, as were p-n junctions. The intrinsic band gap is estimated from junction rectification data to be 0.78 ev

at -196°C. The mobility of electrons was found by measurement on n-type material to be several times greater than the hole mobility. The mobilities of both holes and electrons are found to vary approximately at $T^{-3/2}$ in the lattice-scattering range. (Contractor's abstract)

THE APPLICATION OF ZONE-MELTING TO HIGH-MELTING-POINT METALS (Abstract), by R. L. Smith and J. L. Rutherford. [Jan. 1955] 1p. [AFOSR-TN-55-36] (AF 18(600)465) Unclassified

The floating-zone technique used by Keck (Rev. Sctent. Instruments, v. 23: 331, Apr. 1954) has been applied to such high-mp metals as Fe, Zr, Ni, and Cu in order to avoid cructble contamination during purification by zone-melting. Fe spectmens, 1/8 to 1/4 tn. tn dtameter, have been zone melted in H_2 ustng tnduction-type heating. The floating-zone ts roughly as long as the spectmen's dtameter. C ts readtly removed by this process, micrographs of a low-C alloy showing a complete absence of vistble C or carbide precipttates after zone-melting. It ts potnted out that Fe purified by zone-melting and tested tn tenston at -196°C has a very ductile cup-type fracture (78% reduction of area).

Induction heating equipment for the floating technique of zone melting ts described. Major changes in the tnduction equipment tnvolve the glass-to-metal seals, the bottom chuck mount, and the top specimen-support rod. Fe and Ti, melted by this technique, are betng evaluated. A radioactive tracer technique is being used to estabtish the dtstribution of controlled additions to the specimen. After 6 zone passes, the concentration of P in the starting end dropped to 2.2% of its original concentration. The concentration of solute did not exceed the initial concentration for the first 90% of the bar, because of the short zone length (7% of the bar length). Photographs show the mtcrostructure of the Swedish iron before and after zone purification. Studies of substructure suggested that Pb segregation accounts for the observed substructure and pits formed in the etched Zn, although it is possible that the Pb segregates in the region of a dislocation. The cellular structure ts bounded by simple crystallographic planes and not by boundartes that are apparently oriented randomly.

ZONE PURIFICATION OF REACTIVE METALS, by R. L. Smith and J. L. Rutherford. Feb. 1, 1956 [33]p. tncl. illus. diagrs. (Interim rept. no. I-A1878-1) (AFOSR-TN-56-70) (AF 18(600)1581) AD 81522 Unclassifted

Also published in Jour. Metals, v. 9: 1-7, Apr. 1957.

The floating-zone method ts described for zone melting reactive, high-melting potnt metals. The method consists of the formation of a narrow molten zone in a rod by tnduction heating. The molten zone ts supported between the 2 solid sections of the rod by surface tenston, and ts moved longitudtnally along the rod to effect a redtstrtbution of solute. The method ts more advantageous than the hortzontal method since cructble contamination ts avoided, but tt ts a more difficult technique. Only one zone can be formed at a time wtth the floating-zone method. High-purity metals can be obtained, but the method does not remove all tmpurity elements. The impure elements which cannot be redistributed in an ingot during zone melting must be removed by some other means. The use of radioactive tracers ts dtscussed for determtning the redistribution of solute durtng zone melting. Rods of Fe, Tl, Zr, Ni, and Mo were zone melted tn prelimtnary expertments. Results are given for P^{32} tn Fe, Au^{198} tn Tt and Zr, and Zn^{65} tn Ti. P and C in Fe, and Au and Zn tn Tt segregrated to the end of the ingot and were the last to solidify durtng melting. At 77.3°K, tensile tests on Fe showed that a progressive increase in ductility occurs as purer specimens are used. Tenstle tests at 4.2°K showed that a large reduction tn area can be obtained tn highly purified Fe. (ASTIA abstract)

TENSILE PROPERTIES OF ZONE-REFINED IRON IN THE TEMPERATURE RANGE FROM 198 K TO 4.2 K, by R. L. Smith and J. L. Rutherford. Interim repl. Sept. 1956 [44]p. incl. illus. diagrs. tables, refs. (Repl. no. 1-AI878-2) (AFOSR-TN-56-490) (AF 18-(600)1581) AD 110304 Unclassified

Also published in Jour. Metals, v. 9: 857-864, July 1957.

The tensile properties of zone-refined iron have been evaluated in the temperature range from 298°K to 4.2°K. It has been found that the higher the purity, the lower the flow stresses and the better the low

temperature ductility. Yield stresses as low as 3, 800 psi have been observed at room temperature and elongations of 10% have been observed at 4. 2°K. The major portion of the ductility at 4. 2°K arises from twinning. Deformation by twinning at 4. 2°K is not suppressed by prestraining at room temperature and the twins occur all through the test. Slip traces were observed to initiate at the ends of previously formed twin traces. (Contractor's abstract)

MACH NUMBER MEASURING DEVICES FOR USE IN HIGH-SPEED WIND TUNNELS, by C. L. Frederick. Dec. 1954, 30p. incl. refs. [AFOSR-TN-54-363] (NATO AGARDograph rept. no. 2) (AF 18(600)797) Unclassified

The results of a critical review of progress in the development and use of Mach number measuring devices in the field of high-speed wind-tunnel testing, analysis, and evaluation of the various methods of measuring and indicating Mach number is presented. The paper is devoted primarily to transonic and supersonic testing because of the basic differences in testing at subsonic and supersonic speeds. The following Mach number ranges are used: (1) subsonic, $M < 0.9$; (2) transonic, $0.9 \leq M < 1.2$; (3) supersonic, $1.2 \leq M < 5$; and (4) hypersonic, $M \geq 5$. A brief listing of the development of Mach number measuring devices is given, followed by a description of Mach meters in use today, together with their advantages and disadvantages.

DESIGN AND CONSTRUCTION ASPECTS OF HIGH POWER WIND TUNNEL DRIVE SYSTEMS AND LARGE DIAMETER WIND TUNNEL COMPRESSORS, by J. Clark. Apr. 1954 [54]p. incl. illus. diagrs. [AF 18(600)797] Unclassified

Presented at the Netherlands meeting of the NATO-AGARD, May 1954.

A brief review is presented of certain aspects of the design criteria used for large wind tunnel drives which have been conducted by various groups in the NATO nations. Although this design information was used for large wind tunnel drives, it is applicable to most small and medium-size installations. A particularly valuable feature is that it may be used to predict the performance characteristics of drive systems whose component parts have been obtained from various sources. Thus, difficulties can frequently be predicted in advance and, if necessary, slight changes can be made to these parts before they are assembled into a drive system, with a consequent reduction in time required to place such drives in successful operation. The requirements and arrangement of various types of large wind tunnel drives are compared. Section I, discusses some of the major design problems that are usually encountered in these drives. In Section II, a comparison is presented of the various types and mechanical characteristics of wind tunnel compressor rotors. This is followed by a general discussion of some of the major problems encountered in the mechanical design of large wind tunnel compressors.

AUTOMATIC PRESSURE MEASURING SYSTEMS USED WITH HIGH-SPEED WIND TUNNELS, by C. L. Frederick. June 1955, 51p. incl. illus. diagrs, refs. [NATO AGARDograph rept. no. 10] [AF 18(600)-797] AD 77895 Unclassified

A brief review is given of high-speed wind tunnel characteristics, particularly with respect to instrumentation needs. Major elements of pressure measuring systems are surveyed, and representative United States' systems are described. The representative systems can be subdivided into those characterized by fast response, short running time, and a small number of pressure channels and those characterized by repeated multiple measurements, long tunnel running time, and long insirument stabilization time. Refinements of the first group are needed in the pressure connecting system, the sensing element, and the transducer. For the second group, novel meniscus transducers are necessary when conventional pressure connecting systems and conventional manometers are used. Diaphragm transducers coupled to relatively slow response pressure connecting systems can be used. The metal diaphragm and wire filament provide the shortest response times, but only the diaphragm can be made to provide an effectively linear response over a relatively narrow pressure range. Electrical transducers for measuring diaphragm response are highly developed and useful in automatic recording systems. For determining and recording a discrete, stabilized pressure value for each gage, the liquid manometer with electrical transducer competes with the diaphragm. (Extracted from repi.)

[ISOTOPIC EFFECTS AND THERMODYNAMIC PROPERTIES IN THE CONDENSED PHASE, 1] Effets isotopiques et propriétés thermodynamiques en phase condensée. 1, by I. Prigogine, R. Bingen, and J. Jeener. [1954] [12]p. [AF 61(515)635-C] Unclassified

Published in Physica, v. 20: 383-394, July 1954.

The zero point of energy of solid isotopic mixtures is discussed, and their properties are compared with those of the pure isotopes. The case of a 1-dimensional chain of molecules is considered in some detail because the

calculations may then be performed in a rigorous way. Only harmonic oscillators are considered. It is shown that the zero-point energy increases steadily with the number of couples of first neighbors between molecules of different masses. The zero-point energy is lowest for the pure isotopes and highest for the ordered lattice ABAB .... Also its value for a random distribution of the isotopes is higher than that for the pure isotopes. The stable state at 0°K always requires a separation into pure isotopes. Differences in masses, i.e., isotopic effects, may give positive deviation from Raoult's law without any effect of the statistics. The results obtained indicate the possibility of pure quantum transitions in the phase diagram due to isotopic effects at sufficiently low temperatures. These transitions are quantum analogues of order-disorder transitions. The differences in the zero-point energies due to different spatial distributions of the isotopes are small, however, so that these effects can only appear at extremely low temperatures. They are much smaller than the effects calculated by Prigogine and Phillppot which are related to volume changes on mixing and thus to the anharmonicity of the motion of the molecules. (Contractor's abstract)

[ISOTOPIC EFFECTS AND THERMODYNAMIC PROPERTIES IN THE CONDENSED PHASE, III] Effets isotopiques et propriétés thermodynamiques en phase condensée. III, by I. Prigogine and J. Jeener. [1954] 5 p. incl. diagrs. tables, refs. [AF 61(514)635-C] Unclassified

Published in Physica, v. 20: 633-654, Sept. 1954.

The basic assumption of this paper is introduced in the following form: the free energy of an isotopic mixture is, for given values of volume per particle and temperature, the sum of the free energy of the pure isotopes and of a term due to the entropy of mixing. This assumption is automatically satisfied in simple statistical models of condensed phases like the cell model or an assembly of anharmonic oscillators, the change on mixing of the zero-point energy not being taken into account. It thus constitutes a satisfactory method of approach for the understanding of the thermodynamic properties of isotopic mixtures. From this hypothesis the free energy of mixing, the excess volume and the heat of mixing can be expressed in terms of properties of the pure isotopes. This theory predicts for isotopic mixtures heat absorption and positive deviations from Raoult's law. Some simple statistical models are considered in some detail in order to understand the thermodynamic properties of the pure isotopes. By applying the fundamental assumption of this paper, the qualitative features of the mixture can then easily be discussed. The effects calculated in this paper and the change in zero-point energy on mixing are compared. (Contractor's abstract)

STATISTICAL MECHANICS OF IRREVERSIBLE PROCESSES IN CRYSTALS, PART I, by I. Prigogine and R. Bingen. 1954, 42p. (AF 61(514)635-C) Unclassified

Published in Physica, v. 21:299-311, Apr. 1955.

This study is concerned with irreversible phenomena in crystals, which are not related to processes involving energy dissipation, e.g., anharmonicity. An infinite 3-dimensional assembly of harmonic oscillators is studied. Their position and velocities are considered as random variables whose probability distributions are known at the initial moment. The asymptotic values of these distribution functions can be calculated by solving the equations of motion of the lattice points in terms of the initial conditions. "Influence functions" are introduced, which are related to the frequency spectrum of the lattice. Some of their asymptotic properties can be established after a long period regardless

of the frequency spectrum. They show that all the local dtstribution functions tend to Gaussian dtstributions, and the crystal ttself to local homogeneity. In constrast with the 1-dimenstonal case, it ts not posstble to ftnd simple linear combtnattons of the second moments which are invartant; however, the second moments are known to be quasi-invariant, t.e., they tend to a definite asymtotic value after a more or less complicated vartatton. No other condition is imposed on the initial distribution function than the absence of correlation at l.. ge distances. If they are such, however, that the equtpartttion of the energy is initially achieved between the normal modes, without any correlation between their phases, all the various moments and local dtstribution functions tend to thetr equtlibrium value. That ts, each finite part of the crystal tends to local thermodynamic equilibrium. This local ergodtcity of the crystal can be considered as a consequence of the central limit theorem of statistics. After a long pertod, the local distribution functions are determined by a very large number of random vartables (owing to the dispersion of the frequency spectrum, this number is proportional to t^3). STATISTICAL MECHANICS OF IRREVERSIBLE PROCESSES AND THE STEADY STATE, PART II, by I. Prigogtne and R. Brout. 1954 [22]p. (AF 61(514)-635-C) Unclassified

The thermodynamic consequences of our previous studtes on the harmonic systems ts examined. It is found that the entrophy, corresponding to the asymptotic distribution in time, (subject to rather broad condttions) is a maximum, defined ob the surface gtven by the mechanical invariants of the system. An H theorem is found in a time smoothed sense, systematic oscillations being due to the second order differential equations of motion. Anharmonicities are then introduced into the system which destroy all mechanical invariants other than the energy, thereby allowing the system to come to the standard canonical ensemble (energy the only mechanical invariant). The evolution of entropy at this stage is then examined using equations previously developed by Peierls in the study of thermal conductivity of solids. Finally, the stationary state of heat flow is examined in the presence of a temperature gradient. This study introduces the concept of an intermediate time scale, which allows the study of the stationary state without introducing extraneous interactions with the external world. Rather, the thermal gradient is propagated from the ends of the system itself. A stationary state exists for times long enough to establish the space smoothed and time smoothed equations of Peierls, and short enough so that the effects of the propagating gradient do not disturb the stationary character of the system. The conditions on this time are given and such times are shown to exist for sufficiently large systems and sufficiently small temperature gradient. The stationary state arises from harmonic propagation of the gradient compensated by local decay of heat flow due to anharmontcttles. It ls further shown to correspond to a state of minimum entropy production for ftxed gradient, thereby corroboratttng a well known theorem in phenomenologtcal trreversible thermodynamtcs. THERMAL CONDUCTIVITY OF REAL GASES, PART III, by I. Prtgogine and S. Lafleur. 1954, 15p. incl. table, refs. (AF 61(514)635-C) Unclassified

Published tn Physica, v. 21: 667-675, Aug. 1955.

In a real gas, in the presence of a temperature gradient, the relative concentrations of the molecular cluster vary from point to potnt; this leads to a diffuston of the larger clusters towards the warm regtons and of the smaller clusters, and monomolecules towards the cold parts of the apparatus, where they respectively dissociate or recombtne with the absorption or ltberation of the heat of formation. The tncrease in the thermal conductivtty of the gas resulting from this circulation of the heat of formation of the clusters can be evaluated wtth reasonable accuracy at low pressures when only stmple and double molecules need to be taken into account. This effect is negltgible at htgh temperatures (above Boyle point), where the vartation of thermal conductivity with pressure can be represented to a high degree of accuracy by Enskog's theory; tt increases wtth decreastng temperature, and becomes approximately equal to Enskog's effect in the netghborhood of the critical temperature; it is evaluated that in the case of argon the increase is of the order of 6% per atm at the boiling point. At higher pressures, the larger clusters carrying an important heat of formatton can no longer be neglected; an exact evaluation of their contribution is difficult, but qualttative calculations based on crude models indicate that the calculated value depends strongly on the model assumed, and that for homopolar molecules at high pressures and relatively low temperatures this excess thermal conductivity is largely due to polydimensional clusters with internal cyclic links. KINETIC THEORY OF POLYATOMIC GASES, PART IV, by I. Prigogine and S. Lafleur. 1954 [43]p. incl. refs. (AF 61(514)635-C) Unclassified

An extension of the kinetic theory of gases taking into account inelastic collisions is considered, and the effect of these inelastic collisions on transport properties (e.g., thermal conductivity) is investigated. The kinds of inelastic collisions considered are collisions leading to a molecular association or "dimerization" (and inversely decomposition of an associated molecule) and those leading to an excitation (and inversely de-excitation) of one of the colliding molecules, this kind

of process being very likely in polyatomic gases. The Boltzmann's equation of a system consisting of simple molecules, stable and excited double molecules subject to these inelastic processes together with the usual elastic collisions are derived. Following Grad's method of solution the moments equations are written, and from them the thermal conductivity is deduced for a simple case. In this case suppose that the concentrations of the different molecules in local chemical equilibrium and a sufficiently small equilibrium concentration of excited molecules so that it can be neglected. It is shown that this condition is satisfied if the heat of association is larger than a few times the thermal energy kT. The results corroborate the macroscopic theory of Nernst, Dirac, Prigogine, and Meixner, and show that inelastic collisions can give rise to an important increase in the thermal conductivity through a "circulation" process of the heat of association between the hot and cold parts of the system. It is shown that Onsager's reciprocity relations are satisfied by the system. The deviations from local chemical equilibrium are then shortly discussed; it is found by qualitative evaluation, that in usual conditions, these deviations are appreciable, and that the increase in the thermal conductivity due to inelastic collisions is less than in the case of local chemical equilibrium. QUANTUM EFFECTS AT ABSOLUTE ZERO IN PURE CRYSTALS AND ISOTOPIC MIXTURES, PART V, by I. Prigogine and R. Bingen. 1954, 1v. incl. diagrs. table, refs. (AF 61(514)635-C) Unclassified

The influence of the anharmonicity of motion is studied, in connection with the properties at very low temperatures of solids such as H_2, He, and their isotopes, which are sufficiently light to display large quantum effects. In Chapter I, the properties of pure crystals at absolute zero were studied. A one dimensional chain of anharmonic oscillators is taken as statistical model, with Lennard Jones' "6-12" interaction between nearest neighbors only. Two effects of quantum origin are taken into account: the change of zero-point energy with volume, due to changes of elastic constants, and on the other hand the additional contribution to the zero-point energy due to the anharmonicity of the interaction potential. The volume, the free energy and the Debye temperature are calculated as functions of de Boer's quantum parameter Λ. The light crystals are found to show important deviations from classical laws. Chapter II is devoted to the mass effect in solid isotopic mixtures, i.e., the influence of the spatial distribution of the two isotopes upon the zero-point energy. The latter is always higher when the two isotopes are mixed than when separated; in the case of equimolecular mixtures, the zero-point energy is the highest for the ordered lattice ABAB... The stable state at $0^{\circ}K$ is thus given by the separation into the pure isotopes. In Chapter III, the volume effect is discussed, i.e., the volume change and the corresponding variation of zero-point energy which occur when two isotopes are mixed. This volume effect is more important than the mass effect, at least for light substances. It is first evaluated in the case of 1-dimenstonal crystals. The calculations are then extended to real 3-dimenstonal crystals, showing that the excess free energy is always positive. This theory indicates that a quantum phase transition must be expected at a sufficiently low temperature, below which the two isotopes are separated. The heat mixing of mixtures such as H_2 - D_2 are found to be in agreement with experimental data on analogous liquid mixtures. (Contractor's summary)

STATISTICAL MECHANICS, by I. Prigogine. [1955] [26]p. incl. refs. (AF 61(514)635-C; continued by AF 61(514)817) Unclassified

Published in Ann. Rev. Phys. Chem., v. 6: 457-482, 1955.

Recent literature primarily of 1954 on selected topics in statistical mechanics is reviewed. The 166 publications surveyed are concerned with the thermodynamics of irreversible processes, the statistical mechanics of irreversible processes, some equilibrium properties including condensation of imperfect gases, the Monte Carlo method of evaluating partition functions for interacting particles, the cell-cluster model for the liquid state, and the vibration spectrum of perturbed lattices and isotopic mixtures. Also discussed are some recent papers on liquid helium.

ON THE DIFFERENTIAL PROPERTIES OF ENTROPY PRODUCTION, by P. Glansdorff and I. Prigogine. [1954] [8]p. ([AF 61(514)817] continuation of AF 61(514)635-C) Unclassified

Published in Physica, v. 20: 773-780, Oct. 1954.

The time variation of the entropy production (per unit volume and unit time) is split into two parts. The first is related to the changes of the generalized forces with time and the second to the changes of the rates of the irreversible processes. If some restrictive conditions are satisfied (linear phenomenological laws, Onsager's reciprocity relations, constancy of the phenomenological coefficients) both parts are equal and decrease in time. This does no more hold if these conditions are not satisfied. Postulating only mechanical equilibrium and time independent boundary conditions, it is shown that the first part, related to the change of the generalized forces, is always negative zero. The change of the generalized forces with time is therefore such that

it lowers the value of the entropy production. Some consequences of this theorem are briefly discussed. (Phys. A. abstract)

STATISTICAL MECHANICS AND THERMODYNAMICS OF IRREVERSIBLE PROCESSES, by I. Prigogine. [1956] 1v. incl. diagrs. refs. (AFOSR-TN-56-417) (AF 61(514)817) AD 96226 Unclassified

A study is made of the statistical mechanics and thermodynamics of irreversible processes, and Poincare's theorem is extended to systems of oscillators. A systematic theory is developed which gives, for simple classes of Hamiltonians, a general procedure for describing the irreversible behavior starting from first principles. The connection between statistical mechanics and thermodynamics is pointed out. The more conventional approach of the thermodynamics of irreversible processes is discussed by using a differential property of the entropy production to study variational principles associated with stationary nonequilibrium situations; the case of 1 and 2 independent variables is solved in a general way, and restrictions which exist for more than 2 variables are discussed. The thermodynamical systems which are described by antisymetrical phenomenological laws are studied in the neighborhood of a stationary nonequilibrium state; an example of such systems is given by Volterra's (Theorie Mathematique de la lutte pour la vie, Paris, Gauther Villars, 1931) model of interacting biological populations. STATISTICAL MECHANICS OF IRREVERSIBLE PROCESSES, PART I. GENERAL THEORY OF WEAKLY COUPLED SYSTEMS, by R. Brout and I. Prigogine. [1956] 16p. (Bound as Chapter 2 of AFOSR-TN-56-417; AD 96226) (AF 61(514)817) Unclassified

Also published in Physica, v. 22: 621-636, July 1956.

In this mathematical study, a general procedure for the classical mechanical study of irreversible processes in weakly-coupled multiply periodic systems is presented. By weakly coupled systems, it is meant that the total Hamiltonian may be divided into two units, $H = H^0 + \lambda V$, where $|\lambda V| \ll |H^0|$. λ is a coupling parameter characteristic of the magnitude of the perturbation, and H^0 is taken to be a sum of many sub-Hamiltonians $H^0 = \sum_{1=1}^{N} H_1$. Thus, the dynamical system described by H^0 has N analytic invariants and hence is nonergodic. The small addition λV is taken so as to destroy these invariants which presumably insures ergodicity. At the same time, λV is considered so small that it does not enter into the equilibrium properties of the system. In this it serves the familiar role of rare collision in dilute gases. It is the purpose of this paper to study the irreversible evolution of ensembles of systems governed by the Hamiltonian two units mentioned above.

STATISTICAL MECHANICS OF IRREVERSIBLE PROCESSES, PART I. BOLTZMANN EQUATION, by R. Brout. [1956] 18p. (Bound as Chapter 3 of AFOSR-TN-56-417: AD 96226) (AF 61(514)817) Unclassified

Also published in Physica, v. 22: 509-524, June 1956.

The transfer from the reversible equation of Liouville to an irreversible "master equation" is effected under the following hypotheses: (1) the transitions of the molecules from one state to another are almost instantaneous events; (2) the system is infinite; and (3) the initial distribution is such that in the dilute gas, all the positions of the molecules are equally likely beyond a certain region of microscopic correlation (Stosszahlansatz). It is also shown that an ulterior reduction of the master equation to the Boltzmann equation can only be realized by initial conditions such that the distribution is already factored.

The connection between statistical mechanics and

FRE. 02:007 - FRE. 02:011

irreversible thermodynamics is studied with emphasis on weakly coupled, multiply periodic systems (of predominantly homogeneous variety). Entropy and entropy production are discussed where neighborhood of equilibrium conditions hold: $P = \sum V_i$, $X_i (V_i, X_i$ conjugate rates and affinities. A variational principle characterized by the extreme of a certain integral is made to describe thermodynamic equilibrium. As a result, Onsager's reciprocal relations occur in the moment equations near equilibrium. Ideal gases and chemical reactions are investigated by the self-adjoint transformations. The self-adjoint operator Ω is used in describing the irreversible evolution towards equilibrium.

STATISTICAL MECHANICS OF IRREVERSIBLE PROCESSES, PART VI. THERMAL CONDUCTIVITY OF CRYSTALS, by R. Brout and I. Prigogine. [1956] [10]p. [AF 61(514)817] Unclassified

Published in Physica, v. 22: 263-272, Apr. 1956.

It was shown in parts III and IV of this series that under general conditions local distribution functions in an infinite harmonic crystal tend asymptotically to multivariate gaussian distributions. This result has interesting consequences which are discussed in the present paper. The evolution towards equilibrium of a slightly anharmonic crystal can be subdivided into two steps which proceed according to quite different time scales. The first step corresponds to the appearance of the multivariate gaussian distribution and is reached in times of order $1/\omega$ (ω = characteristic

fequency of the harmonic crystaI). The second step ts the disappearance of all second order correlattons (except of course autocorrelations) through the effect of anharmonic forces. This part corresponds to the evolution towards equipartition of energy between normal modes and corresponds to a "long" time scale related to the anharmonictty of the crystaI. It tc shown that if we take account of this initial "preparation" of the system by harmonic forces, the molecular theory of thermaI conductivtty takes a remarkably stmple form. Instead of ustng the full Boltzmann equation for thts problem, it becomes sufficient to use the equatton for the second moments alone. In this way it is easy to obtain an explcit form for the thermal conductivity of the crystal tn terms of molecular quantities. The phenomenologtcal equation for the change of temperature (Fourier's equation) may be justified in the same way. This study is restricted to one-dtmenstonal chains with nearest netghbor tnteractions. An appendtx is attached in which three-dimensional systems are constdered. (Contractor's abstract)

VAPORIZATION OF COMPOUNDS AND ALLOYS AT HIGH TEMPERATURE, by R. E. Honig and J. Drowart. Oct. I956, 32p. incl. dtagrs. tables, refs. (Technical note no. 1) (AFOSR-TN-56-555) (AF 61(514)868) AD 110374 Unclasstfted

Elements of groups IB and IIIB were studted tn a 60°, 20-cm-radius mass spectrometer which was modified to permtt the vaporization of milltgram samples from small, electrtcally heated crucibles made of suttable matertals such as C, Mo, Al_2O_2, and BeO. The matertal was chosen tn order to mtnimtze any interaction between sample and crucible. A pyrex window opposite the crucibte altowed the sample to be vtewed and its temperature to be measured. A fraction of the neutral particles vaporizing from the sample was tonized by a 30 μ a-beam of 70-ev electrons, accelerated, and mass-analyzed in the usual fashion. For Cu, Ag, and Au, the expected atomtc species and small concentrations of the dimers were found. The tonic ratios X_2^+/X_I^+ (about 10^{-3}) were measured over ranges of about 100°K at pressures between 10^{-4} and 10^{-5} mm Hg. Neutral ratios X_2/X_1 were obtained by assuming that the total tonization cross section of a molecule is the sum of the cross sections of the consttuent atoms. For Ga and In, no dtmers were found. Dtssociation energies were computed for Cu_2, Ag_2 and Au_2; the values agreed well with those obtained by the slope method which utiltzes directly measured heats of vaporization of the monomers and dimers. The absotute entropy method was used to obtatn the dtssoctatton energies of the Group lVB molecules (C_2, Si_2, Sn_2, Ge_2, and Pb_2). The mass spectrometer was considered to be an instrument capable of supplying much detailed information concerning the vapor phase of substances which are solid at room temperature. (ASTIA abstract)

MASS SPECTROMETRIC STUDY OF GALLIUM AND INDIUM, by J. Drowart and R. E. Honig. Dec. I956, 3p. (AF 6I(514)868) Unclassified

Publtshed tn Bull. Soc. Chim. Belg., v. 66: 4I1-413, May-June 1957.

Galltum and tndium were evaporated from BeO and graphite cructbles into the ion source of a modified 60° mass spectrometer at temperatures ranging from 1035° to I320°K for Ga and from 800° to I130°K for In. Small Ga_2^+ and Ga_2O^+ and In_2^+ and In_2O^+ peaks were observed. The heat of evaporated was calculated to be 59 ± 4 kcal/mole for Ga_1^+ (plot of log (I • T) vs 1/T). Between 1200°and 1320°K durtng the Ga evaporation small peaks appeared at masses 138 and 142. These are interpreted as Ga_1^{++} tons which lose one charge during transit. During the evaporatton of In a small mass 230 peak of nonreproductble intensity was observed between 1020°and 1130°K.

FROM THE ORIFICE, by H. Görtler. Final rept. Mar. 10, 1954, 40p. [AFOSR-TN-54-164] (AF 61-(514)627-C) AD 33781 Unclassified

Also published in Rev. Mat. Hispano Americana, Ser. 4, v. 14: 143-193, 1954.

By linearizing the equations of motion of laminar jet flow with respect to the swirl component (the latter being weak relative to the velocity component in the direction of the axis), an eigenvalue problem of a second-order ordinary differential equation is developed. A change of variables reduces it to a Legendre equation, providing a complete and exact solution of the eigenvalue problem. The theory is similarly applied to turbulent jet under the conditions of a hypothesis originally due to L. Prandtl. The theory shows that the swirl in a free jet always decreases according to a higher power of the inverse distance from the orifice than the velocity component of the jet in the direction of the axis. For a given weak swirl distribution in a cross section of the jet, the theory provides a precise evaluation of the progress of the swirl further downstream. (ASTIA abstract)

THEORETICAL INVESTIGATIONS OF THE LAMINAR BOUNDARY LAYER. PROBLEM I: GROWTH OF THE LAMINAR BOUNDARY LAYER OF YAWED CYLINDERS STARTING FROM REST, by H. Wundt. Final rept. Apr. 5, 1954, 42p incl. diagrs. tables, refs. [AFOSR-TN-54-165] (AF 61(514)627-C) AD 33782 Unclassified

A system of 3-dimensional boundary-layer equations for incompressible fluids is solved for the case of a yawed cylinder. The method of solution employs power-series expansions in terms of the time as given by Blasius (Zeit. Math. u. Phys., v. 54: 1-37, 1908). Different laws of motion lead to universal coefficient functions of the coordinate representing the distance from the wall. The functions are calculated to a high degree of accuracy for the case of an impulsive start from rest to a state of uniform motion. Calculations are given for: (1) the components of the transverse flow (perpendicular to the axis) as an extension of the results of Görtler (Arch. Math., v. 1: 138-147, 1948 and 1949; v. 3: 216-231, 1952; and Ing. Arch., v. 14: 286-305, 1944); and (2) the additional axial component as a continuation of previous work of Görtler (FIAT Rev. Ger. Sci. 1939-1946, 5, pt. 3: 68, 1948). The circular cylinder is chosen as an example, and the growth of the boundary layer is studied numerically and graphically from the beginning of the motion. The process of separation is investigated. (ASTIA abstract)

A NEW SERIES FOR THE CALCULATION OF STEADY LAMINAR BOUNDARY-LAYER FLOWS, by H. Görtler. Sept. 1955, 100p. incl. illus. diagrs. refs. (AFOSR-TN-56-8, vol. 1) (AF 61(514)642-C) AD 82006 Unclassified

A new and general rigorous method was developed to solve problems of plane and incompressible steady laminar boundary-layer flows with arbitrary outer pressure distribution. This method is based on the introduction of the dimensionless quantities

$$\xi = \frac{1}{\nu}\int_0^x U(x)dx, \qquad \eta = U(x)\, y \Big/ \left\{ 2\nu \int_0^x U(x)dx \right\}^{1/2}$$

as new independent space variables, where x and y are the usual boundary layer coordinates, U(x) the given outer velocity distribution, and ν the kinematic viscosity. The solution of the boundary layer problem is then given as a power series with respect to ξ with coefficient functions depending on η. A number of examples were evaluated to show the success and also the limitations of the method. For flows along flat plates the convergence of the new series was very satisfactory, and in most cases (mainly of retarded flows) provided a good approximation by the truncated series (fifth-order approximation) from the leading edge to a point immediately ahead of the separation point. The separation point can then be easily determined by a short extrapolation. Application of the new series to cylinders with rounded noses showed no advantage over the equally applicable Blasius series. However, a one-term zero-order approximation of the new series should be advantageous for certain theoretical investigations involving the separation of variables in a large domain from x = 0 downstream. The quality of convergence appeared to be best for monotone (retarding or accelerating) outer velocity distributions. (For vol. 2 see Harvard U. item no. HAR. 0.001) (ASTIA abstract)

TERNARY PHASE SYSTEMS OF POLYSTYRENE AND POLYISOBUTYLENE IN CARBON TETRACHLORIDE R. M. Kallo and D. E. Braun. Technical note. June 4, 1954 [29]p. incl. diagrs. tables. (Rept. no. 6) ([AF]OSR-TN-54-222) (AF 18(600)588) AD 55125 Unclassified

The phase diagrams of five ternary systems were determined, consisting of polyisobutylene and polystyrene in carbon tetrachloride. It was found that the region of immiscibility increases as the molecular weights of the two polymers increase, but that the tie line slopes are essentially insensitive to the molecular weights. A new method for the determination of tie lines by osmotic pressures is proposed. This method is especially useful for higher molecular weight polymer pairs, where light scattering effects make difficult any visual means for the determination of the composition of the conjugate phases. (Contractor's abstract)

TERNARY POLYMER SOLUTIONS, by R. M. Kallo and D. E. Braun. Jan. 12, 1956 [31]p. incl. diagrs. tables, refs. (Technical rept. no 8) ([AF]OSR-TR-56-33) (AF 18(600)588) AD 83674 Unclassified

Weight-ratio and osmotic-pressure methods were used to determine the tie lines of polystyrene-polyisobutylene-carbon tetrachloride compositions of different polymer molecular weights. Results showed that the region of immiscibility increases with the molecular weights of the polymer pairs, and that the tie lines dip toward the polystyrene vertex either on a volume- or weight-percentage plot. Ternary phase diagrams were determined for the polystyrene-benzene-methanol and polystyrene-benzene-isopropanol systems. The region of immiscibility was greater for the MeOH system. In both cases, the tie lines slope toward the alcohol vertex either on a weight- or volume-percentage plot. (ASTIA abstract)

THE MECHANISM OF COMBUSTION OF SOLID PROPELLANTS, by R. D. Geckler. [Dec. 1953] [51]p. incl. diagrs. tables, refs. (AF 18(600)846) Unclassified

Presented at NATO-AGARD Combustion Colloquium, Cambridge U. (England), Dec. 7-11, 1953.

Published in Selected Combustion Problems, Cambridge U. (England) (Dec. 7-11, 1953), London, Butterworths Scientific Publications, 1954, p. 289-339.

The normal linear burning rate of solid propellants increases with (1) an increase in the pressure of the gases in contact with the burning surface, (2) an increase in the temperature of the solid propellant, and (3) an increase in the velocity of the combustion gases parallel to the burning surface. Experimental data on these phenomena are summarized for both colloidal and composite propellants. An attempt is then made to show the relationship between the concepts and methods developed for the study of deflagration in gases and the theories of solid-propellant combustion. The present status of the theoretical study of solid-propellant combustion is reviewed with particular attention being given to the theories of Professor O. K. Rice and Professor B. L. Crawford, Jr. The values of various kinetic parameters deduced by the application of their theories to experimental burning-rate data are compared with values obtained in other ways. A summary of experimental and theoretical information on unstable combustion is also given. The distinctive feature of this phenomenon is an abnormally high burning rate that accompanies high-frequency pressure oscillations in rocket combustion chambers. It is concluded that the theoretical understanding of the combustion of solid propellants is not sufficient to be of much practical aid to the propellant chemist seeking formulations with improved properties. (Contractor's summary)

A REVIEW AND COMPARISON OF AERO-MEDICAL RESEARCH EFFORTS IN NATO COUNTRIES; CRITIQUE, by R. Margaria. Final rept. Oct. 1956, 4p. (Project no. 56-16) (AF 18(600)1180) Unclassified

Dr. R. Margaria compares the aero-medical research in the U. S. with that in Europe. The research in the U. S. is of a more practical nature and is developed in response to actual information often urgently needed by engineers and pilots. The research carried on in Europe is generally diversified and is apt to have a single application; but it is also of a basic scientific character. Collaboration is urged between European and U. S. research workers, both civilian and military. An action by the U. S. toward a more intensive exchange of individuals and more collaboration would bring not only greater achievement in the field of aviation medicine, but it would be also of a great social and political importance, for it would constitute a means of cultural penetration of the U. S. in Europe.

CYSTEAMINE OXIDASE (Abstract), by R. Salvador and R. O. Brady. [1956] [1]p. [AF 18(600)853] Unclasstfted

Presented at meeting of the Amer. Soc. of Btol. Chemists, Atlantic Ctty, N. J., Apr. 16-20, 1956.

Published in Fed. Proc., v. 15: 345, Mar. 1956.

The presence has been observed of an enzyme in soluble extracts of pigeon liver acetone powder which catalyzes the oxidation of 2-mercaptoethylamtne when incubated in the presence of 2, 3, 5-trtphenyltetrazoltum chlortde. The enzyme has been purtfied 15-fold by fractionation with ammonium sulfate (0-30% saturation), alcohol (0-21% ethanol), and elution from calcium phosphate gel. Diphosphopyridtne nucleotide ts required although triphosphopyrtdtne nucleotide shows slight activity in the crude extract. N-acetyl-2-mercaptoethylamine ts oxidized about 1/10 as raptdly as cysteamine, whereas pantetheine, mercaptoethanol, cystetne, glutathione, and cystamine are inactive as substrates for this enzyme. Coenzyme A appears to be oxidtzed only very slightly tn the parttally purified system. When S^{35}-labeled cysteamine was incubated with the enzyme precipitating between 0-21% ethanol, which still exhibited diaphorase activity, one of the major products appeared to be cystamine disulfoxide. Cell-free extracts of C. kluyveri contain a similar enzyme although the product of this reaction has not been identified. This preparation differs somewhat from that obtained from pigeon liver stnce 2-mercaptoethanol as well as cysteamtne was rapidly oxidized by the enzyme system obtained from C. kluyveri. EFFECT OF VARIATION OF TEMPERATURE AND PRESSURE ON COMPOSITION OF ALLOYS, by W. M. Spicer. Final rept. Jan. 1, 1954-Dec. 31, 1955, 56p. incl. diagrs. tables, refs. [AFOSR-TR-56-6] (AF 18(600)974) AD 81533 Unclasstfied

Expertments were performed on several solid alloys tn an attempt to show that concentration gradtents mtght develop as a result of a pressure gradtent or a temperature gradtent. The results on the pressure effect were tnconclustve. However, the results on the temperature effect, espectally those on the Pb-14.8 per cent Sn and the Al-21.9 per cent Zn alloys, tndtcate strongly that a concentration gradtent dtd develop as a result of the temperature gradient. In the case of the Pb-14.8 per cent Sn alloy, the percentage tin reached a maximum of 15.71 per cent near the hot end and a mtnimum of 13.84 per cent near the cold end. Wtth the Al-21.9 per cent Zn alloy, the percentage of ztnc attained a maximum of 25.57 per cent and a mtnimum of 18.12 per cent in one of the three runs. (Contractor's abstract)

BOUNDS ON INFLUENCE COEFFICIENTS FOR CIRCULAR CYLINDRICAL SHELLS, by E. Retssner and M. B. Sledd. Dec. 1, 1956 [33]p. tncl. dtagrs. (Rept. no. 1) (AFOSR-TN-56-575) (AF 18(600)1459) AD 110397 Unclasstfted

Rotationally symmetric deformations of a thtn elastic circular cylindrical shell of variable wall thickness and of finite or semi-infinite axial length are considered. The determination of upper and lower bounds for the dtrect tnfluence coefftctents c and the tnverse influence coefficients k is made by the application of the mtnimum prtnciples for dtsplacements and for stresses of the theory of elasttcity. The bounding of several such coefficients is attempted simultaneously. An application is made to a semi-infinite circular cylindrical shell wtth exponentially varying wall thickness. The results are seen to extend to ranges of thtckness variations over short axial distances.

A METHOD OF MEASURING THE MOBILITY SPECTRA OF NEGATIVE IONS IN GAS MIXTURES (Abstract) by E. W. McDaniel and H. R. Crane. Oct. 1956, 1p. (AF 18(600)1524) Unclassified

GOT. 01:001

Prssented at Gaseous Electronics Conference Pittsburgh, Pa., Oct. 31-Nov. 3, 1956.

Prssented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Serter II, v. 2: 82, Jan. 30, 1957.

A new pulse method of measurtng the low-fteld mobility of negative gaseous tons is described. Negative tons are formed by the capture of the electrons produced in the tonization path of an α particle which crosses one end of a long, uniform-field drift tube. The α particls entsrs a proportional counter at the end of tts path. The arrival of each indtvldual negative ion at the other end of the drift tube ts stgnalled by a second proportional counter. The ftrst counter trtggers the sweep of a synchroscope, and the second counter modulates the beam brtghtness. A large number of such sweeps ts integrated photographically. In each run, with a different gas mixture, a sharp line appears in the photographic spectrum. This gives the drift time for the negative ion in that gas. The mobilities of the negative ions in pure oxygen, and in mixtures consisting of varying percentages of oxygen in He, Ne, A, Kr, Xe, CO_2, and H_2 were measured and will be discussed. The mobility of the negative ion in pure SF_6 was found to be .57. This agrees well with the range for SF_6 predicted by the Langevin theory including charge exchange, namely .46 to .58 (Contractor's abstract)

FINITE DIFFERENCE METHODS FOR THE FIRST BOUNDARY VALUE PROBLEM OF $\Delta u(x, y) = r(x, y, u)$ AND CURVED BOUNDARIES, by W. Uhlmann. July 1956, 39p. incl. diagrs. (AFOSR-TN-56-390) (AF 61(514)-881) AD 96048 Unclassified

Approximate solutions $u(x, y)$ are sought for the differential equation $\Delta u(x, y) = r(x, y, u(x, y))$ for a given domain G of the x, y plane such that $u(x, y)$ takes on prescribed values on the boundary Γ of G. Mehrstellen formulas are compared with the ordinary formulas of finite difference methods in the numerical computation of the torsion problem for a girder with a semicircular cross section. Relative errors, compared with the exact solution, of the order of 0.05% are obtained for the most favorable Mehrstellen method. (ASTIA abstract)

A DIFFERENTIATION TECHNIQUE FOR PARTIAL DIFFERENTIAL EQUATIONS WITH NONLINEAR BOUNDARIES, by J. Albrecht. Jan. 18-July 18, 1954, 7p. incl. diagrs. table. (Technical note no. EOARDC-TN-54-1) (AF 61(514)631-C) AD 74984 Unclassified

Boundary conditions in the cases of curved boundaries and of rectangular ranges are treated, and direct computation of the first partial derivatives u_{10} and u_{01} are given. Approximate numerical solution of the differential equation, $\Delta u = u_{20} + u_{02} = r(x, y)$ in B, by means of the difference method, requires a consideration of the boundary conditions $u = f(s)$ on Γ or $u_n = f(s)$ on Γ, (n = outer normal of the boundary of the range B in the x, y-plane). Some finite expressions are presented for this purpose showing a higher "Taylorabgleich" (equalizing up to terms of h^2 inclusive) than the formula of linear interpolation (equalizing up to h^1 inclusive). The attempt to improve these formulas to correspondence up to terms of h^3 inclusive was not successful. An attempt was also made to approximate the boundary condition $u_n = f(s)$ more accurately in the case of rectangular ranges by considering the values of f and also those of the derivatives of the functions f(s) and $r(x, y)$. Formulas are stated which permit computation of the partial derivatives $\frac{du}{dx}$ and $\frac{du}{dy}$ from the differential equation $\Delta u = r(x, y)$ and the boundary conditions $u = f(s)$ or $u_n = f(s)$ numerically in a direct manner.

[A VARIANT OF THE TECHNIQUE OF SOLUTION OF DIFFERENCE EQUATIONS THROUGH THE METHOD OF "MEHRSTELLENVERFAHREN"] Eine Variante des Mehrstellenverfahrens, by J. Albrecht. [1955] [6]p. [AF 61(514)631-C] Unclassified

A generalization of a technique, attributed to Numerow, in the process of central differences for problems with initial values with differential equation $u''(x) = r(x)u(x)$ is made through the central difference process multiplace method (Mehrstellenverfahren). The formulas attained simplify the computation without affecting the accuracy. The general formulation of a special "Mehrstellenverfahren" for initial and boundary conditions in N^{th} order differential equations follows the method description for ordinary 2nd order differential equation. Examples given are finite equations for heat conduction $\Delta u - Ku_1 = ru$ and $\Delta u = q + ru$ (in addition, the formula for the generalized problem $\Delta u = q$). The "Mehrstellen" procedure of Collatz for eigenvalue problems $\Delta u + \lambda u = o$ arrange themselves.

[A FINITE DIFFERENCE METHOD OF PARABOLIC AND HYPERBOLIC DIFFERENTIAL EQUATIONS] Zum Differenzenverfahren bei parabolischen und hyperbolischen Differentialgleichungen, by J. Albrecht. [1955] [34]p. incl. diagrs. tables. [AF 61(514)-631-C] Unclassified

Several general points are of significant importance in the setting up of computation formulas for the finite difference method in parabolic and hyperbolic differential equations, as shown in examples of the heat conduction and rod and membrane vibration equations. These points include (1) verification of the stability of the technique; (2) use of a multiterm Taylor expansion to get a greater accuracy; (3) the step parameter should be as large as possible; and (4) efficient easy and simple numerical methods. Stability and instability expressions are proved and the dependence upon the

HAR. 01:001 - HAR. 02:004

chotce of lattice points is seen for each step value. Regions of the x_1, x_2 - plane bound by curves are studted, with consideration both of "regular finite expressions" and of "irregular finite expressions." Finally the Runge-Ketta method, used on regular differential equations, is applied to partial differential equattons.

RELAXATION EFFECTS IN THE FERROMAGNETIC RESONANCE, by R. W. Damon. Jan. 15, 1952, 73p. incl. illus. diagrs. refs. (Technical rept. no. 136) (Sponsored jointly by Office of Naval Research, Stgnal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) U21473 Unclassified

<u>Also published in</u> Rev. Modern Phys., v. 25: 239-245, Jan. 1953.

Ferromagnetic resonance in nickel ferrite was studied at high levels of mtcrowave power. Saturation of the spin system was observed by (1) the decrease in relative energy absorbed by the sample and (2) the change in z-component of magnetization at high power levels. The microwave magnetic field strength required for

saturation differed in these 2 instances. The change in magnetization occurred at the resonant value of static field and extends to smaller fields. These effects were essentially independent of crystallographic orientation although they showed some dependence on crystal imperfections. The calculated spin-lattice relaxation time was 3×10^{-8} sec. Spin-lattice interaction contributed little to the resonance line width. The selection rule for conservation of wave number in a transition did not appear to be rigorously true, but the spin waves of short wave length could be excited by induced transitions. An explanation is offered for the discrepancy between the spectroscopic splitting factor (g), obtained from resonance experiments, and the gyromagnetic ratio (g-), measured by magnetomechanical methods. AN EXPERIMENTAL INVESTIGATION OF THE SINGLE WIRE LINE, by T. E. Roberts, Jr. Feb. 1, 1952, 25p. diagrs. tables, refs. (Technical rept. no. 139) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) U21600; ATI 150036 Unclassified

Also published in Jour. Appl. Phys., v. 24: 57-67, Jan. 1953.

Experiments were performed to check theoretical results concerning the single-wire transmission line. Measurements were made of attenuation and phase velocity of the principal mode, an equivalent circuit for the transition from a coaxial to a single-wire line, and current and charge distributions. The equipment consisted of a stable RF generator, detecting equipment, a straight wire supported at each end, and a traveling probe. A wave length of 3.2 for the RF signal permitted a line length of 80 λ. A current distribution calculated for the case of connecting the wire to a coaxial line of very small outer radius agreed well with experimental results. The theoretical efficiency of exciting the guided mode was verified by observation. Some measurements were obtained to illustrate the loss of power with gradual curves in the wire, and the additional reflection loss with sharp bends. (TIP abstract)

RAY THEORY APPLIED TO A SPHERICAL IONOSPHERE, by A. T. Waterman, Jr. Feb. 15, 1952, 68p. incl. diagrs. refs. (Technical rept. no. 142) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7628) U22014; ATI-150436 Unclassified

A theoretical analysis was undertaken on the application of simple ray-theory to HF sky-wave propagation over large distances when the curvature of both the earth and the reflecting layers is considered. Limitations in the extension of the plane-ionosphere equivalence theorems to conditions of spherical geometry are discussed. For the interrelationships between distance, equivalent path length, and equivalent virtual height, inequalities are derived which establish bounds within which the exact relations must lie. A method of approximate solution for ray paths is developed for the case of oblique-incidence reflection by a single ionospheric layer having a parabolic distribution of electron-density. Comparison is made between the approximate solutions for a parabolic layer and numerical solutions for a Chapman layer with and without a region of ionization (F_1) beneath that causing the reflection (F_2). The methods used in computing the distance, equivalent path length (or transmission time), focusing effect, and absorption for reflection from a Chapman-type ionosphere are outlined; results are presented in graphical form. Curves are given for these quantities as a function of relative critical frequencies of the ionospheric layers when the distance is kept fixed. (TIP abstract)

IONOSPHERIC ABSORPTION OF OBLIQUELY INCIDENT RADIO WAVES, by A. T. Waterman, Jr. Mar. 20, 1952, 69p. incl. illus. diagrs. refs. (Technical rept. no. 143) (Sponsored jotntly by Office of Naval Research, Signal Corps, and [Air Force Offtce of Scientific Research] under N5ori-7628) U22668; ATI-155831 Unclassified

A stable, logarithmic, automatically-calibrating receivtng equtpment was used to record the amplitude of individual sky-wave pulses transmitted over a 1309-km path at 12.9 mc. The arrivtng wave-train was interpreted in terms of the absorption encountered tn the ionosphere. Consistency between computed and measured results at oblique incidence confirmed the naiure of ionosphertc influences on received signal strength. The F-region exhibited negligible absorption, but defocusing strongly influenced the amplitude of Pedersen rays. The E-region had a reverse effect on rays reflected from the F_2-layer. Focusing appeared to be a minor factor (except at longer distances, where it can become critical), and absorption was the major influence. A quantitative determination of these influences was achieved. The procedure provided a means of assessing the collisional frequencies in the E-region. Values obtained were lower than those elicited from ionospheric cross-modulation experiments, though the discrepancy could be removed by a slight adjustment in E-layer height. The resulting distribution of collisional frequency and the dependence of this distribution on the height of the E-layer are summartzed. Implications regarding the frequency of electron-molecule collistons in the ionosphere, and the effective cross section for such collisions are discussed. (TIP abstract)

THEORY OF ELECTRICALLY SHORT TRANSMITTING AND RECEIVING ANTENNAS, by R. King. Mar. 20, 1952 [48]p. incl. tables, refs. (Technical rept. no. 141) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Offtce of Scientific Research] under N5ori-7601) U22096; ATI-150729 Unclassified

Also published in Jour. Appl. Phys., v. 23: 1174-1187, Oct. 1952.

Complete and quanlitatively accurate solutions of the properties of electrically short transmitting and receiving antennas (of length 2h such that $2\pi h/\lambda_0 \leq 1$) are obtained by determining the distributions of current that actually satisfy the integral equattons. Components of current in phase and in phase-quadrature with the drtving voltage or the incident electric field are evaluated together with the impedance, the effective length, and the gain. It is shown that when the King-Middleton method of solving Hallén's integral equation by iteration is applied correctly, quite accurate results are obtained even in a first-order solution. The greatest error in the first-order formulas is shown to be in the resistance, a small quantity of higher order compared with the reactance. The newly determined values are combined with the King-Middleton second-order results to obtain more complete and more accurate tmpedances and effective lengths in the range of $0 \leq 2\pi h/\lambda \leq 1.4$. AN ANALOG COMPUTER FOR CORRELATION FUNCTIONS IN COMMUNICATION SYSTEMS, by R. A. Johnson. Mar. 25, 1952, 28p. incl. illus. diagrs. table, refs. (Technical rept. no. 144) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Atr Force Office of Scientific Research] under N5ort-7601) U22255; ATI-152473 Unclasstfied

The analog computer was designed to measure correlation functions of noise and signal voltages before and after detection in an AM communication system. Variable time delay is achieved by moving a pickup head along a rotating magnetic drum on which the signal under investigation is recorded. A second channel has a fixed delay, so that zero (or negative) delays can be obtained. Multiplication of the 2 signals is accomplished by an analog electronic multiplier. The desired correlation function is then plotted by a recording meter which tndicates the average value of the multiplier output as the time delay is varied. The basic components of the correlator, the multiplier and delay unit, are explained in detail. The associated equipment necessary for the study of noise and signals before and after rectification by a linear detector is discussed. The limitaitons and advantages of the equipment are compared to those of other correlators. (TIP abstract)

RADIATION OF THE BOSS ANTENNA, by C. H. Papas and D. B. Brick. Apr. 1, 1952, 8p. incl. diagrs. refs. (Technical rept. no. 148) (Sponsored jotntly by Office of Naval Research, Stgnal Corps, and [Atr Force Office of Sctentific Research] under N5ori-7601) U22256; ATI-152471 Unclassified

Ideally the boss antenna consists of a conducting hemisphere placed so close to a perfectly conducting image plane that the field distrtbution across the gap between hemisphere and plane can be represented by a Dirac δ function. The problem differs from that of Stratton (Electromagnetic Theory, N. Y., McGraw Hill, 1941, p. 555-557) in that the antenna is driven. The coaxial line which drives the radiator consists of an inner

conductor which connects to the hemisphere and an outer connector of which 1 boundary forms the infinite image plane. The radiation field is derived in spherical harmonics, making use of the image theorem. The apparatus used to measure the radiation pattern consisted of a λ/4 dipole pickup attached to a swinging arm actuated under seisyn control. Good qualitative agreement between theory and experiment was obtained. (TIP abstract)

A GENERAL THEORY OF PLANE-WAVE SCATTERING FROM FINITE CONDUCTING OBSTACLES WITH APPLICATION TO THE TWO-ANTENNA PROBLEM, by J. Sevick and J. E. Storer. Apr. 10, 1952, 44p. incl. diagrs, refs. (Technical rept. no. 149) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) U22914; ATI-158450 Unclassified

Also published in Jour. Appl. Phys., v. 25: 369-376. Mar. 1954.

An approximate procedure is presented for the handling of 3-dimensional electromagnetic scattering by finite, perfectly conducting obstacles where coupling is explicitly taken into account. The variational formulation of Levine and Schwinger (Communications on Pure and Applied Mathematics, III, no. 4, 1950) is used in deriving an expression for the scattered field distribution in the far zone in terms of the currents flowing on the obstacles. An expression obtained for the back-scattering cross sections in terms of stationary quantities is applied to the study of the back-scattering cross section of 2 identical, nonstaggered, unloaded antennas which are oriented parallel to the incident field. The case of broadside radiation is treated for half-wave and full-wave antennas. Curves of back scattering vs antenna spacing are similar in shape for both antennas but greatly different in magnitude. This difference may be explained by the resonant current of the full-wave-length antenna being an odd function and therefore not excitable by an incident plane wave polarized parallel to the antenna. WAVE PROPAGATION IN A TWO-DIMENSIONAL PERIODIC MEDIUM, by J. E. Storer. May 1, 1952, 29p. diagrs. refs. (Technical repl. no. 152) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) U24292; ATI-169954 Unclassified

An approximate solution to the problem of propagation of electromagnetic waves in a 2-dimensional array of perfectly conducting cylinders is presented. The method used to obtain a solution is similar to that employed by Levine and Schwinger (Phys. Rev., v. 74: 958-974, 1948) in diffraction problems. An integral equation is derived for the currents flowing on the cylinders, and a variational principle is used to obtain an approximate solution to this equation. This method can be generalized to 3-dimensional periodic arrays. (Contractor's abstract)

MICROWAVE DIFFRACTION MEASUREMENTS IN A PARALLEL-PLATE REGION, by R. V. Row. May 5, 1952, 30p. incl. illus. diagrs. (Technical rept. no. 153) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) U23775; ATI-165612 Unclassified

Also published in Jour. Appl. Phys., v. 24: 1448-1452, Dec. 1953.

An experimental arrangement for scattering problems was constructed for use in the 3-cm wave-length region. The finite parallel plates support a transverse electromagnetic wave with the electric field normal to the plates. Absorbing wedges at the outer boundary of the plates reduce reflections from these boundaries. The scattered fields may be investigated by means of a dipole penetrating into the region. Measurements of the total field scattered by 0°, 45°, and 90° conducting wedges showed satisfactory agreement with theory. The effect of finite thickness of the diffraction screen (for the 0 wedge) in increasing the amplitude of the scattered wave is noted and compared to theoretical results derived for scattering from a conducting half-plane with a cylindrical edge. TANDEM-SLIT DIFFRACTION MEASUREMENTS, by L. R. Alldredge. May 18, 1953, 14p. illus. refs. (Technical rept. no. 176) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-760f) AD 22430
Unclassified

The diffraction of a plane electromagnetic wave by 2 identical slits in tandem was investigated experimentally for normal incidence with polarization parallel to the edges of the slits. The slits were assumed to be infinitely long, a condition which is approximated experimentally by use of a parallel-plate system described by R. V. Row. Measurements were made for tandem separations of slits from 0 to nearly 2 wave lengths and for slit widths from 0 to f.4 wave lengths. For a tandem-slit separation of zero, which corresponds to single slit, the results for the transmission coefficients were in good agreement with established theoretical results. The results showed interesting resonance phenomena as the tandem-slit separation was changed. (ASTIA abstract)

EXPERIMENTAL AND THEORETICAL RESULTS ON THE BACK-SCATTERING CROSS SECTION OF COUPLED ANTENNAS, by J. Sevick. May 26, 1952, 9p. incl. diagrs. refs. (Technical rept. no. 150) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) U22913; ATI-158449
Unclassified

A general theory on the plane-wave scattering of obstacles where coupling is taken into effect was applied to the determination of the back-scattering cross section of 2 identical, nonstaggered, unloaded antennas oriented parallel to the incident radiation. Three aspects of the general problem are the determination of (1) the back-scattering cross section ( ) as a function of the spacing (b) and the angle ( ) between the plane of the antennas and a plane perpendicular to the direction of the incident radiation, (2) as a function of b and the thickness for 0, and (3) as a function of b and the height of the antenna for 0. It was concluded that broadside scattering is greater than that for any other angle; back scattering amplitudes depend on independent scattering of the elements. The shapes of the back-scattering curves are similar for half- and full-wave antennas. A theoretical treatment considering the antennas as independent scatterers is inaccurate even at spacings of 3 .

AN EXPERIMENTAL METHOD OF MEASURING BACK-SCATTERING CROSS SECTION OF COUPLED ANTENNAS, by J. Sevick. May 28, 1952, 18p. illus. diagrs. (Technical rept. no. f5f) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-760f) U23222; ATI-f59852
Unclassified

A method of measuring back-scattering cross sections is described in which the measuring scheme utilizes an image plane and cancellation procedure. The technique involves measuring the incident field at a point in the far zone with respect to the scattering obstacles before they are in place, canceling out the effect of the incident signal with a signal taken from the transmitter, and then measuring the absolute value of the scattered signal after the obstacles are placed in position. If the distances between the source, testing probe, and scatterer are known, a simple relationship can be obtained for the back-scattering cross section. The system offers a means of obtaining quick experimental results with a knowledge of the errors involved. The method is limited to obstacles containing a plane of symmetry. The derivation of the experimental equation for the back scattering cross section is given as well as the procedure used in the experimental process, a description of the equipment, and a discussion of the possible sources of error.

THE SUSCEPTANCE OF A CIRCULAR OBSTACLE TO

AN INCIDENT DOMINANT CIRCULAR-ELECTRIC WAVE, by L. S. Sheingold. June 15, 1952, 22p. illus. table. (Technical rept. no. 159) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ort-7601) AD 6566 Unclassified

Also published in Jour. Appl. Phys., v. 24: 414-422, Apr. 1953.

Lower- and upper-bound expresstons were obtained for the susceptance of a circular obstacle excited by the TE_{01} mode tn a circular wave guide. The solutions were obtained by a variational method. Experiments showed the TE_{01} mode to be about 60 db above extraneous modes over a free-space, wave-length range of 7.30 to 11.90 cm. The discrepanctes between theoretical and experimental results are attributed to finite thickness and conductivity of the obstacle, ellipticity of the circular wave guide, presence of lower-order propagating modes, and typical errors involved in the measurement of admittance by the resonance-curve method.

AN ALTERNATIVE METHOD OF SOLVING HALLEN'S INTEGRAL EQUATION AND ITS APPLICATION TO ANTENNAS NEAR RESONANCE, by R. King. July 1, 1952, 14p. diagrs. (Technical rept. no. 154) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ort-7601) U24191; ATI-169048 Unclassified

Also published in Jour. Appl. Phys., v. 24: 140-147, Feb. 1953.

Hallen's complex integral equation for the current tn a cylindrical antenna ts separated into 2 real integral equations for the components of current in phase and in phase-quadrature with the driving voltage. Each of these equations ts solved by iteration using zeroth-order currents and vector-potential differences to define expansion parameters. It is shown that for electrical half-lengths near odd multiples of a quarter-wavelength, at least a third-order solution is required in order to determine accurately the component of current in phase with the driving voltage and the conductance. Conductances for a range of radii are evaluated by the new third-order formula and compared with the King-Middleton second-order values and the experimental data of Hartig. The new formula agrees excellently with experimental results at h $\lambda_0/4$, whereas the earlier second-order formula has its largest error (near 8 to 10%) in a small range near resonance It is concluded that for antennas near resonance, just as for very short and very long antennas, adequate account must be taken in the iteration of both components of current. SKY-WAVE FIELD INTENSITY. 1. LOW AND VERY-LOW RADIO FREQUENCIES, by J. A. Pierce. Sept. 1, 1952, 107p. dtagrs. (Technical rept. no. 158) (Sponsored jointly by Office of Naval Research, Signal Corps and Air Force Office of Scientific Research under N5ori-7601) U24899; ATI-185675 Unclassified

A general theory of unabsorbed sky-wave field strength is developed which is applicable to transmission by

either E- or F-layer reflections. The application of the theory is worked out only for low radio frequencies. Based on an expression given to define unabsorbed field strength, the transmission losses at low frequencies fall into a simple and coherent pattern. The logarithm of the losses in these cases is nearly linear. The theory is used in the analysis of measurements of field strength in the frequency region below 100 kc which were made during 1951. The observed variations of atmospheric noise with frequency and time are used as the basis for computing the power requtred to maintain communication and the corresponding S/N's and optimum radio frequencies.

THE EFFECT OF THE SURFACE ON THE MAGNETIC PROPERTIES OF AN ELECTRON GAS, by H. Brooks and F. S. Ham. Mar. 10, 1953, 46p. illus. refs. (Technical rept. no. 169) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Atr Force Office of Scientiftc Research] under N5ori-7601) AD 6210 Unclassified

Also published in Phys. Rev., v. 92: 1113-1119, Dec. 1, 1953.

A determinatton of the magnetic susceptibility of a system of electrons confined in a box is presented whtch considers the dependence of susceptibtlity on the form of the wall potential. An tmproved argument is given for a cylindrical box in which the balancing of diamagnetic and paramagnettc states is clarifted, and which determines (by means of the WKB approximatton) the nature of the boundary states. A more detailed derivation is given which establishes corrections to the terms in the susceptibility that dominate at htgh field strengths. The derivation is valid only if the radius of the confining box is considerably larger than the classical orhit radius of an electron moving in a plane perpendicular to a magnetic field with energy equal to the Fermi energy of the system. Darwtn's model is shown not to gtve the same results as the electron-in-a-box model when Fermi statistics are used. (ASTIA abstract)

EXPERIMENTAL AND THEORETICAL IMPEDANCES AND ADMITTANCES OF CENTER-DRIVEN ANTENNAS, by P. A. Kennedy and R. King. Apr. 1, 1953, 1v. incl. diagrs. tables, refs. (Technical rept. no. 155) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 11434 Unclassified

Recent experimental and theoretical results pertaining to the impedance and admittance of center-driven antennas have been consolidated into one report. A complete set of tables and curves with instructions for their use follows a general discussion of the problem. The essentials of the King-Middleton second-order theory and the final equation for the second-order impedance are presented along with necessary spacing and end-effect corrections which must be considered. Experimental results from various sources have been compared with theory. In particular Hartig's experimental results on the effect of circular apertures in a horizontal ground plane on the impedance of a half-dipole have been reevaluated and found to agree well with theory. Special related topics such as the electrically short antenna and the receiving antenna have also been discussed. (Contractor's abstract)

ELECTROMAGNETIC SCATTERING FROM TWO PARALLEL CONDUCTION CIRCULAR CYLINDERS, by R. V. Row. May 1, 1953, 58p. illus. refs. (Technical rept. no. 170) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ort-7601) AD 14953 Unclassified

Also published in Jour. Appl. Phys., v. 26: 663-675, June 1955.

The problem of the scattering of an incident cylindrical electromagnetic wave by an arbitrary array of perfectly conducting circular cylinders is solved for the case of the electric vector parallel to the axes of the cylinders. The total field is calculated by the use of a Green's theorem. The application of the boundary conditions results in a set of integral equations for the current on each cylinder; arbitrary excitations and coupling between all the elements are taken into account. The currents are expanded in a complex Fourier series; this transforms the integral equations into an infinite set of linear algebraic equations in the unknown Fourier coefficients. The theory is specialized to the case of 2 identical cylinders. In addition, neglect of the coupling between different current modes yields a simple formula for the scattered field in which the effect of coupling is apparent. For 2 cylinders equidistant and far from the source, the scattered field is computed from these approximations for cylinders as large as a wave length in diameter and for spacings of 1 to 4 λw between the centers. The approximations were confirmed by measurements at 3.185 cm w in a parallel plate region. Both theory and experiment indicate significant departures from the predictions of the independent scattering hypothesis. (ASTIA abstract)

MODE CONTROL AND OPERATING VOLTAGES OF INTERDIGITAL MAGNETRONS, by A. Singh. May 5, 1953, 13p. illus. (Technical rept. no. 179) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601] AD 12828 Unclassified

Studies were made controlling the frequencies of all the modes up to the second order, and investigations were made to study the electronic operation [illegible]rst- and second-order modes. Experiments with operating tubes show that under given conditions, the first- and second-order modes can operate at more than 1 voltage. The different voltages can be attributed to the excitation of different Fourier components of the field configuration. Variation of resonance frequency of modes of different orders with changes in resonator parameters was studied by using a demountable resonator. It was indicated that an increase of cavity radius reduces the resonance frequency and increases the separation of the different modes; the ratio by which the resonance frequency changes for a given variation of cavity radius is smaller for the higher-order modes. An increase of radial thickness of the fingers, or a decrease of the separation between fingers, reduces the resonance frequency. A mode of separation of the order of 40% is obtained by choosing the ratio of cavity radius to anode radius to be 3:1. Sensitive control over the various modes can be

HAR. 02:034 - HAR. 02:038

obtained by introducing radial vanes in the cavity. The degenerate pairs of modes can be separated out, and the modes can be accurately located at equal intervals if the radial penetration of the vanes is chosen properly. (ASTIA abstract)

THE RADIATION OF A HERTZIAN DIPOLE OVER A COATED CONDUCTOR, by D. B. Brick. May 10, 1953, 49p. incl. illus. refs. (Technical rept. no. 172) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 16104 Unclassified

The idealized problems of (a) an infinitesimal Hertzian dipole in and over a perfect dielectric coating a perfect conductor and (b) as Abraham dipole lying on the conductor are treated. Unintegrated forms of the Hertz potentials are obtained for both electric and magnetic dipoles. Integrated far-zone forms of the potentials and fields are obtained for electric dipoles by means of asymptotic integrations. Far-zone radiation are given in order to indicate the distortions of the fields and the magnitudes of the residue waves caused by the dielectric coatings. It is proved that the power radiated by the dipole, may be divided into two independent quantities: the power fed to radiation type and that fed to surface or guided type fields. For certain cases numerical results are given for the total power radiated and the relative powers fed to the two types of fields. Formulas are derived and illustrated with numerical examples of the radiation resistances of the dipoles and the attenuation constants of the surface modes due to finite conductivity of the ground plane. VARIATIONAL APPROXIMATIONS TO THE DIFFRACTION BY CIRCULAR AND ELLIPTICAL APERTURES, by C. Huang. June 5, 1953, 34p. illus. refs. (Technical rept. no. 164) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 24680 Unclassified

Different methods are reviewed briefly for attacking the problem of the diffraction of a plane electromagnetic wave by a circular aperture in a plane screen which is infinitesimally thin and perfectly conducting. Specifically, the variational method derived by Levine and Schwinger has been used to evaluate the transmission coefficient of circular and elliptical apertures. For the circular aperture, a high-order vector trail function with undetermined frequency-dependent coefficients is

chosen. By using the stationary property of the expression for the transmission coefficient, equations for the undetermined coefficients are derived. These equations are solved to give a first-order approximation of the transmission coefficient, and the numerical values are compared with previous results. For elliptical apertures, a zeroth-order approximation of the transmission coefficient is evaluated using a one-component trail function. Numerical results are given for ellipses with minor-to-major-axis ratios of 1/2 and 1/3. (Contractor's abstract)

THE MEASUREMENT OF APERTURE TRANSMISSION COEFFICIENTS, by C. Huang and R. D. Kodis. June 10, 1953, 7p. illus. refs. (Technical rept. no. 165) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 18563 Unclassified

The transmission coefficients of circular, elliptical, and square apertures in a plane conducting screen are determined from measurements of the far-zone scattered field in the direction of incidence. The measurements were carried out at K-band frequencies using an image-plane technique. Experimental values of the transmission coefficient are compared with the results of a number of theoretical formulations. (Contractor's abstract)

BABINET'S PRINCIPLE FOR PLANE OBSTACLES, by C. Huang. June 15, 1953, 9p. (Technical memo. no. 8) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori 7601) AD 24689 Unclassified

Integral formulas are deduced for representing electric and magnetic fields throughout a region. The formulas are applied to the problem of the diffraction of electromagnetic waves by a perforated plane conducting screen. Integral equations are obtained from which a compact proof of Babinet's principle is obtained for the diffraction by the screen. (ASTIA abstract)

MODIFICATION OF STANDARD NETWORK SYNTHESIS TECHNIQUES TO USE LOSSY ELEMENTS, by J. E. Storer. June 20, 1953, 7p. incl. illus. (Technical rept. no. 180) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force of Scientific Research under N5ori-7601) AD 16102 Unclassified

A method is presented for adapting standard network synthesis techniques to yield circuits having lossy elements. The usual procedures of synthesizing transfer impedances or transfer functions can be modified so that the final circuit has a resistance in series with each inductance and a resistance in parallel with each capacitance. The procedure used is the inverse of the one outlined by Guillemin (Communications Networks, v. 2, John Wiley, N. Y., 1951) for calculating the effect of lossy elements. (ASTIA abstract)

IMAGE-PLANE AND COAXIAL-LINE MEASURING EQUIPMENT AT 600 MC, by H. W. Andrews. July 1, 1953, 27p. illus. refs. (Technical rept. no. 177) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 22429 Unclassified

Consideration is given to the construction of the measuring lines and the associated electronic devices for determining the driving point impedance and the current and charge distributions upon antennas. Configurations possessing a plane of symmetry are mounted over an image screen behind which is located the measuring equipment. The measuring line connects into the image screen, and its center conductor may be extended to form an antenna. The conductor is slotted, and the currents and charges distributed on it may be determined by probes sliding within it. An unmodulated source of RF energy is used, and the modulation is introduced in the superheterodyne receiver used to measure the signal level. The frequency of the source is monitored by comparison, in a spectrum analyzer, with a crystal-controlled source of energy.

THE COLLINEAR ANTENNA ARRAY. THEORY AND MEASUREMENTS, by H. W. Andrews. July 15, 1953, 47p. illus. refs. (Technical rept. no. 178) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601 and -7628) AD 27101 Unclassified

A theory for the close-spaced collinear antenna array was formulated on the basis that the array is the superposition of a doubly and a singly driven dipole. Values for computation of impedances, comparison of probes, and gap ($0 < \text{gap} < \lambda/10$) capacitance were obtained both theoretically and experimentally. The theory was evaluated for specific configurations typical of the applicable range of the theory as a check of the basic assumptions and of the region of usefulness.

FULL-WAVE DETECTION OF SIGNALS IN NOISE, by N. Stone and D. Middleton. Aug. 1, 1953, 62p. illus. table, refs. (Technical rept. no. 182) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 40540 Unclassified

The experimental background for the theoretical problems to be investigated is first reviewed, and then a brief sketch of the classical detection problem is included. A signal-to-noise ratio is defined, and the principal results of the study are summarized and discussed in some detail, with the important quantities in the derivation of the output signal-to-noise ratio after full-wave rectification, for input background noise of gaussian statistics, being obtained from the correlation function for the output. The cases treated are: 1(a) a sinusoidal signal in narrow-band noise; 1(b) a narrow-band noise "signal" in a narrow-band noise background; 2(a) a sinusoidal signal in broad-band noise; and 2(b) a narrow-band noise "signal" in a broad-band noise background. The half-wave and full-wave cases are compared. The important devices, the ideal clipper, linear detector, and square-law detector, are considered, and compared for the extremes of very large and very small input signal-to-noise ratios. Thus, for all varieties of input outlined above if p is the input power signal-to-noise ratio, then for very small p, the output power signal-to-noise ratio, P, is related to p by $P \sim p^2$, for all devices. For sinusoidal signals (large p) and linear and quadratic detectors, P is proportional to p, whereas for the ideal clipper, $P \sim (\ln p)^2 p$. The exact relations are summarized in Part I, sec. 4 of this report. (Contractor's abstract)

ON THE NUCLEAR MAGNETIC RESONANCE IN METALS AND ALLOYS, by N. Bloembergen and T. J. Rowland. Aug. 20, 1953, 28p. illus. tables, refs. (Technical rept. no. 186) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 19236 Unclassified

Also published in Acta Metallurgica, v. 1: 731-746, Nov. 1953.

A Pound-Knight-Watkins type of RF spectrometer (Rev. Scient. Instruments, v. 21: 219, 1950) was used in measuring the shift of nuclear resonance and the line width in α- and β- Sn, Th, Pb, and several alloys. A permanent magnet with a field of about 6000 gauss in a 1.25-in. gap and with 4-in.-diam pole faces was also used. A few measurements were made with an electromagnet at fields between 2000 and 5500 gauss. The samples were made from powdered metals suspended in mineral oil. Gray Sn showed no shift relative to the resonance in insulating compounds, but white Sn had an anistropic shift of 0.79% along the tetragonal axis and 0.74% perpendicular to it. A theory is given for the anistropy and symmetry of the observed line. Thallium had an anomalously broad resonance line with a shift of 1.54%. The shift in Th alloys varied continuously with composition in each phase and had discontinuities when phase transitions occurred. The intensity of the Cu resonance in pure Cu was increased by annealing and decreased by cold work. The intensity in alloys such as α-brass and Cu-Ag decreased rapidly with increasing Zn or Ag content. These effects are explained in terms of quadrupole interaction. (ASTIA abstract)

FERROMAGNETIC RESONANCE ABSORPTION IN COBALT SINGLE CRYSTALS, by T. Ohtsuka. Aug. 30, 1953, 18p. illus. refs. (Technical rept. no. 187) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 25240 Unclassified

The ferromagnetic resonance absorption of Co single crystals was measured at about 24,200 mc by using an experimental technique similar to that described by Bloembergen (Phys. Rev., v. 78: 572, 1950). Three crystals cut in different orientations and in the shape of thin rectangular slabs were used. By using experimental values and assuming that the spectroscopic splitting factor g is isotropic, the anisotropy constants K_1' and K_2' were calculated. The line width was determined from relative values of the resonance permeability μ_R. The shift in the easy direction from the hexagonal axis to the hexagonal plane arises from the temperature dependence of the first-order effect of dipolar coupling; the second-order effect tends to suppress the switchover and spread it out over a finite temperature range. The g- value decreased from 2.6 at 180° C to 2.2 at about 240°C, leveled off, and stayed constant up to 380°C. The line widths for all crystals were of the order of a few hundred oersteds. Measurements at 200° to 400°C confirmed the phenomenon of the reversal of sign in K_1'. (ASTIA abstract)

THE POLARtZATION OF RADIO WAVES REFLECTED FROM THE tONOSPHERE AT NONVERTICAL tNCtDENCE. tt. MEASUREMENT TECHNtQUES AND EXPERIMENTAL RESULTS, by G. Inouye. Sept. 1, 1953, 46p. tllus. refs. (Technical reot. no. 191) (Sponsored jointly by Office of Naval Research, Stgnal Corps, and [Air Force Offtce of Scientific Research] under N5ort-7601 and -7628) AD 31605 Unclasstfied

The effect of the ground on the total field as measured is discussed as a functton of the ground constants and the vertical angle of arrtval. As part of the determinatton of the polarization, the techniques for measuring the horizontal and vertical angles of arrival are also discussed. Equipment is described for simultaneously recording the phase difference of signals consisting of trains of RF pulses. The amplitude ratio in the polarization determination is recorded in a manner similar to the phase angles. The direction of arrival of downcoming ionospheric radio waves was measured on the 9.1-mc pulsed transmisstons on the Glenville, N.C. to Lexington, Mass. path (1310 km). The angles of arrivat had random vartations of a few degrees about a mean value, wtth pertods ranging from 10 to 30 mtnutes. Aside from these fluctuations, the horizontal angle of arrtval corresponded to propagation vta the great-circle path except for an unexplained deviation of about a degree to the NW. The vertical angle averaged about 5° higher than theoretical predictions for F-layer transmissions. The polarization was as predicted by the theory when the magneto-ionic components were separated in time of arrival so that phase interference was not obscuring the polarization of individual modes. For the particular conditions obtaining in measurements, the polarization was nearly circular with the ordinary ray havtng a left-handed, and the extraordinary ray havtng a right-handed, sense of rotatton looking tn the dtrection of the wave normal. RELAXATION EFFECTS IN PARAMAGNETIC AND FERROMAGNETIC RESONANCE, by N. Bloembergen and S. Wang. Sept. 10, 1953 [12]p. incl. diagrs. tables, refs. (Technical rept. no. 188) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 21718 Unctassified

Also published tn Phys. Rev., v. 93: 72-83, Jan. 1, 1954

Magnetic resonance experiments have been carried out at 3-cm wavelength in paramagnetic and ferromagnetic samples at very high microwave power levels in a temperature range between 77° K and 700° K. Changes tn the microwave susceptibtlity and the dc magnettzatton have been observed for mtcrowave amplttudes between 1 and 50 oersted. For a paramagnettc salt, $MnSO_4 \cdot 4H_2O$, these changes are readtly interpreted in terms of a spin-lattice relaxatton mechanism. The value for the spin-lattice relaxatton ttme ts dertved in three different ways and agrees well wtth that obtained by Gorter's nonresonant method. When a large exchange tnteraction occurs between the sptns, the situation above the Curte point can be described in terms of a converston of magnetic into exchange energy. The magnetic and the spin-exchange systems are not always tn thermal equtlibrium. The characteristic time for the transfer of energy between these systems is equal to the tnverse of the line width, whtch is given by the Van Vleck-Anderson formula for exchange narrowing. Experimental results for an organic free radical and some ferrites confirm this potnt of view. Below the Curie temperature the situation is more complicated. The experimental data for several ferrites and supermalloy show quatitatively the same behavior. The absorbed magnetic energy is again converted into exchange energy with a characteristic time which is atways shorter than 3×10^{-8} sec. At high temperatures this time is equal to the tnverse line width and the transitton to the paramagnetic region is continuous. At low temperatures

HAR. 02:051 - HAR. 02:054

the relaxation time increases roughly inversely proportional to the temperature although the width remains constant. The microwave susceptibility has an anomalous decrease at high power levels. No satisfactory explanation has been found for these effects in existing theories. (Contractor's abstract)

THE MAXIMUM-MINIMUM SHIFT METHOD FOR MEASURING COMPLEX DIELECTRIC CONSTANTS AND PERMEABILITIES, by R. King. Dec. 15, 1953, 21p. illus. refs. (Technical rept. no. 192) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 28257 Unclassified

An absolute method for measuring dielectric constants of solids and liquids (Rev. Scient. Instruments, v. 8: 202, 1937 and Phil. Mag., v. 29: 521, 1940) is generalized to permit the determination of both dielectric constant and permeability of a moderately low-loss or fluid medium. The method is absolute in the sense that only measurements of length are required to determine E_r and μ_r. A special feature is the fact that E_r and μ_r are each determined under conditions of maximum sensitivity. The determination of losses involving complex dielectric constants and permeabilities is also described. (Contractor's abstract)

DIFFRACTION BY APERTURES, by C. Huang, R. D. Kodis, and H. Levine. Feb. 27, 1954. [15]p. incl. diagrs. refs. (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force] Office of Scientific Research under N5ori-7601) Unclassified

Published in Jour. Appl. Phys., v. 26: 151-165, Feb. 1955.

The diffraction of plane electromagnetic waves by apertures in a plane screen which is infinitesimally thin and perfectly conducting is studied both theoretically and experimentally. The theoretical analysis employs a dyadic Green's function to develop vector formulas for the scattered fields, and from these formulas integral equations are obtained for the aperture distributions. The vector representation makes possible a compact demonstration of the electromagnetic form of Babinet's principle by means of which one may extend the aperture analysis to complementary disks. The integral equations are then used to construct a variational principle for the aperture transmission coefficient. Detailed analysis and numerical computations are carried out for two configurations. For the circular aperture a first-order vector trial function with frequency dependent coefficients is chosen for the aperture distribution. The approximate transmission coefficient is found to agree closely with the exact value in the region $2\pi a/\lambda \leq 3$. For elliptical apertures a zeroth-order approximation is evaluated using a one-component trial function. Numerical results are given for minor-to-major axis ratios of 1/2 and 1/3. Transmission coefficient measurements were carried out in the 24,000 mc band ($\lambda = 1.25$ cm) using an image plane technique. The apparatus was first calibrated with the exact solution of the circular aperture. The approximate results calculated for elliptical apertures are then seen to be in good agreement with the measurements over the accessible range. (Contractor's abstract)

FOLDED ANTENNAS, by C. W. Harrison, Jr. Mar. 1, 1954, 65p. illus. (Technical rept. no. 193) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601 and -7628) AD 33389 Unclassified

Also published in Jour. Amer. Soc. Naval Engineers, v. 67: 213; 238, Feb. 1955.

The integral-equation technique for solving electrodynamic problems involving circuits comparable to the wave length in the maximum dimension is employed to develop formulas for the driving-point impedance of various folded-wire structures. The general procedure is to equate the Helmholtz integral for the total vector potential at a point on the surface of a wire to the solution of the differential equation for the total vector potential at the same point. Formulas are developed for the driving-point impedance of 2-, 3-, and 4-wire antenna-transmission lines, and a general theory is advanced for 3-wire antenna-transmission lines whose cross sections are equilateral triangles. A

formula is developed for the driving-point impedance of a structure resembling the conventional 3-wire folded dipole, but consisting of a center-driven wire of a given radius and 2 other wires of another radius. (ASTIA abstract)

A THEORETICAL AND EXPERIMENTAL INVESTIGATION OF RADIATION OF A VERTICAL ANTENNA OVER A COATED CONDUCTOR, by D. B. Brick. Mar. 15, 1954 [57]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 195) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 33472 Unclassified

The idealized problem of a base-driven cylindrical antenna over a perfectly conducting dielectric-coated image plane is treated theoretically. An integral equation which is utilized in arriving at an approximation to the current distribution on the antenna is derived. Use is made of the results of a previous report in the derivation. The far-zone fields for the configuration are shown to be composed of two types of waves — those of spherical type, the radiation or compensating field, and those of cylindrical type which attenuate exponentially with height above the dielectric surface, the surface or guided waves. These two are combined at a typical distance to yield theoretical field patterns. The experimental approximation to the idealized configuration is described at length. Measurements made using this apparatus are seen to be in good agreement with theory, thus verifying the theory contained in this and the previous report. Experimental results are also given for partially coated surfaces as an aid towards the understanding of the phenomena. Considerable space is devoted to the choice and the calibration of the measuring antennas. In the course of this study a new concept of the complex effective receiving length is introduced. PRESSURE DEPENDENCE OF THE HALL EFFECT IN GERMANIUM (Abstract), by W. Paul, G. B. Benedek, and H. Brooks. [Mar. 1954] [1]p. (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under [N5ori-601])
Unclassified

Presented at meeting of the Amer. Phys. Soc., Detroit and Ann Arbor, Mich., Mar. 18-20, 1954.

Published in Phys. Rev., v. 94: 1415, June 1, 1954.

The pressure dependence of the Hall constant and resistivity of n- and p-type samples of germanium of different impurity concentration has been measured from 0 to 12 000 kg/cm^2. In n-type samples chosen so that the carriers are all of one type and their density remains constant — a condition deducible from the known dependence of energy gap on pressure (Phys. Rev., v. 90: 336, 1952) — the Hall constant increases by some 8 percent to 12 000 kg/cm^2. Assuming constant carrier concentration, this can be interpreted as an increase in the ratio of Hall to drift mobility for electrons. Taken in conjunction with the resistivity data this implies a decrease in both Hall and drift mobility for electrons under pressure. The results for n-type germanium with a considerable number density of minority carrier are not inconsistent with this explanation. The changes in the Hall constant and resistivity in the p-type samples under pressure are smaller than in the n-type but do indicate an increase of both Hall and drift mobility for holes under pressure, with a decrease in their ratio. THE NUCLEAR QUADRUPOLE RESONANCE AND CRYSTAL STRUCTURE OF SOLID IODINE, by K. W.

HAR. 02:060 - HAR. 02:062

H. Stevens. Apr. 20, 1954, 11p. incl. diagrs. (Technical rept. no. 197) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601 and -7628)
AD 34779 Unclassified

Previous attempts to explain the anisotropy of the quadrupole resonance in solid iodine are critically reviewed and an attempt is made to set up a valence bond description of the iodine molecule which contains the possibility that additional weak bonds are formed in crystalline iodine. This is primarily accomplished by introducing d-hybridization. The observed bond angles are then used to estimate some of the parameters in the orbits. Use is made of knowledge about nuclear quadrupole interaction in solid I_2 and in the iodine atom to determine further parameters, and in this way a picture of the iodine molecules and its behavior in a crystal is obtained. An interesting possibility which then arises is that the lobes of the wave-function of different iodine molecules do not overlap very strongly because a maximum of one molecule seems to be directed towards a minimum of another. This does not correspond to the usual ideas about bonds, but as the theory passes smoothly from the notion of maximum overlap to this new situation, no discussion is given about how it should be described. It is also seen that the observation of the quadrupole resonance in single crystals of iodine (if this becomes possible) would provide very useful information and checks on the theory. THE COLLINEAR ANTENNA ARRAY WITH A SECTION OF TWO-WIRE LINE AS COUPLING ELEMENT, by C. C. H. Tang. May 1, 1954 [30] p. incl. illus. diagrs. (Technical rept. no. 196) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601)
AD 35948 Unclassified

The problem of a symmetrical three-element collinear antenna array with a section of two-wire line as the coupling element between antennas is studied in order to obtain qualitatively the conditions under which the currents in the parasites are in phase with the currents in the driven antenna. The phase of the currents in the parasitic elements is reversed only when (1) the overall length of the section of two-wire line and the parasite is near an odd integral multiple of a quarter-wavelength, and (2) the position of the short-circuiting bar or tandem bridge on the section of line is about a quarter-wavelength away from the array. The reversal of the phase of the current on the parasite is independent of the length of the driver, but the length of the driver is involved in the driving-point impedance. The current on the array as a whole can be decomposed into a main antenna current and a secondary antenna current. The main antenna current due to the driving voltage is excited on the driver and the two-wire line, while the gap voltage produced indirectly by the main antenna current is responsible for the secondary antenna current on the driver and parasite. It is the secondary antenna mode that causes the reversal of the phase of the current on the parasite. The radiation field of the array as a whole is a superposition of the two-fields produced respectively by the current on the two-wire line and that on the driver and parasites. SOME SPIN PROPERTIES OF FERRIMAGNETIC AND ANTIFERROMAGNETIC SIMPLE CUBIC CRYSTALS, by J. S. Kouvel and H. Brooks. May 20, 1954, 36p. illus. tables, refs. (Technical rept. no. 198) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 34778 Unclassified

The model, whose "bulk" spin wave properties (i.e., the temperature variation of the magnetization and of the spin specific heat) at temperatures very low compared to the Curie temperature are derived semi-classically in this paper, is a simple cubic single crystal consisting of two magnetic spin sublattices. Due to nearest-neighbor negative exchange interaction between the sublattices, their associated spin vectors tend to be oppositely directed. Hence, when the magnitudes of the spin vectors of the sublattices are unequal, the structure is ferrimagnetic, and when they are equal, the structure is antiferromagnetic. The magnetization and spin specific heat of the former are found to follow a $T^{3/2}$ law (similar to the results of previous investigations of ferromagnetics) while the spin specific heat of the latter is found to vary as T^3. The effects of magnetic anisotropy, externally applied magnetic fields, and next-to-nearest neighbor exchange interaction on these properties are also considered. (Contractor's abstract)

RECTIFICATION OF NEARLY GAUSSIAN NOISE, by J. A. Mullen and D. Middleton. June 1, 1954, 85p. illus. tables, refs. (Technical rept. no. 189) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 35947 Unclassified

Nongaussian noise occurs sufficiently often that a study of its points of similarity to and difference from gaussian noise is desirable. This report considers an important sub-class of non-normal statistics, viz., nearly normal noise. A new form for the nearly gaussian probability densities has been found; this is discussed, compared to the conventional Edgeworth series, and related to earlier work. Next a survey of physical noise sources is made in order to classify the statistical nature of the noise that each produces. The rectification of nearly normal noise and a c-w signal in a half-wave 7th-law detector is analyzed and the correlation

functions of the output obtained. The behavior of the output is compared to the corresponding results for gaussian noise of the same input intensity. For the linear and square-law detectors, the cases of prime interest, detailed figures and a number of more tractable formulas are given. Finally, the problem of finite averaging is briefly considered. (Contractor's abstract)

NUCLEAR MAGNETIC RESONANCE IN IMPERFECT CRYSTALS, by N. Bloembergen. June 18, 1954, 1v. incl. diagrs. table, refs. (Technical rept. no. 199) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 40603 Unclassified

A systematic survey is made of how various kinds of imperfections in a crystalline lattice will affect the position, breadth, shape and relaxation time of the nuclear magnetic resonance. In accordance with Seitz's classification the following imperfections are considered: (a) dislocations; (b) vacant lattice sites and interstitial atoms; (c) foreign atoms in either interstitial or substitutional position; (d) electrons and holes; (e) phonons; and (f) excitons. Their interaction with the magnetic dipole moment and the electric quadrupole moment of the nuclei at the normal lattice sites is discussed and the available experimental information is reviewed. DISCONTINUITIES IN OPEN-WIRE LINES, by R. King. July 10, 1954, 1v. incl. diagrs. tables. (Technical rept. no. 200) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 45400 Unclassified

Also published in Transmission Line Theory, by R. King. N. Y., McGraw Hill, 1955, Sec. 13-21, Chap. V.

Conventional transmission-line theory takes no account of variations in the parameters of the transmission line or of coupling between conductors near a junction or termination. A first-order correction may be made for this omission by introducing junction-zone networks of lumped series and shunt elements which may be evaluated for each discontinuity. Following the general theory developed in earlier work junction-zone networks are obtained for a bend, a shunt T-junction and series T-connections with applications to certain types of antennas in an otherwise uniform two-wire line or single-wire line over an image plane. A PROBE SIGNAL STUDY OF THE HULL MAGNETRON DIODE, by J. A. Bradshaw. July 20, 1954, 68p. illus. refs. (Technical rept. no. 185) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 40609 Unclassified

The inner cylinder of the Hull magnetron diode was an Ni sleeve 1/4 in. in diam with an oxide coating 10 cm long. The outer cylinder was a heavy Cu anode. The sleeve could be heated above 1200°K, and a steady voltage could be applied between the sleeve and the anode. Anode and sleeve were also sections integrated in a coaxial transmission line between a HF oscillator and a detector. A TEM wave could pass from the oscillator through the diode to the detector, probing or exciting, as it passed, the space charge of electrons emitted from the hot oxide coating. When a uniform steady magnetic field is imposed on the diode, parallel to its cylindrical axis, the flow of electrons from sleeve to anode may be virtually cut off, and the diode operates as a magnetron. The probe signal suffered a sharp resonance absorption in transmission through the magnetron when the cyclotron frequency was close to the probe frequency. Near this absorption frequency the transmitted signal suffered changes of phase as well as of amplitude. These were observed over wide ranges of probe frequency, anode voltage, magnetic field, and cathode temperature. The changes were correlated with other effects, the disturbance of the residual current by the probe signal, the noise generated in the tube, and the signal at the second harmonic of the probe frequency. An examination of the orbit equations yielded an expression for the conductivity of the space-charge cloud. The conductivity depends on the ratios of probe and orbit frequency to the cyclotron frequency, u and u_0, respectively, on a phenomenological damping parameter τ, and on the average charge density. (ASTIA abstract)

THE DISTRIBUTION OF SPACE CHARGE IN THE HULL MAGNETRON DIODE, by J. A. Bradshaw. Aug. 15, 1954, 53p. illus. refs. (Technical rept. no. 201) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 45403 Unclassified

An attempt is made to fit TEM probe resonance data into a self-consistent model of the magnetron diode. Consideration is given to the effects of the transit time of electrons in a weak magnetic field in the regime before cutoff. An integral equation is developed as a means of finding the anode current as a function of the ratio of steady anode potential to the square of the magnetic field imposed in a cylindrical tube. A review is given of the characteristics of a virtual cathode without

a magnetic field, and an analysis is made of experimental data on the emission current. A rough calculation is presented of the thermal effects to be expected in the Hull cutoff transition. The results of a numerical calculation provide a means of contrasting some of the features of the cathode region before and after a steady magnetic field is imposed. Studies of the magnetron diode after cutoff result in the conclusion that the space charge entirely fills the interaction space in the diode. The potential function for this model is formulated. An extension is made of the statistical approach of G. Hok (Jour. Appl. Phys., v. 23: 983-989, 1952) to the problem of the charge distribution within a magnetron after cutoff, and consideration is given to the density distribution of electrons in phase space. ANTENNAS OF DISCONTINUOUS RADIUS, by C. Faflick. Sept. 7, 1954, 41p. incl. illus. refs. (Technical rept. no. 171) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force] Office of Scientific Research under N5ori-7601) AD 53607 Unclassified

A transmission-line analogy method is described which utilizes the known input impedance of the uniform antenna and the analogy between an antenna and a corresponding transmission line to approximate the input impedance and current distribution of an antenna with discontinuous radius. Comparisons made with the experimental values indicate that this method is more accurate than previous methods, and that for sufficiently thin antennas the results are acceptable for most engineering purposes.

PARASITIC SLEEVE ANTENNA, by C. Faflick. Sept. 7, 1954, 45p. illus. refs. (Technical rept. no. 157) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 51174 Unclassified

This research treats theoretically and experimentally the problem of the parasitic sleeve antenna, consisting of a coaxial sleeve mounted on a cylindrical antenna center driven over an image plane. It is first shown that the problem of the parasitic sleeve antenna can be resolved into two problems: (1) the center-driven cylindrical antenna of discontinuous thickness; and (2) the sleeve antenna of discontinuous radius. Equipment is described for measuring both the input impedance and the current distribution of a parasitic sleeve antenna. Current distributions on the outside of the sleeve are measured by a separate probe connected to the detecting system by miniature cable coiled inside the sleeve wall and threaded down the inside of the antenna. The errors in impedance measurement are discussed and it is shown that the measurements are accurate to within a 1% circle on a Smith Chart. Errors in phase measurements using a slotted matched line are considered and a method of minimizing errors due to a poorly matched line is presented for the case when it is impossible to adjust the relative amplitude of the two comparison signals. Graphs of input impedance vs sleeve tuning of an integral sleeve antenna in which case the sleeve is contained within the cylindrical antenna are shown for several positions of the sleeve mouth. As predicted the locus is a circle on a Smith Chart. Curves of the measured input impedance of a large number of parasitic sleeve antennas are given for various antenna lengths, sleeve positions, sleeve lengths, and sleeve diameters. Several representative current distributions are shown and the general behavior of the current is shown succinctly in a novel presentation. Finally the effectiveness of the parasitic sleeve antenna in reversing the current in the outer portion of the antenna is compared with that of the phase reversing stub. (Contractor's abstract)

MOVEMENT OF THE F-REGION, by K. Toman. Sept. 24, 1954 [30]p. incl. illus. diagrs. refs. (Technical rept. no. 207) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-760t) AD 47116 Unclassified

In the course of a fixed-frequency ionospheric study, employing a pulse-triggered transmitter operating on 3.5 mc/s and three spaced-receivers, the transmission-delay was continuously recorded. Aside from a vertical-

incidence transmission two oblique transmissions were thus available with 62 and 109 km as base-linee, the latter being correspondingly oriented in an approximate west-east and north west-south east direction. An analysis of the echoes from the F-region was made for the period between Aug. 1952 and Dec. 1953. Successive irregularitiee observed simultaneously on three records displayed frequently consistent time displacements. Assuming the mid-pointe of the transmissions to be characteristic and preferred areas for the reflection of the hf-pulsee, the time-displacements were interpreted as being due to a mechanical motion of the F-region. Direction and speed of this movement was thus obtained and semiannual and annual periods of these components became apparent. (Contractor'e abstract)

NUCLEAR SPIN EXCHANGE IN SOLIDS. THE Tl^{203} AND Tl^{205} MAGNETIC RESONANCE IN THALLIUM AND THALLIC OXIDE, by N. Bloembergen and T. J. Rowland. Oct. 5, 1954, 46p. illus. tables, refs. (Technical rept. no. 205) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 51264 Unclassified

Also published in Phys. Rev., v. 97: 1679-1698, Mar. 15, 1955.

The line width of the Tl^{203} and Tl^{205} nuclear magnetic resonance in thallium and thallium oxide greatly exceeds the dipolar width, and is a function of the abundance of the other isotope. The results can be interpreted in terms of an exchange interaction $AI_1 \cdot I_2$ between a pair of nuclear spins which exceeds the normal dipolar interaction. The exchange between different isotopee leade to broadening. Exchange between like nuclei should lead to narrowing, but it was found that samples containing 98.7 per cent Tl^{205} still exhibit linee broader than the dipolar interaction. Two causee are shown to exist; anisotropy of the chemical shift and pseudo-dipolar exchange interaction. Analysis with the method of the moments givee for the exchange interaction constant Ah^{-1} = 15.5 kc/sec with a 30% anisotropic pseudo-dipolar character in the hexagonal metal, and Ah^{-1} = 12 kc/sec with less than 10% pseudo-dipolar character in thallic oxide. The oxide has a chemical shift of +0.55% with an anisotropy of 34% of thie amount. The metal exhibits a shift of 1.56% with 16% anisotropy. Ramsey'a theory of nuclear spin exchange via exctted etectron statee in molecules, is extended to solide. Most heavy tsotopee in metals and insulators should exhibit exchange effects. From the anisotropy of the exchange information about the relative amount of p- or d-character of the electron wave function in the solid can be obtained. It is predicted that thallic oxide has a nuclear Curie point at 3.5×10^{-6}°K. Whether tt will become nuclear ferro- or antiferromagnetic depende on detaile of the electronic band structure. THE DIURNAL CARRIER-PHASE VARIATION OF A 16-KILOCYCLE TRANSATLANTIC SIGNAL, by J. A. Pierce. Oct. 10, 1954, 10p. illus. (Technical rept. no. 209) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601 and -7628) AD 53753 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 43: 584-588, May 1955.

The diurnal variation of the time of arrival of a 16 kilocycle signal traversing a transatlantic path has been found to be about 40 microseconds. This variation is presumably caused by a day-to-night change in the equivalent height of reflection of 10 to 12 km, and appeare to be very predictable. The great phase stability of very low-frequency transmission permits intercontinental frequency comparison to a precision of at least 1 part in 10^{10}. Variatione of the frequency of the arriving signal are apparently alwaye less than ±3 parts in 10^9; a figure to be compared with estimatee of the order of ±2 parts in 10^7 for high-frequency transmission. With such stability of propagation, extremely narrow receiving bandwidths are attainable. These bandwidths, in turn, make possible highly reliable networking of frequencies for communication station allocation and for navigational purposee. (Contractor'a abstract)

A NOTE ON STRAY LOADING OF PHASE BRIDGES, by J. C. Williams. Jan. 5, 1955, 11p. incl. diagrs. (Technical rept. no. 208) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601 and -7628) AD 56734 Unclassified

The quadrature voltagee derived by means of phase bridgee are subject to error in relative magnitude or phase angle because of loading of the bridge output points

HAR. 02:075 - HAR. 02:077

by stray impedances. Two resistance-capacitance bridges with either resistance-capacitance or purely capacitive loading are considered, and it is shown that output voltages can be made errorless. For one configuration it is sufficient to satisfy certain relationships among the values of bridge and loading elements alike, while in the case of the other circuit constraint equations must be supplemented by attenuation, without phase shift, of one voltage in each quadrature pair. When the phase bridge is connected to the quadrants of a capacitor-type continuous phase shifter, it becomes desirable to augment the resultant loading. (Contractor's abstract)

A SPIN WAVE ANALYSIS OF THE MAGNETITE STRUCTURE, by J. S. Kouvet. Feb. 1, 1955, 26p. incl. diagrs. tables, refs. (Technical rept. no. 210) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-760t) AD 60834 Unclassified

A semiclassical spin wave treatment is applied to the ordered spin configuration that magnetite is believed to have below its transition temperature of about 120°K. All nearest neighbor AB, AA, and BB exchange interactions are considered. Expressions are obtained for the dispersion equation (for very long wavelengths compared to the lattice spacings) and for the magnetization and spin specific heat. They are compared quantitatively with the expressions previously derived by Kaplan for the inverse spinel having no long-range spin order in the B-sites. Some antiferromagnetic cases for this structure are also discussed. (Contractor's abstract)

NUCLEAR MAGNETIC RESONANCE SATURATION AND ROTARY SATURATION IN SOLIDS, by A. G. Redfield. Feb. 15, 1955, 57p. incl. diagrs. refs. (Technical rept. no. 206) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 60147 Unclassified

Nuclear spin-lattice relaxation times of Al^{27} in pure Al and Cu^{63} in annealed pure Cu have been measured with a nuclear induction spectrometer, by the method of saturation. The experimental values of T_1 are 4.1 ± .8 msec for Al^{27} and 3.0 ± .6 msec for Cu^{63}, in reasonable agreement with theory. The dispersion mode of the nuclear resonance was also observed, and it was found that χ' (the real part of the rf susceptibility) does not saturate at the same level as the absorption, χ'', but remains roughly constant out to a radio-frequency field intensity of about 2 gauss. Both χ' and χ'' become narrower and nearly Lorentzian in shape above saturation. When the dc magnetic field modulation is increased from 14 to 41 cycles the phase of the dispersion signal lags behind the modulation, presumably because the modulation frequency is then comparable to T_1. Large dispersion signals above saturation have also been observed for the Na^{23} resonance in NaCl. This behavior of the dispersion mode is in conflict with the predictions of Bloembergen, Purcell, and Pound and of the Bloch equations. The validity of these theories is reexamined, and it is concluded that although they are applicable to nuclear resonance in liquids and gases, and to solids at small rf intensities, they contain incorrect assumptions as applied to solids at high rf power levels. The theory of Bloembergen, Purcell and Pound is based on an assumption equivalent to that of a spin temperature. It is shown that the spin state cannot be strictly described by a spin temperature because the phases of the spin quantum states are not incoherent, as required by the temperature concept. The transverse decay of the nuclear magnetization predicted by the Bloch equations is shown to be partially forbidden by energy and entropy considerations if a large rf field at the resonance frequency is continuously applied to the solid. A theory is developed which is applicable only to solids at rf magnetic field intensities well above the saturation level and which is in reasonable agreement with the experimental observations. The Hamiltonian is transformed to a coordinate system rotating at the frequency of the rf field. The resulting time-dependent parts of the spin-spin interaction are non-secular perturbations on the time-independent part, and can therefore be ignored. Statistical mechanics is applied to the remaining stationary spin Hamiltonian; specifically it is assumed that the spin system is in its most probable macrostate (a canonical distribution of quantum states) with respect to the transformed spin Hamiltonian. This assumption is justified because the transformed spin Hamiltonian is effectively time independent and the spin-lattice interaction is small, and it is analogous to assumptions basic to classical acoustics and fluid mechanics. The spin-lattice interaction merely determines the expectation value of the transformed spin Hamiltonian, which can be readily calculated under the assumption that the expectation value of the spin angular momentum of each spin is relaxed independently to its thermal equilibrium value by the lattice in time T_1. Both fast and slow modulation of the dc magnetic field can be treated. "Rotary saturation" is observed by applying an audio-frequency magnetic field to the sample in the dc field direction while observing the dispersion derivative at resonance with a large rf field H_1. When the audio-frequency approaches γH_1 the dispersion signal decreases and goes through a minimum. The effect is easily treated theoretically in solids, liquids and gases by using a rotating coordinate system, and is a rotary analogue of ordinary saturation. It is a convenient method for calibrating rf magnetic fields and appears potentially capable of providing useful information on the solid state. Experimental data on rotary saturation are presented and discussed. (Contractor's abstract)

INTENSITY SPECTRA AFTER HALF-WAVE DETECTION

OF SIGNALS IN NOISE. I. THEORETICAL DISCUSSION, by G. E. Fellows and D. Middleton. Feb. 20, 1955 [33 p. incl. diagrs. refs. (Technical rept. no. 217) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 66276 Unclassified

When narrow-band noise centered about a frequency f_0 and an unmodulated carrier of frequency f_0 are added and passed through a nonlinear device, the intensity spectrum of the output wave consists of zones centered about harmonics of the frequency f_0. The spectral shape and the carrier and noise power in the first six harmonic zones have been determined both theoretically and experimentally for half-wave νth-law rectifiers (ν = 1/2, 1, 2) over a wide range of input carrier-to-noise ratio. The theoretical aspects of this problem are presented in this report, along with a number of computed results. (Contractor's abstract)

THE RECTIFICATION OF LOW-DENSITY NOISE, by J. A. Mullen and D. Middleton. Mar. 1, 1955, 48p. incl. diagrs. tables, refs. (Technical rept. no. 219) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ort-7601) AD 66274 Unclassified

This report considers the rectification by a half-wave power law detector of a c-w signal in noise made of randomly occurring pulses which overlap only slightly. It is shown that for this problem, though not in general, the distributions may be approximated by a form of Edgeworth series. The mean square and correlation function of the output of the rectifier have been obtained. If the law of the detector is greater than 1, the output power is greater for low density noise than for gaussian noise of the same input power. The correlation in the output relative to gaussian noise of the same input correlation function depends on the shape of the noise pulses. Figures are presented showing the effect of signal-to-noise ratio and detector law on the correlation of the output. (Contractor's abstract)

CAUSALITY AND FREQUENCY-RESPONSE FUNCTIONS, by T. T. Wu. Apr. 1, 1955, 45p. incl. refs. (Technical rept. no. 223) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 66291 Unclassified

A general system is studied under the assumptions of linearity, passivity, reproducibility, and causality. Under essentially no further assumption, frequency-response functions are defined for such systems and identified with positive functions, suitably defined. Through the Lebesque decomposition theorem, any frequency-response function may be decomposed to be the sum of a minimum-reactive part and two reactive parts, one of which is of unfamiliar nature. This procedure is carried through for a system with one input-output and again for a system with multiple input-outputs. As an illustration, the result is applied to the study of the Kronig-Kramers relations. One of the relations is proved to be true under very general conditions, but not the other. (Contractor's abstract)

COHESIVE ENERGY OF NOBLE METALS, by K. Kambe. Apr. 5, 1955, 9p. incl. tables, refs. (Technical rept. no. 227) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ort-7601) AD 62656 Unclassified

The method, developed by Kuhn and Van Vleck, and later simplified and extended by Brooks, for calculating the cohesive energy of monovalent metals, is here further extended to include the effects of the deviation of the effective ion core potential from pure hydrogenic form in the vicinity of the surface of the s-sphere. A formula is derived for calculating the logarithmic derivative of the wave function at the surface of the s-sphere. From the logarithmic derivatives of the s- and p-functions the ground state energy and the Fermi energy can be evaluated. The method thus extended is applied to the calculation of the cohesive energy of the monovalent noble metals. For these metals, the repulsion between ion-cores is important. Combining the repulsive energy, which is calculated by Fuchs with a modified Thomas-

Fermi method, with the energy of valence electrons calculated by the present method, we obtain the total cohesive energy of copper. Since there is no calculation of the repulsive energy for silver and gold, the ion cores are assumed to be rigid and the energies of the valence electrons at the observed lattice spacings are determined and considered as the approximate total energies. The cohesive energies calculated at the observed lattice spacings with the rigid ion-core assumption are 61.7 for Cu, 55.8 for Ag, and 49.2 for Au in comparison with the experimental values of 81.2, 68.0, and 92.0 respectively. Here the energy unit is K cal/mole. (Contractor's abstract)

CHARACTERISTICS OF SPORADIC-E IONIZATION AT MIDDLE LATITUDE, by D. Davidson. June 15, 1955, 90p. incl. illus. diagrs. tables, refs. (Technical rept. no. 230) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 80003 Unclassified

Operation of a system of triangulating pulse-sounding stations for 3 yr during the declining phase of the sunspot cycle showed that clouds of ionization which display apparent movement occur very infrequently in the E region and are confined to periods of elevated geomagnetic activity. Speeds between 400 and 1000 km/hr were observed, and the favored motion appeared as an approach from an east-northeasterly direction. The clouds occurred primarily about midnight local time.

Vertical motion of ionization was observed, but with less frequency than the other clouds of ionization. The predominant form of sporadic-E ionization was marked by multiple reflections from a thin layer in the 100- to 120-km region. Comparison of the records of 3 stations indicated that this layer is distributed over a wide geographical area. An inverse correlation exists between the occurrence of sporadic-E ionization and the sunspot number; this correlation is best during Oct. through Dec., is fair during the summer months, and is practically absent around the equinoxes. An improved correlation is obtained if the square of the F2-layer critical frequency is used instead of the sunspot number. (ASTIA abstract)

SEQUENTIAL DETECTION OF SIGNALS IN NOISE, by J. [J.] Bueegang and D. Middleton. Aug. 31, 1955 [101]p. incl. illus. refs. (Technical rept. no. 175) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ort-7601) AD 88055 Unclassified

The sequential test and the sequential method of analysis which were devised by A. Wald (Sequential Analysis, John Wiley, N. Y., 1947) are applied to the problems of detecting signals in noise. Sequential detection is discussed within the framework of the general statistical decision theory. The role of a priori information is examined. The following special examples are studied which are frequently encountered in communication problems: the incoherent detection of a sine wave in noise, coherent sequential detection of casual signals in normal noise, and the sequential detection of normal random signals in normal noise. The importance is emphasized of the correction of the square law term. The operating characteristic function of a sequential test for normal noise is independent of the correlation matrix, the specified signal waveform, and the number of observations. The treatment of correlated samples and its application to continuous processes is illustrated on RC-filtered noise. Detection can be performed in an arbitrarily short time in sequential detection of variation with a Gaussian random signal and noise. The saving in the minimum detectable signal level caused by sequential operation is discussed. Exact expressions for the error probabilities which result from truncation of the sequential processes are derived and compared with the original approximations of Wald. Distribution functions of the sample size are considered. Symmetry properties of the distributions are obtained for the case where the random variable is normally distributed. (ASTIA abstract)

OPTIMUM DECISION SYSTEMS FOR THE RECEPTION OF SIGNALS IN NOISE: PART I, by D. Van Meter and D. Middleton. Oct. 5, 1955 [77]p. incl. illus. table, refs. (Technical rept. no. 215) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 92755 Unclassified

Also published in part in Jour. Soc. Indus. and Appl. Math., v. 3: 192-253, Dec. 1955. (Title The Deception and Extraction of Signals in Noise from the Viewpoint of Statistical Decision Theory)

The techniques of the decision theory of A. Wald (Statistical Decision Functions, Wiley, N. Y., 1950) are used in the design of detection and extraction systems. A general criterion is supplied for the solution of any statistical-inference problem which calls for a decision. Desirable properties are demonstrated of solutions based on the criterion. Reception is discussed as statistical inference. The formulation of reception problems is treated in general terms as a decision problem. The reception situation is analyzed to determine what system inputs are possible and what decisions are required. A loss is assigned to each possible combination of input and decision in accordance with the constraints of the problem. Bayes and Minimax decision rules for average and conditional loss ratings are discussed. The general properties are described of optimum decision rules. Detection systems are presented that minimize average risk. Risk theory is applied to the general binary detection problem. Fixed sample size or nonsequential decision rules alone are considered. The Bayes system is a generalized likelihood-ratio detector when the preliminary cost assignment is such that the signals are weighted according to the class of input which they represent (null, alternative, or overlapping class), except when the hypothesis classes overlap. The use of decision curves which relate the Bayes risk to signal amplitude is discussed as an aid to defining the detectable signal of a detection system. (ASTIA abstract)

STATIONARY FORMS FOR THE SCATTERING CROSS SECTION OF AN OBSTACLE, by I. Stakgold. Oct. 10, 1955, 11p. (Technical rept. no. 231) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ort-7601) AD 80717 Unclassified

Two new stationary forms for the scattering cross section of an obstacle are presented. These forms involve the field everywhere in space, whereas the Schwinger-Levine principle uses only the current on the obstacle. The advantage of the new forms is the simplification in integration (the Green's function is absent); the disadvantage is that trial fields are three-dimensional instead of two-dimensional, thereby requiring more guessing in the trial functions. These new stationary principles are derived by analogy with the capacity problem. After these principles have been surmised, it is easy to show by direct computation that they are actually stationary. (Contractor's abstract)

BIASED LINEAR AND QUADRATIC DETECTION OF SIGNALS IN NOISE, by G. E. Fellows. Oct. 25, 1955 [12]p. incl. diagrs. (Technical rept. no. 229) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 89314 Unclassified

Experimental results are presented for the cases of biased linear and quadratic detectors. The noise power and the carrier power in each of the first 6 spectral zones were measured over a wide range of bias and input carrier-to-noise ratio. For a given output zone, the curves of carrier power vs bias have the same general form as the curves of noise power vs bias. As a result, the zonal carrier component power-to-noise power ratio p_1 is not a sensitive function of the bias. Values of bias exist for which the carrier component in a given zone disappears (for a given value of p). No corresponding bias values exist which enhance the ratio p_1 significantly over its value for zero bias. For biased linear and quadratic detectors, it is not possible to obtain values of p_1 for $1 > 1$ which exceed, or approach, p_1 for a given input carrier-to-noise power ratio p. (ASTIA abstract)

OPTIMUM DECISION SYSTEMS FOR THE RECEPTION OF SIGNALS IN NOISE: PART II, by D. Van Meter. Oct. 25, 1955 [54]p. incl. illus. refs. (Technical rept. no. 216) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 90935; PB 104046 Unclassified

Also published in part in Jour. Soc. Indus. and Appl. Math., v. 4: 86-119, June 1956. (Title The Deception and Extraction of Signals in Noise from the Viewpoint of Statistical Decision Theory)

Statistical decision theory is applied to extraction problems. Discussions are presented of extraction systems that minimize average risk and on information loss as a criterion for optimum detection and extraction. The classical maximum likelihood estimate maximizes the probability of a correct decision. It is a Bayes estimate either (1) when unit loss is assigned to every incorrect decision and zero loss to a correct one or (2) when the loss is proportional to the square of the decision error and the joint distribution of signal and noise has a certain symmetry. The general characterization of Bayes estimates for the squared error-loss function is discussed. Specific cases are examined of (1) coherent and incoherent extraction with Gaussian and Rayleigh statistics and (2) Minimax extraction with additive signal and noise. The relevance of optimum predetection filters to extraction is indicated. Optimum smoothing and prediction of structurally determinate and indeterminate signals is treated; previously known results are exhibited as special cases of the general solutions. Sufficient statistics and their relation to information loss are discussed. The information measure of Shannon (Bell System Tech. Jour., v. 27: 397, 623, 1948) and is compared with that of Fisher (Proc. Cambridge Phil. Soc., v. 22: 700, 1925). Optimum detectors for the information loss function are also likelihood ratio detectors. Universal curves are given for determining the optimum detection threshold. The general condition under which an estimate minimizes information loss is satisfied by a sufficient statistic. (ASTIA abstract)

TABLES FOR THE CALCULATION OF COULOMB WAVE FUNCTIONS, by F. S. Ham. Nov. 5, 1955, 84p. incl. illus. tables, refs. (Technical rept. no. 204) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 83437 Unclassified

Tables of the coefficients in the series expansions of Coulomb wave functions in powers of the energy $\varepsilon = -1/n^2$ are given, and the theory of these expansions is reviewed and extended. It is shown that the series used by Kuhn to calculate the irregular Coulomb function (Quart. Appl. Math., v. 9: 1, 1951) diverges but represents this function asymptotically in the limit $|n| \to \infty$, $|\arg(n)| \leq \pi - \Delta < \pi$. A convergent series is derived which may be used to calculate this function to greater accuracy than is possible with the asymptotic series. The coefficients in the series for both the regular and irregular functions and their derivative with respect to the radial parameter z are tabulated for $L = 0$, $z = 3.5(0.1)7.5$. Coefficients in both the asymptotic and convergent series for the irregular function are given, together with tables of a function $G_n(0, n)$, needed in calculating the irregular function $(z/2)N_1^n(z)$ from the convergent irregular series. Tables of the coefficients for the regular function and its z-derivative for $L = 8$ are also given for the same range of z. Related tables of an appropriate power of $(z/2)$ times the series coefficients for both $L = 0$ and $L = 8$ are given which make possible interpolation in z. Recurrence relations given by Infeld are put in a form suitable for use in calculating the functions of $0 \leq L \leq 8$ from functions of $L = 0$ or 8 obtained from these tables. The present tables extend those given by Kuhn and correct several errors in his tables. Both sets of tables make possible the calculation of Coulomb functions for an attractive Coulomb potential only. (Contractor's abstract)

ELECTROMAGNETIC RADIATION OVER AND INTO AN IMPERFECT DIELECTRIC, by S. Stein. Dec. 1, 1955, 1v. incl. illus. tables, refs. (Technical rept. no. 226) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research]

under N5ori-7601) AD 105487 Unclassified

The electromagnetic fields are studied in relation to a vertical electric point dipole source located above a horizontal plane interface between two distinct but individually homogeneous media. A general saddle-point method of evaluation of the resulting integrals is used, leading to asymptotic (far-zone) results. Specific formulas are derived for the case where both media are "imperfect dielectrics" subject only to the lower medium being electrically denser, and computational results are presented for the specific case where the upper medium is air. Various ranges of the material parameters are considered and the corresponding changes in the character of the wave complex are shown to be related mathematically to the behavior of the singularities of the integrands. The transition to well-known limiting cases is also described. (Contractor's abstract)

DIURNAL ROTATION OF THE IONOSPHERE, by K. Toman. Dec. 5, 1955 [9]p. incl. illus. diagrs. table. (Technical rept. no. 233) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601 and -7628) AD 88056 Unclassified

Ionospheric transmission-delay irregularities were recorded at Concord, Gloucester, and Sandwich, Mass. from 2 simultaneous oblique transmissions (with baselines of about 61 and 109 km) and 1 vertical transmission from Concord. The receiving arrangement was previously used by Toman (Jour. Geophys. Research, v. 60: 57, 1955). The F-region transmission-delay records from 0600 to 1600 EST on Oct. 24, 1952 were sampled from minute to minute. Two-hour correlation periods which overlapped by 1 hr were chosen and correlation coefficients (r) were obtained for variable time lags between records. The time displacements with maximum r's between the F-region traces of the Concord to Gloucester and Concord to Sandwich transmissions were evaluated and the direction and speed of movement were deduced. Straight frontal irregularities within the reflecting region were assumed which move perpendicularly to their orientation. The mean direction of movement, mean speed of movement, and maximum values of r are tabulated. Plots are given of the diurnal variation of the mean direction and mean speed of the movement of the ionosphere. The mean values of r diminished as the day advanced. The over-all movement was a clockwise rotation from about 85° to 220° east of north between 0800 and 1500 EST. The speed behavior suggests a transition from observed irregularities in the F-region reflection level to those in the E-region retardation level. The mean speed (expressed in km/hr) decreased until the 0800- to 1000-hr interval, increased until noon, decreased, and increased starting in the 1300- to 1500-hr interval. (ASTIA abstract)

FIELD EMISSION FROM GERMANIUM IN A MUELLER FIELD EMISSION MICROSCOPE, by F. G. Allen. Dec. 5, 1955 [32]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 237) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 91606 Unclassified

Attempts were made to use single-crystal Ge tips as emitters in studying the work function, its variation with crystal direction, and gas contamination processes on a clean Ge surface. One end of a small rod of Ge 0.030 in. square in cross section and cut with a (110) axis was turned to a tapered conical tip with emery paper. The tip was etched electrolytically in a CF-4 solution (25 cc concentrated HNO_3, 15 cc glacial HAc, 15 cc concentrated HF, and several drops of Br). Electron-microscope profiles were taken at 3500X and 7000X magnification by an MIT-built microscope similar to the RCA-type UMT. Magnification was computed for each tip from the image size of a fine 0.0003-in.-diam W wire. Field emission-producing visible spots on the fluorescent screen was obtained with all the Ge tips at initial anode voltages of 1500 to 10,000 v. Scatter in the data was caused by a slight instability of the emitting surface. Electron microscope profiles of the tips after field-emission use and cleaning by A bombardment revealed that bombardment, when excessive, can sputter away the entire tip. Field emission was obtained from intrinsic and n- and p-type Ge tips. Results are summarized with respect to the effect of applied field on energy levels at the surface for no surface states; modifications introduced by surface states; field strength at tips for emission; the effect of the penetration of field into surface on the field strength at the tip; the effects of finite emission densities; field strengths required for Ge field emission; the slope of the field-emission curve and the absolute value of the work function; and reasons for failures to obtain good emission patterns. GERMANIUM SURFACE POTENTIAL STUDIES AT HIGH VACUUM, by F. G. Allen. Dec. 15, 1955, 73p. incl. illus. diagrs. tables, refs. (Technical rept. no. 236) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 91809 Unclassified

In this study, the following subjects are discussed: I. Dependence of the work function ϕ on crystal face orientation. (a) Previous results with metals; (b) variation of the work function with crystal face orientation for germanium; and (c) an attempt to measure the work function variation with face orientation on a single nickel crystal. II. Variation of the work function of germanium with temperature and doping. (a) Theoretical predictions for

HAR. 02:097 - HAR. 02:101

the simple surface model; (b) previous experimental evidence; (c) experimental methods used; (d) results of observations on variation of germanium work function with temperature; (e) results on the variation of germanium work function with doping; and (f) absolute value of the work function for germanium. III. Photovoltage at a free semiconductor surface. (a) Apparatus and techniques used in change in contact potential with light $(\Delta CP)_L$ measurements; and (b) results of $(\Delta CP)_L$ measurements in germanium. IV. Some observations on the changes in contact potential of germanium surfaces produced by gas contamination. Appendixes present the correction for the thermoelectric voltage in CPD (contact potential difference) circuit and the applicability of the Schottky exhaustion layer theory to a sample.

SOME NOTES ON HIGH-VACUUM APPARATUS AND TECHNIQUES, by F. G. Allen. Dec. 15, 1955 [17]p. incl. illus. diagrs. (Technical rept. no. 238) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 91810 Unclassified

Some of the apparatus and techniques used in the high-vacuum studies on single crystal germanium surfaces are described. A schematic diagram and a photograph of the apparatus are presented. The combination of 2 mercury diffusion pumps, patterned after a design of W. B. Nottingham (Massachusetts Inst. of Tech.), utilizes a divergent jet to produce the high vacuum (5×10^{-10} mm Hg or less) and a convergent jet to serve as its backing pump. Pumping speed is 5 to 10 l/sec. In addition observations are presented on the rate of deposition of gas contamination on a tungsten-surface in a high vacuum, on the use of argon-ion bombardments for cleaning germanium surfaces, and on the application of a conducting-transparent coating for the pyrex vacuum apparatus.

COMPLEMENTARY LOOP ANTENNAS, by T. Kaliszewski. Feb. 1, 1956 [20]p. incl. illus. diagrs. tables. (Technical rept. no. 241) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 103263 Unclassified

Measurements of the transverse electric field distribution and of the driving-point impedance have been performed on a set of complementary (slot) circular and square loops at a wavelength of ten centimeters. It has been established that the transverse field distribution on both the circular and square loops approximates that of

the current on a uniform, short-circuited transmission lins of comparable slectrical length. Application of Babinet's principle to the complementary impedance msasured here permits direct comparison with the thsory and alternativs image-plane measurements carried out on the conventional wire loops of idsntical size. Such a comparison shows excellent agrsement but only between the real components of the driving-point impedance. The unbalance inherent in the used msthod of measurements and the end-sffect which could not be estimated here are believed to account for the discrepancies observed between the imaginary componsnts. It is suggested that the use of the so called twin-slot transmission line, for ths purpose of impedancs measursmsnt, may result in slimination of the above difficulties. (Contractor's abstract)

AN EXPANSION OF THE KUMMER FUNCTION $_1F_1(\alpha; \frac{1}{2}; \beta x^2)$, by G. Kent. Mar. 5, 1956, 5p. (Technical repl. no. 234) (Sponsored joinly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-7601) AD 92752

Unclassified

An expansion of ihe Kummer function, $_1F_1(\alpha; \frac{1}{2}; \beta x^2)$, is given in terms of elemenlary functions. The first 4 lerms of this expansion are

$$\cosh kx + \left(\frac{\beta x^2}{2}\right)\left\{\cosh kx - \frac{\sinh kx}{kh}\right\}$$

$$+ \frac{1}{2!}\left(\frac{\beta x^2}{2}\right)^2\left\{\left[1 - \frac{1}{(kx)^2}\right]\cosh kx - \left[\frac{2}{3} - \frac{1}{(kx)^2}\right]\frac{\sinh kx}{kx}\right\} + \frac{1}{3!}\left(\frac{\beta x^2}{2}\right)^3\left\{\left[1 - \frac{7}{(kx)^2} - \frac{15}{(kx)^4}\right]\cosh kx + \left[1 + \frac{12}{(kx)^2} + \frac{15}{(kx)^4}\right]\frac{\sinh kx}{kx}\right\} + O(\beta^4),$$ where $k^2 = 4\alpha\beta$. The terms in the $\{\ \}$ brackets vanish uniformly as $x \longrightarrow 0$. For small values of x, these lerms, in the order given in the expansion, approach the forms $\frac{2}{3}(kx)^2$, $\frac{7}{18}(kx)^2$, and $\frac{107}{120}(kx)^2$ so that in the neighborhood of the origin the approximation is very good. Hall measurements on Ni wsre made between room temperature and 568°C using an a-c measurement technique. The ordinary Hall coefficient of Ni is roughly constant between room temperature and 300°C. The data suggest that the extraordinary Hall effect persists into the paramagnetic region. The strong temperature dependsncs of the observed effect does not exhibit a temperature dependsncs similar to the susceptibility and hence thsre is ambiguity in the dstsrmination of the ordinary Hall coefficient above the Curie tsmperature. Hall measurements on a 70 Ni - 30 Cu alloy also suggest the presence of the extraordinary Hall sffect above the Curie temperature, but in this alloy, ths observed effect possesses a $1/T-\theta$ temperaturs dependence. The ordinary Hall coefficient of the 70 Ni - 30 Cu alloy is smaller in absolute value above the Curis temperature than at liquid air tsmperaturs. These data are discussed using Pugh's two-band and four-band models. Hall measurements at room temperaturs were made on a synthetic crystal of Fe_3O_4 and on a synthetic single crystal of $(NiO)_{75}(FeO)_{25}(Fe_2O_3)$. The ordinary Hall measursment on Fe_3O_4 suggests that ths number of conduction electrons at room temperature is large, in rough agreemsnt with Vsrwey's hypothesis. The ordinary Hall coefficient of $(NiO)_{.75}(FeO)_{.25}(Fs_2O_3)$ also suggesis a largs carrier concentration. Ths conductivities of $(NiO)_{.75}(FeO)_{.25}(Fe_2O_3)$ and of a synthetic single crystal of $(NiO)_{.56}(ZnO)_{.14}(FeO)_{.30}(Fe_2O_3)$ are compared with the conductivity of Fe_3O_4 employing a simple model for the mobility and associating the activation energy obtained from resistivity data with the number of conduction slecirons. The observed datc are in good agreement with the simpls modsl. Extraordinary Hall measuremsnts wsre made on Grade A Ni(99.4 Ni), 499 Alloy (99.9 Ni), and R-63 Alloy (95 Ni, 4 Mn, 1 Si) between liquid air temperature and their Curie tsmperaiures, and on the 80 per cent Ni-Fe alloys, Supermalloy, Mumetal, and Carpenter Hymu 80 between liquid air temperaturs and room temperaturs. The extraordinary Hall coefficients of these materials do not generally exhibit the resistivity dependence predicted by Karplus-Luttinger theory, but they do suggest thai ihe essential features of the theory are probably correci. The extraordinary Hall coefficienis of Fe_3O_4 and $(NiO)_{.75}(FeO)_{.25}(Fe_2O_3)$ between - 100° and their Curie tsmperaiures indicate no resistivity dependence, and their magnitude, temperaiure dependence, and sign reversal have not beeu explained. Auxiliary measuremenis of resistivity as a function of tsmperaiure, for all samples, and the thermoelectric power of Fe_3O_4 against Cu are also reported. (Contractor's absiract)

THE ELECTROLYTIC TANK: DESIGN AND APPLICATIONS, by P. A. Kennedy and G. Kent. May 1, 1956 [48]p. incl. illus. diagrs. (Technical rept. no. 214) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 98096 Unclassified

The theory of the electrolytic tank analogue as a device for the solution of potential problems is reviewed, and some of the more important applications are discussed. The mechanical requirements of an electrolytic tank design are stated. A description of the Harvard tank is given, indicating how these problems were met. The figure of mechanical uncertainty for the Harvard tank is estimated to be .01 inch. A discussion of experimental error in tank measurements covers problems of electrode and electrolyte materials as well as difficulties resulting from surface tension. Control experiments for determining the accuracy of level and tilted tank measurements are described, and the results presented. Although high accuracy is possible in the level tank, only great care can produce results in the tilted tank which are reliable to within three per cent. (Contractor's abstract)

ON HIGH ENERGY POTENTIAL SCATTERING I, by T. T. Wu. May 10, 1956, 12p. (Technical rept. no. 246) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 98092 Unclassified

Asymptotically in the limit of high energies, successive approximations are obtained for the problem of potential scattering where the total phase shift through the potential is not small. Only the Schrodinger wave equation is treated. The method consists of first applying the stationary-phase approximation to the integral equation and then solving the resulting equation by iteration. HIGH-FREQUENCY SCATTERING, by T. T. Wu. May 25, 1956 [49]p. incl. diagrs. refs. (Technical rept. no. 232) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 98093 Unclassified

Also published in Phys. Rev., v. 104: 1201-1212, Dec. 1, 1956.

In recent years, there has been a revival of interest in the phenomena of scattering at high frequencies. The simplest problems of this sort are treated here, where the obstacle is either a circular cylinder or a sphere. The treatment is limited to the total scattering cross sections, even though the method is by no means restricted in this way. The specific problems treated here include the scattering of a plane electromagnetic wave by a perfectly conducting circular cylinder (two possible polarizations) or a perfectly conducting sphere, the acoustic scattering by a rigid sphere, and the quantum-mechanical scattering by an impenetrable sphere. By considering the creeping waves as defined on the universal covering space, the scattering cross sections of a circular cylinder may be expressed by asymptotic expansions for vanishingly small wavelengths. Analogous calculations yield the corresponding results for a sphere. It turns out, as expected, that the resulting expressions are accurate even for fairly large wavelengths. The numerical results are summarized in Section 7. In conclusion, the application of the method to the determination of the approximate current distribution on the obstacle is considered briefly; also some generalizations about the scattering cross section are conjectured. ON THE THEORY OF RELAXATION PROCESSES, by A. G. Redfield. June 25, 1956, rev. Aug. 17, 1956 [13]p. refs. (Technical rept. no. 240) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under [Nonr-186616]) AD 120545 Unclassified

Also published in IBM Jour. Research and Development, v. 1, 19-31, Jan. 1957.

A general procedure is given for finding the equation of motion of the density matrix of a system in contact with a thermal bath, as for example a nuclear spin system weakly coupled to a crystal lattice. The thermal bath is treated both classically and quantum mechanically, and the theory is similar to, and a generalization of, conventional theories of time proportional transition probabilities. Relaxation of the system by the thermal bath is expressed by a linear matrix operator, and it is stressed that elements of this operator can be regarded as secular or nonsecular perturbations on the equation of motion and can be treated accordingly. When the motion of the system is slow compared to that of the thermal bath, the equation of motion can be expressed in an operator form which is independent of representation. If the system has a time-dependent Hamiltonian which varies slowly compared to the motion of the thermal bath, the same equation of motion is obeyed and the system is relaxed by the bath toward a Boltzmann distribution with respect to its instantaneous Hamiltonian. If the time variation of the Hamiltonian is more rapid, higher order corrections to the equation of motion must be applied. The theory is applied to spin-lattice relaxation of a coupled nuclear spin system in a metal, for arbitrary externally applied fixed magnetic field. (Contractor's abstract)

Measurements of the pure quadrupole resonance frequency (ν) of the Cu^{63} nucleus in cuprous oxide, and the

HAR. 03:010 - HAR. 03:013

Cl^{35} nucleus tn potassium chlorate and paradichlorobenzene have been made as a function of pressure in the range 1 to 10,000 kg/cm^2 for temperatures between -77°C and 100°C. A theory is presented in which the static value of the electric field gradient tensor (ϕ^o_{ij}) and the amplitudes ξ^o_t of the normal modes of the lattice vibrations play a central role. The volume dependence of these quantities can be deduced from v-versus-v volume isotherms which are constructed from the experimental data by using the equation of state. Information on the latter is augmented by theory. It ts found that the temperature variation of the resonance frequency at atmospheric pressure can be understood by considering not only the explictt temperature dependence of the vibration amplitudes, but also by including the appreciable effects of the volume expansion on q_o and ξ^o_t. Furthermore, the pressure dependence is found to be explicable tn terms of the volume dependence of q_o and ξ^o_t. In Cu_2O, tt ts found that q_o depends on volume roughly as V^{-1}, thereby indicating an ionic character for this crystal. On the other hand, in paradichlorobenzene, $q_o \propto V^n$, with $0 < n < .04$, thus exhibiting the effect of an increase tn the intermolecular hybridization of the C-Cl covalent bond. SPIN RELAXATION PROCESSES IN A TWO-PROTON SYSTEM, by N. Bloembergen. Aug. 10, 1956, 19p. incl. refs. (Technical rept. no. 249) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 108888 Unclassified

Also published in Phys. Rev., v. 104: 1542-1547, Dec. 15, 1956.

The general theory of nuclear spin relaxation, based on the Boltzmann transport equation for the density matrix, is applied to the very simple, non-trivial system of two identical spins I = 1/2. A proton pair undergoing hindered rotation around one axis shows a resolvable doublet. The relaxation processes in this doublet are investigated. Explicit formulae for the longitudinal and transverse relaxation times are derived, which display a dependence on the angles of the axis of rotation with the external magnetic field and the radius vector. Experimental evidence for this dependence is discussed. General expressions for the Overhauser and saturation effects with two applied radiofrequency fields are given, which may also be applied to a magnetic ion or nucleus with I > 1 and crystalline field splitting. THEORY OF THE MICROSTRIP, by T. T. Wu. Oct. 10, 1956, 7p. incl. diagrs. (Technical rept. no. 248) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 118572 Unclassified

An iterative procedure is proposed for finding the current distribution, and thus the electromagnetic field, of the lowest mode of the microstrip transmission line. This line consists of a thin metallic strip pasted on a dielectric layer which is in turn a coating on a ground plane. Each iteration involves solving 2 electrostatic problems. Exact coupled integral equations are set up for the 2 components of the current density, and approximations are made tn their kernels. The analysis is not rigorus, but it is valid if the strip is not too wide and the dielectric sheet not too thick. (ASTIA abstract)

DETERMINATION OF AN ANALYTIC FUNCTION BY ITS VALUES GIVEN IN A COUNTABLE INFINITY OF POINTS, by J. L. Walsh. Sept. 1955, 22p. refs. ([AF]OSR-TN-55-269) (AF 18(600)998) AD 73277 Unclassified

Also published in Bull. Soc. Math. Belgique, 1954, p. 52-70 (1955).

A necessary and sufficient condition for the existence of an analytic function $f(z)$ of bounded norm is derived for a given multiply-connected region D of the z-plane, where $\alpha_1, \alpha_2, \ldots$ are given points of D and values $w_1, w_2, \ldots$ are prescribed with $f(\alpha_k) = w_k$ for $k = 1, 2, \ldots$. The principal result is given by the following theorem: let $f(z) \sim c_1\psi_1(z) + c_2\psi_2(z) + \ldots$, whose coefficients are calculated by $c_n = (f, \bar{\psi}_n)$ and $f(\alpha_k) = w_k$, $k = 1, 2, \ldots$; a necessary and sufficient condition that there exist a function $f(z)$ of class H such that

$\iint_D |f(z)|^2 \, dS$ exists and which satisfies $f(\alpha_k) = w_k$, $k = 1, 2, \ldots$ is the convergence of the series $\sum_1^\infty |c_n|^2$.

The $\psi_n(z)$ are normalized functions of $\varphi_n(z)$ which is a unique function in H; among all functions $f(z)$ in H satisfying $f(\alpha_1) = f(\alpha_2) = \ldots = f(\alpha_{n-1}) = 0$, $f(\alpha_n) = 1$, this unique function possesses the least norm. If the convergence of $\sum_1^\infty |c_n|^2$ is satisfied, the series

$f(z)$ $c_1\psi_1(z) + c_2\psi_2(z) + \ldots$ converges in the mean in D to the function of class H of minimum norm which satisfies $f(\alpha_k) = w_k$, $k = 1, 2, \ldots$. (ASTIA abstract)

ON THE CONFORMAL MAPPING OF MULTIPLY CONNECTED REGIONS, by J. L. Walsh. Oct. 55 [33]p. refs. ([AF]OSR-TN-55-391) (AF 18(600 , AD 102141 Unclassified

Also published in Trans. Amer. Math. Soc., v. 82: 126-146, May 1956.

Proofs are presented for the following theorem:
Theorem 1: Let D be a region of the extended z-plane whose boundary consists of mutually disjoint Jordan curves $B_1, B_2, \ldots, B_\mu; C_1, C_2, \ldots, C_\nu$. There exists a conformal map of D onto a region Δ of the extended Z-plane, 1:1 and continuous in the closures of the 2 regions, where Δ is defined by $1 < |T(Z)| < e^{1/\tau}$,

$$T(Z) \equiv \frac{A(Z-a_1)^{M_1}(Z-a_2)^{M_2}\ldots(Z-a_\mu)^{M_\mu}}{(Z-b_1)^{N_1}(Z-b_2)^{N_2}\ldots(Z-b_\nu)^{N_2}}, \quad \sum M_j = \sum N_j = 1,$$

$\tau > 0$. The exponents M_j and N_j are positive but need not be rational. The locus $|T_n(Z)| = 1$ consists of μ mutually disjoint Jordan curves, respective images of

HAR. 04:006 - HAR. 04:008

the B_j, which separate Δ from the a_j; the locus $|T_n(Z)| = e^{1/\tau}$ consists of ν mutually disjoint Jordan curves, respective images of the C_j, which separate from the b_j. A limiting case of the theorem is also established, and proofs are presented that the maps given by the theorems are uniquely determined except for a possible linear transformation. (ASTIA abstract)

LEAST pTH POWER POLYNOMIALS ON A REAL FINITE POINT SET, by T. S. Motzkin and J. L. Walsh. [1955] [14]p. incl. refs. [In cooperation with California U., Los Angeles] (Sponsored jointly by [National Bureau of Standards, Office of Naval Research, and Air Force Office of Scientific Research under [AF 18(600)-998]) Unclassified

Published in Trans. Amer. Math. Soc., v. 78: 67-81, Jan. 1955.

The authors consider polynomials $T_{n+1}(z) = z^{n+1} + \sum_{t}^{n+1} b_r z^{n+1-r}$ which minimize a deviation from zero of the form $\Delta(|T_{n+1}(z_1)|, \ldots, |T_{n+1}(z_m)|)$ and the z_k form a finite real point set E; in most of the cases the T_{n+1} are not unique. For a general class of Δ, between two zeros of a T_{n+1} lies a point of E; numerous other properties are proved. In the case $\Delta = \sum u_k |T_{n+1}(z_k)|$, $u_k > 0$, the totality of T_{n+1} form a convex set generated by basic polynomials having their zeros at points of E; the set of T_{m-1} can be found explicitly, even if E is not real. If $\Delta = \sum u_k |T_{n-1}(z_k)|^p$, $p > 1$, a separation property holds for the zeros of T_n, T_{n-1}. Other results connect best approximations with interpolation, covering also cases of approximation by families of functions more general than polynomials. (Math. Rev. abstract)

THE LEAST pTH POWER POLYNOMIALS ON A FINITE POINT SET, by T. S. Motzkin and J. L. Walsh. [July 28, 1955] [26]p. (In cooperation with California U., Los Angeles) (Sponsored jointly by Office of Naval Research, Office of Ordnance Research and Air Force Office of Scientific Research under [AF 18(600)998]) AD 134807 Unclassified

Also published in Trans. Amer. Math. Soc., v. 83: 371-396, Nov. 1956.

Let $E:(z_1, \ldots, z_m)$ be a set of points of the complex plane, and let $\mu_1, \ldots, \mu_m$ be positive. The first section of this paper is devoted to the explicit determination of polynomials $T_{m-1}(z) = z^{m-1} + \ldots$ minimizing (*) $\sum_{1}^{m} \mu_k |T_{m-1}(z_k)|^p$. Having previously [same Trans. 78 (1955), 67-81; MR 16, 585] solved the case $p = 1$, they treat separately the cases $p > 1$ and $0 < p < 1$, with uniqueness for $p > 1$. §§2-3 deal mainly with the distribution of the zeros of $T_n(z)$ minimizing more general deviations (cf. the previously cited paper and also L. Fejér, Math. Ann., v. 85: 41-48 (1922)); one such result concerns the separation of E by an arbitrary equilateral hyperbola with the join of two zeros as diameter. §4 deals with the effect on the $T_n(z)$, for the deviation(*), of adding points to E or removing them; under various conditions the same $T_n(z)$ may be extremal for the modified set, or may be so after the addition or removal of factors. In §5 the aim is to characterize the set of T_n for deviation (*), where E (now real) is fixed but not the μ_k; for $0 < p < 1$ and $n < m$ they are the polynomials of the above form which vanish in n points of E; for $p > 1$ they are the polynomials whose zeros are simple, lie in the smallest closed interval containing E, and separate strongly a set of $n + 1$ points of E on which $T_n \neq 0$, while for $p = 1$ the set of T_n can be identified with two other sets. §6 gives certain consequences of the orthogonality condition appropriate to (*) for $p > 1$. Finally §7 deals with best approximation to a continuous f(z) over a closed bounded set E containing infinitely many points by means of a polynomial p(z) of a fixed degree. It is shown that the polynomials $p_k(z)$ corresponding to a suitable sequence of finite point sets E_k converge to p(z), using the deviation $\max |\mu_k(f(z) - p(z))|$. The same holds for the deviation corresponding to (*) if $p > 1$, while for $0 < p < 1$ result is qualified on account of nonuniqueness. (Math. Rev. abstract)

UNDERPOLYNOMIALS AND INFRAPOLYNOMIALS, by

T. S. Motzkin and J. L. Walsh. Technical rept. July 13, 1956, 32p. (AFOSR-TN-56-359) (Sponsored jointly by Office of Naval Research, Office of Ordnance Research, and Air Force Office of Scientific Research under AF 18(600)998) AD 95445 Unclassified

Also published in Ill. Jour. Math., v. 1: 406-426, Sept. 1957.

The properties of the class of infrapolynomials of given degrees on a bounded set are investigated, including those which have zeros on the given point set. In § 1 the relation of $|g(z)| < f(z)|$ on E where $f(z) \neq 0$ to the inequality $|g(z)| \leq f(z)|$ on E. § 2 and 3 show that the class of infrapolynomials on a closed bounded set E is closed and connected. § 4 studies some special properties and § 5, the finite generation (on finite subsets of E) of such polynomials. Convexity of the class is proved whenever it exists in § 6, and factorization is discussed in § 7. Infrapolynomials on a real set have special properties of separation § 8, analogous to those previously established for a linite set and of finite generation.

ON APPROXIMATION BY BOUNDED ANALYTIC FUNCTIONS, by J. L. Walsh. Sept. 1956, 30p. refs. (AFOSR-TN-56-440) (AF 18(600)998) AD 96783 Unclassified

Recently proved results on conformal mapping (Trans. Amer. Math. Soc., v. 82: 128-146, 1956) and on series of interpolation of rational functions permit the study of problem [illegible] in the subject of the title. A function f(z) analytic in a region D bounded by Jordan curves is approximated on a portion B of the boundary of D by functions $l_n(z)$ analytic, and in modulus not greater than M_n in D. Degree of convergence on B in terms of M_n is investigated, depending not merely on regions of analyticity of f(z), but also on the continuity properties (Lipschitz conditions, etc.) of f(z) on the boundaries of such regions. ON INFRAPOLYNOMIALS WITH PRESCRIBED CONSTANT TERM, by J. L. Walsh. Oct. 1956, 28p. refs. (AFOSR-TN-56-582) (AF 18(600)998) AD 115006 Unclassified

The class of infrapolynomials with prescribed constant term $z^n + \ldots$ in the complex variable z are investigated with respect to the geometry of the zeros of the polynomials. The use of convex sets, orthogonality relations for infrapolynomials and the general theory of zeros of polynomials are utilized. The infrapolynomials are prescribed for the first and the last or last several coefficients. Among the topics considered are the existence and uniqueness of restricted infrapolynomials, orthogonality relations, real infrapolynomials, disc containing E, special configurations and additional geometric results. Theorem 6 is given concerning the zeros of polynomials in general without reference to infrapolynomtals.

BEST-APPROXIMATION POLYNOMIALS OF GIVEN DEGREE, by J. L. Walsh. [1956] [6]p. (Sponsored jointly by Office of Naval Research, and Air Force Office of Scientific Research under [AF 18(600)998]; continued by AF 18(600)1461) Unclassified

Published in Proc. of the Symposia in Applied Math. VI. Numerical Analysis, 1956, p. 213-218.

It is the purpose of this paper to consider the properties of individual extremal polynomials of given degree, of best approximation according to various measures of

HAR. 05:001 - HAR. 06:004

approximation. Emphasis is placed on the real domain, with special attention given to results of Kirchberger, Tonelli, de la Vallée-Poussin, Fejér, Fekete, and von Neumann. The present results of this author are to be considered basic research but are significant both in the computation and geometric properties of approximating polynomials.

SQUARE-INTEGRABLE DIFFERENTIALS ON OPEN RIEMANN SURFACES, by L. V. Ahlfors. July 26, 1956 [3]p. [AFOSR-TN-56-319] [AF 18(600)1461; continuation of AF 18(600)998] AD 94855 Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 42: 758-760, Oct. 1956.

The author considers various decompositions of the space Γ_h of quadratically integrable harmonic differentials on an open Riemann surface W, which generalize the fact that on a finite Riemann surface every harmonic differential decomposes orthogonally into the sum of a differential of an analytic function, the differential of a harmonic measure, and a harmonic differential whose normal component on the boundary vanishes. The Schottky differentials of W are defined as the limits of the Schottky differentials of finite Riemann surfaces which exhaust W, and it is proved that the orthogonal complement in Γ_h of the space of Schottky differentials of W is the space of harmonic differentials which are both exact and coexact. This implies that all harmonic differentials of W are Schottky if and only if $W \in O_{AD}$. If the "harmonic measures" of W are defined to be the limits of differentials of the harmonic measures of an exhaustion of W, then they are the orthogonal complement in Γ_h of the space of harmonic differentials whose duals have no periods around dividing cycles of W. Let Γ_{h0} denote those harmonic differentials which are orthogonal to all coexact differentials. Then to each cycle c on W there is a unique differential $\omega_c \in \Gamma_{h0}$ such that for each closed square-integrable σ

$$\int_c \sigma = \iint_W \sigma \wedge \omega_c.$$

The differentials ω_c span Γ_{h0} and those for which c is a dividing cycle span the harmonic measures. The author then goes on to discuss conditions under which the generalized Riemann bilinear relation holds for W. (Math. Rev. abstract)

NOTE ON THE VIBRATIONAL SPECTRA OF $SiHCl_3$, SiH_2Cl_2, AND SiH_2Br_2, by J. A. Hawkins, S. R. Polo, and M. K. Wilson. Mar. 27, 1953, 1p. incl. diagr. tables. (AF 18(600)590) Unclassified

Published in Jour. Chem. Phys., v. 21: 1122, June 1953.

Measurements of gaseous $SiHCl_3$ were made. The absorption spectrum between 450 cm^{-1} and 700 cm^{-1} is plotted on a graph, and the observed frequencies and their assignments are presented. Investigations were also carried out with SiH_2Cl_2 and SiH_2Br_2. Thermodynamic functions are given for SiH_2Cl_2 and fundamental frequencies are given for SiH_2Cl_2 and SiH_2Br_2.

THE INFRARED SPECTRUM OF $S^{16}O^{18}O$ AND THE FORCE CONSTANTS OF SO_2, by S. R. Polo and M. K. Wilson. Feb. 1954 [22]p. incl. illus. tables. (Rept. no. 1) ([AF]OSR-TN-54-37) (AF 18(600)590) AD 28816 Unclassified

Also published in Jour. Chem. Phys., v. 22: 900-903, May 1954.

An investigation of the infrared spectrum of $S^{16}O^{18}O$ results in the following frequency assignment: $\nu_1 = 1122 \pm 1\ cm^{-1}$, $\nu_2 = 506.8 \pm 0.5\ cm^{-1}$, $\nu_3 = 1341 \pm 0.5\ cm^{-1}$. These data combined with the fundamental frequencies of $S^{16}O_2$ have been used to calculate the potential constants for sulfur dioxide. These are $f_d = 10.02$, $f_{dd} = 0.63$, $\frac{1}{d}f_{d\alpha} = 0.20$, $\frac{1}{d^2}f_\alpha = 0.793$. (Contractor's abstract)

THE MATRICES D^{-1} AND G^{-1} IN THE THEORY OF MOLECULAR VIBRATIONS, by S. R. Polo. May 1955, 15p. incl. diagrs. (Rept. no. 6) ([AF]OSR-TN-55-153) (AF 18(600)590) AD 79873 Unclassified

Presented at the Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 1954.

Also published in Jour. Chem. Phys., v. 24: 1133-1138, June 1956.

A vector method is given by which to determine the elements of the matrices D^{-1} and G^{-1} which occur in the study of the vibration-rotation spectra of polyatomic molecules. D^{-1} is the matrix of the transformation giving the mass-weighted Cartesian displacements in terms of the internal coordinates, and G^{-1} has as elements the coefficients in the expression of the vibrational kinetic energy in terms of the velocities. The determination of the elements of D^{-1} is reduced to finding by inspection a set of displacement vectors to which is added an appropriate rigid translation and rotation of the whole molecule. The G^{-1} matrix elements are obtained from the equation. (ASTIA abstract)

VIBRATION-ROTATION INTERACTION IN POLYATOMIC MOLECULES. II. THE DETERMINATION OF CORIOLIS COUPLING COEFFICIENTS, by J. H. Meal and S. R. Polo. July 1955 [27]p. incl. diagrs. tables, refs. (Rept. no. 8) ([AF]OSR-TN-55-207) AD 79875 Unclassified

Presented at the Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 1953.

Also published in Jour. Chem. Phys., v. 24: 1126-1133, June 1956.

A general method for the analytical treatment of vibration-rotation interaction in polyatomic molecules is presented. The method is especially adapted to carry out the calculation of the Coriolis coupling coefficients along with the normal coordinate treatment in terms of any chosen set of internal coordinates. The relations existing among the ζ-elements and the potential constants are established in a general and convenient form. Particular attention is given to symmetric top molecules, and the effect of vibration-rotation interaction on band structure is discussed. Approximate methods for the calculation of ζ values are considered also. (Contractor's abstract)

THE VIBRATIONAL SPECTRUM OF BORINE CARBONYL, by G. W. Bethke and M. K. Wilson. June 11, 1956, 1v. incl. diagrs. tables, refs. (AFOSR-TN-56-245) (AF 18(600)590) AD 88365 Unclassified

Also published in Jour. Chem. Phys., v. 26: 1118-1130, May 1957.

The complete IR gas spectra of BH_3CO, $B^{10}H_3CO$, BD_3CO, and $B^{10}D_3CO$ were examined, and the solid IR and partial gas Raman spectra were investigated. The BH_3 rock and B-C-O bend symmetry coordinates, S_7 and S_8, respectively, mix to a large extent. The actual normal vibrations are neither BH_3 rocking nor B-C-O bending motions. If the normal vibrations (Q_7 and Q_8) are estimated from the approximate $B^{11}H_3CO$ equations ($Q_7 = \frac{1}{2}S_7 - \frac{1}{2}S_8$ and $Q_8 = \frac{1}{3}S_7 - \frac{2}{3}S_8$), the actual vibrations are found to be an unsymmetrical body bend ($\downarrow H_3B \uparrow C \downarrow O\uparrow$) for Q_7, and a type of symmetrical body bend ($\downarrow H_3BC\uparrow O\downarrow$) for Q_8. In the deuterated compound, Q_8 is more of a symmetrical body bend than that shown for the H compound. From the actual vibration forms, Q_7 should have a much larger B^{10}-B^{11} isotope shift and a slightly smaller H-D isotope shift than Q_8. In the hydrogenated and the deuterated borine carbonyls, a shift of about 10 cm^{-1} B^{10}-B^{11} occurs for assignment ν_7 but essentially none occurs for ν_8; also, $\nu_7(H)/\nu_7(D) = 1.14$ and $\nu_8(H)/\nu_8(D) = 1.18$. Results indicated that ν_7 is Q_7 (the antisymmetrical body bend) and that ν_8 is Q_8 (the symmetrical body bend). The large interactions between S_7 and S_8 should cause ν_7 and ν_8 to strongly repel each other resulting in the low ν_8 and high ν_7 frequencies which were observed. Ionic or other repulsive terms apparently have a greater effect on the interaction constants than those arising from the changing hybridization of the B atom; this effect is expected from the number of contributing structures which exhibit charge separation.

THE VIBRATIONAL SPECTRUM OF DISILANE, by G. W. Bethke and M. K. Wilson. June 11, 1956, 1v. incl. diagrs. tables, refs. (AFOSR-TN-56-246) (AF 18(600)590) AD 88366 Unclassified

Presented at the Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 11-15, 1956.

Abstract published in Symposium on Molecular Structure and Spectroscopy. Abstracts, 1956, p. 10.

Also published in Jour. Chem. Phys., v. 26: 1107-1117, May 1957.

Complete IR gas spectra and Raman liquid spectra were obtained for Si_2H_6 and Si_2D_6. The IR and Raman spectra of Si_2H_6 and Si_2D_6 agreed well with the assumption of D_{3d} symmetry. The resolved Q branch structure of all the perpendicular E_u fundamentals showed that the disilane molecule hindered internal rotation. These two considerations mean that disilane has the staggered C_2H_6-type configuration. The IR and Raman spectra of Si_2H_6 and Si_2D_6 were similar to the spectra of the corresponding ethanes. The results were true for the zeta constants of the E_u fundamentals in Si_2H_6 and C_2H_6. The decomposition products include much silane and traces of higher silanes which interfere with the disilane bands of interest. The main spectral impurity, silane, interfers with the ν_7 and ν_8 assignments of disilane, but not with the ν_9. Since the hot bands of ν_9 in disilane are already strong at room temperature, they contribute to give a very complex ν_9 band at higher temperatures. If the transition from hindered to free internal rotation is to be observed in the vibration-rotation bands of disilane, a high-resolution grating spectrometer is necessary. (ASTIA abstract)

THE TIN-HYDROGEN BOND DISTANCE, by G. R. Wilkinson and M. K. Wilson. Aug. 29, 1956, 2p. refs. (AFOSR-TN-56-365) (AF 18(600)590) AD 95801 Unclassified

Also published in Jour. Chem. Phys., v. 25: 784, Oct. 1956.

An analysis was made of the Sn-H stretching vibration (ν_3) of $SnHD_3$ using a sample of SnD_4 containing a small percentage of $SnHD_3$. The Sn-H stretching vibration spectrum was recorded with a grating spectrometer in the 2nd order – lines separated by 0.1 cm^{-1} being resolved. Because of the many isotopes of Sn H was necessary to measure the position of maximum absorption of the many components making up each "line." The usual combination plots lead to the following molecular constants: $\nu_0 = 1905.91\ cm^{-1}$; $B_0 = 1.3373\ cm^{-1}$; $B_1 = 1.3327\ cm^{-1}$; $B_0 - B_1 = 0.00425\ cm^{-1}$; $D^J \approx 10^{-1}\ cm^{-1}$. Under the assumption of tetrahedral angles, equality of the Sn-H and Sn-D bond distances, and a mean atomic weight for Sn of 119, the Sn-H bond length was calculated to be 1.701 ± 0.001Å. This value compares with 1.700 ± 0.015 Å reported by Lide (Jour. Chem. Phys., v. 19: 1605, 1951) from an analysis of the microwave spectra of CH_3SnH_3.

THE PREPARATION OF GERMANE, by T. S. Piper and M. K. Wilson. Sept. 25, 1956, 4p. (AFOSR-TN-56-424) (AF 18(600)590) AD 96506 Unclassified

In this study, pure germane, GeH_4, (germanium tetrahydride) (I) was prepared in 60 to 75% yields by reducing aqueous acidic GeO_2 solutions with $NaBH_4$. Digermane, Ge_2H_6, formed 6% by volume of the total, as determined by trapping out at -140° C. With 45% D_2O solvent, 25% of the I contains a D atom. This indicates that hydride transfer from borohydride is not a unique mechanism. Pure GeH_3D (II) was prepared by reducing sodium germanyl with DCl in Bu_2O. Its IR spectrum is like that of II prepared from the $GeCl_3H$-$LiAlD_4$ reaction of Lindeman and Wilson (Zeit. für Physik Chem. (Frankfort), v. 9: 29-48, 1956). Plumbane was not formed by action of $NaBH_4$ on bivalent Pb.

THE EFFECT OF DIFFERENT ATMOSPHERES ON ELECTRODE TEMPERATURES IN THE DC ARC (Abstract), by B. L. Vallee and M. R. Baker. Sept. 1953 [1]p. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Presented at Thirty-Eight annual meeting of the Opt. Soc. of Amer., Oct. 15-17, 1953.

Published in Jour. Opt. Soc. Amer., v. 43: 817, Sept. 1953.

Marked differences in volatilization rates, intensities of spectral lines, and their signal-to-noise ratio have been noted in the dc arc burning in air, argon, helium, and their mixtures. In the present study the electrode temperatures and voltage drop across the arc column have been observed using an arcing chamber with standardized geometry. This chamber may be employed with gas pressures varying from 1 mm of mercury to twice atmospheric. A continuously recording optical pyrometer employing thermistors as sensitive elements has been constructed for the measurement of temperatures. Marked differences in temperatures have been noted when the dc arc is burned in different gases; but with any particular gaseous environment, high reproducibility of temperature conditions is exhibited. The details and significance on the data will be discussed. (Contractor's abstract)

THE EFFECT OF ARGON ATMOSPHERES ON THE INTENSITY OF CERTAIN SPECTRAL LINES, by B. L. Vallee and S. J. Adelstein. Feb. 1954 [5]p. incl. diagrs. tables. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Published in Spectrochimica Acta, v. 6: 134-138, Feb. 1954.

The use of argon as an environment for the direct current arc results in the enhancement of the lines of many elements when compared with helium and argon-helium mixtures. This is particularly true of the more volatile elements. A number of lines have been studied in this regard and the results have been qualitatively grouped as lines definitely, equivocally, and not at all enhanced. In some instances the use of an argon environment for the direct current arc markedly increases the sensitivity of analysis with this source. (Contractor's summary)

STUDIES ON METALLOPROTEINS. SOLUBLE ZINC-CONTAINING PROTEIN EXTRACTED FROM HUMAN LEUCOCYTES, by B. L. Vallee, F. L. Hoch and W. L. Hughes, Jr. [1954] [14]p. incl. diagrs. tables, refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Published in Arch. Biochem. and Biophys., v. 48: 347-360, Feb 1954.

Studies are presented on the purification of soluble zinc-containing proteins from human leucocytes. The criterion for purification is an increase in the zinc to protein ratio, and conditions are defined under which this criterion is valid. Carbonic anhydrase is present in erythrocytes contaminating the leucocytes from which it can be separated by fractional precipitations with ammonium sulfate. This is shown by measurements of carbonic anhydrase activity, zinc, and protein. Further purification of the leucocyte proteins having high zinc to protein ratios was achieved by variations of pH, μ, and ethanol concentration. The maximum zinc to protein ratio attained was 3000 μg Zn/g protein. This content of zinc in leucocyte protein is comparable to the magnitude of the metal contents of other metalloproteins. Published in Blood, v. 9: 804-809, Aug. 1954.

The separation of polymorphonuclear leucocytes from lymphocytes and erythrocytes has been accomplished by employing a method which takes advantages of their density differentials. During a single centrifugation the lymphocytes accumulate at a plasma-albumin interface (albumin I, density = 1.065 to 1.085), the polymorphonuclear leucocytes accumulate at an albumin I—albumin II interface (albumin II, density = 1.094) and the erythrocytes pass to the base of a Wintrobe tube. The yields are over 90 per cent pure cell types. All layers are isosmotic with blood. (Contractor's abstract)

Examination of several crystalline preparations of pancreatic (bovine) carboxypeptidase by use of quantitative emission spectrography indicated the presence of large amounts of Zn, while all other metals were either completely absent or present in minute amounts. For a carboxypeptidase of molecular weight 34,000, the mole ratio of Zn-carboxypeptidase is 1:1. O-Phenanthroline inhibited the enzymic activity of the carboxypeptidase and removed Zn from it. Zn was not removed by dialysis. (C. A., 1955:9505h)

SIMULTANEOUS DETERMINATION OF SODIUM, POTASSIUM, CALCIUM, MAGNESIUM AND STRONTIUM BY A NEW MULTI-CHANNEL FLAME-SPECTROMETER, by B. L. Vallee. June 23, 1954 [2]p. incl. diagrs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) ([Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research] under N5ori-07660]) U72411 Unclassified

Published in Nature, v. 174: 1050-1051, Dec. 4, 1954.

Design, construction and operation are described of a direct-reading multi-channel flame-spectrometer for the simultaneous analysis of Na, K, Ca, Mg, and Sr. The instrument components include an oxy-hydrogen burner, a Wadsworth stigmatic mounting grating spectrograph, photomultiplier tubes at the grating focal plane on the Mg line at 3838.258A, the CaO bandhead at 5495A, the Na line at 5889.953A, the Sr line at 4607.331 A, and the K line at 7664.907A, with 0-200 μamp microammeters as recorders at each channel, as well as null and sensitivity adjustment controls. Calibration curves for all five elements are included and discussed, and sensitivity limits noted. Study of "interference" in light intensity measurements indicate these effects can be attributed to the superposition of cation monochromatic emission upon heterochromatic background radiation which has been found to increase in direct proportion to the concentration of each radiating species. As the apparatus can be corrected readily for this background contribution, more accurate and precise flame spectrophotometry is possible.

[GLUTAMIC DEHYDROGENASE], by S. J. Adelstein, B. L. Vallee, and J. A. Olson. [1955] [2]p. [In cooperation with Peter Bent Brigham Hospital, Boston, Mass.] [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Published in Faraday Soc. Discussions, No. 20: 298-299, 1955.

Several preparations of crystalline glutamic dehydrogenase have been examined. The enzyme has been found to contain 4-5 g atoms of zinc/mol of protein. Quantitative emission spectroscopy of beef liver fractions obtained in the preparation of GDH shows the disappearance of all metals except zinc with progressive purification. The ratio, activity/[zinc], increased with purification reaching its highest value in the third crystals. The rate of conversion of DPN to DPNH at pH 7.7 in the presence of glutamate is inhibited significantly when the enzyme is pre-incubated with a number of metal-binding agents including sodium sulfide, sodium diethyldithiocarbamate, and 1,10-phenanthroline. With the first and the last of these agents, the inhibition was successfully inhibited by the prior addition of 2×10^{-2} M DPN.

[KINETICS OF ALCOHOL DEHYDROGENASE], by F. L. Hoch and B. L. Vallee. [1955] [2]p. incl. diagrs. [In cooperation with Peter Bent Brigham Hospital, Boston, Mass.] [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Published in Faraday Soc. Discussions, No. 20: 299, 1955.

Study was made of the effect of DPN on the inhibition of yeast ADH activity by 1,10 phenanthroline (OP). It was determined that when 4×10^{-3} M OP is added to ADH, a time-dependent inhibition occurs which is complete in 20 min. Addition of 5×10^{-2} M DPN to the OP-inhibited ADH does not restore activity. When 5×10^{-2} M DPN is added to ADH before 4×10^{-3} M OP is added, 55% of the initial activity remains after 32 min. DPN reduces the degree of inhibition by OP when the coenzyme is added to ADH before the inhibitor, but not when it is added after the inhibition has occurred. The kinetics involved were also studied in order to determine quantitatively the relationship between the zinc binding inhibitor and the coenzyme. It seems that DPN and OP compete for the "same" enzymatic site of yeast ADH. Since OP combines with the zinc atoms of $[(ADH)Zn_4]$, it appears that one molecule of DPN binds with each zinc atom of the enzyme, to form the enzyme-coenzyme complex, $[(ADH)Zn_4](DPN)_4$.

ANODE TEMPERATURES IN THE NOBLE GAS DIRECT CURRENT ARC WITH ALKALI AND ALKALINE EARTH METALS (Abstract), by B. L. Vallee and R. E. Thiers. [1955] [1]p. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Presented at the Conference on Analytical Chemistry and Applied Spectroscopy, Pittsburgh, Pa., Feb. 28-Mar. 4, 1955.

Published in Anal. Chem., v. 27: 32f, Feb. 1955.

Marked differences in temperature of the electrodes were noted previously in the dc arc when operating in He, Ne, and A, and data have now been obtained in Kr. Marked differences in the voltage drop across the arc were also observed. Pure graphite rods and a constructed recording pyrometer were used. These studies have been extended to temperature and voltage measurements in He and A with the anode containing a sample. The chlorides of the elements from groups I and II of the periodic system were arced individually. Preliminary data analysis indicates a correlation of the temperature to the boiling points of the salts and the position of the cation in the periodic table. Similarly, there was good correlation between the temperatures observed and the disappearance of the salt from the electrode. The presence of all salts depresses the voltage, more in column IA than in column IIA in a given gas, but the magnitude of the depression differs between He and A. The implications and experimental detail are discussed. (Contractor's abstract, modified)

Published in Anal. Chem., v. 27: 323, Feb. 1955.

Erratic precisions and accuracies when using 103-0 plates in quantitative spectrochemical trace analysis led to an investigation of the densitometric methods used. Data obtained with 3 densitometers — 2 of these of the same make — were found interconvertible only when calibration curves of each instrument were constructed. While this aided the analytical performance, it was not deemed satisfactory until plates were developed to constant gamma. This required a development time of f2 instead of 3 min as recommended by the manufacturer. The characteristics of this emulsion imply that further changes in the evaluation of photometric data may become necessary.

PHYSICAL BASIS OF SPECTRAL LINE ENHANCEMENT IN THE NOBLE GAS CURRENT ARC (Abstract), by M. R. Baker, S. J. Adelstein, and B. L. Vallee. [1955] [2]p. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Presented at the Conference on Analytical Chemistry and Applied Spectroscopy, Pittsburgh, Pa., Feb. 28-Mar. 4, 1955.

Published in Anal. Chem., v. 27: 320-321, Feb. 1955.

Studies have confirmed the enhancements of spectral lines previously noted in A and He and have newly demonstrated a similar effect in Kr. The enhancement is the greater the lower the concentration in which the elements occur in the sample. The largest enhancements for a fixed concentration of elements are observed for lines, the excitation potentials of which are in the vicinity of the first excited levels of the noble gas atmosphere employed. It is concluded that a mechanism of excitation in these sources is as follows. The noble gas is energized to its lowest excited levels by the arc discharge. Through collisions of the 2nd kind, this energy is transferred to neutral metal atoms present. The metal atoms are thus ionized and excited. The ion lines of the metal atoms whose excitation potential occurs in the vicinity of the lowest excited levels of the gas employed are consequently strongly enhanced. The excitation of lines of the neutral atoms primarily occurs through thermal collisions. The experimental findings and the physical basis of these phenomena are documented and discussed. Crystalline alcohol dehydrogenase (ADH) of yeast

contains firmty-bound zinc as an integral and enzymatically functional component of the apoenzyme motecute. Qualitative and quantitative emission spectrography and microchemical determinations of zinc were employed to anatyze crystalline preparations, which were uniformty found to contain targe quantities of zinc, tesser and variabte quantities of magnesium, and insignificant amounts of all other elements. A purified and dialyzed crystatline preparation of alcohol dehydrogenase contained 3.9 mot of zinc/mot of protein based on a motecutar weighi of 150,000. Fractionation of ADH from yeasi demonstraied an increase in the zinc:protein ratios in fractions in which the activity:protetn ratio was increased. The zinc was shown to be a functionat component of the apoenzyme by inhibition studies emptoying chetating agents. Both the dehydrogenation of ethanol and the hydrogenation of acetaldehyde were inhibited markedty. The inhibttion by chetating agenis appears to be competitive with the co-enzyme, indicating thai the 4 molecules of DPN may be bound io the apoenzyme through zinc. These data establish yeast ADH as a zinc metaltoenzyme and may be used to explain the known high zinc conteni of animal liver and retina, organs known to have a high ADH conteni. The mechanism of action of ADH based on these findings witt be discussed. (Coniractor's absiraci)

Published in Third International Congress of Biochemistry, Brussels (Belgium), 1955. Abstracts of Communications, p. 52, Aug. 1955.

Yeast alcohol dehydrogenase (ADH), containing 4 moles of zinc, is reversibly inhibited by chelating agents with high affinity for zinc. The degree of inhibition varies with the chemical characteristics of the agent and with the conditions of exposure of ADH to it. The effects of pH, temperature and time of incubation have been studied. ADH activity, markedly inhibited by 1, 10-phenanthroline are preincubated before activity is measured, the inhibition is competitive between chelating agents and DPN. When ADH and 1, 10-phenanthroline are preincubated alone, and DPN and ethanol are added only at the time at which activity measurements are started, the inhibition is noncompetitive with either substrate. It thus appears that zinc is a site of binding between DPN and ADH. (Contractor's abstract)

YEAST ALCOHOL DEHYDROGENASE, A ZINC METALLOENZYME (Abstract), by B. L Vallee and F. L. Hoch. [1955] [1]p. [In cooperation with Peter Bent Brigham Hospital, Boston, Mass.] [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Published in Third International Congress of Biochemistry, Brussels (Belgium), 1955. Abstracts of Communications, p. 52, Aug. 1955.

The crystallized enzyme (mol wt 150, 000) contains 4 atoms of Zn, which are not removed by dialysis with water, though other metals (mainly Mg) are removed. The functional role and firm attachment of Zn to the rest of the enzyme molecule is shown by the concomitant rise of Zn and activity per gram of protein during purification while other elements decrease in concentration. The action of compounds with affinity for Zn in decreasing the activity of the enzyme increases in the order: dithizone; 1, 10-phenanthroline; 8 hydroxyquinoline, and α, α^1-dipyridyl. The oxidation of EtOH and the reduction of AcH are affected equally. Inhibition is prevented when Zn or Cu is added to the enzyme simultaneously with the chelating agent. Thus Zn is an integral functional componen of the enzyme. (C. A., 1957:8850h)

Also published in Jour. Amer. Chem. Soc., v. 77: 5t96, Oct. 5, 1955.

Several crystalline preparations of beef liver glutamic dehydrogenase were examined and it was found that zinc is an integral and functional component of the enzyme molecule. Fractionation of beef liver shows an aggregation of zinc with purification of the enzyme, and as the activity:protein ratio reaches its maximum value. The metal:protein ratio of all other elements studied decreases with progressive enzyme purification. The activity:zinc ratio increases progressively with purification. The rate of conversion of DPN to DPNH at pH 7.7 in the presence of glutamate is inhibited significantly when the enzyme is preincubated with a number of metal binding agents, including sodium sulfide, sodium diethyldithiocarbamate and 1, 10-phenanthroline. These data establish glutamic dehydrogenase as a zinc metalloenzyme. The oxidation of glutamic acid is the second DPN dependent dehydrogenation reaction known to be catalyzed by a zinc metalloenzyme.

CARBOXYPEPTIDASE, A ZINC METALLOENZYME, by B. L. Vallee and H. Neurath. [1955] [9]p. incl. diagr. tables, refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Scientific Research under N5ori-07660) AD 89317 Unclassified

Presented at Third International Congress of Biochemistry, Brussels (Belgium), Aug. 1955.

Also published in Jour. Biol. Chem., v. 217: 253-261, Nov. 1955.

Quantitative emission spectroscopy and chemical analyses established that crystalline pancreatic carboxypeptidase is a Zn metalloenzyme containing 1 atom of Zn/mol of enzyme protein. Metal analyses of the fractions attending the isolation of the enzyme from pancreatic extract showed that Zn is the only metal aggregated in the fractions with increasing enzymic activity. The Zn-activity ratios reached a constant value. Enzymic activity is inhibited by metal-chelating agents such as 8-quinolinol-5-sulfonic acid, 1, 10-phenanthroline, or 2, 2'-bipyridine. Zn is both a structural and functional component of carboxypeptidase and participates in the mechanisms of its catalytic action. (C. A., 1956:3523c)

DIRECT READING FLAMESPECTROMETRY PRINCIPLES AND INSTRUMENTATION, by M. Margoshes and B. L. Vallee. [1956] 28p. incl. diagrs. tables, refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] PB 111743 Unclassified

A review is given of the development of instruments and techniques of flame spectrometry, as well as of various factors affecting light emission and its accuracie, precise measurement. The design characteristics and operation of a new direct-reading, multichannel flame spectrometer (see U 72411, item no. HAR. 07:008) is described in detail. Results of its use for analytic work and in studies of the nature of the excitation process in the flame are tabulated and discussed. Results of new investigations of interferences are included.

ANODE TEMPERATURES AND CHARACTERISTICS OF THE DC ARC IN NOBLE GASES, by B. L. Vallee and M. R. Baker. July 22, 1955 [6]p. incl. illus. refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660) AD 121537 Unclassified

Also published in Jour. Opt. Soc. Amer., v. 46: 77-82, Feb. 1956.

The construction of a gas-tight arcing chamber and continuously-recording optical pyrometer is described. The system is reproducible. The current and voltage of the dc carbon arc in noble gases show a sensitive and systematic dependence on the atmospheres employed. A small admixture of a foreign gas, such as air, markedly alters the characteristics of the arc. The arc voltage for fixed current decreases in the order He, Ne, A, and Kr; the power input decreases in the same order. The anodic temperature is linearly related to the power input. The behavior of the cross sections of the gases to electrons in the energy range of the Ramsauer-Townsend effect is suggested as a major contributor to the observed behavior of the dc arc in noble gases. THE EFFECT OF ALKALI AND ALKALINE EARTH CHLORIDES ON THE ANODE TEMPERATURE OF THE DC ARC, by B. L. Vallee and R. E. Thiers. Feb. 1956 [5]p. incl. diagrs. table, refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Published in Jour. Opt. Soc. Amer., v. 46: 83-86, Feb. 1956.

Temperatures of graphite anodes have been measured for the dc arc in helium and argon by means of a recording thermistor pyrometer when pure chlorides of the alkali and alkaline earth metals are present as samples. Anode temperatures and gap voltages were depressed by all of the samples. The data for helium indicate a correlation of anode temperature to the boiling point of the sample salt and the lowest excitation potential of the cation. Correlation was also observed between the boiling point of the salt and its rate of volatilization. Temperatures in argon are lower and correlation between anode temperatures and either boiling points or excitation potentials was not observed. However, rates of volatilization were related to the boiling points and excitation potentials of the samples. These effects are large enough to account for the poor precision of the dc arc as a spectrochemical source and show the physical-chemical basis for the use of "spectroscopic buffers." INSTRUMENTATION AND PRINCIPLES OF FLAME SPECTROMETRY. 1. MULTICHANNEL FLAME SPECTROMETER, by B. L. Vallee and M. Margoshes. July 19, 1955 [5]p. incl. illus. table, refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660) AD 89315 Unclassified

Also published in Anal. Chem., v. 28: 175-179, Feb. 1956.

An instrument for the simultaneous photoelectric determination of several elements, using a flame source, is described. The instrument consists of an oxygen-hydrogen burner, a grating monochromator, photomultiplier detectors, and associated power supplies, amplifiers, and meters. Five elements — sodium, potassium, magnesium, calcium, and strontium — are determined simultaneously. The instrument detects as little as 0.002Y of sodium in 1 ml of water. The

calibration curves cover a 1000-fold range of concentrations for each element. The precision of the instrument is within 1 to 2%.

INSTRUMENTATION AND PRINCIPLES OF FLAME SPECTROMETRY. II. EFFECT OF EXTRANEOUS IONS IN SIMULTANEOUS DETERMINATION OF FIVE ELEMENTS, by M. Margoshes and B. L. Vallee. July 19, 1955 [5]p. incl. illus. tables, refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660) AD 89316 Unclassified

Also published in Anal. Chem., v. 28: 180-184, Feb. 1956.

The effects of extraneous ions on flame spectrometer or photometric analyses have been studied with the multichannel flame spectrometer. Extraneous cations produce heterochromatic background radiation and have no effect on the monochromatic emission intensity measured above background. A method of background correction is described. The precision of the correction depends upon the line-to-background ratio. Certain anions are shown to reduce the emission intensity of the alkaline earths. These anions form compounds with the alkaline earths with high melting and boiling points; their crystals, formed in the spray, do not evaporate during their passage through the flame. Methods of obviating anion interference are discussed briefly. (See also item no. HAR. 07:046) (Contractor's abstract)

THE PHYSICAL BASIS OF LINE ENHANCEMENT IN ARGON AND KRYPTON, by M. R. Baker, S. J. Adelstein, and B. L. Vallee. Feb. 1956 [3]p. incl. illus. diagrs. tables. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Published in Jour. Opt. Soc. Amer., v. 46: 138-140, Feb. 1956.

The enhancement of certain metallic ion lines, obtained from the dc arc in atmospheres of argon, krypton, and helium has been examined. The ratios of the intensities of these lines in argon to their intensities in helium and krypton are maximal for those whose excitation potentials (EP) lie in the vicinity of the EP of the lower excited energy levels of argon. This observation is accounted for by the following mechanism. The noble gas is energized to its lowest excited levels by the arc discharge through collisions of the second kind. This energy is transferred to neutral metal atoms volatilized in the arc. The metal atoms are thus ionized and excited; they then fall to the ground state emitting their characteristic radiation. The maximum energy is transferred from argon to metal atoms when the energy of the excited noble gas atom equals the EP of the metal ion line, resulting in the selective enhancement observed. INHIBITION OF YEAST ALCOHOL DEHYDROGENASE BY METAL BINDING AGENTS (Abstract), by F. L. Hoch and B. L. Vallee. [1956] [2]p. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Presented at meeting of the Amer. Physiol. Soc., Atlantic City, N. J., Apr. 16-20, 1956.

Published in Fed. Proc., v. 15: 93, Mar. 1956.

Yeast alcohol dehydrogenase (ADH), containing 4 functional atoms of zinc per molecule has previously been shown to be inhibited by certain agents having high affinity for zinc. Yeast ADH is now shown to be inhibited by other metal-binding agents such as BAL, thiosemicarbazide, azide, cupferron and diethyldithiocarbamate. The degree and rate of inhibition are a function of the concentration of inhibitor and the pH, time, and temperature of incubation of the agents with ADH. The effects of DPN, DPNH, ethanol, and acetaldehyde on the inhibition produced by incubation with orthophenanthroline (OP) have been studied in detail. The degree of inhibition is reduced only when DPN is added to ADH at the same time or before OP is added. When DPNH, ethanol or acetaldehyde are added to ADH before OP, inhibition is more rapid and complete than when OP is added alone. DPN competes with OP, but DPNH does not, as shown by kinetic experiments. It thus appears that the zinc of [(ADH)Zn_4] is a site of interaction between DPN and ADH, an interaction which differs from that of DPNH with [(ADH)Zn_4] under these conditions. INTERACTION OF BEEF LIVER GLUTAMIC DEHYDROGENASE WITH METAL BINDING AGENTS (Abstract), by S. J. Adelstein and B. L. Vallee. [1956] [1]p. (In cooperation with Peter Bent Brigham

Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Presented at annual meeting of the Amer. Soc. for Exper. Pathol., Atlantic City, N. J., Apr. 15-16, 1956.

Published in Fed. Proc., v. 15: 505, Mar. 1956.

Beef liver glutamic dehydrogenase contains 4-5 gm atoms of zinc/mol of protein based on a molecular weight of 10^6. As the activity/zinc ratio reaches a maximum value with progressive purification and crystallization, there is an aggregation of zinc and virtual disappearance of all other metals. Zinc is firmly bound to this relatively heat stable enzyme. The oxidation and reduction of DPNH and DPN is inhibited by incubating the enzyme with a number of metal binding agents: Na_2S, BAL, azide, orthophenanthroline (OP), thiourea, diethyldithiocarbamate (NaDDC), tetraethylthiuram disulfide (Antabuse), 8-hydroxyquinoline and ammonium N-nitrosophenylhydroxylamine (cupferron). In several instances the inhibition has been prevented by the addition of DPN prior to incubation of the enzyme with these reagents. In the presence of a large excess of complexing agent, the initial rate of inhibition is found to be first order with respect to enzyme concentration. This reaction rate has been studied both as a function of temperature and inhibitor concentration. The concentration dependence of the inhibition by various complexing agents has also been investigated at equilibrium. (Contractor's abstract)

METAL CONTENT OF SUBCELLULAR RAT LIVER FRACTIONS (Abstract), by R. E. Thiers and B. L. Vallee. [1956] [1]p. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Presented at annual meeting of the Amer. Soc. of Biol. Chemists, Atlantic City, N. J., Apr. 16-20, 1956.

Published in Fed. Proc., v. 15: 370, Mar. 1956.

The amount and distribution of manganese, zinc, calcium, iron, magnesium, sodium and potassium in rat livers and their subfractions were determined by spark and flame spectroscopy. The livers of 25 normal rats were analyzed in groups of 5. Each liver was perfused with metal-free 0.25 M sucrose; 5 livers were then pooled, the connective tissue was removed and fractionation was performed by differential centrifugation. Connective tissue, nuclei and whole cells, mitochondria, microsomes and all supernatant fluids were obtained in known yield. Each fraction was analyzed by a micro-Kjeldahl method for nitrogen, by flame spectrometry for sodium and potassium, and by spark spectrography for the other elements. The resulting data are presented as amounts and concentrations of the metals in each sample and their absolute and relative distributions between the fractions. The differences in metal content of the various subfractions proved to be statistically significant. Each showed a definite and characteristic pattern both with regard to the concentration of metals and share of the total amount of each metal. (Contractor's abstract)

ZINC, A COMPONENT OF ALCOHOL DEHYDROGENASE OF HORSE LIVER (Abstract), by B. L. Vallee and F. L. Hoch. [1956] [2]p. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660] Unclassified

Presented at meeting of the Amer. Physiol. Soc., Atlantic City, N. J., Apr. 16-20, 1956.

Published in Fed. Proc., v. 15: 619, Mar. 1956.

The molecular weight of horse liver ADH is 73,000, and it contains 2 mol of zinc. Spectrographic, microchemical, polarographic and enzymatic examination of horse liver ADH demonstrate a concomitant rise of zinc and enzymatic activity with increasing purification. The zinc content approaches 2 mol of zinc/mol of enzyme in highly purified crystalline horse liver ADH. Simultaneously, extraneous metals are removed. The enzyme is inhibited by chelating agents such as orthophenanthroline, 8-hydroxyquinoline, and sodium diethyldithiocarbamate. The inhibition is a function of temperature, time, pH and concentration of inhibitor. The molecular configuration and dentate structure of the chelating agents employed condition the inhibition significantly. The effect of DPN and DPNH on the inhibition of chelating agents will be discussed. Zinc is firmly bound to the apoenzyme, and the active complex has been assigned the empirical formula $[(AD)Zn_2](DPN)_2$. (Contractor's abstract)

THE RELATION OF COPPER TO CERULOPLASMIN ACTIVITY AND ZINC TO MALIC AND LACTIC DEHYDROGENASE ACTIVITY IN ACUTE MYOCARDIAL INFARCTION (Abstract), by W. E. C. Wacker, S. J. Adelstetn and others. [1956] [2]p. [In cooperation wtth Peter Bent Brtgham Hosptal, Boston, Mass.] [Sponsored jotntly by Offtce of Naval Research and Air Force Office of Scientiftc Research under N5ort-07660] Unclasstfied

Presented at annual meeting of the Amer. Soc. for Clin. Invest., Atlantic Ctty, N. J., Apr. 30, 1956.

Published in Jour. Clin. Invest., v. 35: 741-742, June 1956.

A study of serum metalloenzymes in acute myocardial infarction was conducted. It has been observed that the serum copper concentration rtses and becomes maximal between the fifth and eleventh post-infarction day, and the serum zinc concentration is significantly decreased in this disease. The data indicate an increased rate of paraphenylenedtamine oxidation in the patient's sera tn proportion to the rise in serum copper content. Also the enzymatic activtty of malic and lactic dehydrogenases ts significantly elevated. The increase tn malic and lactic dehydrogenase and the decrease of serum zinc occur within 24 hours followtng the acute injury becoming maximal on the thtrd post-tnfarction day. The apparently paradoxical reciprocal relationship between serum zinc concentratton and zinc dehydrogenase activtty can be explained on the basis of btochemtcal ftndtngs. Lactic dehydrogenase and malic dehydrogenase acttvtties are being employed as routtne atds to diagnose myocardtal tnfarction. These methods are simple and rapid. They represent valuable adjuvants in the management of thts disease providing pertinent information not available by non-enzymatic techniques. (Contractor's abstract)

KINETIC STUDIES ON THE ROLE OF ZINC AND DIPHOSPHOPYRIDINE NUCLEOTIDE IN THE ACTIVITY OF YEAST ALCOHOL DEHYDROGENASE, by F. L. Hoch and B. L. Vallee. Oct. 24, 1955 [10]p. incl. illus. tables, refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N5ori-07660) AD 121539 Unclassified

Also published in Jour. Biol. Chem., v. 221: 491-500, July 1956.

The kinetics of the interaction between DPN and 1, 10-phenanthroline, a Zn-binding inhibitor of ADH activity, were studied to elucidate the mechanism of action of yeast [$(ADH)Zn_4$]. Inhibition of ADH activity is competitive between OP and DPN. When DPN is added to ADH before OP, inhibition of activity is decreased, indicating protection of the enzyme against the action of OP. When DPN is added to ADH after OP, activity is not changed, indicating that there is no restoration of activity in the OP-inhibited enzymes. Two molecules of OP seem to bind to 1 Zn atom of [$(ADH)Zn_4$] to form the inactive enzyme-inhibitor complex [$(ADH)Zn_4$]-$(2OP)_4$; the apparent dissociation constant, K_{op}, is 6.5×10^{-6} M. The data indicate that 1 molecule of DPN binds to each Zn atom of yeast [$(ADH)Zn_4$] to form the active enzyme-coenzyme complex [$(ADH)Zn_4$]$(DPN)_4$. (Contractor's abstract)

Serum lactic and malic dehydrogenase are stable in all human serum studied and readily assayed. Activities for both were elevated two or ten times above those normally observed in all cases of clinically proved myocardial infarction. Serum zinc levels are lowered significantly after acute myocardial infarction. Serum lactic dehydrogenase activity is not elevated in angina pectoris, severe coronary insufficiency and myocardial ischemia. Although serum lactic dehydrogenase rises in other

pathologic states, such as renal necrosis and parenchymal liver disease, it is relatively precise and useful to employ this test for the diagnosis of acute myocardial infarction.

PYRIDINE NUCLEOTIDE DEPENDENT METALLOHYDROGENASE, by B. L. Vallee, F. L. Hoch and others. [1956] [5]p. incl. tables, refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research under N5ori-07660]) Unclassified

Published in Jour. Amer. Chem. Soc., v. 78: 5879-5883, Nov. 20, 1956.

The demonstration of zinc as a functional component of four highly purified dehydrogenases had led to the proposition that metals participate in the catalytic activity of other pyridine nucleotide dependent enzymes. This hypothesis was tested by emission spectrochemical analysis for metal content and by inhibition of activity. The following dehydrogenases were examined: the glyceraldehyde 3-phosphate of yeast and of rabbit muscle, the α-glycerophosphate of rabbit muscle, the malic of pig heart and the glucose 6-phosphate of yeast (TPN dependent). All of these enzymes were inhibited significantly by exposure to 1,10-phenanthroline, 8-hydroxyquinoline and sodium diethyldithiocarbamate. They contained zinc, iron and copper as the only elements combining with all three chelating agents employed as inhibitors. The data indicate one of these metals, possibly zinc, to be involved in the mechanisms of action of the dehydrogenases, which are now referred to as pyridine nucleotide dependent metallodehydrogenases (PMD). The determination of the metal, specific to each enzyme, awaits further study. This delineation emphasizes the salient role of metals in oxidative, enzymatic catalysis. (Contractor's abstract)

FATE OF ENERGY-RICH PHOSPHATES IN RED BLOOD CELLS AND BRAIN IN ANOXIC STATES, by F. Eichholtz, E. Gerlach, and J. Döring. Technical rept. May 1, 1955-Apr. 30, 1956. July 18, 1956 [12]p. incl. diagrs. table. (AFOSR-TN-56-404) (AF 61(514)823) AD 96212 Unclassified

An effort was made to solve the problem of biochemical changes in brain tissue in states of anoxia and their prevention (or repair) by chemicals inducing increased resistance against anoxia. A method was developed for the estimation of energy-rich phosphates in red corpuscles and brain. The main advantage of the method is reliability, the error seeming to be less than 5%. Experiments were started with human erythrocytes. Results indicated that anoxemia does not lead to any change in the content of energy-rich phosphates. Experiments were also performed to determine the effects of anoxemia on energy-rich phosphates in rat's brain. Results indicated that a stop of brain circulation for 1 min produced a breakdown of CP (creatine phosphate) of about 40%, while the decrease in energy-rich nucleotides, especially ATP

HER. 01:001 - HER. 02:003

(adenosinetriphosphate), is still very small. But after an interruption of brain-circulation for 3 min a considerable fall in the content of all energy-rich phosphates, mainly CP, ATP, and GTP (guanosinetriphosphate), could be observed with a corresponding increase in orthophosphates and AMP (adenosinemonophosphate). Under the same conditions Verbindung X (compound X) remained nearly unchanged.

VORTEX MOTION AND TURBULENCE OF FREE JETS IN STEADY FLOW, by U. Domm and O. Wehrmann. Final repl. Dec. 1, 1953-Nov. 30, 1954, 36p. illus. diagrs. refs. ([AF]OSR-TN-55-118) (AF 61(514)-629-C) AD 76722 Unclassified

Experimental results are reported on the structure of a free air jet, stable in the mean Reynolds number values, near the nozzle; the design and operation of the low-pressure chamber containing the free jet are described. Hot-wire measuring techniques have been applied for determining velocity distributions and vortex-frequencies. The problem of hot-wire calibration at low free stream velocities has been treated using three methods. A comparative study proved that the stable vortex frequency behind cylindrical bodies is the best means for calibrating hot-wires at low velocities. The wiring diagrams of the applied hot-wire techniques are included. Hot-wire measurements indicated that, in the range of the Reynolds number $1830 < Re < 14700$, the free jet in the neighborhood of the nozzle has a periodic structure in time and in space as a function of the velocity. This periodic structure results from a system of annular vortices. The frequency of vortex generation and the group-velocity of the system have been measured. Finally the terms "Anlauflange" (start-length) and "Lauflange" (run-length) have been defined, and examples of measurements are included. These investigations are to be continued. A detailed description is included of a newly developed hot-wire instrument equipped with automatic control of the constant temperature of the hot-wire and having a linearization stage for the signal. THE STABILITY OF VORTEX STREETS WITH CONSIDERATION OF THE SPREAD OF VORTICITY OF THE INDIVIDUAL VORTICES, by U. Domm. Nov. 5, 1954, 5p. [AF 61(514)808) Unclassified

Published in Jour. Aeronaut. Sciences, v. 22: 750-754, Nov. 1955.

The stability of vortex streets consisting of 2 parallel rows of staggered real vortices of identical structure whose vorticity spreads with time into the ambient fluid is considered. It is found that for the case of stability, the ratio of centerline width and pitch of the street is a function of the nondimensional time $\tau = (4\nu/l^2)t$, where ν = kinematic viscosity, l = pitch of the vortex street and t = time. For vanishing viscosity and also for vanishing time, the value calculated by von Kármán, $k = h/l = 0.281$, is obtained. (Contractor's abstract)

HOT-WIRE ANEMOMETER FOR MEASUREMENTS IN UNSTEADY FLOW, by O. Wehrmann and R. Wille. [1955] [25]p. incl. illus. diagrs. refs. [AFOSR-TN-56-26] (AF 61(514)808) AD 84466 Unclassified

This hot-wire instrument utilizes carrier-frequency amplification and automatic control of the constant wire temperature. The output is linearized. The following assemblies are provided: (1) an amplifier and demodulator stage for amplification and demodulation of the bridge voltage for obtaining an amplified dc voltage at the output proportional to the bridge voltage; (2) an oscillator, control, and power stage for generating a dc voltage with a constant amplitude and a low harmonic content, using the dc voltage produced by the assembly in the control stage for the modulation of the ac voltage supplied by the generator stage, and for producing an output of 25 w in the power stage to meet measuring conditions; and (3) a linearizing stage for forming the logarithm inherent to the measuring value, multiplying this value with the desired exponent of the linearization function, forming the antilogarithm of this value, and amplifying the linearized function for immediate application to the deflecting plates of an oscillograph. The instrument was designed originally for measuring the periodical velocity changes in the scavenging ports of a model 2-stroke engine. An example of its application is given. Researchers studying the free jet are using the instrument for determining the distribution of the mean velocity. The components of the anemometer are discussed separately. (ASTIA abstract)

CONTRIBUTIONS ON THE MECHANICS OF LAMINAR-TURBULENT TRANSITION OF JET FLOW, by U. Domm, H. Fabian and others. Ftnal rept. Nov. 1955 [52]p. incl. tllus. diagrs. refs. (AFOSR-TR-56-9) (AF 61-(514)808) AD 82004 Unclassified

An analytical and experimental study of free jet flow with emphasts on the phenomena occurrtng tn the ftrst few dtameters downstream from the nozzle has been made. In the analytical treatment, the annular vortex system ts tdealtzed as a plane system in an tdeal flutd. An equation for the trajectories ts derived and tt ts shown that the vortex system ts an unstable equtltbrtum. Expertmental studies were conducted by drawtng atmospherte atr into a cyltndrical chamber, 2-m tn dtameter and 6-m long, through a nozzle. Nozzles of 1.0, 2.5, 5.0, and 10-cm tn dtameter were used. Mean-velocity and velocity-fluctuation measurements were made by a conventtonal hot-wtre technique. It was located on a probe mechanism wtthin the chamber. For mean-velocity measurements a Wheatstone bridge circuit was used, and for velocity fluctuations an osctlloscope was employed in conjunction with constant current operatton of the hot wire. Fluctuation-frequency and frequency-spectrum measurements were also made using a frequency meter and a harmonic wave analyzer. Experimental mean-velocity profiles are shown tn several planes normal to the jet axis at dtstances up to four nozzle dtameters downstream from the nozzle. The results of velocity-fluctuation measurements are correlated with the nozzle efflux Reynolds number in the range from 0 to 25,000. The growth in the amplitude of the fluctuations along the jet ts very clearly shown. Some preliminary results are reported on the measurement of the frequency of fluctuations of various amplitudes.

INVESTIGATION OF A NEW METHOD FOR THE DETERMINATION OF THE COEFFICIENTS OF SURFACE DIFFUSION OF METALS, by P. F. Mataich. Ftnal rept. Sept. 10, 1956, 57p. incl. tllus. dtagrs. refs. (AFOSR-TR-56-54) (AF 18(600)644) AD 110344 Unclassifted

The 3 bastcally dtfferent methods of measurement studted were: (1) an optical method which follows the hetght changes of a dtffustng strtp by ustng interferometrtc measurements; (2) an electrolytic method which utilizes a soltd electrolyte to transform the mass flow of the diffustng atoms into an electrtc current; and (3) an autoradiographic method whtch utilizes photographic processes to trace the progress of the dtffustng atoms. For the tnterferometrtc method, differences tn surface level could be theoretically determtned with accuractes of ±10 Angstrom units under tdeal condittons. This method gave conststent reproducible results when the base surface was made sufftctently flat. For the different electrolytic systems studied, the diffuston rate was so low that tt was masked by background currents inherent tn the system. The autoradiographic measurements varted wtth the film and the small devtations in the processtng techniques. However, the radtoactive technique has an tmportant advantage in cases where the dtffustng layer is very thin. In these cases, the exposure time could be increased to the potnt where the layer becomes vtsible whereas the interferometrtc method would not be sensttive enough to show the layer at all. The autoradtographic and tnterferometrtc methods can supplement each other. (ASTIA abstract)

A STUDY OF A FAMILY OF LAVES-TYPE INTERMEDIATE PHASES, by R. P. Elliott. Aug. 1954, 65p. incl. dtagrs. tables, refs. (Technical rept. no. 1) ([AF]OSR-TN-54-247) (AF 18(600)642) AD 42490 Unclasstfted

Fourteen transition elements were examined for the occurrence of the Laves-type intermediate compounds (Metallwtrtschaft, v. 14: 645, 1935). Laves-type compounds are of the form AB_2, and 3 crystal types characteristic of the phases are $MgCu_2$, $MgZn_2$, and $MgNi_2$. Alloys were prepared by arc-melting or by powder-metallurgical techniques at ccmposttions considered to be of these crystal types. After the identtfication of such compounds by x-ray powder camera techniques, the occurrence of allotropy was tnvesttgated by annealing at 200°C intervals from 600°C to the melting temperature. Lattice parameters and crttical tnteratomtc spactngs are reported. The ftndtngs tndtcated that a crttical d_A/d_B ratio was necessary for the existence of a Laves-type AB_2 phase (where d_A and d_B are the atomtc dtameters of A and B atoms), but tt was not sufftctent to govern tts extstence. A conststent decrease tn the atomtc dtameters compared to the elemental state was evtdenced by the tntersection of the distortton of the A-A and B-B bonds at negative distortion values. The $MgCu_2$ structure seemed to occur at lower electron-atom ratios and the $MgZn_2$ structure at higher electron-atom ratios. (ASTIA abstract)

A STUDY OF A FAMILY OF LAVES-TYPE INTERMEDIATE PHASES, by R. P. Elltott. Dec. 20, 1954, 20p. tncl. dtagrs. tables, refs. (Technical rept. no. 2 (Ftnal)) ([AF]OSR-TR-55-4) (AF 18(600)642; conttnued by AF 18(600)1399) AD 54386 Unclassified

Investigations tndtcated on the basts of the study of btnary Laves-type phases that the valenctes of the ftrst transttion sertes tncrease and decrease as the atomtc number tncreases from Tt to Nt. The valenctes of this transttton sertes were calculated. Contrary to the prevtous ftndtngs, the valenctes decreased continuously from Tt to Nt. Calculations were made by ustng the valency of Tt as a parameter. Evidence ts cited to substanttate the best values of the valenctes as calculated for an assumed valency of 4 for Tt.

IIT. 03:001

Illinois Inst. of Tech. Armour Research Foundation, Chtcago.

A STUDY OF A FAMILY OF LAVES-TYPE INTERMEDIATE PHASES, by R. P. Elltott. Apr. 25, 1956, 27p. tncl. dtagrs. tables, refs. (Technical rept. no. 1) (AFOSR-TR-56-22) (AF 18(600)1399; continuatton of AF 18(600)642) AD 88033 Unclasstfted

Effort was initiated to systemattze and complete current knowledge on the extstence of Laves phases tn btnary and selected ternary systems wtth transition elements and attempt to correlate these data wtth a valency assignment to the indivtdual elements and with Brillouin zones for the crystallographtc structures. Ltterature and tesl results showed that the pertodtc vartation of the crystal structure type of the Laves phases of Tt, Zr, Hf, Nb, and Ta may be correlated with electron vartattons; allotropy ts the exceptton rather than the rule and occurs only for those btnary phases that have electron to atom ratios near a crttical value. Constderatton of ternary Laves-type phases tndtcated that there are 2 Brtllouin zone overlaps governing the structure type. On the assumption that the valency of Tt is near 4, tt was possible to calculate the valencies of the

first transition elements as follows: (1) Ti = 3.92; (2) Zr = 3.25; (3) V = 2.19; (4) Cr = 1.69; (5) Mn = 1.35; (6) Fe = 0.92; and (7) Co = 0.72. Valencies of 0.25 and 0.00 for Ni and Cu, respectively, were considered consistent with the foregoing valencies. (ASTIA abstract)

CRYSTAL MONOCHROMATIZED X-RADIATION. PART I. A TECHNIQUE FOR THE MEASUREMENT OF INTEGRATED INTENSITIES. PART II. THE POLARIZATION CORRECTION, by L. V. Azaroff. Jan. 1955 [28]p. incl. illus. diagrs. tables. (Technical note no. A052-1) ([AF]OSR-TN-55-38) (AF 18(600)1168) AD 54833 Unclassified

Part I. The use of a bent-crystal monochromator with conventional photographic techniques is described. The reflections, which are recorded on the film, have uniform intensity distributions over the entire area of each spot. This enables the determination of the integrated intensity to be made directly with a microphotometer. The exposure time is approximately the same as for standard film methods. The total time spent to determine the integrated intensities from the photograph is reduced by semiautomation. The sensitivity of the film is increased by decreasing the background. Part II. The polarization correction for diffraction of a crystal monochromatized x-ray beam is derived. Suitable expressions are also given for different experimental methods. The polarization correction is tabulated first in parts so that the appropriate correction for any wavelength and monochromator crystal can be determined. Another table gives the polarization correction, in a final form, for use with Ag $K\alpha$ and a quartz monochromator crystal cut parallel to $(10\bar{1}1)$. (Contractor's abstract, modified)

IIT. 04:002

SIMPLIFIED UTILIZATION OF THE DAWTON METHOD FOR MEASURING INTEGRATED INTENSITIES, by R. J. Robinson, D. A. Poniarelli, and L. V. Azaroff. July 1956, 5p. incl. diagr. (Technical note no. A052-3) (AFOSR-TN-56-351) (AF 18(600)1168) AD 95437 Unclassified

A procedure is described for calibrating x-ray positive print films prepared as part of a method suggested by Dawton (Proc. Phys. Soc., v. 50: 919, 1938 - for British films) and given by Griffith for American films (Jour. Opt. Soc. Amer., v. 42: 31, 1952). No special treatment of the x-ray negative was required. The positive was prepared by making a contact print onto Eastman Commercial Ortho film. The light source, exposure time, source-to-film distance and developing time in DK-50 developer were selected to satisfy $Tp = -\log Ep$, where Tp is the transmittance and Ep the exposure, respectively, of the positive film. The actual arrangement consisted of a 6 w bulb operated at 60 v and placed 10 ft from the film. It was found necessary to prepare 2 positive films films from each x-ray negative to cover the full useful range of intensities. Advantages of the described modification are the saving of time: the necessity of calibrating only the positive film; the determination of the linear transmittance limit in each case; and the applicability to existing as well as new x-ray negatives.

ELECTRON DIFFRACTION STUDIES OF FRICTION, by P. L. Copeland and E. J. Scheibner. Feb. 1953-June 1954. June 1954, 58p. incl. illus. diagrs. refs. (Technical rept. no. 1) ([AF]OSR-TR-54-18) (AF 18(600)643) AD 39815 Unclassified

The nature of the frictional wear of single crystal and polycrystalline materials is determined primarily by electron diffraction methods. The current viewpoint of the friction mechanism ts reviewed, as well as methods for studying friction. A theory is developed for the interpretation of single crysial electron diffraction patierns from imperfect crystals based upon the intensity distribution in reciprocal space and the use of the Ewald sphere to determine possible reflections. Studies of frictional behavior for polycrystalline materials sliding on polycrystalline materials and for single crystals sliding on single-crystal and polycrystalline materials are reported. It is concluded that the electron diffraction method is sufficiently sensitive to detect fracturing of the crystal surface and for identifying material transferred during sliding. It is noted that for copper the presence of a thin oxide film tends to reduce the coefficient of friction, but it does not prevent the deformation of the copper crystal. (Contractor's abstract)

THE POLYMORPHIC MODIFICATIONS OF SILICA IN CERAMIC COATINGS, by J. H Lauchner. Feb. 1957, 20p. incl. diagrs. lables, refs. (Rept. no. 77) (AFOSR-TN-56-446) (AF 18(603)28) AD 96791; PB 126367 Unclassified

In this study, the polymorphic modifications of silica present in ceramic coatings owing to devitrification or

as a result of direct additions were identified by thermal-strain, x-ray diffraction, and differential-thermal analyses. Comparison of the analytical results indicated thermal strain analysis to be the most sensitive method in identification of all silica modifications studied. Analysis of the tessellated stresses developed in the systems was applied in determining effective linear thermal-expansion characteristics, and interpreting residual stress development. The solubilities of $La(NO_3)_3$ and $LaBr_3$ in anhydrous ethylenediamine (I) were measured as 3.81 and 0.135 g/l of solution, respectively. $La(NO_3)_3$ and $LaBr_3$ were soluble in dimethylformamide (II), the latter being 251.2 g/l of solution at 30°C. Conductance curves for $La(NO_3)_3$ and $LaBr_3$ in I indicated that the equivalent conductance increased on dilution in low-concentration ranges; the salts behaved as weak electrolytes in both solvents. Limiting conductance values could not be obtained. The presence of H_2O did not appreciably change the shape of the curves in either system and did not affect the strength of either solute as an electrolyte. Light yellow cathode deposits were generally obtained from the electrolysis of $La(NO_3)_3$ in anhydrous I and in I containing small quantities of H_2O. A black deposit was obtained when 2 sintered-glass barriers were placed between the catholyte and the anolyte in the anhydrous I solution. A violent reaction occurred between the anolyte and catholyte during the electrolysis of II solutions of $La(NO_3)_3$. The electrolysis of II solutions of $LaBr_3$ yielded gelatinous appearing cathode deposits. Photomicrographs and chemical reactions of the cathode deposits obtained in the I systems indicated the presence of small quantities of free metal after the deposits were vacuum-heated. Similar analysis of the cathode deposits obtained in the II-bromide system yielded less evidence for the presence of La.

A FIXED POINT INDEX, by D. G. Bourgin. Terminal rept. Oct. 27, 1955, 16p. ([AF]OSR-TN-55-410) (AF 18(600)1398; continued by AF 18(603)32)
AD 83019 Unclassified

This mathematical study considers the index of a transformation relative to an open set for an ANR or LC^n space. The spaces occurring are all compact Hausdorff and are denoted by X with points x. Maps are understood to be continuous. The boundary of a set g is written $\dot{g}$. The complement of a set A is indicated by a prime, i.e., A'. Small Greek letters are used for finite open covers with the ordering relation defined by $\alpha < \beta$ if β refines α. The open sets or elements of α are written a_1. The nerve of a cover is a Euclidean complex and is indicated by the corresponding small Roman letter, thus a is the nerve of α. The points of a are written y. The vertex of a corresponding to a_1 is indicated by (a_1). The symbol St for star is utilized in both the point set and the algebraic senses, but the context avoids confusion. The notation $\bar{b}$ is employed both for the algebraic and the topological closure of the simplex b. If β is a cover and L is a subcomplex of the finite complex K containing all the vertices of k, then β is a mesh of the partial realization of L by α if for each simplex of K the map of its faces in L is contained in a single element of β. A homotopy is over α if for each point the orbit under the homotopy lies in an element of α. R is the symbol for a retraction and I or I_A for the unit segment. The parallelotope $P = P^{\{A\}}_{I_A}$, where script set $\{A\}$ is arbitrary and not necessarily denumerable. The space X is usually assumed to be a NR in a parallelotope. The LC^n property is that for every α there is a β such that to every partial realization of a finite complex with a mesh β there is a full realization, or extended realization with a mesh β. The mesh α is termed an extension mesh for β, and is written $\alpha \geq \beta$. Q_a is written for a canonical map from X to a. Throughout, the Čech homology groups $H_n(X)$ are over the rationals. H(X) is used for the direct sum $\sum H_n(X)$. Moreover if P^a_b is the projection transformation on b into a then P^a_b stands not only for the induced chain homomorphism on the chain groups over b into those over a, but also for the homomorphisms of the cycle groups as well as the homology groups. Use is made of I for the identity map $Ix = x$. Q_b is a cocanonical map over α, or more simply, a cocanonical map if $q_b Q_b \cong I$ over α. Lemma O: For arbitrary α there is a β such that every pair of points in an element b_1 of β can be joined by a unique path in some element a_j of α, $j = j(i)$. (Extracted from rept.)

NON LOCALLY CONNECTED SPACES RELATED TO ABSOLUTE NEIGHBORHOOD RETRACTS AND FIXED POINT PROPERTIES, by D. G. Bourgin. Jan. 30, 1957, 10p. (AFOSR-TN-56-578) (AF 18(603)32; continuation of AF 18(600)1398) AD 110400 Unclassified

Spaces which are limits of absolute neighborhood retracts or non-locally connected spaces are considered from the point of view of significant Lefschetz numbers and as natural extensions of absolute neighborhood retracts. Two theorems are discussed. First, if X is a neighborhood retract δ satisfying $t^{\nu} r^{\rho}{}_{\nu} = i^{\rho}$ then $Lf = Lf^{\rho}$ for $\rho_0 < \rho$. If X satisfies Q_1 also, $Lf \neq 0$ implies f has a fixed point. Secondly, suppose X is a neighborhood retract δ satisfying Q_1 or, if X is a NR, and if G is open with fixed point of free boundary G under $f: X \longrightarrow X$ and if the index $\Delta(f^{\rho}, G^{\rho})$ is non-zero for all the values of f for which it is defined, then f has a fixed point in G.

[AN INDEX OF A FIXED POINT, PARTS I AND II] Topologia - Un indice dei punti uniti. I, II, by D. G. Bourgin. [1955 and 1956] [12]p. (AF 18(603)32) Unclassified

Published in Atti Accad. Naz. Lincei. Rend. Cl. Sci. Fis. Mat. Nat., v. 19: 435-440, Dec. 1955; v. 20: 43-48, Jan. 1956.

In these two notes the author lays the foundations for a fixed-point-index theory for transformations $f: X \longrightarrow X$ where X is a compact Hausdorff space, assumed to be an ANR. Using Čech homology theory over rational coefficients, the author exploits the fact that the homology theory of such an X, and its influence under f, can be transferred to a finite approximating polytope where, of course, an index theory is readily available. The principal results are 1) the Lefschetz number of f equals the Lefschetz number of the transformation induced in the nerve of any sufficiently fine covering; 2) if G is an open subset of X whose boundary contains no fixed points, the index of the transformation induced in a sufficiently fine nerve over a certain open subset of the nerve, determined by G, is independent of the nerve chosen. [AN INDEX OF A FIXED POINT, PART III] Topologia - Un indice die punti uniti. III, by D. G. Bourgin. 1956. 6 p. (AF 18(603)32) Unclassified

Published in Atti Accad. Naz. Lincei. Rend. Cl. Sci. Fis. Mat. Nat., v. 21: 395-400, Dec. 1956.

The author considers spaces which are limits of ANR's and obtains fixed-point theorems for such spaces. A compact subset X of a fixed parallelotope P is called an NR_{δ} if it is the intersection of a family $\{X_{\alpha}\}$ of ANR's, subsets of P, such that X_{α} is a retract of X_{β} whenever $X_{\alpha} \subset X_{\beta}$. Let X be an NR_{δ}. Then X is homologically finite, so that every mapping $f: X \longrightarrow X$ has a Lefschetz number L(f). Assume now that there exists a family of mappings $t_{\alpha}: X_{\alpha} \longrightarrow X$ which are compatible, in a certain homological sense, with the retractions $X_{\beta} \longrightarrow X_{\alpha}$. Assume further that the t_{α} satisfy a uniformity condition which states roughly that t_{α} is near the identity when X_{α} is near X. Under these conditions the nonvanishing of L(f) implies the existence of a fixed point. There are a number of interesting corollaries. (Math. Rev. absiract)

BROWNIAN MOTION ON A GREEN SPACE, by J. L. Doob. Oct. 31, 1957 [31]p. (AFOSR-TN-56-573) [AF 18(603)11] AD 110395 Unclassified

Also published in Teoriia Verofatnostei i EE Primeneniia, v. 2: [3]-33, 1957.

The basic results of Brownian motion theory developed for spaces which are subsets of Euclidean N-space are extended to Green spaces. The study is found to be useful in studying not only harmonic functions, Brownian motion stochastic processes on Green spaces, but also parabolic functions and heat motion stochastic processes on heat spaces. The probabilistic attack is found to be of utility in defining the boundary points of the space in the general problem involving stochastic processes with non-constant lifetimes. The necessary definitions and theorems, relevant to the investigation, are presented.

THE MECHANISM OF PHASE TRANSFORMATIONS IN METALS, by D. S. Lieberman. Mar. 19, 1956, 11p. incl. illus. (Rept. no. MEDUI-17-AF) (AFOSR-TN-56-412) (AF 18(600)1311) AD 96221 Unclassified

In this study, the graphical formulation of a crystallographic theory of diffusionless phase transformations is discussed. The theory of Wechsler, Lieberman, and Read (Trans. Amer. Inst. Mining, Metallurgical, and Petroleum Engineers, v. 197: 1953) permits calculations to be made of the following features of martensitic transformations from a knowledge of the lattice parameters and the pattern of inhomogeneity: (a) the orientation of the interface plane separating the parent and product phases; (b) the magnitude and direction of the macroscopic shear accompanying the transformation; (c) and the orientation relationships between the crystal axes in the 2 structures. The graphical method is

ILL. 07:002 - ILL. 08:003

GROWTH BENDS IN IRON WHISKERS, by G. S. Baker. Oct. 15, 1956, 3p. incl. table. (Rept. no. MEDUI-18-AF) (AFOSR-TN-56-413) (AF 18(600)1311) AD 96222 Unclassified

Also published in Jour. Appl. Phys., v. 27: 1561-1562, Dec. 1956.

It has been proposed that the bent part of the whisker is the site of a twin boundary, or of some other type of boundary. The purpose of the present study is to show that this is not the case for Fe whiskers grown from the vapor. Whiskers were grown by the reduction of $FeCl_2$ by H_2. Back reflection Laue x-ray patterns of those whiskers which exhibited bends were taken above, below, and at the position of the bend. The orientation of the crystal lattice is identical at all 3 positions for all specimens x-rayed, 12 in all. This proves that the crystal structure is continuous through the bend, and that no boundary need be postulated in the bend. The bend itself, is caused by the whisker axis shifting from one crystal direction to another, often, but not always, an equivalent crystallographic direction. Tabular data are presented, giving whisker axes, surface planes, and angle of several types of whisker bends. The measured angle always agreed with that calculated within a couple of degrees. In addition to the crystallographic angles, there are occasionally whiskers bent in a smooth arc over long regions. X-ray pictures of 2 of these show the crystal lattice to be uniformly rotated in orientation over these arcs.

POLARIZATION IN INSULATING CRYSTALS (Abstract), by C. Inchauspé and N. Inchauspé [1955] [1]p. [AF 18(600)662] Unclassified

Presented at meeting of the Amer. Phys. Soc., Baltimore, Md., Mar. 17-19, 1955.

Published in Phys. Rev., v. 98: 1543, June 1, 1955.

An elementary analysis has been made of the problem of the development of space-charge within an illuminated insulating crystal which exhibits photoconductivity. The analysis is applicable to crystals similar to alkali-halides in which the displacement, w, of the photoelectrons by the field is much smaller than the distance, d, between the electrodes. The analysis has been carried out for various types of nonuniform illumination in the form of a plane parallel condenser. The initial slope of the photocurrent time curve is given by $(1/i_0)(di/dt)_0 = (d/a)(i_0/q_0)$, where i_0 is the initial current and q_0 is the charge of the condenser before illumination. The length, a, characterizes the nonuniform illumination and is a measure of the distance within which the radiation is absorbed.

PHOTOCONDUCTIVITY IN POTASSIUM IODIDE (Abstract), by N. Inchauspé. [1955] [1]p. [AF 18(600)-662] Unclassified

Presented at meeting of the Amer. Phys. Soc., Baltimore, Md., Mar. 17-19, 1955.

Published in Phys. Rev., v. 98: 1550, June 1, 1955.

Photoconductivity in potassium iodide at the temperature of liquid nitrogen has been investigated with crystals containing additive F-centers and radiation in the photon energy range from 1.9 ev to 5.8 ev. The maximum of the F-center absorption occurs at the lower limit of this photon energy range and the upper limit marks the maximum of the first (exciton) peak of the fundamental optical absorption. The concentration of F-centers was varied from 10^{14} to 10^{17} cm^{-3}. The number of quanta incident per second upon the crystal was about 10^{11} per second. The observed photocurrents were less than 10^{-15} amperes in crystals which had not been additively colored. When the crystals were prepared in such a low-vapor pressure of K as to contain less than 10^{15} F-centers cm^{-3}, photocurrents became observable at 3 ev and increased to a broad maximum at 5.1 ev. For F-centers concentrations between 10^{15} and 10^{17} cm^{-3}, additional maxima were observed at 1.9 ev and 5.51 ev where the F- and p-bands occur. The photocurrents decreased rapidly as the photon energy was increased beyond 5.51 ev. (Contractor's abstract)

SELF DIFFUSION OF SODIUM AND IONIC CONDUCTIVITY IN NaCl-$CaCl_2$ CRYSTALS, by J. O. Thomson. Feb. 1956 [20]p. incl. diagrs. tables, refs. (AFOSR-TN-56-59) (AF 18(600)662) AD 81051 Unclassified

Presented at meeting of the Amer. Phys. Soc., Baltimore, Md., Mar. 17-19, 1955.

Abstract published in Phys. Rev., v. 98: 1536, June 1, 1955.

The diffusion of Na^+ in NaCl containing small, known concentrations of $CaCl_2$ was measured as a function of temperature. The diffuston data were compared with the ionic conductivities of the crystals. The degree of association of Ca ions with positive ions to form complexes appeared smaller than theoretically expected. Results showed a small magnitude of discrepancy in the Einstein-Nernst diffusion-conductivity relationship. The small discrepancy appears to substantiate Bean's conclusion (Thesis, Illinois U., 1952) that Ca ions do not readily associate with Na ion vacancies. Effects are discussed which obscure the application of the association theory to the NaCl-$CaCl_2$ system. Anomalous data include (1) similar discrepancies in the Einstein-Nernst relation for crystals with large impurity-content variations and (2) parabolic instead of straight-line conductivity isotherm-vs-concentration curves at lower temperatures. The ratio of free vacancies to impurity atoms apparently increases with increasing impurity concentration and decreasing temperature. A comparison of the NaCl-$CdCl_2$ and NaCl-$CaCl_2$ systems showed a marked difference in the calculated mobility of the free vacancies. A disparity in the calculated mobilities was obtained which was well outside experimental error, and indicated that not all of the Ca introduced into NaCl crystals is effective in creating free or associated vacancies. An irreversible effect may occur with Cd in the NaCl-$CaCl_2$ system. (ASTIA abstract)

DIELECTRIC LOSS IN SODIUM CHLORIDE, by J. O. Thomson. Dec. 1956 [10]p. incl. diagrs. tables, refs. (AFOSR-TN-56-427) (AF 18(600)662) AD 96509 Unclassified

Dielectric loss measurements were made on crystals of NaCl, which contained small additions of $CaCl_2$, in the frequency range between 0.1 and 100 kc at 50° to 150°C to obtain information on point imperfections in ionic crystals. The crystals were grown by the Kyropoulos method from a melt of NaCl having appropriate amounts of $CdCl_2$. They were cleaved into plates about 0.3 to 0.4 mm thick and 3 to 4 sq cm in area. The faces of the specimens were covered with Ag-conducting paint, and Pt leads were cemented to the electrodes using the same paint. The dielectric loss was measured by means of a General Radio 716C bridge with a bridge voltage of 50 to 100 mv. The concentration of impurity was determined by a nephelometric method (accurate to 25%). Measurements suggested that the number of complexes at low temperatures is substantially less than the number of impurity ions. The data show that in the most highly-doped crystal, the low-temperature defects persist to higher temperatures. The widths of the dielectric-loss peaks (on a log frequency plot) of test crystals were roughly 20 and 60% wider than theoretical values. This may be explained on the basis of the low-temperature defects. (ASTIA abstract)

SELF-DIFFUSION OF SODIUM AND CONDUCTIVITY IN SODIUM CHLORIDE CRYSTALS (Abstract), by J. O. Thomson. [1956] [1]p. [AF 18(600)662] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Ser. II, v. 1: 214, Apr. 26, 1956.

Na^{24} tracer diffusion measurements and conductivity measurements have been made on single crystals of NaCl containing small amounts of $CaCl_2$ (6 and 20 x 10^{-4} mole fraction). The measurements were made in the temperature range from 240°C to 590°C. The self-diffusion coefficient of the sodium ion was obtained from the tracer diffusion coefficient by application of the Bardeen-Herring correlation factor. The ratio (σ/D) of the conductivity to the self-diffusion coefficient satisfies the Einstein-Nernst relation much better than data obtained from NaCl-$CdCl_2$ crystals. This result may not be due to a small binding energy of the calcium ion-positive ion vacancy complex, because the ratio, (σ/D), and the conductivity, σ, do not depend upon the temperature and concentration of calcium in the manner predicted by association theory. DISLOCATION LINE ENERGY AND SLIP IN NaCl AND

ILL. 09:002 - ILL. 10:001

AgCl CRYSTALS (Abstract), by R. Thomson. [1955] [1]p. [AF 18(600)689] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 27-29, 1955.

Published in Phys. Rev., v. 98: 1171, May 15, 1955.

Calculations of the elastic energy of dislocations in NaCl and AgCl have been made which include the effects due to the elastic anisotropy of the crystals. At low temperatures the calculations give some evidence in NaCl for the choice of (110) slip planes over (100) slip planes. However, the calculations do not predict the large difference in the yield stress experimentally observed. This result suggests that other mechanisms such as a differential pinning of edge dislocations in different slip planes are also important. At high temperatures the preference for (110) slip planes due to crystal anisotropy disappears, in agreement with suggestions by early experimenters that other slip planes become active at high temperatures. The calculations for AgCl do not predict any marked preference for (110) slip planes over (100) slip planes in agreement with the observed pencil glide in AgCl.

DISLOCATION ENERGIES IN NaCl, by H. B. Huntington, J. E. Dickey, and R. Thomson. May 1956 [12 p. incl. diagrs. tables, refs. (AFOSR-TN-56-181) (In cooperation with Rensselaer Polytechnic Inst., Troy, N. Y.) (AF 18(600)689) AD 87054 Unclassified

Published in Phys. Rev., v. 100: 1117-1128, Nov. 15, 1955.

The energies for both screw and edge dislocations in rock salt have been investigated. The effect of elastic anisotropy has been incorporated into the contribution from the region outside the core. Detailed calculations have been carried out for the energies of the cores themselves as a function of radius, and joined smoothly to the curves of the elastic theory. The core calculations are based on the Born-Mayer model, and employ the formulas of Madelung for the potentials of rows of uniformly spaced charges. For dislocations in the observed plane of slip (110), the constant term associated with the core energy is 1.0×10^{-7} ev/cm more for the edge than for the screw. Approximate calculations show this term to be appreciably larger for the edge dislocation in the (100) plane. Also, there appears to be large lattice potential barrier for dislocation motion in this plane arising from anion closed shell repulsion. This result may explain why these planes, though close-packed, are generally not active in glide for alkali halides. The stability of dislocations with Burger vector longer than the minimum lattice translation is investigated. The possibility of hollow dislocations is also considered. (Contractor's abstract)

ASSOCIATED ENERGY OF VACANCIES AND IMPURITIES WITH EDGE DISLOCATIONS IN NaCl, by F. Bassani and R. Thomson. Sept. 1956 [12]p. incl. diagrs. tables, refs. (AFOSR-TN-56-309) (AF 18-(600)689) AD 96050 Unclassified

Also published in Phys. Rev., v. 102: 1264-1275, June 1, 1956.

Calculations were made of the energies of association of Sr^{++} ions, Cd^{++} ions, and positive-ion vacancies with the core of a (110) edge dislocation in NaCl. It is found that the vacancy has an association energy of 0.4 ev, but that other impurities have smaller association energies. On the basis of this energy of association, the numbers of vacancies and divalent ion-vacancy complexes pinned in the cores of the (110) edge dislocations in a well-annealed crystal were calculated. These numbers are large enough at room temperature to suggest that impurity and vacancy pinning might be the agent determining the critical yield stress in annealed NaCl. The elastic field interaction between point defects and dislocation is tabulated and compared with the interaction obtained within the core. It is shown that the elastic energy of interaction does not necessarily project into the core in a smooth fashion, but that in the case of the vacancy, an elastically "large" inclusion behaves like a "small" inclusion in the core. Several possible suggestions are made which may explain the strong hardening effect of divalent impurity additions to NaCl. (Contractor's abstract)

HALL EFFECT AND CONDUCTIVITY OF SYNTHETIC RUTILE CRYSTALS AND SOME ALKALINE EARTH TITANATES, by M. C. Andrews. [1952] 128p. incl. illus. diagrs. tables, refs. (AF 33(038)12644) Unclassified

Determination of the Hall effect and electrical conduction properties are reported of six titanates, $MgTi_2O_5$, $MgTiO_3$, Mg_2TiO_4, $CaTiO_3$, $SrTiO_3$ and $BaTiO_3$, varying in stoichiometric composition from unreduced to a near-maximum reduction, primarily over a temperature range of 25° to -195°C. As these crystalline double oxides have a common component, TiO_2, similar measurements were made of synthetic single crystals of titanium oxide. The physical properties of test materials, measurement methods and semiconductor models are discussed, and experimental results analyzed.

A MAGNETIC EFFECT IN MAGNESIUM TITANATE, by E. K. Weise and H. Katz. [1952] [2]p. [AF 33-(038)12644] Unclassified

Published in Phys. Rev. v. 86: 1046-1047, June 15, 1952.

Measurements were made on $MgTiO_3$, Mg_2TiO_4, and $MgTi_2O_5$ of the paramagnetic susceptibility vs percentage of oxygen removed by reduction with H at 850-1450°. The values plotted for $MgTiO_3$ and Mg_2TiO_4 increased smoothly with a decrease of the oxygen. $MgTi_2O_5$, however, showed a remarkable peak between 0.15 and 0.25%. The dependence on magnetic field strength was determined. There was no apparent influence using the laboratory electromagnet, which could be varied from zero to about 2000 gauss field strength. This behavior is typical for paramagnetism and eliminates the possibility of a ferromagnetic effect, which was assumed at first because of the size of the observed forces.

ON THE ELECTRICAL CONDUCTIVITY OF SOME ALKALINE EARTH TITANATES [Part I], by E. K. Weise and I. A. Lesk. [1953] [6]p. incl. diagrs. [AF 33(038)12644] Unclassified

Published in Jour. Chem. Phys., v. 21: 801-806, May 1953.

The compounds Mg_2TiO_4, $MgTiO_3$, $MgTi_2O_5$, $CaTiO_3$, $SrTiO_3$, and $BaTiO_3$ were prepared in crystalline form by reaction in the solid state between TiO_2 and the carbonate or oxide of the appropriate alkaline earth. Samples in the form of rods were sintered in O at 1450° and were reduced in H at temperatures from 560° to 1400°, n-type semiconductors being produced. The most highly reduced Mg titanates lost 3% in weight during this treatment, but the largest reduction in weight with $CaTiO_3$, $SrTiO_3$, and $BaTiO_3$ was 0.25%. Resistivity values from 10^{-1} to 10^8 ohm-cm were obtained. The plot of log resistivity vs reciprocal absolute temperature was linear in most cases over a wide range of temperature and resistivity. The curves for $BaTiO_3$ changed slope abruptly at approximately 115°; this is probably attributable to the crystal structure change at the Curie temperature of approximately 120°. The dependences of impurity activation energy and Fermi level on percentage reduction were determined for the case of Mg_2TiO_4. The Bilitz-Meyer rule, stating a linear relation of impurity activation energy with resistivity at a reference temperature, was not obeyed over the large range of reductions obtained.

SIMPLE THERMOCOUPLE NEEDLE THERMOMETER WITH HIGH SENSITIVITY, by E. K. Weise and A. C. Hershberger. Oct. 25, 1955, 7p. incl. diagrs. (Technical note no. 4) ([AF]OSR-TN-55-423) (AF 33(038)-12644) AD 80106 Unclassified

A simple thermocouple needle thermometer was used directly with a sensitive galvanometer and a salt bath as a reference for temperature measurements in living animal tissues. The thermocouple was constructed of a 0.20-in.-od, 0.014-in.-id, 2.5-in.-long nickel tube with a copper wire soldered at one end and a nickel wire soldered at the other end. The reference bath was a melt of ordinary Glauber salt (sodium sulfate decahydrate), which has a conversion point at 32.38°C. Dropping a small crystal of the salt into the melt is recommended to remedy the frequent occurrence of supercooling. Any galvanometer with a high sensitivity and a low impedance can be used. With a Rubicon galvanometer, a sensitivity of 6.7 mm/0.1°C from 36° to 39°C was obtained.

ON THE ELECTRICAL CONDUCTIVITY OF SOME ALKALINE EARTH TITANATES, PART II, by E. K. Weise and M. C. Andrews. Mar. 15, 1956, 23p. incl. diagrs. tables, refs. (Technical note no. 8) (AFOSR-TN-56-125) (AF 33(038)12644) AD 86001 Unclassified

Measurements are described of the electrical conductivity of the following reduced heavy metal titanates from room temperature down to about -190°C: Mg_2TiO_4, $MgTiO_3$, $MgTi_2O_5$, $CaTiO_3$, $SrTiO_3$, and $BaTiO_3$. Samples 1 x 3 x 12 mm were prepared with Pt strips, 5 mm apart, and fired on one of the wide surfaces to serve as voltage probe contacts. Before reduction, all samples were sintered in O for about ½ hr at 1360° to 1415°C. Reduction times and temperatures were varied, and a combination of H and H-He atmospheres were used. Voltages and currents were measured with a vacuum-tube electrometer capable of measuring voltages as low as about 0.01 v and currents as low as 10^{-16} amp. The degree of reduction was determined by cleaning and weighing the samples after all electrical measurements had been taken and then weighing again after heating the samples in O. The change in weight was assumed to be equal to the weight of the O removed from the sample by reduction. The densities of the oxygen vacancies were computed from the change in weight data. Plots were made of the log of the resistivity vs the reciprocal of the absolute temperature. The removal of O from the lattice brings about n-type semiconductivity. A 1- or 2-donor-level model was used for the interpretation of the results. Gap width, density, and activation energy of donors, and concentration and mobility of electrons in the conduction band were determined. (ASTIA abstract, modified)

VARIABLE TEMPERATURE CHAMBERS, by M. C. Andrews, A. S. Chodakowski, and E. K. Weise. May 10, 1956, 7p. incl. diagrs. (Technical note no. 5) (AFOSR-TN-56-206) (AF 33(038)12644) AD 87520 Unclassified

The construction of 2 different temperature chambers which were built for measurements of Hall effects and magnetic susceptibilities on semiconducting materials is described. The temperature range covered was from lower than -190° up to about 200°C. For measurements below room temperature, a cryostat was built. A second chamber was built for temperature ranges above room temperature. The cryostat has a built-in heating element which enables the temperature of the sample chamber to be raised from its lowest value (-175°C) to some value above 200°C. Temperatures between -60°C and room temperature required frequent heater-current adjustments and additions of liquid N to prevent temperature variations during measurement. Temperature equilibria were maintained easily from room temperature to 200°C. (ASTIA abstract, modified)

COMPLEX IMPEDANCE OF CONDUCTING THIN FILMS (Abstract), by C. E. Drumheller. [1952] [1]p (AF 33(038)21255) Unclassified

Presented at meeting of the Opt. Soc. of Amer., Boston, Mass., Oct. 9-11, 1952.

Published in Jour. Opt. Soc. Amer., v. 42: 877, Nov. 1952.

A new point of view is proposed to account for the observed optical characteristics of conducting thin films without the necessity of postulating any unusual or anomalous frequency dependence of resistivity. By considering the complex impedances associated with the structure of such films it is possible not only to account theoretically for their observed optical behavior, but important new information concerning the structure can be derived from simple electrical and optical measurements. Measurements on evaporated bismuth films indicate that those in the resistance range of 10,000 to 50,000 ohms per square have a parallel capacitance of about 2.5×10^{-6} micromicrofarad per square. Those evaporated to a resistance of 90 ohms per square have both parallel and series capacitances of about 3.8×10^{-5} micromicrofarad per square. These results can be explained satisfactorily if one assumes that the resistance is contributed primarily by the grain boundaries between adjacent bismuth crystals and that a wide variation exists in the grain-to-grain resistances. This conclusion is also consistent with electron micrograph observations of the oxidation process of bismuth films. (Contractor's abstract)

ANOMALOUS THERMAL TRANSITION IN THE INFRARED OPTICAL PROPERTIES OF EVAPORATED BISMUTH FILMS (Abstract), by C. E. Drumheller. [1954] [1]p. (AF 33(038)21255) Unclassified

Presented at meeting of the Opt. Soc. of Amer., New York, Mar. 25-27, 1954.

Published in Jour. Opt. Soc. Amer., v. 44: 345, Apr. 1954.

Studies of the effect of temperature variations on the infrared optical properties of evaporated bismuth films have led to the discovery of an anomalous transition in the infrared transmission. Heating of a bismuth film (on cellulose nitrate substrate) by any of several means caused a slight increase in transmission at wavelengths less than 1.7 micron and a decrease at longer wavelengths. The transition wavelength is essentially constant for films of various thicknesses. Careful examination of this transition revealed a sharp crossover resembling the familiar anomalous dispersion curves in optics. The mid-point corresponds to an energy of 0.68 electron volt. The results can be explained by taking into account three different effects on transmission, i.e., (1) film structure, (2) variations of conductivity with temperature, and (3) variations in index of refraction with temperature. The nature of these effects are discussed in relation to possible inferences concerning the electronic structure of bismuth in thin-film form. (Contractor's abstract)

DIELECTRIC PROPERTIES OF NITROBENZENE IN THE REGION OF ANOMALOUS DISPERSION, by G. L. Clark. Aug. 23, 1955 [5]p. tncl. diagrs. tables, refs. [AFOSR-TN-55-295] [AF 18(600)1013] Unclassifted

Published in Jour. Chem. Phys., v. 25: 125-129, July 1956.

This study was carried oul to delermine the highest frequency at which nitrobenzene can be used as a Kerr medium, and to obtain design data for microwave Kerr cells. A determination was made of the complex dte-lectric constant of htghly purified nitrobenzene tn the region of anomalous dispersion by measuring the input impedance of a variable length of a coaxial transmission ltne filled with the liquid. Measurements were obtained at frequencies ranging from 0.65 kmc/sec to 3.00 kmc/sec in the temperature range from 15°C to 50°C. They indicated that at low frequencies, the effect of increasing temperatures is to decrease the real part of the dielec-trtc constant owing to the shift in the staltstical equtlib-rium between the aligning force of the field and the ran-domizing effect of thermal motion. In the region of anomalous dispersion, however, the dielectric conslant may rise with increasing temperalure as a result of the effect of temperature on the relaxation time. It is observed that there is a frequency region in which the 2 effects tend lo neutralize each other, causing the dielectric constanl lo be insensitive to temperature changes. Concerning lhe frequency limitation on nitro-benzene as a Kerr medtum, the behavior of the dielec-trtc constant reveals lhal above 1000 mc/sec, the di-pole polartzation falls away rapidly as the frequency increases.

THERMAL ACCEPTORS IN GERMANIUM, by H. Letaw, Jr. Aug. 20, 1955, 38p. incl. dtagrs. tables, refs. [AFOSR-TN-55-298] (Sponsored jointly by Office of Naval Research as Technical rept. no. 7 under N6ort-07140 and Office of Sctentific Research as Technical note no. 1 under AF 18(600)1310) AD 72718 Unclassified

Thermal acceptors are identified as vacancies with an energy of formation of 2 ev. The annealing of thermally tnlroduced acceptors in germanium ts described by a mechanism involving lhe formation of divacancies as the first step. The activation energy for the formation of a divacancy is 1.7 ev, consisting of a contribution of 0.97 ev from the activation energy for the diffusion of a vacancy and 0.7 ev from the laltice strain repulsion of 2 vacancies. The energy of formation and the bindtng energy of a dtvacancy are 1.1 and 2.9 ev, respectively. The diffuston coeffictent of a divacancy may probably be represented by $D_{VV} = 0.1 \exp(51,000/RT)\ cm^2\ sec^{-1}$. At dry tce temperatures, a vacancy accepts 1 electron and a divacancy, 4, while at room temperature these are 1 and 2, respectively. The second step of the an-nealing process involves the formation of clusters of 4, the acttvation energy of formation of which is 2.8 ev, a contribution of 2.2 ev from the acttvaiion energy for the diffusion of a dtvacancy and 0.6 ev from the lattice strain repulsion of 2 divacancies. Further annealtng takes place through the formation of clusters of higher order. The behavtor of the mathemattcal model is com-pared to experiments reported by others. The model is shown to account for the slow rate of annealing, as well as the lnittal increase in acceptor density often observed during annealing. (Contractor's absiract)

MELTING AND GROWTH PATTERNS APPEARING ON SINGLE CRYSTALS OF InSb, by M. F. Millea and C. T. Tomizuka. [Oct. 1955] 8p (AF 18(600)1310) Unclasstfted

Published in Jour. Appl. Phys., v. 27: 96-97, Jan. 1956.

It has been found that melting originates on a surface of InSb at discrete nucleation sites and proceeds from those in a definite pattern. The melting patterns are intersections of (111) planes with the surface of the specimen. Facets and striations occuring on the surface of single crystals pulled from the melt are characteristic of the growth process and not due to external influences. A surface of InSb which was the interface between the liquid and a growing crystal quickly removed from the melt was examined. In order to account for the observed structure, it was postulated that growth proceeds by a layer mechanism. The similarities between InSb, Ge, and Si crystals are discussed. (Contractor's abstract)

THE EFFECT OF DOPING ON THE SELF-DIFFUSION OF GERMANIUM (Abstract), by M. W. Valenta and C. Ramasatry. Feb. 1956, 1p. (Sponsored jotnily by Motorola, Inc. and Atr Force Office of Scientiftc Research under AF 18(600)1310) Unclassified

Presented at meeting of the Amer. Inst. of Metallurgical Engineers, New York, Feb. 1956.

If vacancies in germantum act as acceptors, ihe equilibrtum concentration ts expected to be higher tn the n-type than in p-type germanium. To delermine whether or not self-diffusion in germanium occurs by a vacancy mechanism, measurements were made in (1) As-doped, (2) intrinsic and (3) Ga-doped specimens in the temperature range of 750° to 900°C. Self-diffusion coefficients obtained for the intrtnsic specimens were in good agreement with earlier work, those for the As-doped (about 1×10^{19} atoms/cm^3) ranged from 1.1 to 2 times the corresponding ones for the intrtnsic samples, and those of the p-type (about 6×10^{19} atoms/cm^3) ranged from 0.5 to 0.25 times those of the intrinsic samples. The observed changes are in the direction predicted by the vacancy mechanism, although those tn the case of Ga-doping are not as large as expecled from the shifts in the Fermi level with doptng. The doped specimens were prepared by W. W. Tyler of the G. E. Research Laboratory. X-ray measurements made there tndicale only small changes tn the lattice parameter (about a 0.02% decrease) and in the same dtrection for both As- and Ga-doped germanium. The data indicate that self-diffusion probably takes place vta vacanctes. (Contractor's absiract)

COMPRESSIBLE TWO-DIMENSIONAL JET MIXING AT CONSTANT PRESSURE, by H. H. Korst, R. H. Page, and M. E. Childs. Apr. 22, 1954, 22p. incl. diagrs. (ME Technical note no. 392-1) ([AF]OSR-TN-54-82) (AF 18(600)392) AD 32990 Unclassified

This analysis of turbulent conslant-pressure mixing takes into consideration the effects of the initial boundary layer. Velocity profiles in the mixing region are represented tn a transformed plane by 1-parameter families of curves, wtth no specification for the mtxing mechanism beyond that of an exchange coefficient concept being made. The exchange coefficient is represented by the kernel function of an integral transform for the x coordinate of an tnirtnstc system of coordtnates. The intrtnsic system and the physical coordinate system are related by means of a momentum integral. Satisfactory correlation of theory and experimental low-speed data ts obtained with a simple form of kernel function. An asymptotic solution, corresponding to a fully developed velocity profile in the jet boundary, allows the calculation of the mechanical energy level along the separating streamline in the jet boundary without the use of empirical information. A THEORY FOR BASE PRESSURES IN TRANSONIC AND SUPERSONIC FLOW, by H. H. Korst, R. H. Page, and M. E. Childs. Mar. 1955, 73p. incl. diagrs. refs.

ILL. 15:003 - INN. 01:002

(ME Technical note no. 392-2) ([AF]OSR-TN-55-89) (AF 18(600)392) AD 61544 Unclassified

A theory for base pressures in transonic and supersonic flow is developed using a physical model composed of simplified flow components. The model is based on the concepts of interaction between dissipative flow regions with the adjacent freestream, and the conservation of mass in the dead-air region. While the pressures in the dissipative flow regions are impressed by the adjacent freestream, which is, e.g., subject to a Prandtl-Meyer expansion at the trailing edge and to recompression by the trailing shock, a unique and stable solution is determined by the formulation of an escape concept applied to a particular streamline in the jet-mixing component of the flow in order to satisfy the continuity equation. The theory, which employs the mixing mechanism described in University of Illinois Mechanical Engineering Dept. Technical Note 392-1, is capable of dealing with the effects of various established parameters of the base-pressure problem, e.g., Mach number, Reynolds number, and initial boundary-layer configuration, if certain empirical information on the jet-mixing component is available. For thin approaching boundary layers, the theory predicts, for any given Mach number and geometrical configuration, lowest base-pressure values, asymptotically reached as Reynolds number increases. These values, obtained without the use of empirical information, by what is termed the restricted theory, are in good agreement with experimental data. Applications of both the restricted and unrestricted theory to various base-pressure problems are included. (Contractor's abstract)

COMPRESSIBLE TWO-DIMENSIONAL JET MIXING AT CONSTANT PRESSURE. TABLES OF AUXILIARY FUNCTIONS FOR FULLY DEVELOPED MIXING PROFILES, by H. H. Korst, R. H. Page, and M. E. Childs. Apr. 1955, 69p. incl. diagrs. tables. (ME Technical note no. 392-3) ([AF]OSR-TN-55-99) (AF 18(600)392) AD 61678 Unclassified

A tabulation of auxiliary functions applicable to the 2-dimensional jet-mixing problem and to the mixing component of the base pressure model is presented in which numerical values of the integrals

$$I_1(C_{2_a};\eta) = \int_{\omega}^{\eta} \frac{\varphi}{1 - C_{2_a}^2 \varphi^2}\, d\eta$$

and

$$I_2(C_{2_a};\eta) = \int_{\omega}^{\eta} \frac{\varphi^2}{1 - C_{2_a}^2 \varphi^2}\, d\eta,$$

and the function $\omega(\eta) = \frac{1}{2}[1 + \operatorname{erf}\eta]$ are listed as functions of the variable η for 21 values of parameter, C_{2_a}. The value of the location, η_j, and the velocity ratio, φ_j, of the jet boundary streamline, j, and the coordinate shift (rotation), η_m, is also listed for each C_{2_a} value.

A NEW SPINOR THEORY OF ELEMENTARY PARTICLES, by F. Cap. [1954] [1]p. incl. refs. [AF 61(514)633-C] Unclassified

Published in Phys. Rev., v. 93: 907, Feb. 15. 1954.

Sufficient description of an elementary particle by only $2(2S + 1)$ spinor components is considered possible since measurements on such a particle distinguish $2(2S + 1)$ different states of a quantized spinor wave field of spin. Multiple application of formulas of the type

$$\partial_{\mu M \nu N + 1}\, a_{\nu 1 \ldots \nu N - 1 \nu N} = t\,\frac{mc}{\hbar}\, a_{\dot\mu 1 \ldots \dot\mu M - 1 \dot\mu M \nu 1 \ldots \nu N - 1 \nu N \nu N + 1} - \partial_{\dot\mu t \ldots \dot\mu M - 1 \dot\mu M}\, a_{\nu 1 \ldots \nu N - 1 \nu N}$$

yield spinors $a_{\dot\mu 1 \ldots \dot\mu 2s_{2s}}$ which contain only indices of one kind and exactly $2(2S + 1)$ components. These new spinors obey second-order differential equations: $(\Box - m^2c^2/\hbar^2)\, a_{\dot\mu 1 \ldots \dot\mu 2s} = 0$, $(\Box - m^2c^2/\hbar^2)\, a_{\nu 1 \ldots \nu 2s} = 0$, which describe the propagation of the unquantized spinor wave field. First-order differential equations, considered as unnecessary by Pauli are eliminated. A relativistically — and gauge — invariant theory can be built up which is also invariant against inversions $X_k \longrightarrow -X_k (k = 1, 2, 3)$, $X_4 \longrightarrow X_4$. After quantization the new theory reproduces the well-known results of the usual theory for the free particle in a generalized manner. Besides the possibility of giving other results for interacting particles, the new theory is a consistent general theory without superfluous components or accessory conditions, basic to a proposed unified nonlinear spinor theory of all elementary particles.

INVESTIGATION ON THE NONLINEAR PSEUDOSCALAR RELATIVISTICALLY INVARIANT MESON THEORY OF NUCLEAR FORCES, PART I, by F. Cap. Ftnal technical rept., vol. 1. Mar. 1-Dec. 31, 1954, 504p. (Rept. no. EOARDC-TR-1954) (AF 61(514)633-C) AD 69669 Unclassified

A detatled survey of the ltterature (2258 refs.) introduces an evaluation of the linear pseudoscalar meson theory. Known modtftcations of the usual theory are presented, and the static potential according to the 1_0 theory ts discussed. Reasons for the nonlinear meson theortes, justiftcation of a static semiphenomenological approximation, and behavtor of the potential for small dtstances are constdered. Also included are a short survey of Born's nonlinear electrodynamics, ε-formalism of nonlinear theories, Lagrangian formaltsm, nonunitary nonltnear theortes, relations between nonlinear and linear theories, effectlve source density for the 1_0 theory and nonlinear form, calculation of potentials from extended sources, classtcal approxtmation of nuclear forces, dtscussion of special Lagrangians, gage invariance, differential equations, nucleon interaction from unitary nonlinear theories, nucleon interaction from nonunitary nonlinear theories, integration of the nonhomogeneous D'Alemberitan, Lagrangian with complex A, electric charge, as well as the nucleon spin and partial differential equations.

INVESTIGATION ON THE NONLINEAR PSEUDOSCALAR RELATIVISTICALLY INVARIANT MESON THEORY OF NUCLEAR FORCES, PART II, by F. Cap. Ftnal technical repl., vol. 2. Mar. 1-Dec. 31, 195[illegible] [360]p. incl. diagrs. tables. (Rept. no. EOARDC-TR-1954) (AF 61(514)633-C) AD 69670 Unclassified

The equation of motion of the sources of the meson field is treated, as also are quantization of nonlinear theories, and numerical data. A consideration of the binding energy of the deuteron includes wrong formulas, analytical approximation for the interaction and Ritz's method; right formulas, analytical approximation of the interaction energy and Ritz's method; right formula, March's interaction and Ritz's method; right formulas numerically given interaction, and Ritz's method. Also treated are different trials of numerical integrations, Groebner's numerical integration with R(x), quadrupole and magnetic moment of the deuteron, and experimental scattering data. A consideration of neutron-proton scattering gives references on methods for cross-section computations, and includes treatment of interaction energies and their exchange character, results of the usual linear theory, experimental data, Born's approximation with tensor force, and calculation of phases. The text also covers proton-proton scattering, as well as velocity dependent terms and relativistic corrections.

An investigation was made of obstacle sense which ts the faculty of blind persons to orient themselves correctly with respect to near objects by the aid of sound. Obstacle sense was measured by making use of a standard obstacle (a round carboard disk with a diameter of 50 cm) which could be quickly and noiselessly brought within range of the test person at any desired distance. The greatest distance from which it was still possible to detect this obstacle with exactitude was used as a measure for the obstacle-sense performance of the respective person. A sonic guidance device to be carried on the person was also developed which consisted of a microphone, an amplifier connected to the latter,

IAS. 01:001 - IAS. 03:001

and measurtng devtces. Measurements were carrted out on 267 persons between the ages of 4 and 85 yr who were blind or normal but blindfold. Results tndtcated that everyone appeared to possess the faculty of blind ortentation tmmedtately wtth the atd of sonic devices when approaching obstacles. Optimum results were obtained tf short tmpulses wtth a broad frequency band are used which are radtated at an angle of the greatest posstble wtdth by a sonic device attached to the person. By tratning, obstacle sense performance ts further tmproved. The tlmtts of efftctency dtffered constderably tn each tndtvtdual case and appeared connected wtth the ftneness of the dtscrtminatory limtts for the modiftcations of sound tntenstties. The quaitty of a person's absolute heartng capactty ts of mtnor tmportance. Expertments showed that skin sensations accompanytng the detection of near obstactes are cortical projections. The sensations are descrtbed as factal vtston. (ASTIA abstract)

[ARITHMETIC REPRESENTATIONS IN FINITE FIELDS AND POLYNOMIAL DOMAINS] by E. Cohen. [Ftnal rept.] [Nov. t952] 1p. [AF t8(600)134] Unclasstfted

The following problem ts constdered: Let r be an arbtrary odd number > 1, and let $a_1, \ldots, a_s$ be tntegers prtme to r. Then we destre the number of solutions $N = N_s(n, r)$ of

$$n \equiv a_1x_1^2 + \ldots + a_sx_s^2 \pmod r.$$

Thts problem ts deftned as a ftnite "stngular sertes" $S = S_s(n, r)$, analogous to the Hardy-Ramanujan sertes tn the non-modular case. The function S ts a dtvtsor sum tnvolvtng the Ramanujan sum tn case s ts even and a Gauss character sum tn case s ts odd. Ustng orthogonallty properties of these stmple exponenttal sums, tt ts shown on the basis of tnductton, that $N = S$. A dtrect proof of this fact ts also gtven. The functton S ts evaluated completely to gtve the followtng result for $s = 2m$,

$$N_{2m}(n, r) = r^{2m-1} \sum_{d/r} \sum_{\substack{d'(n,d) \\ d'e=d}} \left(\frac{a}{d}\right) \frac{d'p(e)}{d^m}$$

$$(a = (-1)^m a_1 \ldots a_{2m})$$

where $(\frac{a}{d})$ ts the Jacobi symbol and μ ts the Möbius functton. The case $s = 2m + 1$ ts more complicated; stmplifications artse under the hypothests that n has no square factor > 1 tn common wtth r. In this case, tt ts shown that

$$N_{2m+1}(n, r) = r^{2m} \sum_{\substack{D^2/r \\ D/n}} \frac{\mu(d)}{D^{2m}} \sum_{\substack{e/r \\ (e,D)=1}}$$

$$(-\frac{an}{e}) \frac{\mu^*(e)}{e^m}, \quad (a = (-1)^{m+1} a_1 \cdots a_{2m+1})$$

where $\mu^*(e) = 1$ or 0 according as e ts or ts not square-free. Correspondtng results for $GF[p^n, x]$, p odd, are also obtained. (Contractor's abstract)

ON THE DERIVATION ALGEBRA AND THE HOLOMORPH OF A NILPOTENT LIE ALGEBRA, by E. Schenkman. July 1954, 11p. (In cooperation with Louisiana State U., Baton Rouge) ([AF]OSR-TN-54-236) (AF 18(600)790) AD 47332 Unclassified

Also published in Mem. Amer. Math. Soc., No. 14: 15-22, 1955.

Derivations of nilpotent Lie algebras are studied in an attempt to determine whether the holomorph of a Lie algebra determines the algebra up to an isomorphism. Proofs are presented of the following theorems: (1) if L is a finite Abelian Lie algebra with holomorph H, then H is the holomorph of no other Lie algebra; (2) if K is an arbitrary Lie algebra and if L is the free Lie algebra with the smallest possible number of generators such that K = L/M (where M is the characteristic ideal of L), then the algebra of derivations of K is isomorphic to $\hat{D}_M/\hat{D}_{LM}$, where $\hat{D}_M$ and $\hat{D}_{LM}$ are maps which send M and L into M, respectively; (3) if L is a free nilpotent Lie algebra of class n generated by q elements, then D_1, a nilpotent ideal of the derivation algebra $\hat{D}$, is the nil radical of D; $L + D_1$ is the nil radical of H, the holomorph of L; and the center of L is the center of $L + D_1$; and (4) if H is the holomorph of L, a free nilpotent Lie algebra of class n generated by $q \geq 2$ elements, the H cannot also be the holomorph of another Lie algebra K, unless K is isomorphic to L.

ON THE STRUCTURE OF THE AUTOMORPHISM GROUP OF A NILPOTENT GROUP, by E. Schenkman. Nov. 1954, 9p. ([AF]OSR-TN-54-311) (AF 18(600)-790) AD 47335 Unclassified

Also published in Portugal. Math., v. 13: 129-135, 1954.

The terminology is as follows: G is a nilpotent group so that $G^* = E$, the identity, where $G^* = \bigcap_{k=1} G^k$, $G^k = [G^{k-1}, G]$ and $G^1 = G$. A is the group of automorphisms of G, and A_k is the subgroup of automorphisms of A which induce the identity transformation in G/G^k. Proofs are presented for the following theorems: (1) A_2 is a normal nilpotent subgroup of A of class at most one less than that of G. (2) If H is the holomorph of the nilpotent group G, then the subgroup of H generated by G and A_2 is normal in H and nilpotent of the same class as G. (3) If G is a nilpotent group, then the elements of finite order generate a characteristic subgroup which is the direct product of (p,∞) groups, where (p,∞) groups are those generated by elements whose orders are powers of the same prime p and which contain no elements of finite order other than those of that prime power. (4) If a $(p-\infty)$ Sylow subgroup P of a group G is normal in G, then P contains all the elements of G whose orders are powers of the given prime p, and so is the only $(p-\infty)$ Sylow subgroup of G. (4) Let G be a nilpotent group of class n generated by elements whose orders divide a certain prime power p^k. If A is the complete group of automorphisms

IAS. 04:001 - IAS. 05:004

of G and if B_1 is the subgroup of A such that the elements of B_1 leave G/G(p) fixed, then B_1 is a normal subgroup of A which is nilpotent of class at most kn. If H is the holomorph of G, then GB_1 is a normal subgroup of H which is nilpotent of class at most kn. (ASTIA abstract)

A GENERALIZED FUNCTION-THEORY AND THE RELATED DIRICHLET PROBLEM. PART 1, by J. Sanders. [1956] [21]p. (AF 18(600)791) Unclassified

Published in Ann. Math., v. 64: 523-543, Nov. 1956.

This paper is concerned with the partial differential equation $N(N(u)) = 0$, where $N(u) \equiv (\sigma(x))^{-1}(\sigma(x)u_x)_x + (\tau(y)((\tau(y))^{-1}u_y)_y$, which includes the biharmonic partial differential equation $\Delta\Delta u = 0$ as the special case $\sigma = \tau \equiv 1$. A function theory, bearing roughly the same relation to the equation $N(u) = 0$ as the classical theory of analytic functions of one complex variable bears to Laplace's equation $\Delta u = 0$, was constructed by L. Bers and A. Gelbart (Trans. Amer. Math. Soc., v. 56: 67-93, 1944). A method for attaching a function theory to the biharmonic equation was given by L. Sobrero [Theorie der ebenen Elastizität ..., Teubner, Leipzig-Berlin, 1934], using hypercomplex numbers. This last approach, together with the procedure of Bers and Gelbart, was used by J. B. Diaz (Amer. Jour. Math., v. 68:611-6[illegible] 1946) to obtain a function theory associated with the n times iterated equation $N^n(u) = 0$. The author proceeds directly to the construction of a function theory for the equation $N^2(u) = 0$, as follows. A function $u(x, y) - iv(x, y)$ is said to be Δ_2-monogenic in a domain D of the $z = x + iy$ plane provided that u and v are four times continuously differentiable in D (i.e., $u, v \in C^4$) and satisfy the system of equations $\sigma(x)u_y - \tau(y)v_x = 0$, $\sigma(x)u_x + \tau(y)v_y = 0$, $N'(w) = 0$, where $\sigma, \tau \in C^3$, $\sigma > 0$, $\tau > 0$, $w \in C^2$, and the operator N' is given by $N'(w) \equiv (\sigma^{-1}w_x)_x + (\tau^{-1}w_y)_y$ for any function w. For such functions, differentiation and integration processes are defined and are shown to be inverses of each other. By repeated integration of some simple functions, a series of functions are defined which are generalizations of the usual powers $a(z - z_0)^n$, and a generalization of Taylor's theorem is proved. Next, a fundamental solution $\Phi(x, y; \xi, \eta)$ of $N^2(u) = 0$ is obtained, and an analogue of Cauchy's integral formula $f(t) = (2\pi i)^{-1}\int_C f(z)(z - t)^{-1}dz$ is derived. The paper concludes with indications as to how the theory can be extended to $N^n(u) = 0$ and to certain non-iterated equations. (Math. Rev. abstract)

ON A GAME WITHOUT A VALUE, by M. Sion and P. Wolfe. [1952] 8 p. incl. diagrs. (AF 18(600)1109) Unclassified

Published in Ann. Math. Studies, "Contribution to the Theory of Games", Rand Corp., Santa Monica, v. 3: 299-396, 1951-1952.

The object of this paper is to show that one of the main results in the theory of infinite games, the theorem of Glicksberg on semi-continuous payoffs, cannot be extended in certain directions. A game is presented on the square (a form of continuous Blotto) which does not have a value, but whose payoff function is topologically even simpler than that of the classical example due to J. Ville. Scarf and Shapley have applied Glicksberg's theorem to a number of infinite games in extensive form. The question of whether the condition of semi-continuity of the payoff is equally important for the determinacy of such games is shown by the fact that any game on the square may be transcribed into a game in extensive form with its value, or lack of value, preserved. It is found that the transcription of the example of the game on the square to extensive form yields a type of "game of pursuit" without a value.

A SINGULAR FUNCTIONAL, by A. D. Martin. May 1955, 15p. ([AF]OSR-TN-55-239[A].) (In cooperation with Washington U., St. Louis, Mo.) (AF 18(600)1109) AD 74651 Unclassified

Also published in Proc. Amer. Math. Soc., v. 7: 1031-1035, Dec. 1956.

A functional J of the type

$J(y) \Big|_x^b = \int_x^b [\, ry'^2 + 2qyy' + py^2]\, dx$ $(0 < x < b)$, is considered in which the functions r, p, and q are continuous on $(0, \infty)$ while r is positive. The point x = 0 is singular for the functional in the sense that the conditions on r, p, and q may not hold for an interval of the form [0, b]. All of the integrals which appear are Lebesgue integrals. The functional J has an X-minimum limit on [0, b] when the lim inf $J(y) \Big|_x^b \geq 0$ for all functions of y in a subclass X[0, b] of F[0, b]. The class F[0, b] consists of all functions y which are absolutely continuous with $y' \in L_2$ on every closed subinterval of (0, b]. The subclasses are: F'[0, b], the set of all $y \in F[0, b]$ for which y is bounded on [0, b]; $F_0[0, b]$, the set of all $y \in F[0, b]$ such that $x \subset 0$ is a limit point of zeros of y; A[0, b], the set of all $y \in F[0, b]$ which are continuous on [0, b] and for which y(0) = 0; and $A_0[0, b]$, the set of all $y \in A[0, b]$ for which x = 0 is a limit point of zeros of y. Necessary and sufficient conditions are given for the existence of F-, F_0-, and A_0-minimum limits. Some sufficient conditions for the A-minimum limit are given for the case q = 0. The results supplement those in which a quadratic functional with a singular endpoint was studied by Leighton and Martin (Trans. Amer. Math. Soc., v. 78: 98-128, 1955). AN APPLICATION OF THE MORSE THEORY TO THE TOPOLOGY OF LIE-GROUPS, by R. Bott. Dec. 1955, 36p. refs. ([AF]OSR-TN-55-464) (AF 18(600)1109) AD 81507 Unclassified

Also published in Bull. Soc. Math. France, v. 84: 251-218, 1956.

A compact group G, acts on itself by inner automorphisms. This action decomposes G into orbits. In this study the space of paths, Ω, on G, which start at a fixed point and end on a fixed orbit, is investigated. By applying the Morse theory, it is shown that: (a) Ω is always free of torsion; (b) Ω has vanishing Betti numbers in odd dimensions; and (c) the Poincaré series of Ω is determined by the infinitesimal structure of G. A similar result concerning the orbits of the adjoint representation of G on its Lie-algebra leads to formulas for the Betti numbers of certain homogeneous spaces. (Contractor's abstract)

HOLOMORPHIC FUNCTIONALS AND COMPLEX CONVEXITY IN BANACH SPACES, by H. J. Bremermann. Feb. 1956, 32p. refs. (AFOSR-TN-56-42) (AF 18(600)1109) AD 80554 Unclassified

Also published in Pacific Jour. Math., v. 7: 811-831, 1957.

A complex valued function f(z) is "Gaieaux holomorphic" in a domain D of a complex Banach space B_c if it is single-valued and if $f(z_0 + \lambda a)$ is a holomorphic function of the complex parameter λ at $\lambda = 0$ for every $z_0 \in D$ and $a \in B_c$. It is shown that in general, as in the case of finitely many variables, all functions that are holomorphic in a domain D can be continued into a larger domain. If this is not the case D is a domain of holomorphy. The domains of holomorphy have the property to be pseudo-convex. This notion is defined by requiring $-\log d_D^{(N)}(z)$, where $d_D^{(N)}(z)$ is the distance of the point z from the boundary of D measured in the norm N, to be plurisubharmonic. It is shown that this property is independent of the norm N. The relationship of the pseudo-convexity to the ordinary convexity is studied and an application to tube domains is made. A METHOD OF PARAMETRIX IN THE THEORY OF HARMONIC FORMS IN A COMPLEX LINE BUNDLE, by S. Nakano. Jan. 1956, 12p. refs. (AFOSR-TN-56-52) (AF 18(600)1109) AD 81044 Unclassified

The theory of harmonic forms in a complex line bundle or in a complex vector bundle is reduced to the usual theory. Vectorial forms on the base space are transformed into usual differential forms on the bundle space, and a spectal metric is introduced into the latter space; thus the method of parametrix can be applied to prove the decomposition theorem $\phi = H\phi + \Box G\phi$. COMPLEX VECTOR BUNDLES OVER AN ALGEBRAIC CURVE, by S. Nakano. July 1956, 40p. refs. (AFOSR-TN-56-432) (AF 18(600)1109) AD 96515 Unclasstfted

In this mathemattcal study, given a nonstngular algebratc curve V, the set $\mathfrak{F}_r$ of vector bundles over V which come from representations of the fundamental group of V into GL(r, C) is constdered. One of the results asserts that if D ts a sufftctently ample ltne bundle over V, then for every $F \in \mathfrak{F}_r$ $D \otimes F$ ts the inverse image of the dual universal bundle over one and the same Grassmannian vartety H, by a regular mapping ϕ_F: $V \longrightarrow H$. Making use of Chow coordinates of the

graphs of Φ_F's, it is shown that $\mathcal{J}_r$ is represented by the set of points of a (possibly reducible and incomplete) algebraic variety w. Uniqueness of w in the sense of birational equivalence is shown and some properties of w are given. (Contractor's abstract)

PERTURBATION THEORY OF PERIODIC SURFACES, by S. P. Diliberto. Oct. 1956, 1v. refs. (AFOSR-TN-56-474) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1109 and Office of Naval Research) AD 97358 Unclassified

Perturbation theory of periodic solutions of ordinary differential equations is equipped with a primary existence theorem. For the perturbation theory for periodic k-surfaces another primary existence theorem is postulated. Situations of interest are the results of geodesics on an ellipsoid. The study of the periodic surfaces is studied in three areas of interest in ordinary differential equations. First, linear differential equations with a. p. coefficients are studied with the analysis of the operator W giving a partial generalization of Floquet's theorem concerning linear differential equations with periodic coefficients. Second, problems where periodic surfaces are used in describing both qualitatively and quantitatively certain physical phenomena concerning motions of a simple oscillatory type as encountered in resonance and entrainment of frequency. Lastly, small divisor problems are considered which are characteristic of the fact that a differential equation possesses periodic k-surfaces and not periodic k-minus-one surfaces.

A VARIATIONAL METHOD fN THE THEORY OF HARMONIC fNTEGRALS, f, by C. B. Morrey, Jr. and J. Eells, Jr. Apr. 1955, 65p. refs. ([AF]OSR-TN-55-87) (AF 18(600)1114) AD 62158 Unclassified

Summary published in Proc. Nat'l. Acad. Sciences, v. 41: 391-396, July 15, 1955.

Also published in Ann. Math., v. 63: 91-128, Jan. 1956.

In this study, a variational method is carried through to prove the following orthogonal decomposition theorem: Any r-form ω in L_2 on a compact orientable smooth manifold can be uniquely expressed in the form $\omega = H + \alpha + d\beta$, where H is a harmonic form and α and β are forms in $\mathcal{D}_2$, with $d\alpha = \delta\beta = 0$; if $\omega \in \mathcal{D}_2$, then α and $d\beta$ are also $\mathcal{D}_2$. The methods and results are extended to orientable manifolds of class C_1^1 (g_{11} Lipschitzian). Harmonic forms are found to be Holder-continuous throughout. Further differentiability properties of H, α, and β are proved which depend on the further differentiability properties of ω and the manifold. (Contractor's abstract)

A VARIATIONAL METHOD fN THE THEORY OF HARMONIC INTEGRALS, II, by C. B. Morrey, Jr. Apr. 1955, 47p. refs. ([AF]OSR-TN-55-108) (AF 18(600)-1114) AD 71319 Unclassified

Also published in Amer. Jour. Math., v. 78: 137-170, Jan. 1956.

The variational method introduced in Part I, is applied to the study of differential forms and boundary value problems on a compact Riemannian manifold with boundary B. The manifold is not assumed to be orientable, and parallel theories are developed for even and odd forms. Complete results, analogous to those for a compact manifold are first obtained for the sub-spaces $\mathcal{L}_2^+$ of $\mathcal{L}_2$, where the normal part $n\omega = 0$ on B, and $\mathcal{L}_2^-$, where the tangential part $t\omega = 0$ on B. By using the results about special potentials in these spaces, an orthogonal decomposition theorem $\mathcal{L}_2 = \mathcal{H} \oplus \mathcal{E} + \mathcal{D}$ is proved; $\mathcal{H}$ consists of all harmonic fields; $\mathcal{E}$ consists of all elements $\delta\alpha$ for $\alpha \in \mathcal{L}_2^+$, and $\mathcal{D}$ consists of all elements $d\beta$, where $\beta \in \mathcal{L}_2^-$. We may take $\omega = d\Omega$, $\beta = \delta\Omega$, where Ω is a "free" potential of $\omega - H$ (ω = given form) in which $n d\Omega = t\delta\Omega = 0$. Using this decomposition, the boundary value results for harmonic fields and forms recently obtained by Duff and Spencer (Annals, 1952) and Conner (Proc. Nat'l. Acad. Sciences, 1954, 1154-1155) are obtained immediately. Complete differentiability results are obtained on manifolds of class $C_j^k \geq C_1^1$. (Contractor's abstract)

ON RIEMANN'S FUNCTIONAL EQUATION, by S. Bochner and K. Chandrasekharan. Sept. 1955, 37p. incl. refs. (Rept. no. 1) ([AF]OSR-TN-55-291) (In cooperation with Princeton U., N. J. under AF 18-(600)1137) (AF 18(600)1189) AD 72175 Unclassified

Also published in Ann. Math., v. 63: 333-360, Mar. 1956.

An examination is made of the number of possible solutions of the functional equation:

$$\pi^{-s/2}\Gamma(s/2)\varphi(s) = \pi^{-(k-s)/2}\Gamma\left(\frac{k-s}{2}\right)\psi(k-s),$$

where s is complex, $k > 0$, and $\varphi(s)$, $\psi(s)$ are represented by the Dirichlet series

$$\varphi(s) = \sum_{1}^{\infty} \frac{a_n}{\lambda_n^s}, \qquad \psi(s) = \sum_{1}^{\infty} \frac{b_n}{\mu_n^s},$$

with suitable domains of absolute convergence. Here $\{\lambda_n\}$, $\{\mu_n\}$ are increasing sequences of positive numbers diverging to ∞, given in advance. The number of linearly independent solutions of the equation depends on what we call the modular density of the sequences $\{\lambda_n\}$, $\{\mu_n\}$. We shall show that, in general if $\{\mu_n\}$ is of finite modular density, then the number of linearly independent solutions of the functional equation is at most equal to the minimum number of λ_n's that lie in any interval of length greater than $d\mu$. The functional equation implies the inequality $d_\lambda \cdot d_\mu \geq 1$, and if there exists an integer k such that $d_\lambda \cdot d_\mu < k + 1$, then the equation has at most k linearly independent solutions. Furthermore, if $d_\mu = d_\lambda = 1$, and the coefficients $\{b_n\}$ are suitably limited in magnitude, the functional equation implies that $\lambda_{n+1} - \lambda_n = 1$, for every n, so that there can be at most 1 solution. On the other hand, if $d_\mu = d_\lambda = 1$, and $\mu_{n+1} - \mu_n = 1$ for $n \geq n_0$, then, of necessity, we have $\lambda_n = n$, or $n - 1/2$, $\mu_n = n$, or $n - 1/2$; and $\delta = 1$, or 3; and the only solutions that can occur are those known. RESEARCH ON APPLICATIONS IN FOURIER ANALYSIS, by K. Chandrasekharan. Final rept. May 1, 1955-Sept. 30, 1955, 3p. ([AF]OSR-TN-55-344) (AF 18-(600)1189) AD 74590 Unclassified

A brief summary is presented of the mathematical research conducted under this scientific task (project no. R-354-10-70). (I). The study of Hecke's theory of modular functions and Dirichlet series led to an examination of the functional equation of the Riemann zeta-function from the standpoint of the uniqueness of its solutions. (II). Some preliminary results on the behavior of differentiated multiple Fourier series were obtained. (III). A tract was prepared on Hecke's theory of modular functions and Dirichlet series. Part I contains preliminary results on the gamma function, which are then utilized in developing the theory of the Riemann zeta function, beginning from general Dirichlet series and progressing to Hardy's theorem, Riemann-Mangoldt formula, prime number theorem, and Hamburger's theorem. Part II is devoted to conformal mapping, leading to the introduction of modular functions by their mapping properties.

AUTOMATIC NETWORK ANALYSIS WITH A DIGITAL COMPUTATIONAL SYSTEM, by M. Kochen and S. Y. Wong. Aug. 1955, 20p. incl. diagr. tables. (Technical rept. no. 55-02) (Sponsored jointly by [Office of Ordnance Research, Office of Naval Research, Air Force Office of Scientific Research] and Atomic Energy Commission under DA 36-034-ord-1646) AD 74872 Unclassified

The use of digital computers, when developed into a system, is a practical way of solving complex network problems. It is demonstrated by the procedure used that high speed digital computers can be programmed such that the problem originator needs little or no information about the computing methods employed. Changes in a circuit which have previously been analyzed are readily effected with very little set-up time. With the increasing adoption of large computers for accounting purposes, the addition of network computation system involves only the creation of a group of program designers skilled in network problems. An operator accustomed to analyzer methods need expertence no loss in convenience when using digital methods instead. It is suggested that a floating point computing machine with a larger internal memory be used because with a fixed point machine, scaling difficulties seriously limit the accuracy. A METHOD FOR FINDING THE GENERAL SOLUTION TO AND ARBITRARY NON-SINGULAR SYSTEM OF LINEAR EQUATIONS INVOLVING n3/2 MULTIPLICATIONS, by J. P. Roth. Jan. 1956, 3p. (Technical rept. no. 56-01) (Sponsored jointly by Office of Ordnance Research, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-034-ord-1646 and Nonr-I35803) AD 88534 Unclassified

A method is presented for obtaining the general solution to a nonsingular system of equations, distinct from the usual representation of the solution in the form of a matrix inverse. It is argued that this method requires significantly less arithmetic operations than the matrix-inverse approach. Certain matrices must be inverted by the scheme presented and it is assumed for purposes of counting operations that it takes k^3 multiplications to invert a matrix of order k The method outlined here makes no special assumptions concerning the character of the system of equations other than those customarily made for partitioning, namely that a principal submatrix and a product of certain other submatrices be nonsingular. ALGEBRAIC TOPOLOGICAL METHODS FOR THE SYNTHESIS OF SWITCHING CIRCUITS IN n VARIABLES, by J. P. Roth. Apr. 1956, 45p. incl. illus. refs. (Technical rept. no. 56-02) (Sponsored jointly by Office of Ordnance Research, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-034-ord-1646) AD 98007 Unclassified

The logical formulation of the synthesis of switching systems is reviewed, and reference is made to the logical problem of determining a normal formula which is a disjunction of conjunctions and in which no letter can occur twice in a clause. The basic structure upon which the whole development depends, after the problem is reformulated in combinatorial topological terms, is that of a cubical complex K(f). A mapping f of the n^{th} Cartesian product Z_2^n of the space Z_2 of integers modulo 2 into Z_2 is defined. Z_2^n is treated as a n-cube, and an inductive definition is given of the cubical complex K derived from the set $f^{-1}(1)$ of elements mapped into 1. The space of 0-cubes is the discrete set $f^{-1}(1)$. Two 0-cubes are said to be faces of a 1-cube if it is possible to transform from one to the other by the change of a single coordinate. The cubical complex K(f) is defined as the collection of cubes K^0, K^1, ..., K^n, ... plus face and coface operators. Mappings $K^r \rightarrow K^{r+1}$ are called coface operators, and mappings $K^r \rightarrow K^{r-1}$ are called face operators. A subcomplex L is called a cover of K if it contains all the vertices of K. If q_k is the number of maximal k-cubes of L, the problem is to find a cover L such that the form

$$\sum_{k=0}^{n} q_k(n-k)$$ is minimized. No scheme is provided

for always obtaining the minimum. The problem of finding the precise relationship between the minimization of Boolean functions and the minimization of the switching circuit problem is discussed.

AN ALGEBRAIC TOPOLOGICAL APPROACH TO KRON'S METHOD 1, by J. P. Roth. June 1956, 35p. incl. illus. refs. (Technical rept. no. 56-03) (Sponsored jointly by Office of Ordnance Research, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-034-ord-1646 and Nonr-135803) AD 118604 Unclassified

The problem is formulated as follows: Given the arbitrary elements 1' of $P^0(K)$ and e' of $H_1(K)$, find elements J of $C^1(K)$ and V of $C_1(K)$ such that $\partial J = 1'$, $C_1V = e'$, and $V = LJ$. The network K is defined as a one-dimensional regular complex, L is a transformation of its group $C^1(K)$ of 1-chains into $C_1(K)$, its group of 1-cochains; $P^0(K)$ is the group of 0-boundaries, and $H_1(K)$ is the first cohomology group. Kron considered the set of all possible networks into which a given network could be transformed through the group of tearing and interconnecting transformations. His method of tearing consists in deducing from the equations of state, or the equations of solution for one element of the set, the equations of state or of solution for any other element in the set by a routine procedure governed by the induced transformations. A condition on L is obtained such that a solution exists for all networks K compatible with L. Tearing is explained, and the invariance of the power under tearing and interconnection is discussed. The construction of a solution by means of tearing is described. A comparison of some methods for solving network problems is made by an example. Solutions are obtained by standard methods, standard partitioning, an algebraic form of solving equations suggested by tearing, and tearing.

AERONAUTICAL ENGINEERING REVIEWS, by S. P. Johnston, W. A. Shrader and others. Jan.-Dec. 1956. (AF 18(600)1504) Unclassified

This work collects, reproduces, and distributes indicative abstracts from current important unclassified technical aeronautical literature, including AFOSR reports of worldwide scientific and technical literature. Approximately 100 abstracts are published monthly in these Reviews (1958 name changed to Aero/Space Engineering) which has a special insert section printed on yellow paper International Aeronautical Abstracts and has appeared regularly since Jan. 1956. The abstracts cover the following scientific fields: acoustics; aerodynamics and fluid mechanics;aeroelasticity; electronics; fuels and lubricants; instruments; missiles and rockets; nuclear energy; power plants; propellers; research and research facilities; rotating wing aircraft; space travel, structures; and thermodynamics.

SOME FUNDAMENTAL PROBLEMS OF COMBUSTION, by G. Millan. [1956] [23]p. incl. diagrs. refs. (AFOSR-TN-56-449) (AF 61(514)734-C) AD 96794 Unclassified

The research program is described of the Instituto Nacional de Tecnica Aeronautica Esteban Terradas (Spain). The program includes the study of problems dealing with premixed laminar flames, diffusion laminar flames and the combustion of droplets. Premixed laminar flames are discussed broadly, including equations of the combustion wave and the difficulties encountered when making specific studies. Published experimental data on the hydrazine decomposition flame are compared

wtth theoretical values computed by 2 different procedures. Diffuston flames and the combustion of isolated droplets are constdered brtefty and tllustrated schemattcally. Laboratory data are furnished for the ttme vartation of the square of the radtus tn tsolated droplet combustion of benzene. Expertmental results are given for benzene and ethyl alcchol, of a study of the effect of interactton and forced convection on droplets as prelimtnary to tnvestigation of the combustion of sprays.

HYDRAZINE DECOMPOSITION FLAME, by G. Mtllan and S. Sanz. June t956, tv. incl. diagrs. tables. (AFOSR-TN-56-466) (AF 61(514)734-C) AD 97084 Unclassified

The propagation vetoctty ts computed for the laminar decomposttion flame of a gas corresponding to a kinetic schema of chain reaction proposed by Adams and Stocks (Fourth Sympostum on Combustion, Cambrtdge, Mass., t952: 239-248, pub. 1953) as a stmplifitcation of the kinetic schema of the decomposttion of N_2H_4 vapors. Computatton is performed by first assumtng that the steady state assumption is sattsfted for the concentration of radtcals. Subsequently a method ts developed for the computation of the vetoctty of the flame not tncluding this assumption. Results are compared and it is verifted that the steady state assumptton is justified, when computing flame velocity. Ftnally, results are discussed and compared to the experimental results for the decomposition flame of N_2H_4. Agreement is found to be satisfactory. (ASTIA abstract)

AN EXPERIMENTAL INVESTIGATION ON THE tNTERACTtON EFFECTS IN THE COMBUSTION OF DtOPLETS, by G. Mtllan and C. S. Tarifa. May 1956, 44p. incl. illus. diagrs. tables, refs. (AFOSR-TR-56-38) (AF 61(5t4)734-C) AD 95208 Unclassified

Research was concerned with the interaction effects in the combustion of benzene drops tn an oxidtzing atmosphere. Three series of experiments were conducted: (1) combustion of two drops side by stde; (2) combustion of a drop withtn the wake of another; and (3) the evaporation of a drop withtn a diffuston flame which is formed on the free surface of a fuel. The drops were suspended from a quartz filament, and time variations of the mean diameter of the drops were measured photographically. The drops were ignited by either a battery and coil or a match. Results tndicated that interaction effects in the combustion of two drops are not important. In the case of two side-by-side drops, the maximum decrease which was observed of the evaporation constant tn compartson with the case of an tsolated drop was of the order of 15%; values of the order of 25% were reached tn some tsotated cases of combustion wtthin the wake of another drop. Ttme variations of the square of the radtus held tn interaction cases, at least wtth the same order of approximation as that for isolated drops. Interaction effects always decreased the evaporation constants. In the case of two stde-by-stde drops (of about the same stze) interaction effects are practically nonexistent when the dtstance between centers is of the order of twice the mean dtameter; thts dtstances tncreases up to four times targer in the case of two drops, one wtthin the wake of the other. Interaction phenomena should produce a decrease of the temperature on the flame front, stnce 0 concentratton ts lower; on the other hand, the heat which is transmitted to the drop should tncrease since there are other heat sources alten to its own flame front. (ASTIA ababstract)

DEFLECTIONS OF A SIMPLE-SUPPORTED L-SHAPED PLATE UNDER A UNIFORM NORMAL LOAD, by D. L. Holland H. J. Weiss. Sept. t954, 18p. incl. diagrs. tables. (Technical note no. 1) ([AF]OSR-TN-54-240) (AF t8(600)574) AD 47339 Unclassifted

The deflections of an L-shaped plate under a uniform normal load are obtained by solving the corresponding problem for two rectangular plates which form the L-shaped plate. Soluttons for the two separate rectangles are taken in the form of Fourier series with unknown coefficients. Applying the appropriate boundary conditions and matching the soluttons along the line which

IOW. 01:002 - IST. 01:002

separates the original plate into two rectangles leads to a set of relations for the coefficients which are solved numerically. The deflections of the L-shaped plate at various points of interest are given. (Contractor's abstract)

DEFLECTIONS OF RECTILINEAR PLATES UNDER UNIFORM NORMAL LOADS, by R. J. Oedy and H. J. Weiss. Technical rept. Sept. 1955 [56]p. incl. diagrs. tables. ([AF]OSR-TN-55-317) (AF 18(600)574)
AD 75415 Unclassified

The deflections of rectilinear plates under uniform normal loads are obtained by subdividing the plates into rectangular pieces, and solving the plate equation with appropriate boundary conditions for each rectangle separately. Solutions are then matched for continuity along the subdivision lines. This method results in a set of infinite linear equations for eight parameters which are the coefficients in a Fourier series expansion for the deflections. These parameters may be obtained by a numerical solution of the set of infinite equations, and thus the deflections may be obtained approximately. Numerical results, for various dimensional ratios, are given for an L-shaped plate and a U (channel)-shaped plate, both completely simply-supported. Analytical results, with no numerical solution, are given for T-shaped and I-shaped plates, both simply-supported, and for an L-shaped plate, clamped on one edge, and on two edges, the other edges being simply-supported. THE SOLUTIONS BY DUAL INTEGRAL EQUATIONS OF AN AXIALLY-SYMMETRIC MIXED BOUNDARY VALUE PROBLEMS, by H. J. Weiss. Sept. 1955, 29p. incl. diagrs. (AFOSR-TN-55-331) (AF 18(600)574)
AD 75216 Unclassified

The linearized characteristics method is applied to determine the non-conical supersonic flow near the nose of a body revolution at zero angle of attack with non-detached shock. In particular a relation between the body and the shock curvatures in meridian planes is developed. After the detailed presentation of the method, its limits of applicability are discussed. As an example the method is applied to the flow about the nose of the RM-10 at a Mach number of 3.18.

SOUND DISPERSION IN HALO-METHANE MIXTURES, by R. C. Amme and S. Legvold. Jan. 1956 [20]p. incl. diagrs. tables. (Rept. no. 319AH) (AFOSR-TN-56-8) (AF 18(600)1496) AD 80541 Unclassified

Also published in Jour. Chem. Phys., v. 26: 514-517, Mar. 1957.

Results of studies of the dispersion of ultrasound in mixtures of $CHClF_2$ and CF_4 and of $CHCl_2F$ and $CClF_3$ at various concentrations are presented. In none of the eight mixtures studied is there evidence of multiple dispersion, each mixture exhibiting a single relaxation time which falls between those of the pure constituents. A simple method of averaging the various quantities entering into the prediction of collision lifetimes in the pure constituents is presented which yields lifetimes for the mixtures nearly matching those found by experiment. [INFLUENCE OF A RETINAL ILLUMINATION GRADIENT AND ITS VARIATIONS ON THE SUBJECTIVE SENSATION OF BRIGHTNESS] L'influenza del gradienti di illuminamento reticini e delle loro variazioni sulla sensazione soggettiva di brillanza, by A. Fiorentini. [1954] [7]p. incl. illus. diagrs. (AF 61-(514)634-C) Unclassified

Presented at the Conference on Problems in Contemporary Optics, Florence (Italy), Sept. 10-15, 1954.

Published in Atti Della Fondazione G. Ronchi, v. 10: 54-60, Jan.-Feb. 1955.

The visual effect which is apparent when a uniform field is viewed through a hole placed close to the eye is visible also when the subject looks at the shadow of an object illuminated by an extended source; a bright line is seen close to the boundary between the illuminated field and the penumbra. It has been demonstrated that this effect is due only to the eye and it has been referred to the phenomenon discovered by Mach and studied by a number of researchers. This effect is due to a rapid change of the illumination gradient on the retina. Two experiments have been carried out to investigate the dependence of visibility of the bright line upon field luminance and observation time. (Contractor's summary)

[THE POWER OF RESOLUTION OF THE EYE WITH REGARD TO FIXED IMAGES ON THE RETINA] II

potere risolutivo dell' occhio per immagini fisse rispetto alla retina, by A. Fiorentini. [1954] [5]p. incl. diagr. table, refs. (AF 61(514)634-C)
Unclassified

Published in Atti Della Fondazione G. Ronchi, v. 9: 470-474, Nov.-Dec. 1954.

Methods followed by different workers for measuring amplitude and frequency of involuntary eye movements are briefly reported. An experiment is described, which employs the method devised by Ditchburn and Ginsborg and independently by Ratliff, Riggs and coworkers. By this method it is possible to fixate images on the retina, even during eye movements. Visibility of a wire on a bright background has been investigated and the results are in agreement with those of the authors quoted above; visual acuity with a parallel bar test object has also been investigated. MEASUREMENTS OF DIFFERENTIAL THRESHOLD IN THE PRESENCE OF A SPATIAL ILLUMINATION GRADIENT, by A. Fiorentini, M. Jeanne, and G. T. di Francia. [1955] 17p. incl. diagrs. refs. (Technical note no. 3; EOARDC-TN-55 N.3) [AFOSR-TN-55-579] (AF 61(514)634-C) AD 154156 Unclassified

Also published in Atti Della Fondazione G. Ronchi, v. 10: 371-379, Sept.-Oct. 1955.

A field where the luminance varies along a given direction is viewed by an observer and the photometric differential threshold is measured in different points of the field. The experimental values of the threshold compare fairly well with the distribution of subjective brightness, as reported by the observer. It has been found that the presence of the gradient of illumination makes the threshold increase. The value of the threshold at the point of the field where the bright Mach band is seen by the observer, decreases when the angular width of the graded field increases. This variation quantitatively corresponds to the decrease of brightness of the Mach band. (Contractor's abstract)

ON THE DIFFERENTIAL AND INTEGRAL PUPIL EFFICIENCIES, by A. M. Ercoles, L. Ronchi, and G. T. di Francia. [1955] 20p. incl. diagrs. tables. (Technical note no. 4; EOARDC-TN-55-N.4) ([AF]OSR-TN-55-580) (AF 61(514)634-C) AD 154157
Unclassified

A study has been made of the sensations which result when rays of different inclinations [angles of incidence] impinge on the same retinal area (the fovea). The measurements have been carried out by adopting the Maxwellian view. The pupil efficiency (relative luminosity) has been determined by focussing at the pupil plane a series of spots of different size and shape, e.g., a single pinhole, 2 pinholes, either symmetrical or not with respect to the center of the pupil, full circles, half circles, and concentric rings. All 3 subjects tested show different behaviors, but none of them indicated a tendency to over-additivity. A tentative theoretical explanation is suggested in terms of inhibition, and of possible differences of inclination shown by the axes of the cones in the fovea. It is conceivable that a component of inhibition may depend on the color differences which go together with the Stiles and Crawford effect.

ON VISUAL FUNCTIONS, by L. Ronchi. [1955] 34p. incl. diagrs. refs. [Technical note no. 1] (AF 61-(514)634-C) Unclassified

Published in Atti Della Fondazione G. Ronchi, v. 10: 285-308, July-Aug. 1955.

The influence on visual functions of mydriatics and miotics instilled into the conjunctival sac had been discovered at the end of the past century and has been investigated by some authors. Nevertheless, in many fundamental and classtcal researches of physiological optics, mydriatics and miotics have been used without taking into account the consequences of their action on visual functions. By means of accurate experimental procedures the author investigates the influence on visual threshold and on resolving power and on the Stiles and Crawford effect, of mydriatics such as sympamine-collirium, euphthalmine, and homatropine. The magnitude of the effects observed on six normal and experienced observers is rather remarkable. It is therefore necessary to avoid the use of any mydriatic, when investigating quantitatively the properties of the normal eye. (Contractor's summary)

THE DEPENDENCE OF HUMAN ELECTRORETINOGRAM ON THE SHAPE OF THE STIMULUS AS A FUNCTION OF TIME, by L. Ronchi and S. Grazi [Dec. 1956] [20]p. incl. diagrs. (Technical note no. 5) (AFOSR-TN-56-193) (AF 61(514)634-C) AD 87066 Unclasstfied

Also published in Optica Acta, v. 3: 188-195, Dec. 1956.

The human electroretinogram was studied for various time-gradients of illumination of the rettna, utilizing an intense white stimulus for both a light and dark adapted eye. In general, the cone response appeared to be masked by rod activity. No remarkable variations in the electroretinogram were observed by varying the time of rise of the stimulus between 1 and 7 msec. When the time of rise ranged from 70 to 600 msec, remarkable changes in both shape and size occured, and the latency time increased. (Contractor's abstract)

THE EFFECT ON THE HUMAN ELECTRORETINOGRAM OF THE DiSTRIBUTION OF FLUX IN A LIGHT STIMULUS OF FINITE DURATION, by L. Ronchi and J. D. Moreland. Aug. 15, 1956 [10]p. tncl. dtagrs. table. [Technical note no. 6] [AFOSR-TN-56-340] (AF 61(514)634-C) AD 95216 Unclasstfied

Also published in Optica Acta, v. 4: 31-40, Mar. 1957.

The dependence of the human ERG (electroretinogram) on the flux distribution in a white light stimulus was examined for 2 observers in the dark-adapted state. The stimulus is broken down into 3 variables: time of rise, time of exposure, and peak intensity. The response was analyzed with regard to 3 characteristics: height, slope, and latency-time of the b-wave. In one experiment the maximum stimulus level was kept constant at 100 lux at the pupil plane and the time of rise kept constant at 10 msec. In the range of time of exposure, 20 to 600 msec, both the height and slope of the b-wave showed an initial rise until the exposure increased to about 50 msec and then tended toward saturation. Latency-time showed little change, remaining at about 50 msec. In a second experiment, time of rise and exposure were held constant at 10 and 20 msec respectively, and records were obtained for relative peak intensities of 1, 2, 3, 3.5, and 5. For both subjects an increase in peak intensity produced first an increase in the height of the b-wave and later no appreciable change. This same kind of change for the slope of the b-wave was recorded for one observer, but no tendency to saturate was seen for the other observer. The latency-time diminished somewhat with intensity for the first observer, and remained fairly constant for the second observer. A Bunsen-Roscoe relation between peak-flux and exposure time appeared to hold for one observer. When the time of rise was changed, keeping exposure time and peak intensity constant, no change in the ERG was recorded although Roscoe relation is therefore an oversimplifying procedure: the rod mechanism cannot be considered as a simple integrating system. Short duration stimuli revealed the x-wave response (characteristic of the cone mechanism) which appeared in 3 modes of roughly equal frequency. Analysis of records obtained for standard stimuli over a period of months showed a typical seasonal variation of appreciable magnitude in the height of the b-wave response. VISION OF OSCILLATING NON-UNIFORM FIELDS, by A. Fiorentini and A. M. Ercoles. [1956] 20p. incl. diagrs. (Rept. no. EOARDC-TN-56-No. 7) (AFOSR-TN-56-366) (AF 61(514)634-C) AD 95802 Unclassified

Also published in Optica Acta, v. 4, 150-157, Dec. 1957.

In order to investigate the possible influence of involuntary eye movements on the contrast effect due to non-uniform fields, the authors measured the minimum spatial gradient of luminance allowing visibility of the Mach band, with a field oscillating perpendicularly to the line of sight. It was found that the movement facilitates the vision of the Mach band, provided its frequency is not too great. The results are discussed in terms of retinal interaction and of on- and off-effects in the nervous pathways. (Contractor's abstract)

ON THE RESPONSE OF THE HUMAN EYE TO LIGHT STIMULI PRESENTING A SPATIAL OR TEMPORAL GRADIENT OF LUMINANCE, by A. Fiorentini and L. Ronchi. [1956] 9p. incl. diagrs. (Rept. no. EOARDS-TN-No. 8) (AFOSR-TN-56-444) (AF 61(514)-634-C) AD 96789 Unclassified

Also published in Jour. Opi. Soc. Amer., v. 47: 639-642, July 1957.

From psychophysical experiments on vision of spatial gradienis of luminance on the retina, some differences have been poinied out between ceniral and peripheral vision In both oases, the brightness distribuiion agrees with the disiribuiion of the differential sensitivity of the eye. The differences are ascribed io 2 differeni mechanisms of interaciion, one relaied to the cones, and the other io the rods. The first gives rise io the perception of Mach bands, while the second simply emphasizes the sensaiion of brightness in ihe graded field. Some observations made by a hemeralopic subjeci confirm the view thai the appearance of the Mach bands is related to cone vision. From the electroretinographic investigation with iime gradienis of luminance, it can be deduced thai, as far as the rod response is concerned, the slowly rising stimuli are more effective than the stimuli o' any form coniaining the same energy. The role of the peripheral mechanism in the vision of spatial or iemporal gradients of luminance has been ascertained both with psychophysical and elecirophysiological experiments. THE DESIGN OF DIFFUSERS TO AVOID TURBULENT BOUNDARY LAYER SEPARATION (Abstract), by F. H. Clauser. [1954] [1]p. (AF 33(038)9862)
Unclassified

Presented at annual meeting of the Amer. Phys. Soc., Columbta U., New York, Jan. 28-30, 1954.

Publtshed in Phys. Rev., v. 94: 783, May 1, 1954.

A recent experimental tnvestigation obtained tnformation about the behavtor of turbulent boundary layers in adverse pressure gradients which were so adjusted that the layers had stmtlar velocity proftles throughout thetr length. The approprtate nondtmensional pressure gradient parameters were also constant throughout the length of the layers. Intermedtate proftles having shapes not too far removed from constant pressure profiles were found to wtthstand the highest pressure gradtents rather than layers having velocity proftles nearest those of separation profiles. The tnformation obtained is sufftclent to permit destgn of dtffusers having shapes for maximum dtffusion. Such dtffusers can give unltmtted amounts of diffuston without separation. The diffuser shapes are particularly easy to calculate if the free-stream velocity ts considered to be constant across the channel. The resulttng shapes are not straight stded, but expand most raptdly at ftrst where the boundary layers are thin and then less rapidly as the boundary layers grow. The expansion rates are greatly affected by the thickness of the boundary layer at the begtnning of the expanston, a fact not usually taken tnto account in the design of diffusers for wind tunnels and the like. THE GENERAL THEORY OF LINEARIZED ROTATIONAL COMPRESSIBLE FLOW AND APPLICATIONS, by C.-C. Chang and B.-T. Chu. Feb. 2, 1951 [24]p. incl. dtagrs. refs. [AF 33(038)12919)
Unclassifted

Presented at annual meeting of the Amer. Phys. Soc., New York, Feb. 2, 1951.

The fundamental equations governtng the motion of a steady nonviscous compressible flow can be linearized for a parallel but not necessarily uniform main stream as long as the dtsturbances are small. For two-dimenstonal or axially-symmetric flow, these equations can be reduced to the generalized Cauchy-Rtemann equations considered by Bers and Gelbart. For general three-dtmenstonal flow, a single second order partial differential equation is obtatned. The procedure of determining the boundary conditions for these equations is presented. It is shown that the linearized equation for the shear flow in general can be applied in the transonic range. For certain main stream velocity distributions, simple solutions can be found. In one case, the pressure distribution on an arbitrary airfoil in supersonic flight is given, and the result can be readily compared with Ackert's thin airfoil theory; the latter

gives only a first approximation for pressure distributions provided that the main stream velocity gradients in the neighborhood of the airfoil are small. The mathematical and physical aspects of the problems are briefly reviewed.

A PRELIMINARY STUDY OF THE AERODYNAMIC THEORY OF TURBOMACHINERY AND OF THREE-DIMENSIONAL SHEAR FLOW OF NONVISCOUS COMPRESSIBLE FLUIDS, by C.-C. Chang, H. Yeh, and B.-T. Chu. Apr. 1-June 30, 1951, 1v. incl. diagrs. refs. (AF 33(038)12919) ATI-158011 Unclassified

Some preliminary investigations on the aerodynamical aspects of turbomachinery and on three-dimensional shear flows are discussed. Study was concentrated on the fundamental equations of nonviscous, non-heat-conductive flow, summing up some of the early theoretical accomplishments in this field from a unified point of view. The thermoaerodynamic relations and the cascade theory are also discussed.

AERODYNAMIC CHARACTERISTICS OF AN OSCILLATING CASCADE, by C.-C. Chang and W.-H. Chu. Sept. 1, 1952 [42]p. incl. diagrs. (AF 33(038)12919) AD 4878 Unclassified

A study is presented of the simplified mechanism of aeroelastic instability or flutter in high-speed aircraft having turbomachinery. The rotor blades are considered approximately as a 2-dimensional cascade of an infinite number of identical airfoils spaced evenly in the lateral direction. The cascade is in an uniform flow of a perfect incompressible fluid and is subject to a quasi-steady harmonic oscillation. The pitching and flopping modes of small oscillations are considered. By assuming all the blades of the cascade to oscillate in synchronization, the conformal mapping technique may be applied in the analysis. The whole cascade is mapped onto a unit circle, and vice versa, by means of a combination of Joukowski's transformation and an exponential function. The flow is decomposed into steady mean flow, noncirculatory oscillating flow, and circulating oscillating flow. The second type of flow is considered as an oscillating doublet sheet replacing each blade; the third type is contributed by the oscillatory circulations in the cascade and the vorticity in the infinitely long wakes shed from the cascade. The lift and moment are not expressed in closed forms. The final expressions are given in integrals and series, and in the expression of the moment two new integrals occur. One of them may be reduced to the Theodorsen function (NACA Technical rept. no. 496, 1934) in the single-airfoil flutter if the gap/chord ratio goes to infinity.

PROPAGATION OF DISTURBANCES THROUGH SHEAR LAYERS OF COMPRESSIBLE FLOW, PART I, by C.-C. Chang and B.-T. Chu. Final rept. Sept. 26, 1951-Sept. 25, 1952, 34p. diagrs. (AF 33(038)12919) ATI-170700 Unclassified

Analytical solutions are given for the propagation of steady two-dimensional disturbances in shear layers bounded by a uniform supersonic stream on one side and by another uniform supersonic or subsonic stream on the other side. There is no restriction on the variation of Mach number inside the shear layers except that it is piecewise differentiable. (Contractor's summary)

THE BEHAVIOR OF TURBULENT BOUNDARY LAYERS, by F. H. Clauser. Feb. 25, 1054 [35]p. incl. diagrs. [AFOSR-TN-54-328] (AF 18(600)671) AD 48122 Unclassified

Presented at the Second Canadian Symposium on Aerodynamics, Toronto U., Feb. 25, 1954.

A review is presented of established work on turbulent boundary layers. The concept of the equilibrium layer is introduced, and a discussion is given of a number of ways in which a boundary layer can be disturbed. Experiments showed that (1) when the boundary layer passes through a changing environment, the layer is in a disturbed condition; and (2) when the environment of the boundary layer is held constant, the layer approaches a natural state appropriate to that environment. An experiment is described in which the skin friction in a conventional constant-pressure layer on a smooth plate was abruptly increased by roughening the wall with corrugated paper. The experiment showed that the region next to the wall is affected first, and that the change propagates outward until the entire profile is shifted over to a new curve. No rescaling of the variables is possible which can cause the profile to have the same shape as in the equilibrium zones ahead of or behind the transition zone. Experiments are described for the measurement of the time required for a boundary layer to return to equilibrium after it has been disturbed (the response time of the boundary layer). The problem of the nonequilibrium behavior of the outer portion of the layer is discussed.

TURBULENT HEAT TRANSFER IN A BOUNDARY LAYER WITH DISCONTINUOUS WALL TEMPERATURE, by D. S. Johnson. Aug. 1955 [133]p. incl. diagrs. refs. ([AF]OSR-TN-55-289) (AF 18(600)671) AD 71773 Unclassified

Results are presented of an experimental investigation of the concomitant thermal and velocity fields occurring when there is a small stepwise discontinuity in the temperature of the wall on which a zero-pressure-gradient turbulent boundary layer has formed. The mean velocity and temperature fields have been measured, and the statistical behaviors of several relevant fluctuating quantities have been obtained at a typical cross-section in the region where the thermal boundary layer has not yet reached the free stream. No over-all similarity between the thermal and velocity fields was found. The instantaneous surface of demarcation between heated and unheated fluid was found to be sharp and distinct at all points, resulting in intermittent temperature fluctuation signals well within the fully turbulent region of the momentum boundary layer. Values have been obtained for the variation of local heat transfer coefficient in the streamwise direction, and of the distribution of the local turbulent Prandtl number through the boundary layer at 1 section. PROBE INTERFERENCE IN MEASUREMENTS IN SUPERSONIC LAMINAR BOUNDARY LAYERS, by M. V. Morkovin and W. S. Bradfield. June 15, 1954, 2p. illus. refs. (Sponsored jointly by [Air Force] Office of Scientific Research and Office of Naval Research under [AF 18(600)1121]) Unclassified

Published in Jour. Aeronaut. Sciences, v. 21: 785-786, Nov. 1954.

Investigations have been made on the effects of the total-pressure probe used for measuring velocity and other profiles of supersonic laminar boundary layers. The existence and partial evaluation of these effects were based on comparison of results obtained from different size probes and on comparison of results with boundary-layer theory, which cannot account for the complicating leading-edge effects. The current study presents direct visual evidence of strong interference near the wall and discusses its implications. Observations were made of local, 3-dimensional separation under various probes (hot-wire and total-pressure) in the Johns Hopkins U. tunnel over a flat plate at M = 1.72 using the light-oil, lamp-black technique. In addition, these observations were rerun at the University of Minnesota (Minneapolis) at M = 3.05 using a short focus schlieren system and the china-film technique (J. S. Murphy and R. E. Phinney, Visualization of Boundary Layer Flow, Jour. Aeronaut. Sciences, v. 18: 771, Nov. 1951).

FLUCTUATIONS AND HOT-WIRE ANEMOMETRY IN COMPRESSIBLE FLOWS, by M. V. Morkovin. Nov. 1956, 102p. incl. diagrs. tables, refs. (AFOSR-TN-56-295) (NATO AGARDograph rept. no. 24) (AF 18(600)1121) AD 90007 Unclassified

Treatment of the problem of extracting information from a heated thin wire cooled by an unsteady compressible flow is based on the concept of local linearization around each operating point of an otherwise nonlinear system. This leads to a general formula for the direct voltage sensitivities with respect to the fluctuation modes of vorticity, entropy, and sound. Empirical evidence on heat transfer to thin wires at high speeds is analyzed in relation to the parameters entering the sensitivities. The potentialities and actual performance of the hot wire as a turbulence indicator, thermometer or microphone were evaluated on the basis of sensitivity expressions derived for different speed ranges. The direct mode sensitivities allow a generalization of Kovasznay's fluctuation diagrams so that decomposition of electrical signals into the separate mode contributions is not limited to supersonic speeds. In the range of Re no corresponding to hot-wire operation, families of straight lines in the Nu vs $\sqrt{Re}$ planes fit the empirical data well (except at very low Re's). Sensitivity expressions indicate that individual calibrations of wires are not required for most fluctuation measurements at supersonic speed. Procedures leading to spectral analysis of the mode fluctuations are given.

ON THE ENERGY TRANSFER TO SMALL DISTURBANCES IN A VISCOUS COMPRESSIBLE HEAT CONDUCTIVE MEDIUM, by B.-T. Chu. July 25, 1956, 38p. [AFOSR-TN-56-377] (AF 18(600)1121) AD 95813 Unclassified

The energy in a small disturbance in a viscous, compressible, heat-conductive medium is defined as a positive, definite quantity characterizing the mean level of fluctuation in the disturbance which, in the absence of heat transfer at the boundaries and of work done by them or by body forces, and in the absence of heat and material sources, is a monotone nondecreasing function of time. A quantity satisfying these requirements is found for small disturbances in a viscous, compressible heat-conductive medium. When viscosity and heat conductivity are neglected, the quantity reduces to the familiar acoustic energy in the theory of sound. Stability in the mean of such a fluid system can then be discussed with reference to the growth and decay of the energy in the disturbance. The effects of body forces, heat, and material sources are discussed. Rayleigh's criterion for the stability of systems involving heat sources is derived, and its limitations are shown. The transfer of energy from a steady main stream to a disturbance is examined, and the particular case of a parallel main stream is considered. A mathematical application of the energy relation is appended which demonstrates the uniqueness of solution of an initial- and boundary-value problem in the linearized theory of a viscous, heat-conductive medium. THOUGHTS ON SUPERSONIC WIND TUNNELS WITH LOW FREE-STREAM DISTURBANCES, by M. V. Morkovin. Nov. 1956 [20]p. tncl. diagrs. refs. (AFOSR-TN-56-540) (AF 18(600)1121) AD 110359 Unclasstfted

Mean-flow nonuniformities tn supersonic tunnels apparentty can be made sufficiently small by standard techniques. Large ratio of the settling chamber area to sonic throat area decreases effectively those mean Mach-number nonuniformtties which come from upstream of the throat. Great care in keeping nozzle contours continuously curvtng wtthout bumps or wavtness minimizes both the mean-disturbance wave pattern seen in many schlteren photographs and the unsteady sound level from "shivering Mach waves." Supersonic turbulence ts effectively suppressed by a large contraction ratio. Entropy (temperature) fluctuations can be reduced by matching mean temperatures at duct junctures and by provtdtng "long passage time" from such junctures to the test section. In particular a low-velocttty settling chamber with graduated screens to decrease the scale of the temperature nonuniformities ts thought effective. In constdertng the effect of free-stream disturbances thetr spectral dtstrtbution may be relevant. Vorticity and entropy fluctuations wtll not be important in the frequency range above 8 kc. The sound generated in the supersonic section, however, wtll have frequencies charactertstic of thtn high-speed layers, i.e., up to 60 kc and higher. The offendtng sound in the supersonic section is generated in the watl boundary layer. This sound is very difficult to measure experimentally or to predict theoreitcally and apparently little can be done to reduce tts ievel apprectably (except tn tunnels with contour nonuniformtties). The restdual sound level, however, ts probably unimportant except in transttion studies and very careful drag measurement.

tSOTOPIC ANALYSIS OF GASEOUS BORON HYDRIDES

BY NEUTRON ABSORPTION, by R. P. Hamlen and W. S. Koski. Jan. 1956, 6p. incl. table. (Technical note no. 1) [AFOSR-TN-56-6] (AF 18(600)1526) AD 88583 Unclassified

An isotopic boron analysis of diborane and pentaborane containing varying amounts of B^{10} has been made using a neutron-absorption technique. The gas was placed in a cell, the inside of which was coated with a ZnS silver-activated phosphor, and exposed to a neutron flux. The number of events from the $B^{10}(n, \alpha)Li^7$ reaction was a measure of the B^{10} content. The accuracy and reproducibility of the results agreed to within 1%. Preliminary results indicate the method is applicable to other gaseous boron hydrides such as dihydropentaborane and tetraborane. (Contractor's abstract)

PERIODIC SOLUTIONS OF DIFFERENTIAL EQUATIONS CONTAINING A PARAMETER, by D. C. Lewis. Dec. 18, 1953, 30p. (Technical rept. no. 1) [AFOSR-TN-54-3] (AF 18(600)665) AD 23315 Unclassified

Also published in Duke Math. Jour. v. 22: 39-56, Mar. 1955.

Consideration is given to a proof by Poincaré thai the existence of a known periodic sotution $x_1 = x_1(t) = x_1(t + 2\pi)$ when $|\mu| = 0$ of a system of differential equations of the iype $dx_i/dt = X_i(x_1, \ldots, x_n, \mu, t) = X_i(x, \mu, t)$, $i = 1, \ldots, n$, impties the existence of periodic sotutions for att sufficiently smati $|\mu| > o$, at teasi if the variationat equations have no nonirivial solutions with period 2π. Definite estimates are obtained for the range of convergence for a powers series expansion in μ, and in the anatytic case upper bounds are obtained for the remainder resulting from cutting the series off afier m terms. The estimates are obtained in terms of Lipschiiz conditions pertineni to functions consiructed from the X's and in terms of quaniities in the Green's matrix of the variational equations. The resuti does not depend expticitty on n. The method of integrat equations and successive approximations is modified in the anatytic case to yietd periodic sotutions for alt comptex values of μ whose absotuie values are bounded by a given positive constant L. A Cauchy criterion for the coefficients of a power series is apptied, and the result provides the desired information on the rapidity of convergence. The resutts for the analytic case are vatid for comptex domains; the resutis for the prior tnvestigaiion are vatid onty in reat domains.

ON THE ROLE OF FIRST INTEGRALS IN THE PERTURBATION OF PERIODIC SOLUTIONS, by D. C. Lewis. Apr. 1, 1955, 28p. (Paper no. 4) ([AF]OSR-TN-55-58) (AF 18(600)665) AD 60505 Unctassified

Also published in Ann. Math., v. 63: 535-548, May 1956.

An appraisat is made of the range of the parameter in the theory of perturbation of periodic sotutions, originated by Poincaré, in case the number of independent first iniegrals is equat to the number of tinearly independent periodic soiutions of the equations of variation. The method consists of successive approximations, use of a generalized Green's matrix, and a discussion of the bifurcation equations, which turn out to be identicatly satisfied. EQUIVARIANT EMBEDDINGS IN EUCLIDEAN SPACE,

by G. D. Mostow. Mar. 1957 [28]p. (AFOSR-TN-56-284) (AF 18(600)1474) AD 89494 Unclassified

Also published in Ann. Math., v. 65: 432-446, May 1957.

Let G be a group of transformations on a topological space E. If $P \in E$ we denote by G_p the set of transformations in G which keep p fixed. If H is a subgroup of G, we denote by (H) the totality of subgroups of G of the form xHx^{-1} with x in G. We denote by L(G, E) the totality of (G_p) as p varies over E. The orbits G_p and G_q through points p and q of E are called equivalent if $(G_p) = (G_q)$. Thus G has but a finite number of inequivalent orbits in E if and only if L(G, E) is a finite set. This is the case for example if E is a compact differentiable manifold and G is a compact group of differentiable transformations. Several theorems are derived and proven in this paper. Among other things they are particularly useful in enabling one (1) to obtain quite directly information about the conjugacy of subgroups of a compact Lie group, and (2) to find conditions under which L(G, E) is finite. ON INTEGRATING FACTORS AND ON CONFORMAL MAPPINGS, by P. Hartman. Oct. 1956, 31p. refs. (Technical rept. no. 1) (AFOSR-TN-56-475) (AF 18-(603)41) AD 97359 Unclassified

Also published in Trans. Amer. Math. Soc., v. 87: 387-406, 1958.

The existence of (local) "integrating factors" for a linear differential form $\omega = P(x, y)dx + Q(x, y)dy$ with functions $T \neq 0$ and W such that $\omega = Tdw$. The first of two cases is where P and Q are real-valued and $P^2 + Q^2 \neq 0$. $1/T$ is called an integrating factor for ω and solution is through ordinary differential equations. The second case is where P and Q are complex-valued and $\mathrm{Im}(P\bar{Q}) \neq 0$. The problem here is conformalizing the Riemannian metric $ds^2 = \omega\bar{\omega} = |P|^2dx^2 + 2\mathrm{Re}(P\bar{Q})dxdy + |Q|^2dy^2$ by an elliptic system of partial differential equations. A positive definite binary ds^2 can be factored into $\omega\bar{\omega}$. P and Q are continuous and conditions are imposed on the set function $\Psi(E) = \int_J Pdx + Qdy$ with E a domain bounded by a rectifiable Jordan curve J. The appendix considers a related problem on indefinite forms in the theory of surfaces.

SELF-ADJOINT, NON-OSCILLATORY SYSTEMS OF ORDINARY, SECOND ORDER, LINEAR DIFFERENTIAL EQUATIONS, by P. Hartman. Oct. 1956, 11p. refs. (Technical rept. no. 2) (AFOSR-TN-56-482) (AF 18-(603)41) AD 97366 Unclassified

Also published in Duke Math. Jour., v. 24: 25-36, Mar. 1957.

A differential equation $x'' + f(t)x = 0$ is called nonoscillatory on $0 \leq t < \infty$ if no (nontrivial) solution has arbitrarily large zeros. This notion is generalized to a self-adjoint system of equations $x'' + F(t)x = 0$ in which x is a vector and F(t) is a continuous Hermitian matrix on $0 \leq t < \infty$. Results concerning solutions of this system (and, more generally, of the system $(Px')' + Fx = 0$ in which P(t) is a continuous Hermitian positive definite matrix), analogous to known facts concerning solutions in the particular cases that F(t) is a scalar or a real Hermitian non-positive definite matrix, are obtained. SPECTRAL PHONOCARDIOGRAPHY: PROBLEMS AND PROSPECTS IN THE APPLICATION OF THE BELL SOUND SPECTROGRAPH TO PHONOCARDIOGRAPHY, by V. A. McKusick, S. A. Talbot, and G. N. Webb. [1954] [12]p. incl. illus. diagrs. [AF 18(600)1040] Unclassified

Presented at meeting of the Amer. Physiol. Soc., Atlantic City, N. J., Apr. 12-16, 1954.

Published in Bull. Johns Hopkins Hospital, v. 94: 187-198, Apr. 1954.

Abstract published in Fed. Proc., v. 13: 522, Mar. 1954.

For optimum results the Bell sound spectrograph requires modification along the following lines: (1) provision for fine definition in both time and frequency in the same record is desirable; (2) display of frequency on a logarithmic scale (the ordinate) produces a more realistic record; (3) instrumentation for the simultaneous parallel recording of other physiologic data (for

JHU. 10:002 - JHU. 10:004

correlative and timing purposes) is essential; and (4) conversion from the use of direct-writing paper to photographic film negative improves intensity definition many-fold. Spectral phonocardiograms incorporate the timing, frequency, and intensity characteristics of heart sounds in a single, objective, detailed, standardizable display. The following hypotheses are discussed and illustrated: (1) spectral phonocardiograms match closely the mental image of the heart sounds. Therefore their interpretation is easy for the experienced stethoscopist; (2) their pedagogic value is considerable; (3) for purposes of clinical record spectral phonocardiography has advantages; (4) spectral phonocardiography permits precise definition in physical terms of the adjectives used in describing heart sounds and murmurs; and (5) information of physiologic and pathologic significance beyond the appreciation of either the ear or the current methods of phonocardiography is made available by spectral phonocardiography. SPECTRAL PHONOCARDIOGRAPHY: CLINICAL STUDIES, by V. A. McKusick, C. N. Webb and others. [1954] [21]p. incl. illus. diagrs. refs. [AF 18(600)-1040] Unclassified

Published in Bull. Johns Hopkins Hospital, v. 95: 90-110. Aug. 1954.

Spectral phonocardiograms of a variety of heart sounds and murmurs have been presented and discussed. Technical modifications which permit simultaneous display EKG, respirations, and other physiologic phenomena and those necessary for a logarithmic frequency scale are described briefly and examples of recordings presented. Since all features of the sounds are visually displayed, quality (timbre), which previously has eluded exact description, can now be defined in physical terms. This "sea-gull" diastolic murmur and terms such as ringing, rasping, rumbling, etc., are so defined. Preliminary observations are presented concerning the operation of one part of the stethoscope on sound reaching the surface of the chest, the operation of the thorax on sound generated in cardiovascular structures, and the dissection of heart sounds by this method. Crescendo, decrescendo, diamond-shaped and similar terms derived from the intensity characteristics as displayed by classical phonocardiography are found to apply to frequency characteristics as well. In general, freak frequency and over-all intensity vary in a parallel fashion in sounds of cardiovascular origin. In the case of one type of vascular sound (uterine souffle) the relation to the generating system and the operation of hemodynamic factors on this sound are discussed. The similarity of the uterine souffle to an arterial pulse pressure curve is pointed out. Spectral phonocardiograms resemble closely the mental image of heart sounds and murmurs. They facilitate the learning of clinical auscultation. And inasmuch as all three dimensions of sound are incorporated in a single detailed display, spectral phonocardiograms are valuable for permanent clinical records and for the detailed presentation of these sounds on the printed page. SOME HEMODYNAMIC EFFECTS OF THE HUFNAGEL OPERATION FOR AORTIC REGURGITATION by V. A. McKusick, D. P. Hahn and others. [1954] [16]p. incl. illus. diagrs. tables, refs. [AF 18(600)1040] Unclassified

Published in Bull. Johns Hopkins Hospital, v. 95: 322-337, Dec. 1954.

The following effects have been found: (1) the implantation of a ball-valve in the descending thoracic aorta in cases of aortic regurgitation results in decrease in mean diastolic pressure in the segment of the arterial tree proximal to the ball-valve and a decrease in the size of the diastolic murmur; (2) the size of the diastolic murmur correlates well with mean diastolic pressure in the proximal segment and poorly with the volume of regurgitation; (3) both the beneficial effect on volume of regurgitation and the adverse one on mean diastolic pressure are greater the smaller the segment proximal to the ball-valve; (4) the exaggeration (by the operation) of the depression of mean diastolic pressure in the proximal arterial segment may limit the over-all benefits of the operation; (5) splitting of the sound produced by the artificial valve is demonstrated by spectral phonocardiography. Asynchronous impingement of the valve on its seatings is suggested as the mechanism of this minute splitting; and (6) the opening and closing sounds of the artificial valve in situ occurs between the normal heart sounds. Systole is abbreviated distal to the artificial valve. (Contractor's conclusions, modified)

ON CARDIOVASCULAR SOUND. FURTHER OBSERVATIONS BY MEANS OF SPECTRAL PHONOCARDIOGRAPHY, by V. A. McKusick, G. N. Webb and others. [1955] [22]p. incl. illus. diagrs. refs. [AF 18(600)-1040] Unclassified

Published in Circulation, v. 11: 849-879, June 1955.

Spectral phonocardiography is an adaptation of the method of sound spectrography devised at the Bell Telephone labs. It differs from conventional oscillographic phoncardiography principally in the fact that frequency spectrum is displayed as welt as the dimensions of time and inlensity. The dtsptay of frequency spectrum is responsible for three advantages of the method: (1) quality, or timbre, ts gtven physical definition; (2) resotution in the time dimension ts tmproved; and (3) a betie· dtsplay of the wide dynamic range of cardiovascular sound is attatned. This method can do, or can be made to do, all the ear can. It can probabty emulate the performance of the ear because (1) it is not wed to a particular frequency-intensity response curve; (2) it suffers from no "psychoacoustic" impediments; (3) it provides better resotution tn the time dimension; and (4) it produces permanent quantifiable records. Discussed here are selected features of mitral valve disease, gallops, systolic clicks, and extracardiac sounds. In general, intensity and peak frequency vary in a parallel manner in sound of cardiovascular origin. Artefacts due to noncardiovascular ambient noise and to electrical interference can be identified and disregarded in the heart sound analysis. (Contractor's abstract)

SPECTRAL PHONOCARDIOGRAPHIC DEMONSTRATIONS OF SELECTED VARIETIES OF CARDIOVASCULAR SOUNDS, by V. A. McKusick, E. W. Kline, and G. N. Webb. [1955] [23]p. incl. diagrs. refs. [AF 18-(600)1040] Unclassified

Published in Amer. Heart Jour., v. 49: 911-933, June 1955.

Demonstrated here is heart sound intensification of 4 types as to the principal factor responsible for the alteration: (1) increased velocity of valve closure; (2) increased force of valve closure; (3) fibrosis and other physical change in the coapting valve cusps; and (4) closure of valves from a wide-open position. Recordings of heart sounds were made on magnetic tape using a condenser-type microphone. Electrocardiogram and respiratory tracings were simultaneously recorded on the tape by means of frequency modulated carriers. A more valid recording was obtained, with less risk of introduction of physiologic artifact as a result of partial Müller or Valsalva experiment, by permitting quiet respiration during the recording. Since artifacts such as breath sounds are easily identified as such in the spectrat phonocardiogram, resptration dtd not interfere with the analyses. (Contractor's summary, modified)

THE ACOUSTIC BASIS OF THE CHEST EXAMINATION. STUDIES BY MEANS OF SOUND SPECTROGRAPHY, by V. A. McKusick, J. T. Jenkins, and G. N. Webb. [1955] [23]p. tncl. illus. diagrs. refs. [AF 18(600)-1040] Unclassifted

Published in Amer. Rev. of T. B. and Pulmonary Diseases, v. 72: 12-34, July 1955.

The features of respiratory sound tn health and dtsease have been studied by the method of sound spectrography. Most of the ftndings noted have been revealed or surmised previously by workers using other techniques. Nevertheless, by use of the method of sound spectrography, it has been possibte to demonstrate the respiratory sounds tn health and disease graphically to a greater extent than has previously been possible. The physical differences which characterize dull, resonant, and tympanitic percussion notes, the several types of breath sounds, and moist and dry rales are demonstrated. The change in whispered and spoken voice sounds in disease can be related to physical alterations in conducting and filtering properties of the lung and its covering tissues. The musicality of asthmatic rales results from the presence of conspicuous harmonics. (Contractor's summary)

MUSICAL MURMURS, by V. A. McKusick, G. E. Murray and others. [1955] [41]p. tncl. tllus. diagrs. refs. [AF 18(600)1040] Unclassified

Published in Bull. Johns Hopkins Hospital, v. 97: 136-176. Aug. 1955.

A classification of musical murmurs has been proposed. Musicality is a function of the presence of harmonic pattern. A brief discussion is presented of the clinical pictures (with particular reference to the musical murmur) associated with retroverted aortic cusp, ball-valve atrial tumor, aberrant tendon of the ventricle, and dissecting aneurysm of the ascending aorta with musical late diastolic murmur. A musical early diastolic murmur can have an extra-cardiac and prognostically benign basis. The followtng hemodynamic and anatomtcal mechanisms tn the genesis of musical murmurs are of particular interest: (1) it is possible to dissect the

JHU. 10:009 - JHU. 10:012

systolic murmur of aortic cusp into musical elements related to the regular vibrations of an elastic structure and noisy components due to turbulence. Certain of these musical murmurs are the loudest known to medicine. Components of the same two general types may be present in the valve closure sound; (2) in general, frequency and intensity in aortic murmurs, both systolic and diastolic, vary directly with aorto-ventricular pressure differential; (3) selective transmission results in alteration in the timbre of the murmur of retroverted aortic cusp as heard at the apex. Resonant absorption apparently operates in changing the timbre of the same murmur as heard in the "aortic" area; and (4) the shape of the musical uterine souffle, which resembles an arterial pressure pulse curve, can be related to cyclical hemodynamic changes at the generator. SYSTOLIC CLICKS (SO-CALLED SYSTOLIC GALLOPS): A STUDY OF THEIR CLINICAL SIGNIFICANCE (Abstract), by J. A. Reid and J. O. Humphries. [1955] [2]p. [AF 18(600)1040] Unclassified

Presented at meeting of the Johns Hopkins Med. Soc., Baltimore, Md., May 9, 1955.

Published in Bull. Johns Hopkins Hospital, v. 97: 177-178, Aug. 1955.

Patients with systolic clicks were studied by means of spectral phonocardiography. In general, the studies indicate that systolic clicks are of benign prognostic significance. The systolic click does not hold the same grave prognosis as does a diastolic gallop. For this reason, it is recommended that the term "systolic gallop" be abandoned. Late systolic clicks may be confused with split second sound or may, with the normal second sound, create a combination simulating second sound plus opening mitral snap. Circumscribed midsystolic murmurs introduced by a systolic click appear to be extra cardiac in origin and hold the same prognosis as do systolic clicks without murmurs. THE SPLITTING OF HEART SOUNDS. A SPECTRAL PHONOCARDIOGRAPHIC EVALUATION OF CLINICAL SIGNIFICANCE, by V. A. McKusick, W. P. Reagan and others. [1955] [13]p. incl. illus. diagrs. refs. [AF 18(600)1040] Unclassified

Published in Amer. Jour. Med., v. 19: 849-861, Dec. 1955.

Normal and pathologic conditions resulting in splitting of heart sounds are reviewed. Because of much overlap of the degree of splitting with that occurring normally, splitting is of limited diagnostic value in the pathologic states with which it may occur: interatrial septal defect, bundle branch block, mitral or aortic regurgitation, and respiratory disease resulting in exaggerated cyclical variations in intrapleural pressure. In general however, splitting has more pathologic significance (1) when it occurs in adults than when it occurs in children, (2) when splitting is exaggerated with expiration rather than with inspiration (left bundle branch block), (3) when there is no clinical evidence of respiratory disease and labored respirations, and (4) when splitting persists throughout all phases of respiration (as usually is the case in interatrial septal defect). A PHASE FILTER APPLIED TO SPECTRAL PHONOCARDIOGRAPHY, by F. H. Middleton, G. E. Gilbert and others. [1956] [9]p. incl. illus. diagrs. [AF 18(600)1040] Unclassified

Presented at IRE Instrumentation Conference and Exhibit, Atlanta, Ga., Nov. 28-30, 1955.

Published in I.R.E. Trans. of Professional Group on Instrumentation, v. I-5: 122-130, June 1956.

Spectral phonocardiography is the name applied to the process of analyzing heart sounds to provide a frequency-amplitude-time display. A segment of heart sound is recorded on a magnetic medium and then repeatedly analyzed by a heterodyne filter system. Because the bandwidth of a conventional filter determines both the frequency and the time resolution, a difficulty arises in that the selection of a wideband filter to obtain adequate time resolution leads to a poor frequency resolution and vice-versa. By making use of the fact that the phase-frequency characteristic of a filter is changing at resonance whereas its amplitude response is not, it is possible to obtain both good time and frequency resolution

at the expense of amplitude information. This paper describes the application of this principle to the design of a phase filter and shows that it produces an analysis having some of the features of the sense of hearing. The design, construction, and operation of the phase filter for this application are described. Included are several sets of sonograms comparing results obtained with the conventional filter and with the phase filter. Suggested changes that could be incorporated in subsequent models are discussed. (Contractor's summary)

SPECTRAL PHONOCARDIOGRAPHIC STUDIES IN CONGENITAL HEART DISEASE, by V. A. McKusick, O. N. Massengale, Jr. and others. [1956] [14]p. incl. illus. diagrs. refs. [AF 18(600)1040] Unclassified

Published in Brit. Heart Jour., v. 18: 403-416, July 1956.

The spectral phonocardiographic patterns in thoracic A-V fistula (exemplified by patent ductus arteriosus), in pulmonary stenosis, and in atrial septal defect are sufficiently distinctive to suggest the diagnosis from examination of the sound recordings alone. The pulmonary reversal snap of valvular pulmonary stenosis is highly diagnostic, particularly when combined with a murmur of the typical ejection stenosis type. Most reported cases of congenital mitral stenosis have not had completely typical auscultatory findings in terms of the experience with rheumatic mitral stenosis. A case is presented, however, in which typical ausculatory findings, including mitral opening snap, did occur. Such cases might be particularly favorable for valvotomy. Some features of the heart sounds in primary pulmonary hypertension have been demonstrated. (Contractor's summary)

DYNAMIC COMPARISON OF CURRENT BALLISTOCARDIOGRAPHIC METHODS. PART I. ARTEFACTS IN THE DYNAMICALLY SIMPLE BALLISTOCARDIOGRAPHIC METHODS. II. EFFECT OF A PLATFORM IN BALLISTOCARDIOGRAPHIC DYNAMICS. PART III. DERIVATION OF CARDIOVASCULAR FORCE FROM BODY MOTIONS, by S. A. Talbot and W. K. Harrison, Jr. [1955] [36]p. incl. illus. diagrs. refs. [AFOSR-TN-56-439] (Sponsored jointly by [Air Force Office of Scientific Research] under AF 18(600)1107) and Public Health Service) AD 96782 Unclassified

Also published in Circulation, v. 12; 577-587; 845-857; 1022-1033, Oct.-Dec. 1955.

This study on ballistocardiography, the science concerning the dynamics (forces, momenta, and motions) of particular cardiovascular mechanisms (heart, great vessels) as deduced from the recorded motion of the body, is presented in 3 parts. In Part I, the nature and magnitude of force artefacts in the ballistocardiogram (BCG) arising from coupling the body to ground is considered. The effect of this grounding on the reading of cardiovascular motion, momentum, and force is explained, using the simple 1-mass dynamics in which the platform effect is negligible or absent. Part II deals with the effects on the BCG of a second mass, a platform supporting the body. The body itself is a cutoff filter of the resonant type because of its springy supporting tissues which couple the body and the platform masses. In the displacement BCG, this attenuated the upper frequencies recorded from stiffly sprung platforms, or from the direct body, whatever its coupling to earth. In the acceleration record, the body mass and spring cut off the lower ballistocardiographic frequencies, while platform mass and spring cut off the higher frequencies. The magnitude of these errors and their bearing on multilateral recording are discussed. In Part III, the validity of the standard assumptions of ballistocardiography, employed in Parts I and II, is examined. Using ballistocardiographic data taken with and without beds, and subtracting the effects of the supports, it is shown that mechanical errors still remain. Constraints to ground as stiff as the direct-body and Starr supports seem to result in more errors of body complexity than do the softer supports of Nickerson, Burger, or von Wittern, beyond the obvious resonance distortions.

TRANSIENT BEHAVIOR FOLLOWING BREAKDOWN AND ITS RELATION TO AFTERGLOW PROCESSES (Abstract), by D. E. Kerr and E. F. Tubbs. [1955] [1]p. [AF 18(600)363] Unclassified

Presented at meeting of the Amer. Phys. Soc., Schenectady, N. Y., Oct. 20-22, 1955.

Published in Phys. Rev., v. 100: 1231, Nov. 15, 1955.

Following application of a pulse of microwave power to form a helium discharge in a resonant cavity, there is a period of about one millisecond which is characterized by a transient behavior of both emitted light and rf properties, particularly transmitted power. In general, atomic radiation first rises sharply, then undergoes quasi-oscillatory behavior in approaching a stationary value. During the pulse, molecular radiation is generally weak but rises many-fold at the end of the pulse. Detailed measurements of certain transitions show atomic light falling abruptly in the afterglow; but molecular light rises sharply then falls more slowly. The radiation is usually characterized by more than one time constant, the larger one being markedly dependent upon pulse length and pressure. The abrupt rise of molecular radiation at the end of the breakdown pulse is strongly dependent upon the pulse length. Consequently the relative predominance of molecular or atomic radiation can be controlled by pulse length. This fact casts doubt on interpretations of afterglow mechanisms which depend upon predominance of either type of spectrum. Other rare gases are under study.

BOSON FAMILY FROM QUANTIZED FINITE-PARTICLE MAXWELL THEORY, by R. [L.] Ingraham and J. Ford Aug. 28, 1956; rev. Dec. 13, 1956 [12]p. incl. diagr. refs. (AF 18(603)143) Unclassified

Published in Phys. Rev., v. 106: 1324-1335, June 15, 1957.

Quantization of finite-particle Maxwell theory yields a family of free bosons of nonzero masses and spins 1 and 0. The existence of a mass spectrum is a direct consequence of the new degree of freedom of particle size. These are quanta of short-range (meson) forces. The force-free theory (i.e., uncoupled to a fermion field) is studied here as a preliminary to the coupled case. An automatic connection with the Pauli-Villars regulator theory is obtained. The nature and position of the singularities in the field commutators of quantum electrodynamics and meson theory is profoundly altered. (Contractor's abstract)

THE INTERACTION OF GRIDS WITH TRAVELLING SHOCK WAVES, by D. C. Dosanjh. Dec. 1953, 29p. illus. refs. ([AF]OSR-TN-54-58) (AF 18(600)757) AD 26941 Unclassified

Experimental equipment used in the study included a shock tube, triggering and timing, grids, and their mounting, hot wire apparatus, and a shadowgraph arrangement. The shock tube consists of a steel box of uniform cross section (about 6 x 4 in. inside) which is divided into 2 chambers by a diaphragm that sustains a pressure differential between them. The total tube length is 29 ft. The grids (1/4-in. thick perforated steel plate with sharp edged holes) were mounted between 2 glass sections to permit the recording of shadowgraphs of the transmitted and/or reflected shocks and the associated turbulent flow. The speeds of incident, transmitted, and reflected shock waves were measured, and the pressure drop coefficient (defined on the basis of the pressure far upstream and the pressure far downstream from the location of the grid) was calculated. The drift flow behind the reflected shock was turbulent after its passage through the grid. The interaction of this turbulent region with the reflected-transmitted shock wave was optically observed. The investigation showed that the combined use of the shadowgraph and the hot wire anemometer was a reliable technique for studying the transient flow fields associated with the interaction of a traveling shock wave and grids mounted in its path.

USE OF THE HOT-WIRE ANEMOMETER AS A TRIGGERING DEVICE FOR WAVE PHENOMENA IN A SHOCK TUBE, by D. S. Dosanjh. Dec. 15, 1953; rev. Aug. 23, 1954 [6]p. incl. illus. diagrs. refs. (AF 18-(600)757) Unclassified

Published in Rev. Scient. Instruments, v. 26: 65-70, Jan. 1955.

The hot-wire anemometer is principally used for turbulence investigations in both subsonic and supersonic flows. Its use has been extended to the observation of transient phenomena in shock tubes. Since its sensitivity to different phenomena varies, depending upon the operating conditions, the hot wire is quite well suited for timing very weak as well as strong traveling shock waves. A triggering and timing arrangement was developed pointing to further improvement. It was found that the hot-wire trigger is a reliable instrument under widely varying shock tube operations. GRAIN BOUNDARY MIGRATION IN ALUMINUM BICRYSTALS, by. K. T. Aust, E. H. Harrtson and others. July 31, 1955 [13]p. tncl. illus. dtagrs. table, refs. [AFOSR-TN-55-226] (Bound with tts technical rept. no. 6 (Ftnal) as Part I; AD 74873; [AF]OSR-TN-55-19) (AF 18(600)1012) AD 74873(a) Unclasstfied

Investtgatton was made to determine the effect of orientation dtfference and temperature on boundary migration tn stratn-free Al btcrystals, where the drtving force results from the reduction of boundary area. Tests were conducted with Al bicrystals havtng 2 different shapes: (1) V-shaped btcrystals in which the boundary was expected to move on annealtng in a direction toward the tip of the V, owing to a reductton of the boundary area; and (2) specimens in which the radius of curvature of the moving boundary is kept constant. No evidence of boundary migration was found tn the V-shaped bicrystals after annealing at temperatures up to 640°C for 90 hr. The grain boundary tn the second-type crystal was observed to mtgrate toward the center of curvature of the curved portton of the boundary. Boundary migration proceeded tn a step-like or discontinuous manner during a stngle annealtng cycle. Uniform boundary migration was plotted as a function of tsothermal annealtng at 640°, 600°, and 560°C for btcrystals having orientation dtfferences (θ) of 55° and 85° about a [110] specimen axts direction. It was apparent that a boundary separating crystals with θ = 85° migrated at a faster rate and wtth a smaller activation energy than a boundary with θ = 55°. The difference tn activatton energy for gratn boundary mtgration between bicrystals wtth θ = 55° and 85° was 22 ± 3 and 10 ± 3 kcal/g-atom, respectively. (ASTIA abstract)

RESEARCH ON GRAIN BOUNDARIES. PART I. GRAIN BOUNDARY MIGRATION IN ALUMINUM BICRYSTALS. PART II. INTERFACIAL ENERGIES OF SYMMETRICAL TILT CRYSTAL BOUNDARIES IN SILVER. PART III. SHEAR ALONG GRAIN BOUNDARIES IN ALUMINUM BICRYSTALS AT ELEVATED TEMPERATURES, by K. T. Aust, E. H. Harrison and others. July 31, 1955 [34]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 6 (Final)) ([AF]OSR-TR-55-19) (AF 18(600) 1012) AD 74873(a), (b), and (c) Unclassified

Part II. The relative energy (γ_R) of symmetrical tilt boundaries in high purity silver crystals was determined for a series of different orientations, θ. It is shown that the boundary energy depends upon the orientation of the boundary. The results are in agreement with the dislocation model of the grain boundary. Part III. Preliminary research on shear along tilt grain boundaries in aluminum crystals is presented. It ts shown that at 400°C, the boundary durtng tnitial loadtng wtll undergo a pure shear that ts followed by boundary mtgration. (For Part I see ttem no. JHU. 15:001.)

CALIBRATION AND PERFORMANCE OF AN AEROSOL GENERATION SYSTEM, by J. F. Skrtvan and H. E. Hoetscher. Apr. 1956, 50p. tncl. ittus. diagrs. tables. (Technical note no. 1) (AFOSR-TN-56-135) (AF 18-(600)1176) AD 86011 Unclasstfied

The performance of an aerosol generation system has been studied wtth regard to particle stze and mass concentration, wtth particular emphasts on the latter phase. The aerosol generator used in the research was constructed following the design of Sinclair and Lamar. A photometer of commercial manufacture was calibrated with respect to the mass concentration of aerosol passing through it. Calibration curves were obtained for silicone oil and Esso motor oil and the slopes were the same for both. Using the caltbration curves, the vartables of the system were studied with respect to thetr tnfluence on mass concentration. The most important parameter of the system was the temperature of the liquid from whtch the aerosol is produced. Curves showing the effects of other variables are also presented. W. T. Biedler, III and H. E. Hoelscher. June 1956, 1v. incl. illus. diagrs. tables, refs. (Technical note no. 2) [AFOSR-TN-56-265] (AF 18(600)1176) AD 88985 Unclassified

A new type of device for measuring flame velocities has been developed. This device is a burner utilizing a stable planar flame front which permits the study of stable flat flames, free from contact with any surface. Flame velocity as a function of concentration of combustible in the unburnt mixture has been determined for an air-propane system. The effect of the geomctry of the system on flame properties is observed and discussed. Temperature and concentration measurements were made in the vicinity of the flame and are reported. OBSERVATIONS ON GRAIN-BOUNDARY MIGRATION IN ALUMINUM BICRYSTALS, by K. T. Aust, E. H. Harrison, and R. Maddin. [1956-57] [2]p. incl. diagrs. [AF 18(600)1587] Unclassified

Published in Jour. Inst. Metals, v. 85: 15-16, 1956-57.

The experimental technique suggested by Dunn, Daniels, and Bolton (Trans. Amer. Inst. Min. Met. Eng., v. 185: 708, 1949) for studying grain-boundary migration is shown to have considerable merit. The rates of grain-boundary migration have been measured at temperatures of 560°, 600°, and 640°C for strain-free bicrystals of aluminum having orientation differences of 55° and 85° about <110>. Activation energies of 43 and 20 kg cal/g-atom, respectively, were calculated from these data.

IDENTIFICATION OF H_2O^{18} AND H_2O^{17} TELLURIC LINES IN THE INFRARED SOLAR SPECTRUM, by W. S. Benedict. [July 1956] [15]p. incl. diagrs. tables, refs. [AFOSR-TN-56-306] AD 90020 Unclassified

Presented at the Seventh International Congress on Astrophysics, Liège (Belgium), July 12-14, 1956.

Also published in Mém. Soc. Roy. Sci. Liège, 4th Series, v. 18: 556-571, 1957.

Abstract published in Mém. Soc. Roy. Sci. Liège, 4th Series, v. 18: 41, 1957.

In the solar spectra observed at the Jungfraujoch there are a number of weak telluric lines, varying with the water-vapor content, that cannot be interpreted as transitions between the known energy levels of H_2O^{16}. Fourteen such lines on the pure-rotation band (420-580 cm^{-1}) and more than 20 in the wings of the 6-μ band (1170-1445 and 1800-2053 cm^{-1}) have been identified as resulting from H_2O^{18}. In all cases where the line of H_2O^{16} is sufficiently strong, a satellite H_2O^{18} line either appears at the calculated frequency shift (which ranges from +1 to -11 cm^{-1}), or else is overlapped. In about 10 favorable cases, the line resulting from H_2O^{17} may be located halfway between the H_2O^{16} and H_2O^{18}. The relative intensities appear to be in agreement with normal isotopic abundances. (Contractor's abstract)

INTERACTION OF STRETCHING VIBRATIONS AND INVERSION IN AMMONIA, by W. D. Benedict and E. K. Plyler. April 1956 [1]p. incl. tables. [AF 18-(600)1557] Unclassified

Published in Jour. Chem. Phys., v. 24: 904, Apr. 1956.

The effects of the inversion doubling of the energy levels of NH_3 have been accurately studied in the microwave region and in the fundamental and higher states of v_2, but little is known about the interactions of the other modes of vibration with the inversion. The purpose of this investigation was to study the absorption of NH_3, in the region from 2.15 - 2.47μ (4050-4720 cm^{-1}), with an effective resolution of 0.15 cm^{-1}. About 1000 lines were measured and all but the weakest were analyzed. Values of the molecular constants, ignoring the higher-order effects, are presented. Comparison is made between the energy-level differences due to inversion-doubling observed in the combination bands and those in the v_2 fundamental.

THEORY OF CAPACITIES, by G. Choquet. May 1954 179p. incl. refs. (Technical note no. 1) ([AF]OSR-TN-54-120) (AF 18(600)959) AD 35285 Unclasstfied

The theory of capacities is developed from a consideration of whether or not the interior Newtonian capactty of an arbitrary Boreltan subset X of the space R^3 is equal to the exterior Newtonian capactty of X. The theory is analogous to the classical theory of measurability and deals prtncipalty with nonaddttive set functions defined on arbttrary Hausdorff spaces. The theory ts developed under the following toptcs: (1) Boreltan and analytic sets in topological spaces; (2) Newtonian and Greenian capactties; (3) alternating and monotone functions (capacities); (4) the extension and reetrictton of a capactty; (5) operations on capactties and examples of capactties; (6) capacitability (fundamental theorems); and (7) extremal elements of convex cones and integral representations (applications).

STUDY AND EXTENSIONS OF THE DIRICHLET PRINCIPLE, by M. Brelot. [1954] 87p. incl. refs. ([Part 1] of tts Technical note no. 2; AD 52489) [AFOSR-TN-54-357(a)] [AF 18(600)959] AD 52489(a) Unclassified

Consideration is gtven to varieties more general than Euclidean domatns; these include Riemann surfaces (S_2-spaces) and analogous varietes with dimension number $n \geq 2$, but where the conditton of the existence of a Green's function is satisfted. In such a space, the approximating spheres of Bochner and their radii are replaced by the loci of G_p = constant and their orthogonal trajectories, respectively. Certain limit or radial functions can then be defined wtthout using any boundary. The Dirichlet prtnctple is interpreted by means of the projection of the origin on the set of the precised Beppo Levt functions introduced by Deny (Acta Math., v. 82: 107-183, 1950) which have the same radial as f, where the functions f are real-valued, finite, and continuous wtth ftnite, continuous, square summable gradient. ON THE BEHAVIOR OF HARMONIC FUNCTIONS IN THE NEIGHBORHOOD OF AN IRREGULAR BOUNDARY POINT, by M. Brelot. [1954] [22]p. ([Part 4] of tts Technical note no. 2; AD 52489) [AFOSR-TN-357(d)] [AF 18(600)959] AD 52489(d) Unclasstfied

Also published in Jour. Analyse Math. (Jerusalem), v. 4: 209-22t, t955/56.

The main results are given in 2 theorems. Theorem 1: Let Q be an irregular boundary point of a bounded Euclidean domain. (More generally, it may be supposed that Ω is a Greenian domain in a ξ-space, and that Q is an irregular boundary point different from A and from a point at infinity). Let u be a bounded harmonic function on Ω in a neighborhood of Q. It is supposed that u vanishes at every regular boundary point of Ω which is close enough to Q. Then $u(M_n)/G_{P_0}(M_n)$ tends to a limit independent of the sequence $M_n \longrightarrow Q$ when this sequence is completely irregular. This limit is the quotient of the pseudo-limits at Q of u and G_{P_0}, where G_{P_0} is the Green function. Theorem 2: Let Ω and Q be as in theorem 1 and let u be any bounded harmonic function on Ω in a neighborhood of Q. Then for any maximal sequence $M_n \longrightarrow Q(M_n \varepsilon \Omega)$, $u(M_n)$ tends to the pseudo-limit λ of u at Q.

TABLES OF ALL IMPORTANT PARAMETERS CONCERNING THE BIFURCATED COMPRESSION SHOCKS IN A STEADY PLANE FLOW OF AIR, by W. Koflink. [1955] 63p. incl. diagrs. tables. [AFOSR-TR-55-24] (AF 61(514)638-C) AD 84918 Unclassified

The mathematical treatment of a bifurcated compression shock in a plane steady flow of an ideal gas with fixed quotient $\Upsilon = c_p/c_v$ of the specific heats (at constant pressure and at constant volume) leads to an algebraic equation of sixth degree in a suitable unknown variable. This equation was developed in earlier papers, (W. Koflink, Annalen der Physik, v. 9: 200, 401, 1951; v. 10: 200, 1952; W. Koflink and T. Vollmer, Zeitschrift für angewandte Mathematik und Mechanik, v. 33: 73, 1953). The algebraic equation has been solved for 374 bifurcated compression shocks in air ($\Upsilon = 1,405$), using the electronic computer G1 of the Max-Planck-Institute in Göttingen, Germany. For air, 2 regions of physically interesting solutions exist: Region I extends between the limits $1,190\ 83 \leq \omega_1 \leq 2,436\ 86$ and region II between the limits $1,672\ 33 \leq \omega_1 \leq 2,436\ 86$ of the dimensionless velocity ω_1 of the oncoming flow. (The upper limit is the maximum velocity.) An extensive table is included containing solutions for the 2 regions. (Contractor's abstract, modified)

INVESTIGATION OF THE OSCILLATING ELLIPTIC LIFTING SURFACE IN INCOMPRESSIBLE FLOW, by H. G. Kuessner. Tech. rept. Mar. 15-Dec. 15, 1955, 49p. incl. tables, refs. ([AF]OSR-TR-56-4) (AF 61-(514)819) AD 84464 Unclassified

Analytical solutions were obtained of the aerodynamics of a harmonically oscillating elliptic plate in steady, incompressible, nonviscous flow for flapping, pitching, rolling, and antisymmetric twisting. A new class of Jacobian hyperbolic functions, elliptic functions with complementary modulus, were introduced which permit a purely real representation of all coordinate transformations and potential functions with the same modulus. Lamé polynomials of the first and second kind, which appear in the doubly periodic solutions of Laplace's equation in ellipsoidal coordinates, are calculated up to the fifth order; they are represented by Weierstrassian and Jacobian functions. Additional representations are given in terms of associated Legendre functions. The characteristic functions G and H of the general lifting surface theory of Kuessner (Jour. Aeronaut. Sci., v. 21: 17-26, 1954 and v. 22: 227-230, 1955) were constructed. Two complex functions T_1 and T_2 occur in this theory which depend on integrals over the characteristic functions G and H but which are independent of the coordinates. Three methods of computing T_1 are given: 2 of these depend on the representation of Lamé polynomials of the second kind by associated Legendre functions of the second kind. (ASTIA abstract)

RESEARCH ON THE OSCILLATING ELLIPTIC LIFTING SURFACE IN COMPRESSIBLE FLOW, by H. G. Kuessner. Annual rept. no. 1. Nov. 1, 1956-Oct. 31, 1957, 47p. incl. tables, refs. (AF 61(514)1081)
Unclassified

A survey of the ellipsoidal wave functions was made. The special cases of these functions represented by known auxiliary functions and mathematical tables are given in a form suitable for the Green function of the elliptic lifting surface. For the general case methods of representation by differential equations and by integral equations are discussed. Starting from the general equations of the lifting surface theory the integral representation of the pressure of the oscillating elliptic lifting surface by a given downwash on it was developed and proved. A method for the calculation of the weight functions of the singular part of pressure by an integral equation is given. According to this method the special cases of infinite aspect ratio and of the circular lifting surface were treated. Numerical values of the weight functions and of the aerodynamic derivatives were calculated for a bilinear downwash distribution and for steady flow. (Contractor's abstract, modified)

HYDROGEN PEROXIDE: THE LOW TEMPERATURE HEAT CAPACITY OF THE SOLID AND THE THIRD LAW ENTROPY, by P. A. Giguère, I. D. Liu and others. [1954] [12]p. incl. diagrs. tables, refs. [AF 18(600)492] Unclassified

<u>Published in</u> Canad. Jour. Chem., v. 32: 117-128, Feb. 1954.

The heat capactty of crystalltne hydrogen peroxide between 12°K and the melting point has been determtned wtth a low temperature adiabatic calorimeter. The heat of fuston was also measured and found to be 2987 ± 3 cal/mole. The two samples of hydrogen peroxide used were 99.97 mote % pure as deduced from behavtor on melting and from premelting heat capacitles; the triple potnt was estimated to be 272.74°K. The only anomaly observed in the heat capactty measurements was the absorption of 1.3 cal/mole at 216.8 ± 0.15°K, the lower eutectic temperature of H_2O-H_2O_2 solutions. Such an effect is to be expected if the only stgntfttcant tmpurity ts water. The entropy of hydrogen peroxide as an ideal gas at 1 atm pressure and 25°C computed from the thermal measurements is 55.76 ± 0.12 cal/mole deg. Comparison of this datum wtth the recalculated statistical entropy leads to a value of 3.5 kcal/mole for the height of a hypothettcal stngle barrter hindertng internal rotation tn the molecule. From these results it ts concluded that hydrogen peroxide does not constst of two tautomeric modiftcations. (Contractor's abstract)

<u>Published in</u> Jour. Phys. et Radtum (Paris), v. 15: 508-510, June 1954.

During the preparation of peroxtde from etther D_2O or H_2O vapor dtssoctated tn an electrodeless discharge, a glassy depostt varying tn color from ltght yellow to dark brown is formed in a ltquid-air trap. This material was studted spectroscoptcally. Besides the well-known bands of tce and solid peroxtde, a few others were observed, particularly a strong, sharp one at 1305 cm^{-1}. This was first attributed to an isomertc molecule, H_2O-O. Further studies indicated that the molecule should have the O-O vibration at approximately 880 cm^{-1}, the same regton as in the normal H_2O_2 molecule. It does not appear possible to establish the presence of an isomer of H_2O_2 on the basis of the avattable spectroscoptc evidence. (C.A., 1957:5554a)

Also published in Jour. Amer. Chem. Soc., v. 77: 6477-6479, Dec. 20, 1955.

Recent spectroscopic and calorimetric data on H_2O_2 have been used to re-calculate the thermodynamic functions of this compound. The contribution of the internal rotation mode was estimated using the potential barrier height obtained from the third law entropy value. Similar calculations were carried out for the isotopic molecules D_2O_2 and HDO_2. Various derived thermodynamic quantities of peroxide molecules are tabulated for convenience. From these the dissociation energy D_{HO-OH} is found to be 51 kcal. (Contractor's abstract)

PRESSURE TRANSDUCERS AS RECORDING MANOMETERS IN CHEMICAL KINETICS, by P. A. Giguère and I. D. Liu. Dec. 1955 [9]p. incl. diagrs. tables. (Technical note no. 2) ([AF]OSR-TN-55-383) (AF 18(600)492) AD 83048 Unclassified

Pressure transducers of the "unbounded strain gage" type (made by Statham Laboratories, Los Angeles, Calif.) are suitable as recording manometers for studying the kinetics of gaseous reactions. Their accuracy and linearity are within ± 1% of full scale and their resolution is better than 0.1%. The output (20 to 40 mv) is sufficient to operate directly a recording potentiometer. Models are available in full-scale ranges from 2.5 mm Hg up to several atmospheres. They may be operated at temperatures from -50° to 120°C and can withstand mildly corrosive gases and vapors. Brief mention is made of certain precautions which are required when the transducers are used as absolute manometers. (Contractor's abstract, modified)

HYDROGEN PEROXIDE AND ITS ANALOGUES. VI. INFRARED SPECTRA OF H_2O_2, D_2O_2, AND HDO_2, by O. Bain and P. A. Giguère. [1955] [29]p. incl. diagrs. tables, refs. [AF 18(600)492] Unclassified

Published in Canad. Jour. Chem., v. 33: 527-545, Mar. 1955.

The absorption spectrum of hydrogen peroxide was re-examined with a prism instrument in the region 1.5 to 25 μ. A pair of well-resolved perpendicular bands arising from torsional oscillation of the OH groups were found centered about 460 and 575 cm^{-1}. The overtone band at 3.8 μ was shown to be a hybrid with prominent rotational structure and some indications of doubling. Its assignment to the combination $\nu_2 + \nu_6$ implies a positive anharmonicity. Four new overtone bands were observed in liquid hydrogen peroxide. The infrared spectrum of deuterium peroxide was measured for the first time in the solid and vapor states. The vapor bands are quite different in appearance from those of hydrogen peroxide. One of the fundamentals, the asymmetric O — D stretching at 2661 cm^{-1}, was resolved sufficiently to allow calculation of the rotational constants of the isotopic molecule. Mixtures of the two peroxides containing around 40% of HDO_2 were also investigated; from the results the frequency of the as yet unobserved symmetric modes ν_1 and ν_2 could be estimated with fair certainty. The O — O stretching vibration at 11 μ was too weak to be located definitely in the spectra of the gaseous peroxides. The structural parameters of the H_2O_2 molecule are now established as follows:

$$r_{O-O} = 1.49 \pm 0.01\text{Å}$$

$$r_{O-H} = 0.97 \pm 0.01\text{Å}$$

$$\alpha_{OOH} = 100° \pm 2°$$

The O — H and O — D stretching bands were studied in solutions of the three isotopic peroxides in carbon tetrachloride.

HYDROGEN PEROXIDE AND ITS ANALOGUES. VII. CALORIMETRIC PROPERTIES OF THE SYSTEMS H_2O-H_2O_2 AND D_2O-D_2O_2, by P. A. Giguère, B. G. Morissette and others. [1955] [17]p. incl. diagrs. tables, refs. [AF 18(600)492] Unclassified

Published in Canad. Jour. Chem., v. 33: 804-820, May 1955.

The heat of mixing of hydrogen peroxide and water and the heat of vaporization of the mixtures were measured over a wide concentration range at 0°C with a Bunsen ice calorimeter and at 26.9° with a diphenyl ether calorimeter. The heat capacities of the solutions were determined between these two temperatures. Similar measurements were carried out on the corresponding deuterium compounds. The heat of decomposition of hydrogen peroxide catalyzed by colloidal platinum was also measured at 26.9° as a function of concentration. Correlation of all the results leads to the following recommended values for the thermochemical properties of the pure peroxides in the liquid state at 25°C:

	H_2O_2	D_2O_2
Heat of decomposition (kcal/mole)	23.44 ± 0.02	23.41 ± 0.02
Heat of vaporization (kcal/mole)	12.34 ± 0.03	12.51 ± 0.05
Heat of mixing (cal/mole)	819 ± 2	807 ± 2
Heat capacity (cal/deg mole)	21.35 ± 0.05	22.9 ± 0.1

A number of related functions are given for convenience

in recalculating these quantities to other temperatures. Apart from their practical value the new data are of interest in connection with molecular association and hydrogen bonds. (Contractor's abstract)

The infrared spectra (from 2 to 30μ) of thin films of H_2O and D_2O were measured at various temperatures between 20° and -180°C. A strong absorption band due to the librational mode of the water molecule has its maximum around 710 cm^{-1} in the liquid. In ice it is shifted to 800 cm^{-1} at -15°C and 850 cm^{-1} at -170°C. The corresponding D_2O bands show the normal isotope shift. Thin films of water pressed between silver chloride plates could not be crystallized even at liquid air temperature as confirmed by their spectra, which were almost identical with those of the liquid. A 27°C ISOTHERMAL CALORIMETER, by P. A. Giguère, B. G. Morissette, and A. W. Olmos. [1955] [8]p. incl. diagr. tables, refs. [AF 18(600)492] Unclassified

Published in Canad. Jour. Chem., v. 33: 657-664, Apr. 1955.

The need for a Bunsen-type isothermal calorimeter operating as close as possible to the standard thermochemical reference temperature, 25°C, was fulfilled by means of diphenyl ether (mp 26.9°C) as the working substance. The instrument was calibrated electrically by comparison with the ice calorimeter and the constant was found to be 19.01 ± 0.02 cal/gm of mercury. From this and other known properties of diphenyl ether the density of the solid at the melting point was estimated at 1.188 gm/ml. Check determinations based on the heat of vaporization of water showed ether must first be melted inside by an amount equivalent to the heat to be measured. The calorimeter was operated in a large water-thermostat kept constant to within 0.001°C. With highly purified diphenyl ether there was no noticeable temperature drift during the measurements. Quantities of heat up to 600 cal could be measured with a reproductibility of the order of 0.2%. The new calorimeter is simpler to operate than the ice calorimeter and its sensitivity is more than three times as great. (Contractor's abstract)

KINETICS OF THE THERMAL DECOMPOSITION OF HYDROGEN PEROXIDE VAPOR, by P. A. Giguère and I. D. Liu. July 25, 1956 [27]p. incl. diagrs. tables, refs. (AFOSR-TN-56-397) (AF I8(600)492) AD 96055 Unclassified

Also published in Canad. Jour. Chem., v. 35: 283-293, Apr. 1957.

The kinetics of the thermal decomposition of H_2O_2 vapor were studied by the static method at low pressures (0.2 to 20 mm Hg) over the temperature range 300°-600°C and in specially treated glass vessels. In all cases the reaction was of the first order with respect to time and the final products were H_2O and O_2. Around 400°C the character of the reaction changed gradually from heterogeneous (surface effects, low activation energy) to homogeneous (reproducible rates in various vessels). With initial pressures of about 10 mm Hg the experimental rates from 400° to 500° lead to an apparent activation energy of 43 kcal and a frequency factor of about $10^{10.7}$. After correction for the residual surface decomposition and extrapolation of the rate constants to the high pressure limit k_∞ the rate equation becomes $k = 10^{13} \exp(-48,000/RT) sec^{-1}$ in good agreement with the most recent value for the O-O bond dissociation energy and with the theory of unimolecular reactions. Packing the reaction vessel with glass rods and adding various gases (including NO and propylene) produced no appreciable effect on the gas-phase reaction. Coatings of fused salts (boric oxide, etc.), claimed to be particularly inert, showed much greater activity than passivated glass and sometimes behaved erratically. The rate of decomposition of D_2O_2 was indistinguishable from that of H_2O_2 under comparable conditions. A mechanism is proposed for the homogeneous reaction in which chains play no significant role. (Contractor's abstract)

THE LIBRATIONAL FREQUENCY IN WATER AND ICE (Abstract), by P. A. Gtguère and K. B. Harvey. [1956] [1]p. [AF 18(600)492] Unclassified

Presented at Tenth Symposium on Molecular Structure and Spectroscopy, Columbus, Ohio, June 11-15, 1956.

The infrared spectrum of H_2O in condensed states was measured between 2 and 30μ. In the liquid a strong absorption band appears at 710 cm^{-1} due to the restrtcted rotation, or libration, of the H_2O molecule. Upon crystalltzation this band is shifted to 800 cm^{-1} at -15°C and 850 cm^{-1} at -175°C. The correspondtng frequencies in D_2O are at 530, 590 and 630 cm^{-1}. From the frequency of thts mode ν_R it is possible to dtfferenttate between supercooled water and tce. Thus it was found that, under certatn conditions, thin films of water do not crystallize even in ltquid air. The contrtbution of latttce vtbrattons to the low-temperature heat capactty of ice are discussed brtefly. (Contractor's abstract)

THE RANGE OF APPLICATION OF THE LAGRANGE FORMALISM, I, by P. Havas. Aug. 13, 1956, 26p. refs. (AFOSR-TN-56-314) (AF 18(600)1462) AD 94850 Unclassified

Also published in Nuovo Ctmento, Suppl., v. 5: 363-388, 1957.

Given a set of equations $G_i(q, \dot{q}, \ddot{q}, t) = 0$; (i = 1, 2, . . . , n), Helmholtz and others have estabtished the necessary and sufftctent conditions for the existence of a function $L(q, \dot{q}, t)$ such that $G_t = \mathscr{L}[L]$, where $\mathscr{L}[\ ]$ stands for the Lagrangian operator. The author extends the range of applicability of the Lagrange formalism to a set of equations $G_i^{\beta} = \ddot{q}_i + g_i(q, \dot{q}, t)$, and presents the conditions for the existence of "integrating factors" $f_i(q, \dot{q}, t)$ and functions $L^{\beta}(q, \dot{q}, t)$ satisfying $f_i G_i^{\beta} = \mathscr{L}[L^{\beta}]$. Five illustrative examples are treated. (Math. Rev. abstract)

GENERALIZED LAGRANGE FORMALISM AND QUANTIZATION RULES (Abstract), by P. Havas. [1956] [1]p. [AF 18(600)1462] Unclasstfted

Presented at meettng of the Amer. Phys. Soc., Chtcago, Ill., Nov. 23-24, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 337-338, Nov. 23, 1956.

It was shown recently that even if a set of equations $G_t = 0$ ts not derivable from a variational principle, there mtght exist an equivalent set $f_t G_t = 0$, obtainable with the hetp of "integrating factors" f_t, which ts so dertvable. The general probtem of equivatent sets has been tnvestigated. It has been found that for any set $G_t = \ddot{q}_t + g_t(q, t) = 0$ there always exist equivatent systems $\sum f_{ik}(q, t)G_k = 0$ whtch are the Euler-Lagrange

equations of a variational principle. As any system of differential equations is equivalent to a system of first-order equations, this implies that any system of nth order ordinary differential equations which may be solved algebraically for the nth order derivatives is derivable from a Lagrangian. In particular this is the case for Newton's equations of motion with arbitrary velocity-dependent forces. For a given set of equations many different Lagranglans exist; quantization by any of the presently available rules (often thought to be as general as the classical formalisms of Lagrange or Hamilton) is either impossible or ambiguous. Some implications are discussed. (Contractor's abstract)

ON PRESSURE AND PONDEROMOTIVE FORCE IN A DIELECTRIC. STATISTICAL MECHANICS OF MATTER IN AN ELECTROMAGNETIC FIELD II, by P. Mazur and S. R. de Groot. [1956] [13]p. [AF 61(514)846]
Unclassified

Published in Physica, v. 22: 657-669, Aug. 1956.

A statistical mechanical derivation of the expressions for both pressure and ponderomotive force in a dielectric is given in terms of averages over microscopic quantities. The existence of microscopic long-range interactions leads to the possibility of defining pressure and ponderomotive force in different ways. A natural way is indicated of dividing the average of the microscopic force into long and short range contributions, which yields the form of the ponderomotive force proposed by Kelvin. It is also shown that, in stattstical equilibrium, one may obtain Helmholtz's expression for the ponderomotive force. In the two cases pressure must be defined differently. The relation between these pressures is as predicted by thermodynamic theory. (Contractor's abstract)

ON THE THEORY OF THE REFRACTIVE INDEX OF NON-POLAR GASES. I. QUANTUM MECHANICAL PART, by P. Mazur and M. Mandel. [1956] [10]p. [AF 61(514)846]
Unclassified

Published in Physica, v. 22: 289-298, Apr. 1956.

A quantum mechanical calculation is given for the effect of molecular interactions on the polarizability of spherical non-polar molecules in a periodic external electric field. The polarizability tensor is obtained from perturbation theory as a power series in the interaction tensor $T_{ik} = \nabla_i \nabla_k (1/v_{ik})$, where v_{ik} is the distance between two molecules i and k. It is found that the constants C_1 and C_2, introduced by Jansen and Mazur in the static case, and characterizing the influence of molecular interactions on the polarizability, in order T^2, become now frequency dependent. This frequency dependence is explicitly evaluated for helium at frequencies of the incident wave small compared to the frequencies of the softest absorption line. (Contractor's abstract)

ON THE THEORY OF THE REFRACTIVE INDEX OF NON-POLAR GASES. II. STATISTICAL PART, by P. Mazur and M. Mandel. [1956] [12]p. incl. diagrs. table, refs. [AF 61(514)846]
Unclassified

Published in Physica, v. 22: 299-310, Apr. 1956.

A calculation is presented of the Lorentz-Lorenz function for gases of non-polar molecules at moderate densities. Taking into account the influence of molecular interaction upon the polarizability, the results obtained constitute an extension of Yvon's theory of the index of refraction. It was found that for frequencies small compared to frequency of the softest absorption line, the increase of the Lorentz-Lorenz function with density is about twice as important as predicted in the basis of Yvon's theory with constant polarizability. The relative importance of the new effect, however, slightly decreases with increasing frequency in the frequency range considered. The total frequency dependance of the Lorentz-Lorenz function could not have been foreseen from the corresponding Clausius-Mosotti expression simply by replacing the polarizability $\alpha_0(0)$ by $\alpha_0(\omega)$. It was found that for frequencies such as $\omega^2/\omega_0^2 = 0, 1$, the correction to the Lorentz-Lorenz function was about 15% larger than the corresponding correction to the Clausius-Mosotti function. The present calculation may be considered as an extension of the theory given by P. Mazur and L. Jansen for the static case. (Contractor's abstract)

RADIOISOTOPE STUDY OF BONE SALT. [n.a.] [1954] 3p. (AF 61(514)647-C) Unclassified

The main constituent of bone mineral is a pseudopatite containing 10-1/2 ions of Ca/6 ions of P (Ca/P = 2.26/. This compound contains a half mole of Ca in excess of the theoretical amount in ideal hydroxyapatite (10 Ca/6 P; Ca/P = 2.14). No lattice position exists in the hydroxyapatite structure which can be occupied by the extra half mole of Ca. Several samples of bone salt (Ca/P = 2.26), freed of organic material, were treated with different quantities of HCl to produce a series of Ca/P compounds ranging down to 2.13. To determine if the extra half mole of Ca in bone apatite was chemically identical to the other 10 Ca ions in the unit cell, each member of the series was immersed separately in $CaCl_2$ solution containing Ca^{45} until equilibrium was reached; then the specific activity of each sample was measured. Results show the unireated pseudoapatite to have a greater specific activity than any of the acid-treated series. The percentage of exchange with the Ca^{45} solution was the same for each compound of the acid-treated bone salt series, as measured by the specific activity. These results indicate that the unireated bone salts contain adsorbed Ca; as the amount is quantitatively very small, a very high degree of exchange for adsorbed Ca is required to explain the observed specific activity. The acid-treated samples are stripped by the HCl of the physically-adsorbed Ca and contain only chemically-bound Ca ions. As the specific activity of all the acid-leached compounds was the same, all 10 1/2 Ca ions bound chemically in the pseudoapatite of Ca/P = 2.26 are apparently equally exchangeable with Ca^{45} when the salts are immersed in such a solution.

THE RELATION BETWEEN BONE SALTS AND CERTAIN SYNTHETIC APATITES, by M. J. Dallemagne, C. Fabry, and A. S. Posner. [1956] [2]p. [AF 61-(514)647-C] Unclassifted

Presented at joint meeting of the Physiol. Soc. with the Belgian Physiol. Soc., University Lab. of Physiol., Oxford (England), Sept. 8-10, 1954.

Published in Jour. Physiol., v. 126: 18P-19P, Nov. 29, 1954.

When any of the synthetic pseudoapatites were suspended in a solution of lime (2 meq/l), the calcium content of the solid increased and stabilized at a Ca/P ratio of 2.26. During the formation and aging of the bone mineral, calcium is also fixed from physiological solution up to the point of a Ca/P ratio of 2:26 as found in adult bone. However, in the case of synthetic phosphates, 2:26 can only be attained if they are not heated above 37°C before their suspension in lime solution. If they are previously dried at 105°C the upper limit of the Ca/P is found to be only 2:14, the theoretical value for hydroxyapatite. Finally, both the calcium concentration in the lime solution in which the synthetic materials are suspended, and the calcium concentration in the biological fluids in contact with bone are of the same order of magnitude. In pseudoapatites where defect structures existed it was possible to fill the calcium defects; it was also possible to fix stoichiometric excesses of calcium.

EXCHANGE OF BONE CALCIUM WITH Ca^{45}, by M. J. Dallemagne, C. Fabry, and P. Bodson. [1955] [2]p. incl. table. [AF 61(514)647-C] Unclassified

Published in Experientia, v. 11: 142-143, Apr. 15, 1955.

KOH-glycol ashed bone was exposed for 1 month to $Ca^{45}Cl_2$ solution and then filtered and dried; the specific activity of this preparation was 9.48×10^3. Fractions of this preparation were suspended for 10 min. After filtration and drying at 105°, Ca, P, and specific activity were ascertained for each sample. The weight loss of the samples in HCl solution increased with the increase of HCl used. As HCl concentration increased the specific activity of the liquid, very high for small amounts of HCl, decreased. However, the specific activity was always higher in the liquid than in the corresponding residual solid phase. For each experiment the liquid always contained more Ca than required for 9 Ca/6 P (Ca/P = 1.94). This excess represents the additional Ca ion content of bone structure. On the other hand, the Ca/P weight ratio in the solid phase decreased slowly to 1.98. The ratio, counts/min/excess Ca, had a constant value of about 62. It is concluded that the Ca^{45} exchanged by bone mineral is exclusively the excess 1¼ moles of Ca of the saturated pseudoapatite. (C.A., 1955:11036f)

IONIC EXCHANGE OF CALCIUM AND RECRYSTALLIZATION OF THE MINERAL SUBSTANCE OF BONE, by M. J. Dallemagne, C. Fabry, and P. Bodson. [1955] [3]p. [AF 61(514)647-C] Unclassified

Published in Jour. Physiol. (Paris), v. 47: 153-155, 1955.

Bone salt, prepared by the method of Gabriel, was equilibrated with a radioactive Ca solution containing 6.2 mg $CaCl_2$/ml. Samples of this labeled bone salt were subsequently treated with 0.4-12.5 meq of HCl/g. The excess Ca (the Ca present in excess of the Ca/P ratio in $Ca_3(PO_4)_2$) was shown to be the most easily exchangeable. Bone salt was equilibrated with a radioactive Ca solution containing 18.3 mg $CaCl_2$/ml and then treated with successive extractions with HCl (0.2 meq/g). In this case the radioactive Ca was found in both exchangeable and lattice Ca, indicating that recrystallization had taken place in addition to exchange. Uptake of radioactive Ca occurred only if the solution caused a hydrolysis followed by recrystallization. Thus, 2 processes are responsible for the uptake of Ca by bone salt in vitro: (1) true exchange, which is concerned only with the excess Ca and not with the lattice Ca, and (2) recrystallization which occurs only to the degree that the Ca phosphate is attacked by the liquid phase. STUDIES ON THE MINERAL FRACTION OF BONE, by M. J. Dallemagne, C. Fabry and others. Technical rept. June 1, 1955-May 31, 1956. 1v. incl. diagrs. tables, refs. (AFOSR-TN-56-258) (AF 61(514)858) AD 88978 Unclassified

The stoichiometric relations between PO_4, Ca, and CO_3 were studied to determine whether CO_3 can be substituted by PO_4 groups. The influence of the organic material of bone on the Ca exchange reaction and the structure of fundamental phosphate molecule of bone and teeth were also studied. Two exchange processes without chemical interactions between the solid and liquid phases occurred when a phosphate with a Ca/P ratio close to 2.14 is involved. The exchange reaction can be decomposed by (1) two steps which correspond to surface exchange and which are reversible and depend on the particles surface; and (2) a third step which corresponds to isotonic exchange in the bulk of the solid, which is probably also reversible, but this is followed by irreversible modifications (recrystallization) of the solid. Recrystallization increased with time and the $CaCl_2$ concentration of the liquid phase, but it was largely influenced by temperature. Chemical interactions appeared for phosphates with a Ca/P ratio higher than 2.14. The exchange percentage seemed to be proportional to the Ca/P ratio. Exchange between Ca^{45} and tricalctum phosphate with the Ca/P ratio of 1.94 was greatly affected by chemical interactions, and always followed by recrystallization of the solid. (ASTIA abstract, modified)

VAPOR PRESSURE OF PLASTIC MATERIALS, by [A. Teets]. Technical paper [1956] [11]p. incl. diagrs. table. (AF 18(600)1498) Unclassified

Published in Jour. Appl. Phys., v. 27: 1460-1466, Dec. 1956.

This research was undertaken for the purpose of evaluating a group of flexible polymeric materials with a view to using these materials in vacuum systems operated in the 10^{-6} mm Hg range. Several methods for determining absolute vapor pressures were investigated but none proved to be too successful, consequently, it was decided that the equivalent nitrogen pressure of a permanent gas or vapor is a better indication of its behavior than absolute pressure, especially since the vast majority of high vacuum pressure measurements are already equivalent nitrogen measurements in the sense that they are made with a ionization gauge. The following polymers were evaluated: (1) polyethylene, (2) butyl rubber, (3) hycar rubber, (4) mylar, (5) saran, (6) vinyl, (7) nylon cloth, and (8) teflon.

THE CONSERVATION EQUATIONS FOR INDEPENDENT COEXISTENT CONTINUA AND FOR MULTICOMPONENT REACTING GAS MIXTURES, by W. Nachbar, F. Williams, and S. S. Penner. Mar. 15, 1957, 30p. (Rept. no. LMSD-2082) (AFOSR-TN-56-458) (AF 18-(603)146) AD 97074 Unclassified

The equations for conservation of mass, momentum, and energy are derived for a set of independent, coexistent continua obeying the laws of dynamics and thermodynamics. The idea of a control volume and a control surface for each continuum is used in the analysis. The derived results are practically identical with relations obtained previously by Th. von Kármán (Quoted in Penner, Introduction to the Study of Chemical Reactions in Flow Systems, Chapt. 2, 1955). A direct comparison is conducted between the continuum theory results and those obtained from kinetic theory by assuming that, for each of the species, the kinetic theory definitions apply. It is found that the new terms appearing in the conservation equations derived from continuum theory are precisely those which are required to make these equations identical with the results obtained from the kinetic theory of multicomponent, reacting gas mixtures. However, the continuum theory forms of the equations are not useful because they require knowledge of the transport properties for individual species in the mixture. (Contractor's abstract)

ADMISSIBILITY OF SEMIGROUP STRUCTURES ON CONTINUA, by R. J. Koch and A. D. Wallace. [1956] 18p. refs. [AFOSR-TN-56-590] (AF 18(603)89) AD 115017 Unclassifted

The structure of certain compact connected semigroups S which satisfy $S^2 = S$ are studied. Instances are shown where the multiplication must be continuous and associative in S. Dense connected sets are considered, as in the following S being a Hausdorff topological semigroup and continuum, $S^2 = S$ if and only if each dense ideal is connected. It is shown that if S is irreducible between its minimal ideal K and some other set and if $S^2 = S$ then S must have a unit, S is commutative, and S/K (in the metric case) is an arc. Maximal ideals are proved to be composants. Examples are given in some detail.

COMPARATIVE STUDY OF C_2H_2/O_2 AND C_2H_2/N_2O FLAME SPECTRA, by A. Van Tiggelen, J. Vaerman, and G. Nenquin. [1956] [16]p. incl. illus. diagrs. tables. [AFOSR-TN-56-83] (Bound with its AFOSR-TR-57-27; AD 126445) [AF 61(514)814] Unclassified

Also published in Bull. Soc. Chim. Belg., v. 65: 435-452, May-June 1956.

A study has been made of the effect of the luminous-zone thickness of a flame on the intensity of spectral bands. It is shown that the measured intensity varies proportionally with the thickness for radicals which do not emit in the exterior mantle of the flame. The emission intensity of the OH, CH, and C_2 radicals have been measured for a series of mixtures of C_2H_2/N_2O and C_2H_2/O_2 with variable supporter of combustion/combustible ratios and increasing dilution by N_2. In addition, measurements have been made in C_2H_2/N_2O flames for the emisston of CN and NH. Application of a kinetic relation permits the determination of an activation energy for the chain-branching process. A good agreement is found, for certain radicals only, with the energies of activation being deduced from the propagation of flames in the same mixtures.

THE INFLUENCE OF HYDROGEN ON CARBON MONOXIDE-OXYGEN FLAMES, by A. Van Tiggelen and P. J. Slootmaekers. [1956] [9]p. incl. diagrs. table. [AFOSR-TN-56-84] (Bound with its AFOSR-TR-57-27; AD 126445) [AF 61(514)814] AD 81539 Unclassified

Also published in Bull. Soc. Chim. Belg., v. 65: 425-434, May-June 1956.

The velocity of propagation of a flame in a mixture of CO and O_2 increases very rapidly when CO is progressively replaced by H_2. By the systematic study of this reaction, using a series of fixed H_2/CO ratio mixtures diluted increasingly with N_2, it is indicated that the reaction of chain branching in pure CO is replaced in the presence of H_2 by one which is valid for pure H_2. The data show that the apparent activation energy of the branching varies from 22 kcal (pure CO) to 18 kcal (pure H_2), and the apparent order of the branching reaction goes from 2 to 3.

Also published in Bull. Soc. Chim. Belg., v. 64: 780-797, 1955.

In this study, the burning velocity, flame temperature, and the distance between the striated and luminous cones were determined for constant ratios of C_2H_2,

H_2, NH_3, or CO and N_2O, increasingly diluted with N_2. The activation energies are all higher with N_2O than with O_2, but the same mechanism is indicated. The relationship between flame velocity, mean flame temperature, and the distance between cones using O_2 holds for N_2O.

AN ATOMIC MASS STUDY OF NUCLEAR SHELL STRUCTURE IN THE REGION $28 \leqslant n \leqslant 50$ AND $28 \leqslant Z \leqslant 40$, by B. G. Hogg and H. E. Duckworth. Nov. 5, 1953 [12]p. incl. diagrs. tables, refs. (Technical rept. no. 1) (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)-484, National Research Council of Canada, and Research Council of Ontario (Canada)) AD 60218 Unclassified

Also published in Canad. Jour. Phys., v. 31: 942-953, Sept. 1953.

New mass spectrographic masses are reported for some of the isotopes of gallium, germanium, arsenic, and selenium. These results are combined with previously reported mass data in order to study atomic mass trends in the region $28 \leqslant n \leqslant 50$ and $28 \leqslant Z \leqslant 40$. The only pronounced mass effects which occur in this region are those associated with 28 and 50 nucleons. No extra stability has been found which can be associated with the filling of the $f_{5/2}$, $p_{3/2}$, and $p_{1/2}$ subshells. A list of mass values used in this study is included. ATOMIC MASSES OF Ru^{98}, Ru^{99}, Os^{189} AND Os^{192}, by E. M. Pennington and H. E. Duckworth. Feb. 24,

1955 [1]p. incl. table. (Technical rept. no. 5) ([AF]OSR-TN-54-354) (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)-484, National Research Council of Canada, and Research Council of Ontario (Canada)) AD 60216 Unclassified

Also published in Canad. Jour. Phys., v. 32: 808, Dec. 1954.

Accurate physical masses are known for 17 of the 22 monoisotopic elements. A graph is presented in which the mass numbers of the even-even isotopes of the even-Z elements are plotted against the mass defects (mass defect, difference between atomic mass of a nuclide and its mass number). The tangent to the curves formed by these isotopes is a comparatively smooth line. By interpolating the 5 not accurately known monoisotopic elements (Cs^{133}, Tb^{159}, Tm^{169}, Ta^{181}, and Au^{197}), reliable estimates of their masses can be obtained. A table shows the determined and estimated isotopic, and physical and chemical atomic, weights of the 22 monoisotopic elements.

RELIABILITY OF ATOMIC MASSES IN THE CHROMIUM-GERMANIUM REGION, by J. T. Kerr, J. G. V. Taylor, and H. E. Duckworth. Mar 6, 1956 [3]p. (AFOSR-TN-56-72) (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)-484]. National Research Council of Canada, and Ontario Research Foundation (Canada)) AD 81524 Unclassified

Also published in Nature, v. 176: 458, Sept. 3, 1955.

In this study, attention is focussed on mass difference discrepancies in the Cr-Ge region. In the hope of discovering some systematic discrepancy between mass spectroscopic and transmutation data, calculations have been made of 30 mass differences in this region, using both sources of data. These calculations show that between stable nuclides of the same element, e.g., Fe^{57}-Fe^{56}, the transmutation- and mass-spectrographic differences are quite consistent. The only major inconsistency is in the case of the Zn^{67}-Zn^{66} difference. The situation is quite different, and much less satisfactory in the case involving stable nuclides of different elements, e.g., Fe^{54}-Cr^{53}. Only 4 of the 16 calculated differences agree within the stated probable-error limits. In 5 cases involving Ni, i.e., Ni^{58}-Fe^{57}, Ni^{60}-Fe^{57}, Cu^{63}-Ni^{62}, Ni^{64}-Cu^{63}, and Cu^{65}-Ni^{64}, the agreement is very poor, indicating that the masses of Ni determined mass spectroscopically are too low by $\sim 60 \times 10^{-5}$ amu. Therefore, it is hypothesized that the Ni masses are in error. It is concluded that the atomic mass values for the other elements in the Cr-Ge region may be used with reasonable confidence.

A LARGE SEMI-CIRCULAR MASS SPECTROMETER FOR ATOMIC MASS DETERMINATIONS (Abstract), by H. E. Duckworth, J. T. Kerr, and G. R. Bainbridge. July 1956, 1p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)484, National Research Council of Canada, and Ontario Research Foundation (Canada)) Unclassified

Presented at Symposium on the Precision Determination of Nuclear Masses, Mainz (Germany), July 9-14, 1956.

A new large double focusing mass spectrometer, consisting of a semi-circular magnetic analyzer followed by a $\pi/2$ electrostatic analyzer has been constructed. This was constructed in two steps: (1) the magnetic analyzer and, (2) the electrostatic analyzer. The magnetic analyzer (radius of curvature = 2.74 meters) alone has a mass resolution of approximately 1/10000 at the base of the peaks, and was used to obtain mass information for some of the elements which can be obtained in gaseous form. The field of the magnetic analyzer is both stabilized and swept by a proton moment mechanism. The position of each mass spectral peak is given by the frequency of the proton signal and the doublet spacing, consequently, is obtained in terms of a frequency difference. The present performance and method of operating the instrument will be discussed, and some remarks will be made concerning future plans. (Contractor's abstract)

SOME RECENT MASS DETERMINATIONS AT McMASTER UNIVERSITY (Abstract), by H. E. Duckworth, G. R. Bainbridge and others. July 1956, 1p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)484, National Research Council of Canada, and Shell Oil Co. of Canada) Unclassified

Presented at Symposium on the Precision Determination of Nuclear Masses, Mainz (Germany), July 9-14, 1956.

The mass differences C_3H_6O-Ni^{58} = 106.52 ± 15 mmu and $C_2H_4O_2$-Ni^{60} = 90.82 ± 15 mmu was determined. The agreement between this and other work was discussed, as well as the agreement between transmutation- and mass spectroscopically-derived mass differences in the Fe-Ni-Zn section of the atomic mass table. An attempt was made to ascertain if the 1/2 Xe^{132}-Zn^{66} and C_3H_6O-Ni^{58} doublet spacings were sensitive to the residual gas pressure in the mass spectrograph. In the former case there appeared to be no pressure dependence in the pressure range 3.5 - 30 x 10^{-6} mm Hg. In the latter case the doublet spacing appeared to decrease with increasing residual gas pressure. In this work ions of 15,000 volts energy were employed in a Dempster-type double focusing mass spectrograph, approximately 2.3 times larger than that employed by Dempster and Sha., who first reported this pressure effect. STANDARDS OF ATOMIC MASS FOR A > 30 (Abstract), by H. E. Duckworth. July 1956, 1p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)484 and National Research Council of Canada) Unclassified

Presented at Symposium on the Precision Determination of Nuclear Masses, Mainz (Germany), July 9-14, 1956.

The question was discussed of designating certain of the heavier atoms as secondary standards of atomic mass. It was hoped that atoms so designated would receive out-of-the-ordinary attention by persons engaged in mass spectroscopic mass determinations, with the result that a series of appropriately-spaced, accurately-known atomic masses would extend through the entire atomic mass table. These secondary standards would be highly useful as points of departure for calculations employing transmutation data. Some of the factors which should govern the choice of standards was discussed and a proposed list of such standards was presented.

REFLECTION OF A PLANE WAVE BY A STRATIFIED MEDIUM, by A. F. Kay. Nov. 22, 1954, 39p. incl. diagrs. refs. (Document no. 1294) ([AF]OSR-TN-54-348) (AF 18(600)1044) AD 51019 Declassified

The reflections R of a plane wave by a stratified medium (one whose electromagnetic parameters depend only on the x-coordinate) satisfy Ricatti-type equations. A comparison of treatments of this subject by several authors leads naturally to more-or-less new physical models of reflection, which in turn suggest expansions of the exact reflection coefficients suitable for computation and useful for further theoretical study. Examples having both physical importance and mathematical simplicity are worked out and serve as a check on the approximations. In Part II, a medium with continuously varying parameters is regarded as limit of a pile of uniform sheets. Considering multiple reflection in such a pile gives rise to the notion of n-th order reflection. A proof is sketched that under certain general conditions R_n has a unique limit as the pile approximates a uniform medium and thus lt_n can be defined precisely even for continuous variation. A formula for R_o and a recursion formula for R_n permits numerical computation. It is shown that lim R_n satisfies the appropriate Ricatti equation, and lim R_n equals the true reflection. Thus is obtained, in principle, a means for approximating the reflection in this most general case. The work is guided by constant reference to the physical model; it leads to new results in the theory of Ricatti equations, which appear difficult to discover by mathematical means alone. (Contractor's abstract)

SOME MATHEMATICAL ASPECTS OF ABSORBER DESIGN, by R. B. Barrar. Nov. 22, 1954, 20p. incl. diagrs. (Document no. 1295) ([AF]OSR-TN-54-349) (AF 18(600)1044) AD 51020 Declassified

Maxwell's equations for a medium whose electromagnetic constants vary only in the x-direction, are shown to reduce to the form of the equations for a non-uniform transmission line. In this way standard methods of transmission line theory are applied to absorber design. For certain cases explicit solutions are given for the reflection from an absorber with a continuously varying dielectric constant ε. (Contractor's abstract)

SOME ABSORBING PANELS WITH VARIABLE DIELECTRIC COMPOSITION, by J. H. Sampson. Dec. 20, 1954, 52p. incl. diagrs. tables. (Document no. 1299) ([AF]OSR-TN-[55]-11) (AF 18(600)1044) AD 57113 Declassified

Results of computations of the complex reflection coefficient for several types of panels are discussed with respect to the design of thin broadbanded absorbers. The panels are backed by metal and have electrical characteristics which, with a suitable choice of rectangular coordinates x, y, and z, depend only on x, the distance from the metallic backing to an arbitrary point (x, y, z) in the panel. The reflection coefficient R is determined by the Riccati-type equation

$$\frac{dR}{dx} = \frac{\pi i\sqrt{\varepsilon - p}}{\lambda}\left[(R+1)^2 a - (R-1)^2 \frac{1}{a}\right]$$ with the

coefficients depending on the polarization of the incident wave, its angle of incidence θ and wavelength λ, and the dielectric constant $\varepsilon = \varepsilon(x)$ of the panel. Values of $|R|^2$ were obtained by high-speed digital computation for several panels. By considering $\varepsilon(x) = u(x) + i.v(x)$, 32 panels are described in the interval $0 \leq x \leq 1/2$ with the initial value $R = 1$ at $x = 0$. Data from the following functions appear promising: (1) $u = 20^{1-2x}$; (2) $u = 50^{1-2x}$; (3) $u = -6272\,x^3 + 4704\,x^2 - 882\,x + 50$; (4) $u = -2432\,x^3 + 1824\,x^2 - 342\,x + 20$; and (5) $\varepsilon(x) = \left[(E-1F)/(E^2 + F^2)\right]^{1/2}$ where E and F are defined in terms of x; the function appeared particularly promising. [THE MATHEMATICAL TREATMENT OF DIELECTRIC ABSORBING PANELS], by J. H. Sampson. Summary

MML. 01:005 - MML. 01:006

repl. Dec. 20, 1954, 16p. (Document no. 1301) ([AF]OSR-TN-55-12) (AF 18(600)1044) AD 57112 Declassified

The mathematical treatment of dielectric absorbing panels is summarized. The somewhat idealized case is considered of an infinite panel bounded by 2 parallel planes and with local electromagnetic properties depending only on the distance from one face. Summaries are presented of: (1) a report which considers propagation of waves in dielectric media as a one-dimensional phenomenon and expressible in terms of familiar parameters of transmission-line theory; (2) an analysis of approximate values of the reflection coefficients R_R and R_S with the term R^2 omitted from the relevant differential equation; and (3) reports which consider minimization of the expression

$$\int_{\lambda_1}^{\lambda_2}\int_{p_1}^{p_2} |R_\perp|^2 \, dp\, d\lambda + \int_{\lambda_1}^{\lambda_2}\int_{p_1}^{p_2} |R_\parallel|^2 \, dp\, d\lambda$$

by suitable choice of the dielectric constant $\epsilon(x)$, where $p = \sin^2\theta$, θ = angle of incidence, and the subscripts $\perp$ and $\parallel$ refer to the polarization. Sources of difficulty in applying the differential equation to the design of non-reflecting panels are reviewed. The minimum problem appears unsolvable. The reflection coefficients for 32 given functions of $\epsilon(x)$ which were evaluated by high-speed digital computation indicate the probability of attaining design criteria for effective thin absorbers. (ASTIA abstract)

A MODIFIED TREATMENT OF SOME REFLECTION PROBLEMS, by J. H. Sampson. Dec. 31, 1954, 16p. (Document no. 1302) ([AF]OSR-TN-55-40) (AF 18(600)-1044) AD 57064 Declassified

Analyses previously presented (see item no. MML. 01:006) are expanded with respect to the application of the differential equation governing the reflection coefficient R of a dielectric panel to the design of panels leaving low reflection over a band of wavelengths λ and incidence angles. Solution of the minimum problem

$$\int_{\lambda_1}^{\lambda_2}\int_{p_1}^{p_2} \bar{R}_n \frac{\partial R_n}{\partial \epsilon_j} \, dp\, d\lambda = 0$$

for a piecewise constant is not near solution with respect to explicit calculation; computation of the minimizing values of $\epsilon_1 \cdots \epsilon_n$ for the integral

$$J(\epsilon_1, \bar{\epsilon}_1 \cdots \epsilon_n, \bar{\epsilon}_n) = \int_{\lambda_1}^{\lambda_2}\int_{p_1}^{p_2} |R_n|^2 \, dp\, d\lambda$$

may be completely beyond the capabilities of any computing machine likely to be developed in the near future. Two approaches are considered to the design of low-reflection panels. One considers the use of a finite difference equation; a stepwise procedure is described which yields a succession of ordinary minimum problems for the function of one (complex) variable. The number of layers does not materially affect the type of calculation.

ON THE REFLECTION COEFFICIENT OF NON-HOMOGENEOUS MEDIA, by J. H. Sampson. Dec. 31, 1954, 16p. incl. diagrs. (Document no. 1303) ([AF]OSR-TN-55-46) (AF 18(600)1044) AD 57063 Declassified

The problem of suppression of reflection is considered for dielectric panels whose complex dielectric constant ϵ depends only on the distance x from one face. The complex reflection coefficient R of the panel is determined from the first-order differential equation

$$\frac{dR}{dx} = \frac{2\pi i v}{\lambda}\left[(R+1)^2 a - (R-1)^2 \frac{1}{a}\right],$$

where $v = \sqrt{\epsilon - p}$, $p = \sin^2\theta$, $a = \epsilon\sqrt{1-p}/v$ for parallel polarization and $a = v/\sqrt{1-p}$ for perpendicular polarization for $0 \le x \le 1$, $0 \le p \le 1$, $0 \le \lambda \le \infty$, λ = the wavelength of the incident wave, and θ = its angle of incidence. Minimization of the reflection for an entire band through an appropriate choice of dielectric constant is formulated as minimization of an integral of the form $\int_{\lambda_1}^{\lambda_2} d\lambda \int_{p_1}^{p_2} |R|^2 \, dp$. The function $\epsilon(x)$ is subjected to physically realizable values which is expressed by inequalities of the form $0 < \arg \epsilon \le \chi$, $\rho_1 \le |\epsilon| \le \rho_2$. For constant ϵ, the equation is explicitly solvable, and it is also explicitly solvable for a piecewise constant $\epsilon(x)$. To obtain satisfactory accuracy in applying the method, at least second-order, and probably higher order, terms of the power-series expansions must be retained. With restriction of ϵ to piecewise constant functions, minimization of J presents no theoretical difficulties and permits resolution of the mathematical problem.

THREE-DIMENSIONAL FLOW THROUGH AN AXIAL COMPRESSOR, by J. Valensi. July 30, 1955, 1v. incl. illus. diagrs. tables. (Technical rept. no. 1) (AFOSR-TN-56-134) (AF 61(514)425) AD 86010 Unclassified

A 0.50-m tip-diameter axial flow compressor stage was designed and operated at low speed (2460 rpm) to study individual blade row performance and secondary flow effects. The stage consisted of 30 inlet guide vanes, 31 rotor blades, and 34 stator blades with sections for the 3 rows computed theoretically. This stage had a hub-to-tip diameter ratio of 0.5, and was designed, with the assumption of perfect fluid and simple radial equilibrium, to give a total pressure-rise coefficient of 0.63 at a flow ratio of 0.48. The design allowed sufficient space between the rows for the instrumentation required in making a detailed analysis of blade-row flow distribution; the casing was made of transparent perspex in order to permit visual observations by smoke. The following studies were made: (1) description of the flow by the use of conventional type of instrumentation (pressure probes); (2) determination of individual blade-sections performance and over-all performance; (3) adaptation of the smoke method for visualizing the flow through the compressor; and (4) determination of the general features of the flow. Observations were made at 3 different values of the flow coefficient corresponding, respectively, to design, maximum pressure rise coefficient, and high rate of flow. Secondary flow effects were thoroughly analyzed and discussed. (Contractor's abstract)

THREE DIMENSIONAL FLOW THROUGH AN AXIAL COMPRESSOR, VOLS. I AND II, by J. Valensi. (Final rept.) July 1956, 2v. incl. illus. diagrs. tables, refs. (AFOSR-TR-56-30) (AF 61(514)425) AD 95820 Unclassified

A 0.50-m tip diameter axial flow compressor stage was designed and built. It was operated at low speed (2460 rpm) on a test bed especially designed and built in order to investigate individual blade row performances and secondary flow effects. Investigation included: (1) description of the flow by the use of pressure probes; (2) determination of velocity diagrams and of overall compressor performances at design and at off design flow rates; and (3) investigation of rotating stall. Secondary flow effects are analyzed and discussed, and recommendations are given for the improvement of the design. (Contractor's abstract, modified)

THE TOPOLOGY OF ALMOST UNIFORM CONVERGENCE, by J. W. Brace. Dec. 1956, 28p. refs. (AFOSR-TN-56-595) (AF 18(603)78) AD 115022 Unclassified

Also published in Portugal. Math., v. 14: 99-104, 1956.

Let $\{f_\alpha,\ \alpha \in A\}$ be a net of real or complex valued functions defined on a set S. Sirvint (Studia Math., v. 11: 71-94, 1950) introduced the notions of almost uniform convergence of such a net. $\{f_\alpha\}$ converges almost uniformly to the function f_0 on a set $T \subset S$ if and only if for every net $\{x_\beta\}$ defined from a directed set B to the set T,

$$\lim_{\alpha}\left[\lim_{\beta}\inf |f_\alpha(x_\beta) - f_0(x_\beta)|\right] = 0.$$

This paper concerns itself with the characterization of weak and weak* convergence on the conjugate X^* of a convex linear topological space X in terms of almost uniform convergence on certain types of subsets of X. The principal theorem states that the weak topology on X^* is equivalent to the topology of almost uniform convergence on bounded subsets of X. This provides a method of characterizing weak convergence on X^* without reference to X^{**}. The paper concludes with several theorems on weak continuity of linear transformations on X. In particular, the above characterization of weak convergence provides a short proof of the weak continuity of the adjoint of a weakly continuous operator. (Math. Rev. abstract)

Also published in Amer. Math. Monthly, v. 61 (Supplement): 46-73, 1954.

The general characteristics of the frequency distribution g (v) of the Born-von Kármán model of crystal lattices is reviewed with special emphasis upon the existence of singularities. The discussion of the vibration of periodic lattices is introduced by an analysis of some 2-dimensional examples, and the discussion is generalized to 3-dimensional systems. Discussions are presented of: (1) the topological basis for the logarithmic singularities in the 2-dimensional frequency spectrum; and (2) the nature of the singularities in 3-dimensional lattices.

THEORY OF THE VIBRATION OF SIMPLE CUBIC LATTICES WITH NEAREST NEIGHBOR INTERACTIONS, by E. W. Montroll. Jan. 1955, 1v. incl. diagrs. refs. (Technical note no. BN-48) ([AF]OSR-TN-55-43) (AF 18(600)1015) AD 54838 Unclassified

A model is analyzed of a simple cubic lattice with interactions between nearest neighbors. Cubes of 1, 2, 3, and a very large number of dimensions are discussed. The number of normal modes is determined for a given frequency interval, and the distribution function of the location of a given atom with respect to its equilibrium position is shown to be Gaussian. Analytical expressions are obtained for the dispersion in terms of dimensionality, temperature, and interatomic forces. A method is outlined for the discussion of the effect of local disturbances such as impurities and holes on lattice vibrations. A brief calculation is made of the quantum mechanical zero point energy of the lattice model. (ASTIA abstract)

ANHARMONICITY AND MONOMOLECULAR REACTIONS, by R. H. Tredgold. Feb. 1955 [8]p. incl. diagr. (Technical rept. no. 12) ([AF]OSR-TN-55-[54]) (AF 18(600)1015) AD 55588 Unclassified

Also published in Proc. Phys. Soc. (London), v. 68A: 920-923, 1955.

A brief summary is given of the present theories of monomolecular reactions and of the significance of anharmonicity. A model involving anharmonic forces is studied in which 3 bodies are constrained to move in a straight line; each body has a unit mass, and the degree of excitation is high enough so that classical mechanics can be used. Exact solutions are obtained, and the results indicate that a treatment of monomolecular reactions based on a purely harmonic model always yields a lower reaction rate than that actually observed. The effect of anharmonicity is not important at high pressures, but may make a substantial difference in reaction rate at medium and low pressures. (ASTIA abstract)

ON THE SOLID PHASE OF THE RARE GASES, by R. U. Ayres and R. H. Tredgold. Aug. 1955, 17p. refs. (Technical rept. no. 20) ([AF]OSR-TN-55-252) (AF 18(600)1015) AD 72639 Unclassified

Previous theoretical work on the crystal structure of the rare gases is discussed. A model is proposed which allows the overlap of adjacent atoms to be taken into account. The Van der Waal forces are studied in a reciprocal space representation. A series expansion

for the zero point energy associated with the dipole-dipole coupling is obtained, and it is shown that the overlap effect favors the stability of the face centered cubic (fcc) lattice as opposed to the close packed hexagonal lattice. It is suggested that this mechanism is responsible for the fact that, with the exception of helium, the rare gases crystallize in the fcc structure. The possibility of using this model to correlate the optical and thermal properties of these substances is also briefly discussed. (Contractor's abstract)

EFFECT OF DEFECTS ON THE VIBRATIONS OF AN ALTERNATING DIATOMIC LATTICE, by P. Mazur, E. W. Montroll, and R. B. Potts. Nov. 1955, 27p. incl. diagrs. (Technical rept. no. 22) ([AF]OSR-TN-55-422) (AF 18(600)1015) AD 78474 Unclassified

In a perfect alternating lattice, the normal frequencies fall into 2 bands separated by a gap. For the monatomic lattice, localized modes can occur with discrete frequency levels out of the bands when the lattice contains such defects as isotopes. For the alternating lattice, 4 cases arise. When 1 of the lighter masses m is replaced by an isotope m', then if $m' < m$, one level jumps from the optical band into the region above, whereas if $m' > m$, one level jumps from the bottom of the optical band into the gap. When one of the heavy masses is replaced by a lighter isotope, one frequency jumps from the top of the acoustical band into the gap, while a second level jumps from the top of the optical band into the region above. When one of the heavy masses is replaced by a heavier isotope, no frequencies emerge. The defect level which rises out of the top of the acoustical band into the gap is of interest; as the defect mass approaches zero the level approaches the level at the gap center. The self energy of an isotope is computed, and the series solutions are obtained which cover the range of variation of the masses. The interaction energy between 2 isotopes is proportional to the inverse cube of the distance of separation and is attractive for 2 light or heavy isotopes and repulsive for a light and a heavy isotope.

THEORY OF DILUTE HIGH POLYMER SOLUTIONS (THE PEARL NECKLACE MODEL), by A. Isihara and R. Koyama. Apr. 1956 [21]p. incl. diagrs. tables, refs. (Technical rept. no. 34) (AFOSR-TN-56-199) [AF 18(600)1015] AD 87512 Unclassified

Also published in Jour. Chem. Phys., v. 25: 712-716, Oct. 1956.

A theoretical expression is derived for the second virial coefficient A_2 of chain polymer solutions. The expression describes the empirical relation between A_2 and molecular weight M in which A_2 is proportional to M^{-a}, where a has a value of about 0.23 over a suitable range of molecular weight. Theoretically, $a \simeq 1/2 - 3/4 (\log 1.684\chi)$, where χ is a variable proportional to the square root of M, when χ becomes large. The theory agreed with the data of Krigbaum and Flory (Jour. Amer. Chem. Soc., v. 75: 1775, 1955). The determination of the potential function between polymer segments is discussed.

ON THE CRYSTAL STRUCTURE OF THE RARE GASES, by R. U. Ayres and R. H. Tredgold. May 1956, 5p. (Technical rept. no. 39) (AFOSR-TN-56-200) (AF 18(600)1015) AD 87513) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago U., Ill., Nov. 25-26, 1955.

Abstract published in Phys. Rev., v. 100: 1257, Nov. 1, 1955.

Also published in Proc. Phys. Soc. (London), v. 69B: 840-842, 1956.

Quantitative investigations were made of the following effects which are likely to influence the lattice energy: (1) the interaction of the repulsive first-order overlap energy with the triple dipole forces, and (2) higher order multipole 3-body forces. The first effect was shown previously to be of insufficient magnitude to explain the face-centered cubic (fcc) crystal structure of rare gases. In the higher order triple multipole forces, the dipole-dipole-quadrupole forces are non-negligible and, because of their marked angular

MDU. 02:012 - MDU. 02:015

dependencs, the resulting energy terms arising from them in the 2 close-packed structures are shown to differ appreciably. The intsraction Hamiltonian is given for 3 atoms located at lattice sites 1, 2, and 3 in the form $H' = H_{dd}(12) + H_{dq}(23) + H_{dq}(31)$ for dipoles at 1 and 2 and a quadrupole at 3. The third-ordsr psrturbation energy is $E_{(3)} = \sum_{j,k}{}'' \frac{H'_{oj}H'_{jk}H'_{ko}}{(E_o - E_j)(E_o - E_k)}$; the other terms which usually appear in a third-order perturbation are zero in this case. The approximation $E_j - E_o = E_{ionization}$ reduces the perturbation energy to $E_{(3)} = \frac{\langle H'^3 \rangle_{oo}}{E^2_{ion}}$. The only nonzero contribution which arises from the cross term $\langle H_{dd}(12)H_{dq}(23)H_{dq}(31) \rangle$ for all permutations 1, 2, 3 is shown. Appropriate lattice sums were determined for the fcc and cph (close-packed hexagonal) lattices on a high-speed computing machine. Results indicate that the hexagonal structure represents the lowest energy state in solid rare gases but that, at higher temperatures, the fcc structure is stable and is frozen in on cooling. EFFECT OF DEFECTS ON LATTICE VIBRATIONS: INTERACTION OF DEFECTS AND AN ANALOGY WITH MESON PAIR THEORY, by E. W. Montroll and R. B. Potts. [1956] [13]p. incl. table, refs. [AF 18 (600) 1015] Unclassified

Published in Phys. Rev., v. 102: 72-84, Apr. 1, 1956.

An analysis is given of ths determination of additive functions of the frequencies of the normal mode vibrations of a lattice. The method is applied to the problem of calculating the self-energiss and interaction energies of dsfects in lattices of any dimension. In particular results are derived for the self-snergiss and interaction energies of isotopes, holes, and "source" defects in simple cubic monatomic and diatomic lattices. For sxample it is shown that two holes in a simple cubic lattice attract each othsr, the energy of interaction being inversely proportional to the cube of the distance of separation. The gensral method is also applied to the problem of the interaction of lattice defects with the boundaries of the lattice. Finally, if the lattice approaches the limit of a continuum, it is shown that the energy of interaction between two holes is just that obtained by Wentzel for the interaction between two fixed nucleons according to the scalar meson pair theory. EFFECT OF DEFECTS ON LATTICE VIBRATION. II. LOCALIZED VIBRATION MODES IN A LINEAR DIATOMIC CHAIN, by P. Mazur, E. W. Montroll, and R. B. Potts. [1956] 11p. incl. diagrs. (AF 18 (600)-1015) Unclassified

Published in Jour. Wash. Acad. Sciences, v. 46: 1-11, Jan. 1956.

The electrical properties of semiconductors due to the influence of defects or local disturbances in otherwise regular media can easily be excited into a conducting state. In a perfect attenuating lattice the normal frequencies fall into two bands separated by a gap. It is shown that localized nodes can occur with discrete frequency levels out of the bands when the lattice contains defects such as isotopes. Four cases arise with the interchange of a lighter or heavier mass with a lighter or heavier isotope. The defect level arising

from the acoustical band into the gap can be interpreted as a surface mode due to the defect mass approaching zero. The self energy of an isotope is computed, and the series solutions obtained, one valid for $m \approx M$ and the other for $m \gg M$, together cover the whole range of variation of the masses. The interaction energy between two isotopes is proportional to the inverse cube of the distance of separation and is attractive for two light or two heavy isotopes and repulsive for a light and a heavy isotope.

THE MOUSE, by S. F. Singer. [1954] [2]p. incl diagrs. [AF 18(600)1038] Unclassified

Published in Sky and Telescope, v. 14: 15, 17, Nov. 1954.

The development of the MOUSE (minimum orbital unmanned satellite of the earth) is proposed for observations from 190 miles above the earth's surface. It would circle the earth, maybe for only a few days and would weigh about 100 pounds. Automatic instruments, powered by lightweight solar batteries, would record data on astrophysical and other observations and transmit the data by radio to ground stations. The proposal is for a 3-step rocket with a few pounds of payload. The first step is planned to take the satellite vertically through the lower atmosphere and to begin its inclined flight. The 2nd step will take over immediately after burnout of the first stage, in order to reach the required altitude and direction of the motion. The 3rd step simply boosts the velocity up to its orbital value. At the point of burnout or fuel cutoff (controlled from the ground), the nose tip will open and the spinning sphere which is the MOUSE itself will begin to describe a relatively stable orbit around the earth. The total cost of 5 MOUSE satellites with their 3-stage rockets is estimated at about 5 million dollars. The IGY, 1957, is suggested as target date.

ORIGIN OF THE CHARGE SPECTRUM OF PRIMARIES (Abstract), by S. F. Singer. [1955] [1]p. [AF 18-(600)1038] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 27-29, 1955.

Published in Bull. Amer. Phys. Soc., v. 30: 24, Jan. 27, 1955.

Evaporation theory, cosmic-ray data, and helium analyses of meteorites were used to determine the charge distribution of the primaries. The required mean path length is 6 g/cm^2. Points for the fragmentation hypothesis are: (1) it leads to the same velocity spectrum for all components. Certain injection mechanisms favor heavy nuclei. Crucial tests are: the presence of Li, Be, B in the primary radiation, as well as He^3 and H^3. Enhancement of heavy primaries during solar flare increases. (Contractor's abstract, modified)

THE ALBEDO CONTRIBUTION IN THE MEASUREMENT OF COSMIC-RAY PRIMARIES (Abstract), by R. C. Wentworth and S. F. Singer. [1955] [1]p. [AF 18(600)1038] Unclassified

Presented at meeting of the Amer. Phys. Soc., Baltimore, Md., Mar. 17-19, 1955.

Published in Bull. Amer. Phys. Soc., v. 30: 23-24, Mar. 17, 1955.

The major uncertainty in the determination of the primary proton spectrum lies in the evaluation of the effects of albedo. A number of experiments have shown that the albedo contribution has a minimum in the vertical direction, but could not assign a value to it. This vertical minimum seems plausible by simple theoretical arguments. Calculation has been made of the "splash" albedo moving vertically upward near the top of the atmosphere at $\lambda = 56°$, using data from balloon emulsions and high energy accelerators. The results are compared with recent experiments. The difficulties inherent in our calculation and in the experimental approach are discussed. A time-of-flight telescope would give data of great value about

MDU. 03:005 - MDU. 03:008

upward-moving albedo. The theoretical treatment is extended to include the effects of geomagnetic albedo in n approximate way. (Contractor's abstract)

A NEW METHOD FOR MEASURING THE LOW ENERGY SPECTRUM OF PRIMARY COSMIC RAYS (Abstract), by S. F. Singer. [1955] [1]p. [AF 18(600)1038] Unclassified

Presented at meeting of the Amer. Phys. Soc., Baltimore, Md., Mar. 17-19, 1955.

Measurements of the primary spectrum with balloons and also rockets suffer from the contribution of unknown amounts of albedo. High latitude measurements have established a "knee" in the spectrum caused by the marked paucity of primaries with momentum/charge less than 1.5×10^9 volts. The actual number is unknown but would be of great importance for our understanding of the relation of cosmic rays to events in the solar system. Present high latitude measurements may be inherently unsuitable because of complicating effects of the earth's quadrupole field and our inadequate knowledge of the shadow cone. An entirely different approach lies in measuring the cosmic ray intensity at the geomagnetic equator as a function of altitude starting at the top of the atmosphere, surmounting the cosmic ray "plateau" and extending the measurements to extreme distances from the earth. A preliminary calculation of the expected intensity variation with altitude has been carried out for the equatorial case, using geomagnetic theory and taking into account the geomagnetic shadow of the earth. The results demonstrate the potentialities of the proposed method for determining accurately the primary cosmic ray spectrum down to energies well below the "knee," away from albedo effects and distortions of the magnetic dipole field near the earth. GEOMAGNETIC ALBEDO AT ROCKET ALTITUDES AT THE EQUATOR (Abstract), by H. Griem and S. F. Singer. [1955] [1]p. [AF 18(600)1038] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Bull. Amer. Phys. Soc., v. 30: 8, Apr. 28, 1955.

Cosmic-ray secondaries above the "top" of the atmosphere ("albedo") present an unknown contribution in experiments designed to measure the flux of primary protons. The question of albedo is of particular importance at the geomagnetic equator; it enters into all considerations connected with the primary spectrum, in particular the energy balance. At the present time knowledge of the equatorial albedo is sparse: it is > 35 percent of the total flux at 45° zenith angle and made up mainly of minimum ionizing particles. In attacking the albedo problem theoretically, it is noted that at the equator the magnetic field confines charged secondaries to the altitude region in which they are produced. Depending on altitude and range they can make many loops between production and absorption, thus enhancing their contribution to the counting rate. This process has been studied in detail for protons and electrons of various energies, and their relative contribution to the albedo is discussed. (Contractor's abstract)

STUDIES OF A MINIMUM ORBITAL UNMANNED SATELLITE OF THE EARTH (MOUSE). PART I. GEOPHYSICAL AND ASTROPHYSICAL APPLICATIONS, by S. F. Singer. [1955] [14]p. incl. diagrs. refs. [AF 18(600)1038] Unclassified

Presented at meeting of the Amer. Rocket Soc., Baltimore, Md., Apr. 20, 1955.

Published in Astronautica Acta, v. 1: 171-184, 1955.

A MOUSE would provide a far-reaching extension of present high altitude rockets in the study of the upper atmosphere and extraterrestrial radiations. Lifetimes of even a few days and payloads as low as 50 pounds would be adequate to allow continuous observations of the solar ultraviolet and x-radiations which have a profound influence on the ionosphere and therefore on radio communications. The cause of magnetic storms and aurorae could be established with more certainty. Observations of cosmic rays would help clear up the question of their origin. Various other astrophysical phenomena, such as micrometeorites, could be brought under direct observation. Measurement of the earth's albedo (reflected sunlight) would give a measure of total world cloud coverage which could be used to predict long term climatic changes. Radio transmissions from MOUSE would send back all data and allow at the same time a study of the ionosphere. The change in the orbit and the lifetime would give information on drag and therefore upper atmosphere densities, while observation of a luminous trail of sodium emitted from the satellite would allow studies of winds, temperature, and turbulence in the outermost layers of the earth's atmosphere. THE PRIMARY COSMIC RADIATION AND ITS TIME VARIATIONS, by S. F. Singer. May 22, 1956, 1v. incl. diagrs. tables, refs. (Technical rept. no. 40)

(AFOSR-TN-56-234) (AF 18(600)1038) AD 88354
Unclassified

Also published as a Chapter in Cosmic Ray and Elementary Particle Physics, Vol. IV, N. Y., Interscience, 1957.

The present status and some of the outstanding problems in the study of the primary cosmic radiation and of its variation with time are reviewed. Experimental data on primary radiation are analyzed to obtain its composition and the energy spectra of the various components. The results obtained indicated the following main conclusions: (1) an appreciable abundance of Li, Be, and B in the primary radiation, (2) the exponent for different ene gy spectra forms of the various components increases with the charge, (3) the possible difference between the originally injected and accelerated radiation, and the primary radiation is the result of fragmentation in interstellar space, and (4) the flux of very low energy primaries varies with the sunspot cycle. Changes in the primary radiation (especially during the large time variations) are discussed relative to solar flare increases, and Forbush type decreases.

METEOROLOGICAL MEASUREMENTS FROM A MINIMUM SATELLITE VEHICLE, by S. F. Singer. Jan. 14, 1956, 1v. incl. illus. diagrs. tables, refs. (Technical rept. no. 30) [AF 18(600)1038] AD 121009
Unclassified

The purpose of this study is to examine some problems connected with the data-collecting satellite itself, its orbit, orientation, and instrumentation, and to indicate some of the applications of the data gathered to meteorology. It is demonstrated that the resolution attainable with the minimum satellite and simple detectors considered would provide information on: (1) global heal balance and general tropospheric circulation patterns; (2) long-term albedo changes and their relation to climatic changes; (3) synoptic albedo changes and the development and motion of storm areas; (4) long-range weather forecasting; and (5) variations in vertical O_3 distribution and stratospheric circulation. Calculations are carried out in appendixes I-III for determining vertical O_3 distribution, planetary temperatures as a function of albedo, and dependence of surface temperature on long-term albedo change. Appendix IV considers the use of the minimum satellite, equipped with a photocell, as a "storm-patrol" station.

MEASUREMENTS OF INTERPLANETARY DUST, by S. F. Singer. Mar. 1956, 22p. incl. diagr. refs. (Technical rept. no. 33) [AF 18(600)1038]
Unclassified

In this study, some aspects of the hypothesis that particles of interplanetary dust carry an electric charge, and are therefore affected by electric and magnetic fields, as well as by gravity and radiation pressure, are developed. The following subjects are treated: (1) physical ideas about dust particles; (2) calculation of magnetic rigidity (momentum/charge); (3) calculation of the charge including photoelectric emission and electron accretion; (4) transient charge effects; (5) dynamics of dust particles including gravitational, electromagnetic, and radiation pressure effects, as well as friction with interplanetary gas; (6) magnetic rigidity spectrum; (7) latitude dependence of dust particle flux; (8) dust particle motion under combined magnetic and gravitational fields and the application of Liouville's theorem from statistical mechanics; (9) geophysical implications, e. g., dust density and total influx, auroral effects; (10) anisotropy, diurnal vibration; (11) impact zones; and (12) magnetic storm effects.

MEASUREMENTS OF THE EARTH'S MAGNETIC FIELD FROM A SATELLITE VEHICLE, by S. F. Singer. Mar. 1956 [25]p. incl. diagrs. (Technical rept. no. 32) [AF 18(600)1038] Unclassified

The application of satellite observations to magnetic measurement on 3 different time scales is considered. Part A discusses the measurement of the earth's main field and its secular variations. The main advantages of the use of a satellite over other methods are described. Part B is concerned with short time variations of the field and atmospheric current systems. It is pointed out that the satellite magnetometer, being located above the ionosphere, observes the magnetic fields produced by atmospheric current systems in opposite phase when compared to sea level magnetometer measurements. Both instruments, however, observe currents external to the earth's atmosphere (the presumed Störmer ring current) in the same phase. As a result, this technique allows determinations to be made of the location and strength of the currents responsible for magnetic storms at low latitudes and in auroral zones, as well as for the disturbed and quiet diurnal variations. Part C focusses on transient variations. These variations, resulting from rapid motions of ionized gases near the earth, produce sudden magnetic commencements and other changes in the earth's field. A physical model is presented in which the approach and penetration of a magnetohydrodynamic shockwave results in a sudden commencement (SC) increase. It is noted that satellite observation data will indicate location of the SC currents and overcome the ionosphere shielding effects. Appendix I describes the proton-free precession magnetometer, its operation, sources of error, data-storage problems, and telemetering. Appendix II discusses a proposed model experiment to verify certain critical points concerning the magnetohydrodynamic shockwave treated in Part C. Appendix III considers some parameters of this

COSMIC RAY EFFECTS ON MATTER AT HIGH ALTITUDES, by S. F. Singer. [1956] [18]p. incl. diagrs. refs. (Technical rept. no. 14) [AF 18(600)-1038] Unclassified

Presented at meeting of the Aeromedical Assoc., Washington, D. C., Mar. 1955.

Published in Jour. Aviation Med., v. 27: 111-116, Apr. 1956.

In this study, major attention is focussed on nuclear effects resulting from cosmic radiation of matter. Though these effects are small, they are cumulative. Numerical values are presented for the effects, and a calculation is described for gauging their biological effectiveness. It is pointed out that the shielding problems against heavy primaries and nuclear disintegrations are similar. Calculations indicate that hydrogen materials (water, kerosene, etc.) provide optimum shielding. In addition, cosmic-ray induced radioactivity is discussed, particularly the radioactivity of the moon's surface.

COSMIC-RAY PRODUCTION OF HELIUM-3 AND TRITIUM IN METEORITES, by M. Galli and S. F. Singer. [1956] [1]p. [AF 18(600)1038] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 231, Apr. 26, 1956.

The production of He^3 and H^3 in meteorites by cosmic-ray bombardment has important consequences for the origin of meteorites, as well as for the origin of cosmic rays. Earlier calculations have been extended to include the depth dependence of He^3. Various cosmic-ray data are considered as well as the recent accelerator measurements of Fireman, and of Libby's group. The results are applied to the problem of mass loss of meteorites in space and in the atmosphere. The "formation age," "solidification age," and "breakup (or cosmic-ray) age" of meteorites are clearly distinguished. Conclusions are drawn about the prehistoric cosmic-ray intensity by viewing the meteorite as an integrating cosmic-ray meter. (Contractor's abstract)

TRAPPED ORBITS IN THE EARTH'S DIPOLE FIELD, by S. F. Singer. [1956] 2p. [AF 18(600)1038] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Also published in Bull. Amer. Phys. Soc., Series II, v. 1: 229, Apr. 26, 1956.

Charged particles emitted by the sun or in its vicinity are usually deviated on approach to the earth by its magnetic field at a distance of about 10 earth diameters. Occasionally this field is sufficiently disturbed by large numbers of such particles to permit their closer approach and possible entrapment by the earth's field. The very complicated motions of these trapped particles can be discussed statistically. While some of the particles will be scattered out by perturbations in the earth's field, the majority remain in and are slowly depleted from this trapped region which extends down to the earth's surface in the auroral zone. Here depletion is greatest, with the particles moving in the earth's atmosphere where they are absorbed. However, only those randomly-oriented particles which move along the magnetic line of force enter the atmospheric portion of the trapped regions; the greater part are reflected back to the trapped region. Connections between this region of trapped particles and geophysical

phenomena are suggested. A current is formed by the drift of these particles around the earth, positive particles moving from west to east and negative particles vice versa, which produce a magnetic field observable on earth; this current has been identified with the hypothetical Störmer ring current, a suggested cause of magnetic storms. Particles entering the earth's atmosphere in the auroral zones are held responsible for the aurora, for the airglow, and probably for considerable atmospheric disturbance. Primary cosmic rays upon hitting the atmosphere generate secondaries some of which scatter into the trapped particle region and thus increase its population; their contribution is small however in comparison to that from low-energy solar corpuscular radiation.

THE EFFECT OF METEORIC PARTICLES ON A SATELLITE, by S. F. Singer. May 1956 [20]p. incl. tables, refs. (Technical rept. no. 41) (AF 18(600)1038) AD 102634 Unclassified

In evaluating environmental effects on vehicles above the atmosphere the influence of meteoric dust is one of the least well known. The present paper deals primarily with the erosion phenomena due to impact of high velocity meteoric dust and constrasts them with radiation damage effects due to cosmic rays. A review is given of the penetration effects of large meteors. Collisions with gas leading to sputtering, and corrosion by highly reactive radicals are also briefly discussed. To calculate the sandblasting erosion of meteoric dust one needs data on the flux of micrometeors and on the effects of individual impacts. Some plausible physical models are developed; they lead to widely differing values for the erosion rate. Laboratory experiments with artificial dust particles accelerated to meteor velocities should furnish more reliable values. An experiment is described for measuring the skin erosion of the Vanguard satellite. It is based on a radioactive method which has many advantages in terms of sensitivity and simplicity. Some of the technical problems relate to the choice of radioactive material and to its incorporation into the skin of the satellite. The erosion experiment is of considerable scientific value in terms of improvement of our knowledge of: the micrometeor flux at normal times and during meteor streams; the electric charge of interplanetary dust; geomagnetic effects on charged dust particles; effectiveness of solar gas streams in sweeping particles from interplanetary space. A METHOD FOR CALCULATING IMPACT POINTS OF HIGH ALTITUDE ROCKETS, by R. C. Wentworth and S. F. Singer. June 1, 1956 [13]p. incl. diagrs. (Technical rept. no. 42) [AF 18(600)1038] Unclassified

A method for calculating the impact point of a ballistic rocket is described which uses a reference system which is fixed with respect to the stars. The rotation of the earth is taken into account by two means: (1) by giving the rocket at burn-out a horizontal velocity component equal to the earth's surface speed due to its rotation; and (2) by finding the impact point (in the fixed coordinate system), calculating the time of flight of the rocket, and calculating, therefore, how far the earth has turned while the rocket has described its trajectory. This method has been found to be less tedious than the alternative method, which uses a coordinate system fixed with respect to the launching point.

THERMONUCLEAR PROCESSES IN THE AURORA, by S. F. Singer. Aug. 1956 [19]p. incl. diagrs. tables, refs. (Technical rept. no. 52) (AF 18(600)1038) Unclassified

The purpose of this study is to point out the possibility that thermonuclear reactions exist in the aurora, and that they are initiated by the same fast particles which are responsible for the luminous displays and the ionization. Of particular interest are capture followed by γ-ray emission, i.e., (p,γ), (d,γ), (α,γ), reactions, since the γ-rays are highly penetrating, being obtained at much lower altitudes ($\sim$50,000 ft). It is noted that: (1) the γ-rays act as specific indicators of the characteristics, energy, and flux of the incident particles; (2) the prominent reactions are thermonuclear and lead to a considerable release of energy, one-half of this being propagated downward; (3) the nuclear effects in the upper atmosphere must be considered in the design of the skin of space vehicles; and (4) the isotropic transmutations have interesting geochemical consequences, e.g., the production of N^{15}, O^{17}, and O^{18}. The reaction $N^{14}(p,\gamma)O^{15} \xrightarrow{\beta^+} N^{15}$ is discussed in detail. The observation of these nuclear γ-rays provides a new method for studying the aurora.

THE APPLICATION OF AN ARTIFICIAL SATELLITE TO THE MEASUREMENT OF THE GENERAL RELATIVISTIC "RED SHIFT," by S. F. Singer. Mar. 1956 [11]p. incl. diagrs. (Technical rept. no. 31) [AF 18(600)1038] Unclassified

Also published in Phys. Rev., v. 104: 11-14, Oct. 1, 1956.

The use of a satellite vehicle to further verify the general theory of relativity is considered. At present, this theory is substantiated only by astronomical measurements, the most important of these being: (1) the advance of the perihelion of the planet Mercury; (2) the gravitational deflection of light rays; and (3) the gravitational displacement of spectral lines. The artificial satellite provides the possibility for testing the gravitational red shift by deriving the shift experienced by a clock located in the satellite with respect to a clock located on the earth's surface. Details of this derivation are presented in an appendix Relativistic Effects of Satellite Clocks. It is pointed out that with respect to an earth clock, the shift is calculated to be a "red shift" for low-altitude orbits, zero shift for an orbit one-half the earth's radius, and a "violet shift" for higher altitudes where it approaches 7×10^{-10}. Some experimental schemes for the measurement of the clock shift are discussed. It is stated that a digital or counting method best fits the needs of the experimental tests, being of great accuracy, and avoiding signalling problems created by the motion of the satellite.

GEOPHYSICAL RESEARCH WITH ARTIFICIAL EARTH SATELLITES, by S. F. Singer. [1956] [67]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 53) [AF 18(600)1038] Unclassified

Published in Advances in Geophys., v. 3: 301-367, 1956.

A review is presented of geophysical experiments which have been suggested for a satellite. A number of additional experiments are also offered for suggestion. All applications are limited to a "minimum" satellite (that is, one which is not very large or heavy and therefore capable of being launched within the next few years). The approach used primarily describes geophysical applications from the core of the earth outward into space regardless of their relationship or causual connections. A discussion is provided of the ionosphere and solar ultraviolet radiation which produces the ionosphere. A group of related subjects are presented as an organic whole, e.g., the complex of meteorological measurements, and the complex of solar-terrestrial phenomena. The technical problems are analyzed and the design features of satellites and requirements which they have to fulfill in order to be capable of various types of observations are discussed.

A NEW MODEL OF MAGNETIC STORMS AND AURORAE (Abstract), by S. F. Singer. [1956] [1]p. [AF 18(600)1038] Unclassified

Presented at meeting of the Amer. Geophys. Union, Washington, D. C., May 1956.

The following model is proposed to explain the sudden commencement (SC) of magnetic storms, the SC and pre-SC disturbances. The solar eruption produces a shockwave which arrives at the earth 22-34 hr later. High velocity particles having a smaller interaction precede the shockwave and cause the pre-SC bay-like disturbances at high altitudes. The shockwave itself is retarded by the body forces produced by the geomagnetic field, splits and enters the auroral zones. In pushing out lines of force it creates the polar SC events. Charge separation in the shockwaves produces the driving force for the SC currents which flow in the atmosphere (in accordance with Vestine's analysis). The storm decrease following about 9 hr after the shockwave, is produced by the high velocity particles which enter, because of field perturbations, into the normally inaccessible Störmer regions around the dipole. Here they are trapped and will drift producing the ring current which gives rise to the storm decrease. Particles with pitch angle < 2-1/2° however can reach the earth's atmosphere and will produce aurora, some of the airglow, and ionsphere disturbances. These particles are replenished by perturbations produced by solar influences having a 27-day recurrence. Many other particles are absorbed or scattered out of the trapping regions so that their number diminishes rapidly in a day or so, concomitant with the magnetic-storm decrease.

STUDIES OF A MINIMUM ORBITAL UNMANNED SATELLITE OF THE EARTH (MOUSE). PART II. ORBITS AND LIFETIMES OF MINIMUM SATELLITES by S. F. Singer. [1956] [20]p. incl. diagrs. table. [AF 18(600)1038] Unclassified

Presented at meeting of the Amer. Rocket Soc., New York, Nov. 30-Dec. 3, 1954.

Published in Astronautica Acta, v. 2: 125-144, 1956.

The (elliptical) orbit of an artificial satellite is described in terms of the launching conditions (i.e., at

"burnout"); in particular minimum and maximum altitudes of the ellipse are given as a function of launching altitudes and of errors in launching velocity and angle. Criteria are then developed for controlling the launching conditions. The subsequent behavior of the orbit is investigated under the influence of the drag of the upper atmosphere. The "lifetime" of the satellite depends on its area and mass, and is related to the upper atmosphere densities; hence, these densities can be determined from measured changes of the orbit by methods discussed in detail. Both circular and elliptic orbits are investigaged using appropriate approximation methods. Three appendices are included which take up: (1) some features of orbit theory; (2) upper atmosphere densities; and (3) critical examination of approximation methods. (For Part I, see item no. A satisfactory method of testing helium sensitive mass spectrograph leak detectors is presented. The detector is evacuated to a pressure within its operating range and then the pressure is raised to a standard amount by admitting a gas mixture containing a known concentration of helium. The resulting indication is a direct measure of the sensitivity. A valve or leak that can be varied is essential to raise the pressure the known amount. A valve which is easily made and fulfills all the requirements for this method of testing is described as well as an apparatus for preparing a known concentration of helium. The soft brass valve body is made on a lathe and the seat is formed by reaming with a 5/0 standard taper pin reamer. It is recommended that the reaming be done on a lathe to insure accurate centering. The threads on the stem were cut after the body was threaded, and the body was used as a gage for the diameter of the stem threads. The leakage rate was variable from 0 to 4 x 10^{-7} standard liters/sec with about 1/2 turn of the stem. It was possible to control the pressure in the leak detector to within ± 3 x 10^{-7} mm Hg. With an Octoil Manometer, it is possible to measure a concentration of helium in air of about 1 part in 3000 to about 10^{7}.

An investigation was made to study existing methods of harmonic generation in order to determine the reason for low efficiency, to determine the required physical properties of a semiconductor device for higher efficiency harmonic generation and the effect of low temperature on the performance of harmonic generators, and to study polyphase harmonic generators. The art of crystal harmonic generation at microwave and millimeter wave frequencies is reviewed. The causes of low efficiency are discussed. Multipliers were constructed which gave better performance by 4 to 10 db for the 2nd and 3rd harmonics. Improvement was achieved by improving the power transfer to the crystal and by controlling the length, contact, and pressure of the whisker. Some improvement was obtained by a 2-phase arrangement; this arrangement is not promising for higher harmonics. In many cases, power inputs of about 30 mw were used with harmonic outputs exceeding 1 mw. (ASTIA abstract)

THE LAMINAR JET MIXING OF TWO COMPRESSIBLE FLUIDS, by S. I. Pai. Feb. 11, 1952, 10p. diagrs. (Technical rept. no. BT-1) (AF 33(038)10481) U22949
Unclassified

Also published in Proc. Second Midwestern Conference on Fluid Mechanics, Ohio State U., Columbus (Mar. 17-19, 1952), Columbus, Coll. of Engineering (Bull. no. 149 of OSU Engineering Exper. Station), 1952, p. 297-307.

The laminar jet mixing of 2 compressible fluids is investigated theoretically under the assumptions that the mixture is a continuous medium, there is no reaction between the fluids, and the fluids are perfect gases. The fundamental equations for 2-dimensional steady flow are derived and solved for jet mixing of 1 compressible fluid and for isothermal and isovel[illegible] mixing of 2 compressible fluids. Numerical exa[illegible]s are worked out for the mixing of a uniform strea... of CO_2 with one of air and for a 2-dimensional jet of CO_2 issuing into surrounding moving air. Results indicate that the spread of mass is wider than that of velocity, and that the momentum of the jet fluid is an important factor in the jet mixing problem.

of compressible jets; the supersonic flow of a two-dimensional jet in a uniform stream; the axially symmetrical jet mixing of a compressible fluid; problems in the study of turbulence; and the growth of a laminar boundary layer behind a shock wave. Considerable effort has been devoted to the design and construction of a 6-in. Mach Zehnder interferometer and some preliminary experiments on a small jet have been performed. A theoretical analysis has been made of a supersonic jet issuing into a uniform stream. The theory of Pai for the 2-dimensional mean velocity and temperature distribution in both laminar and turbulent jet mixing regions has been extended to the axially symmetrical flow. Experimental studies of the flow on the boundary of the jet have been carried out by optical devices and have yielded results in good agreement with the theory of Pai. Through the study of simple models of turbulence some understanding has been gained on the mechanism of turbulence in jets. Some experimental work in a shock tube has been accomplished as an associated research project.

OPTICAL STUDY OF COMPRESSIBLE JETS, by D. Bershader and B. [B.] Cary. [1952] [36]p. incl. illus tables, refs. (Pt. 1 of its Final rept. AD 2221) [AF 33(038)10481] AD 2221(a) Unclassified

Instrumentation problems and techniques for the study of jets are discussed. Construction and operation of a nozzle and a gimbal assembly for use with a 6-in. Zehnder-Mach interferometer is described, and the interferometric evaluation of 2-dimensional flows is discussed. Over-all features of an M = 1.7 nozzle and jet were analyzed, showing the cases of overpressure, full expansion, and underpressure. Studies were made at full expansion but without glass windows to show the growth of turbulent mixing for a jet with 4 free boundaries. Density profiles were measured across the mixing zone at several stations up to 8 jet half-widths downstream of the orifice: the temperature profiles can be computed from the density profiles. The technique of interferometry is shown to be practicable for the quantitative study of the jet mixing problem, and this can be extended to axially symmetric flow. Agreement exists between a constant-exchange coefficient theory of turbulent 2 dimensional mixing applied to compressible flow and the experimental results for a small jet discharging air into the atmosphere under full expansion at M = 1.7. Full-expansion jets were produced which were 2-dimensional up to 15 orifice half-widths from the extrapolated origin, with or without glass walls beyond the orifice. The divergence of a supersonic jet was smaller than that of a slower speed jet. The value for the coefficient of eddy kinematic viscosity was 4.75 sq cm/sec, while the ratio of the turbulent to the laminar exchange coefficient was 1.26 x 10^3, which is of the same order of magnitude as the ratio for incompressible flow.

ON SUPERSONIC FLOW OF A TWO-DIMENSIONAL JET IN UNIFORM STREAM, by S. I. Pai. [1952] [18]p. incl. illus. (Pt. 2 of its Final rept. AD 2221) [AF 33(038)10481] AD 2221(b) Unclassified

Also published in Jour. Aeronaut. Sciences, v. 19: 61-65, Jan. 1952.

It is well known that a supersonic gas jet issuing from a reservoir into a medium at rest has a periodic structure if the difference of pressure of the jet from the medium is not large. This investigation considers a similar situation when a supersonic gas jet is issuing into a uniform stream. It is found that if the uniform stream is subsonic, the supersonic jet has almost periodic structure, and the approximate wavelength increases with the Mach number of the surrounding stream for a given Mach number of the jet. If the uniform stream is supersonic, the supersonic jet does not have periodic structure. The transmission and the reflection of small disturbances at the boundary of the jet, i.e., a vortex sheet, are investigated. Factors of transmission and reflection of disturbances on the vortex sheet are found. They are functions of the Mach numbers of the jet and that of the uniform stream. The reflection wave may be of the same sign or of the opposite sign of the incident wave or zero according to the Mach numbers of the two streams. (Contractor's abstract)

AXIALLY SYMMETRICAL JET MIXING OF A COMPRESSIBLE FLUID, by S. I. Pai. [1952] [13]p. incl. illus. (Pt. 3 of its Final rept. AD 2221) [AF 33-(038)10481] AD 2221(c) Unclassified

Also published in Quart. Appl. Math., v. 10: 141-148, July 1952.

The problems of the flow of a 2-dimensional jet of a compressible fluid issuing from a finite opening into a uniform stream and of the uniform mixing of 2 streams of compressible fluid have been studied (Pai, S. I., Two-Dimensional Jet Mixing of a Compressible Fluid, Jour. Aeronaut. Sciences, v. 16: 463-469, 1949). Both the laminar and the turbulent cases were considered. The effects of compressibility owing to large temperature difference and those resulting from high velocity were treated simultaneously. In the present study, this analysis is extended to the case of an axially symmetrical jet of a compressible fluid issuing into a uniform stream. The flow of the jet is assumed to be under full expansion from a nozzle, i.e., the pressure of the flow at the exit of the nozzle is exactly equal to that of the surrounding stream. The pressure gradient

in the jet is assumed to be negligible. Both the laminar and turbulent cases are considered. First, laminar flow is treated. The usual assumptions of boundary layer theory are adopted to simplify the Navier-Stokes equations. A solution by the method of small perturbations is obtained, and the exact solution is examined. A numerical integration method is used to compute the velocity and the temperature distributions in the jet for the exact solution. Turbulent flow is then considered. The fundamental equation of motion of an axially symmetrical jet is derived by using Taylor's hypothesis concerning the transport of vorticity and Reichardt's assumption of free turbulence, i.e., the assumption that the exchange coefficient over each cross-section of the mixing zone is constant. By suitable transformation of variables, the equations of turbulent flow become identical to those of laminar flow. Therefore the solution obtained for laminar flow can be applied in turbulent flow provided that the empirical quantity of eddy viscosity has been evaluated by experiment.

PROBLEMS IN THE STUDY OF TURBULENCE, by R. Betchov. [1952] [16]p. incl. illus. refs. (Pt. 4 of its Final rept. AD 2221) [AF 33(038)10481; continued by AF 18(600)86] AD 2221(d) Unclassified

The thermal inertia of the hot-wire anemometer is discussed. Results of computations of the distribution of temperature along the wire with a linear differential equation did not check with experiment. Approximations and experiments were used to predict the difference between the time lags due to fluctuations in wind speed and electric current. No visible difference between the 2 time lags occurred either with platinum or tungsten wires. The hot wire was shown to be a possible technique for the study of shock-wave phenomena. The difference between the theoretical time lags was smaller than the experimental error. Electronic instruments were studied for multiplying 2 signals and measuring mean cubes and statistical distributions in turbulence. Multiplication techniques were examined, including nonlinear characteristics, diode-chain multipliers, and chains of pentodes. A 12-tube chain of pentodes operated within 7% error under difficult conditions. A diode-chain circuit gave the mean cube of a signal, having approximately gaussian probability distribution, with an error less than 10%. A statistical analyzer gave the amplitude distribution of an electric signal, falling within the spectral region 10 to 10,000 c, and 3 nearly perfect gaussian distributions. Turbulent flow was compared with a nonlinear system excited by random impulses. This approach amounts to studying solutions of a simplified Navier-Stokes equation in which the partial derivatives are replaced by ordinary derivatives. An electric network analogy was suggested by the transformed equation, and a turbulence model was constructed. The solutions of the system and their stability are discussed. No large differences occurred between the model and the flow observed in a pipe by means of a hot-wire anemometer. (ASTIA abstract)

SUPERSONIC ROTATIONAL FLOW OVER TWO-DIMENSIONAL OGIVES, by S. I. Pai. [1953] 15p. incl. illus. tables. [AF 18(600)86; continuation of AF 33(038)10481] Unclassified

Also published in Proc. Third Midwestern Conference on Fluid Mechanics, Minnesota U. Inst. of Tech., Minneapolis (Mar. 23-25, 1953), Minneapolis, Univ. Press, June 1953, p. 303-317.

The supersonic flow fields behind attached curved shock over plane ogives are calculated by the theory of linearized rotational flow for two cases: One is a sinusoidal ogive, and the other is a wedge with blunt nose. It is found that the finite slope of the surface of the ogive at the tip will cause a big difference between rotational flow and the corresponding irrotational flow. When this slope at the tip is zero, even though the basic disturbance generated from the surface of the ogive is very nearly the same as that of the corresponding irrotational flow case, there is still considerable difference in the resultant velocity field between these two cases because of the reflecting disturbance from the shock. The variation of shock angle of the curved shock is a function of the variation of the slope of the surface of the ogive. (Contractor's summary)

ON TURBULENT JET MIXING OF TWO GASES AT CONSTANT TEMPERATURE, by S. I. Pai. June 1954, 27p. incl. diagrs. (Technical note no. BN-33) ([AF]-OSR-TN-54-174) (AF 18(600)86) AD 36967 Unclassified

The fundamental equations of both two-dimensional and axially symmetrical turbulent jet mixing of two gases at constant temperature are derived and discussed. A general method of solution of these equations is given. The most important factors in these equations are the turbulent exchange coefficient for velocity distribution and that for density distribution. In general, these coefficients are not equal. If we assume that these coefficients are the same, an analytic solution for the mixing of two uniform streams is found which is an extension of Görtler's solution for the case of homogeneous fluids. The first order effect of the difference in densities of the two gases in the mixture on the velocity distribution is small. For two-dimensional and axially symmetrical jet from small opening, if the turbulent exchange coefficients are assumed to be the same, the velocity distribution for the case of homogeneous fluid is the first order approximation of the velocity distribution in the jet of the mixing of two gases and the density distribution is the same as the velocity distribution. Finally the effect of the difference in the two turbulent exchange coefficients is discussed. It is found that the ratio of turbulent exchange coefficient for density distribution to that for velocity distribution is larger than one, and may be as high as 2, and the ratio increases as the difference in density of the two gases increases. The larger this ratio is, the wider the spread of the density distribution than that of velocity distribution will be. (Contractor's summary)

AN INSTRUMENT TO STUDY RELAXATION RATES BEHIND SHOCKWAVES, by E. L. Resler, Jr. and M. Scheibe. Aug. 1954, 23p. incl. illus. diagrs. table. (Technical note no. BN-39) ([AF]OSR-TN-54-188) (AF 18(600)86) AD 38864 Unclassified

The instrument comprises a combination of a schlieren system photomultiplier tube and oscilloscope. The sensitivity and properties of the instrument were checked in a series of experiments using commercial CO_2. Oscillograms are presented of shock waves in CO_2 at 1/2- and 1-atm pressures for M = 1.73, 2.16, 2.36, 2.69, and M = 1.42, 1.86, and 2.05, respectively. This technique for measuring relaxation times has the advantages of good space resolution, high sensitivity, and simplicity of interpretation and application. The instrument was originally intended for use in studying the transition zone behind very strong shock waves; however, the light given off behind the waves by the hot gas itself is difficult to separate from the light used in the light beam. In such cases, other techniques must be utilized.

ON THE STABILITY OF ISOTROPIC TURBULENCE, by R. Betchov. Sept. 1953 [26]p. incl. diagrs. (Technical rept. no. BT-15) [AFOSR-TN-54-345] (AF 18(600)86) AD 18501 Unclassified

Presented at meeting of the Amer. Phys. Soc., Penn. State Coll., University Park, July 1-3, 1953.

Abstract published in Phys. Rev., v. 91: 1031, Aug. 15, 1953.

An analysis of isotropic turbulence indicated that the invariant $\psi = |S_{ik}|$, where S_{ik} is a symmetric tensor, has an upper and a lower limit closely related to the rate of energy dissipation by viscosity. In isotropic turbulence, the average of ψ was proportional to the skewness coefficient S. Experimental evidence suggested that S approaches its maximum value as the Reynolds number tends toward zero. The mean value of the determinant $|U_{ik}|$ was zero for incompressible isotropic and homogeneous turbulence. With certain restrictions and approximations, a perturbation of an incompressible, isotropic and homogeneous field of turbulence had at least one unstable root. The growth of such a perturbation increased with S. (ASTIA abstract)

ON TRIPLE CORRELATIONS IN ISOTROPIC TURBULENCE (Abstract), by R. Betchov. [1954] [1]p. [AF 18(600)86] Unclassified

Presented at annual meeting of the Amer. Phys. Soc., Columbia U., New York, Jan. 28-30, 1954.

Published in Phys. Rev., v. 94: 783, May 1, 1954.

In a turbulent flow, the three points-three velocities correlation functions form a tensor depending on the two displacement vectors A and B. This tensor can be developed in a double power series in A and B with coefficients defined at one point only. Assuming Incompressibility and isotropy relative to rotations and reflexions about one point, we found that the coeffictents of the cubic terms in A^3, AB^2, etc., are all proportional to the mean cube of the local acceleration, that is to the skewness coefficient. Investigations on the stability of such a turbulent flow for perturbations of moderately high-wave numbers lead to the eigenvalues of certain kinematic determinants. The mean values of these determinants are proportional to the skewness coefficient and this parameter appears therefore as an essential quantity Experimental measurements in a turbulent flow behind a grid agree with various consequences of isotropy and confirm the relation between the skewness and the Reynolds number of the turbulence. Furthermore, we found that the mechanism responsible for the skewness coefficient is highly intermittent. (Contractor's abstract)

AN INTRODUCTION TO STRUCTURAL ANALYSIS OF HIGH-SPEED WINGS, by P. J. Theodorides. June 22, 1953. 42p. refs. (Technical rept. no. BT-14) (AF 18-(600)428) AD 57080 Unclassified

This is a review of the present (June 1953) status in analysis of wing structures for aircraft and missiles in high subsonics and beyond. The physical background is emphasized, and the mathematical approach discussed as to research methods and results. The considered wings are thin ones, of low aspect ratio, with sweep and spanwise variation of local rtgidity. It is outlined how their dynamic behavior became predictable by thin plate theory for the solid wtng of constant thickness only. Its static behavior, however, was analytically clarifted by solutions for variable thickness also. As for wings of the stiffened shell type, the Extended Grid method is summarized. It is proceeding with the aid of Green coefficients of tnfluence for determining the alar deformability. Another important new method is surveyed. It achieved a more complete structural analysis by extending the thin plate theory to the reinforced, laminate placoid. The theories are discussed, and the respective solutions are compared as to implications and limitations. Finally it is hinted that work is under way in view of a combined theory for improving this structural analysis. (Contractor's abstract)

LIMITS AND CLASSIFICATION OF SUPERSONIC FLOWS, by T. Theodorsen. Mar. 1954, 26p. diagrs. tables. (Technical note no. BN-23) ([AF]OSR-TN-54-90) (AF 18(600)428) AD 30293 Unclassifted

Necessary and sufficient conditions are presented for the existence or nonexistence of supersonic flow fields. The analysis of the equations of motion of a compressible flow reveals that 2 and only 2 separate and distinct classes of flows exist depending upon whether $(dp/ds)^2 < (1/R^2)f(p)$ or $(dp/ds)^2 > (1/R^2)f(p)$. The first condition is referred to as the sublimit field, and the second is called the translimit field. In both cases, R denotes the radtus of curvature. The sublimit field is exemplified by a potential flow past an airfoil with a supersonic embedded region, and the translimit field is exemplified by the supersonic flow in a Laval nozzle. The 2 fields cannot be joined; a compression flow in a Laval nozzle is prohibited by the second law of thermodynamics whereas a compression flow is the only type possible in the sublimit field. Prandtl-Meyer flow around a corner and the parallel flow represented by a point in the hodograph plane represent a trivial intermediate condition between the sublimit and translimit fields and occur only when $(dp/ds)^2 = (1/R^2)f(p)$.

ELASTIC THEORY OF THE COMPOSITE PLACOID IN STRUCTURAL ANALOGY TO A HIGH SPEED WING, by P. J. Theodorides. July 5, 1954, 47p. incl. diagrs. refs. (Technical note no. BN-37) ([AF]OSR-TN-54-169) (AF 18(600)428) AD 40639 Unclassified

MDU. 08:004 - MDU. 09:001

A theory for the elastic behavior of the composite placoid (plate-like) cantilever as an alar type for high-speed aircraft and missiles is presented which accounts for previously neglected shearing effects in rod-like longitudinats of variable rigidity. The structural analysis combines ideas related to the solid wing and the semimonocoque flattened shell. The theory is based on a quasi 3-dimensionat state for the alar skin and a 2-dimensional state for the longitudinat stiffeners. General analytic expressions are derived for the coefficients of elastic interaction between the alar skin and its swept longitudinals with regard to a structural plagiotropy (the coefficient of rod rigidity (unitary, flexural) as contributed by the i^{th} longitudinat is not equat to zero for atl differing i's) of the exosketeton. Three distinct boundary conditions can be satisfied separately by this analysis, and previously known relations are obtained as special cases of the new theory.

AERODYNAMIC INTERFERENCE OF CASCADE BLADES tN SYNCHRONIZED OSCILLATION, by C.-C. Chang and W.-H. Chu. June 1954 [23]p. incl. diagrs. table, refs. (Technical note no. BN-35) ([AF]OSR-TN-54-170) (AF 18(600)428) AD 36966 Unclassified

Also published in Jour. Appl. Mech., v. 22: 503-508, Dec. 1955.

The failure of a compressor is sometimes due to flutter of the blades. Essentially, this problem is equivalent to a cascade in oscillation. The present analysis is to find the aerodynamic load on cascade in synchronized harmonic oscillations, pitching and flapping. Conformal mapping is used. Two characteristic parameters are involved in the force and moment. One is μ which is related to the gap-chord ratio. The other is k which is known as reduced frequency. The main results are expressed in terms of these two parameters. Most can be reduced to closed form. The rest are given in graphs. The wake interference involves one new function $C(\mu, k)$ which is related to a ratio of two hypergeometric functions and which reduces to Theodorsen's function C(k) in the limit of infinite gap. tn a certain range of frequency and gap-chord ratio, the analysis shows quantitatively that single oscillation airfoil theory may lead to inaccurate estimation of interference effect between blades. AXIALLY SYMMETRIC PUNCH AND CRACK PROBLEMS, by L. E. Payne. Oct. 1953, 30p. incl. refs. (Technical rept. no. BT-17) (AF 18(600)573) AD 21418 Unclassified

A formulation of axially symmetric punch and crack problems is presented for a medium with transverse isotropy. Complete solutions to general problems are obtained without solving dual integral equations. The formulation reduces to that of solving simple potential problems and permits the convenient introduction of curvilinear coordinates. Solutions to the problem of determining the stress distribution in a semi-infinite isotropic elastic medium when the plane boundary is indented by a perfectly rigid, axially symmetric punch are presented for the case in which the indenting surface is flat, a segment of a sphere, an oblate sphere, or a parabolic segment. Solutions are presented for a spherical, oblate-spherical, and paraboloidal pressure distributions. The stress distribution in an infinite elastic medium where the pressure is prescribed on a disk-shaped crack is considered, and solutions are presented for constant, parabolic, and spherical pressure distributions. Solutions are also presented for the crack problem when the displacement is prescribed. The problems of a point force in the z-direction in the interior of a semi-infinite body $z \geq o$ as well as the corresponding problem in a medium with transverse isotropy are discussed.

RIEMANN'S METHOD FOR PARTIAL DIFFERENTIAL EQUATIONS OF HYPERBOLIC, PARABOLIC, AND ELLIPTIC TYPES, by J. B. Diaz and M. H. Martin. Dec. 9, 1953, 32p. (Technical rept. no. BT-18) (AF 18(600)573) AD 21775 Unclassified

Also published in Ann. Mat. Pura Appl., v. 36: 335-359, 1954.

An investigation is made of partial differential equations of second order, $L(u) = a^{ij}u_{x_i x_j} + a^{i}u_{x_i} = 0$, in 2 independent variables x_1, x_2. Instead of the adjoint equation by Riemann a second partial differential equation $M(v) = b^{ij}v_{x_i x_j} + b^{i}v_{x_i}$ is taken, and its coefficients are determined, together with 2 multipliers λ, μ, such that

$\lambda L(u) + \mu M(v) = \frac{\partial A^1}{\partial x_1} \quad \frac{\partial A^2}{\partial x_2}$, where A^1, A^2 are bilinear forms in the 4 arguments u_{x_1}, u_{x_2}, v_{x_1}, v_{x_2}.

When this is completed the line integral $1 = \int\left[-A^2 dx_1 + A^1 dx_2\right]$ vanishes around closed paths, provided u, v are regular solutions of $L(u) = 0$ and $M(v) = 0$. These considerations are used to unify the treatment of the problem of Cauchy for hyperbolic equations, the initial value problem for parabolic equations, and the Dirichlet problem for equations of the elliptic type. FLOW PROBLEMS FOR RING-SHAPED BODIES WITH APPLICATION TO TORSION PROBLEM, by G. Weiss and L. E. Payne. Dec. 1953, 23p. incl. illus. refs. (Technical rept. no. BT-19) (In cooperation with Naval Ordnance Lab., White Oak, Md.) [AFOSR-TN-54-2] [AF 18(600)573] AD 22953 Unclassified

An extension was made of the method of generalized electrostatics (Bull. Amer. Math. Soc., v. 59: 20-38, 1953) so that it will be applicable to flow or torsion problems for ring-shaped bodies. The flow and torsion problems involving toroidal boundaries are presented as special examples. A method was developed for obtaining the flow about a generally axially symmetric n-dimensional body with doubly connected section. The cases for n = 2, 3, and 5 have immediate physical interpretation. The methods proposed can be easily extended to handle problems involving 2 or more bodies which may or may not have simply connected sections. The solution of the problem of a 5-dimensional axially symmetric body in a uniform stream of inviscid incompressible fluid flowing parallel to the axis of symmetry of infinity is shown to be related to the torsion problem for a beam with an axially symmetric cavity. Solutions to the flow problem are obtained for the torus and the torsion problem for a near-cylindrical shaft with a toroidal cavity.

ON THE ISOPERIMETRIC INEQUALITY ON SURFACES

MDU. 09:006 - MDU. 09:009

OF VARIABLE GAUSSIAN CURVATURE, by A. Huber. Jan. 1954, 17p. (Technical rept. no. BT-20) [AFOSR-TN-54-8] (AF 18(600)573) AD 25539 Unclassified

Also published in Ann. Math., v. 60: 237-247, Sept. 1954.

An isoperimetric inequality which includes inequalities given by T. Carleman (Math. Zeitschr., v. 9: 154-160, 1921) and F. Fiala (Comm. Math. Helv., v. 13: 293-346, 1940-41) is proved for any sufficiently regular abstract surface. The demonstration is based on an inequality for subharmonic functions and generalizes a result of Carleman and its extension by Beckenbach and Radó (Trans. Amer. Math. Soc., v. 33: 662-674, 1933). A new method of proof of Fiala's inequality is suggested which is valid under less restrictive regularity assumptions, and the inequality is used to characterize surfaces of non-negative curvature.

THE CAUCHY PROBLEM FOR THE WAVE EQUATION AND THE EQUATION OF EULER-POISSON-DARBOUX, by A. Weinstein and E. K. Blum. Jan. 1954, 38p. incl. refs. (Technical note no. BN-22) [AFOSR-TN-54-23] (AF 18(600)573) AD 26066 Unclassified

Consideration is given to the general Euler-Poisson-Darboux equation which depends on a parameter k and which reduces to the wave equation for k = 0. A recently developed method is presented for the solution of the corresponding singular Cauchy problem with data on the singular hyperplane t = 0 for all values of k. The method utilizes neither a fundamental solution nor a Green's identity. For sufficiently large values of k the solution is written explicitly, and for other values of k the Cauchy problem is solved with the aid of 2 simple recurrence formulas for functions of one variable t. The negative odd integral values of k play an exceptional role with no counterpart in the theory of equations with regular coefficients, a new solution for these cases is appended.

A TRANSONIC APPROXIMATION, by J. B. Diaz and G. S. S. Ludford. Mar. 1954, 21p. illus. refs. (Technical note no. BN-24) ([AF]OSR-TN-54-79) (AF 18(600)573) AD 28934 Unclassified

Also published in Proc. Second U. S. National Congress on Applied Mechanics, Michigan U., Ann Arbor (June 14-18, 1954), N. Y., Amer. Soc. Mech. Engineers, 1955, p. 651-657.

This approximation is based on obtaining that pressure-density relation which best fits that of a polytropic gas near the sonic point, while retaining the analytical simplicity of the Tricomi gas. Third-order contact can be obtained at the sonic point, and there still remains a parameter, which can be chosen in two ways so as to give good supersonic agreement. These two choices give practically identical results. For this approximation the general solution of the partial differential equation for the stream-function is expressible in terms of Bessel functions, as also are the product solutions. ON TWO METHODS OF GENERATING SOLUTIONS OF LINEAR PARTIAL DIFFERENTIAL EQUATIONS BY MEANS OF DEFINITE INTEGRALS, by J. B. Diaz and G. S. S. Ludford. Apr. 1954, 9p. refs. (Technical note no. BN-26) ([AF]OSR-TN-54-87) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)573 and Office of Ordnance Research under DA-36-034-ord-1486) AD 30295 Unclassified

Also published in Quart. Appl. Math., v. 12: 422-427, Jan. 1955.

A connection is established between Bergman's integral operator method (Amer. Jour. Math., v. 74: 444-474, 1952) and a classical method of Le Roux (Annales de l'Ecole Normale Supérieure, 3rd Series, v. 12: 227-316, 1895) for generating solutions of linear differential equations by means of definite integrals with variable limits of integration. A proof is presented that a theorem of Bergman and its modification to include functions of a complex variable are a restatement of part of Le Roux's results. The latter formulation is considered to be simpler in the fluid dynamical application. (ASTIA abstract)

ON THE GROWTH OF SOLUTIONS OF NON-LINEAR ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS, by R. Finn. May 1954. 18p. (Technical note no. BN-32) ([AF]OSR-TN-54-133) (AF 18(600)573) AD 34015 Unclassified

Consideration is given to equations of the form $\mathfrak{M}(x, y, \zeta, p, q)_x + \Lambda(x, y, \zeta, p, q)_y = 0$, where $p = \zeta_x$, and $q = \zeta_y$. It is shown that the condition $\mathfrak{M}^2 + \Lambda^2 \cdot 1$ on the integrals of the coefficients with respect to their arguments, together with the ellipticity condition $4\mathfrak{M}_p\Lambda_q - (\mathfrak{M}_q + \Lambda_p)^2 > 0$ is sufficient to permit an a priori estimate on the growth of a solution; but it is not sufficient to permit a corresponding estimate on the derivatives. The analysis depends on the concept of quasi conformality of a mapping. This concept is defined: let $\omega = u + iv$ be a complex valued function of class C''' defined in a domain D of the $z = y + iy$ plane; ω represents a quasi-conformal mapping of eccentricity not larger than ε, $1 \leq \varepsilon < \infty$, provided that (1) the Jacobian $\left(\frac{uv}{xy}\right)$ of the transformation vanishes only at isolated points, and (2) at all points where the Jacobian is different from zero, $(u_x^2 + u_y^2 + v_x^2 + v_y^2)\left(\frac{x\ y}{u\ v}\right) \leq 2\varepsilon$.

ON A THEOREM OF LE ROUX, by J. B. Diaz and G. S. S. Ludford. Aug. 1954, 6p. (Technical note no. BN-38) ([AF]OSR-TN-54-166) (Sponsored jointly by "Air Force" Office of Scientific Research under AF 18-(600)573 and Office of Ordnance Research under DA-36-034-ord-1486) AD 36551 Unclassified

Also published as Interim technical rept. no. 19. Mar. 1956, 4p. DA-36-034-ord-1486; AD 88238.

An extension to definite integrals with singular kernels is given of a theorem of Le Roux (Annales de l'École Normale Supérieure, Series 3, v. 12: 227-316, 1895) which concerns the generation of solutions of linear partial differential equations by means of definite inte-

MDU. 09:015 - MDU. 09:018

grals. The extended theorem is as follows: Let R be an open region of the x, y plane where the coefficients of $L(u) \equiv U_{xy} + a(x,y)u_x + b(x,y)u_y + c(x,y)u = 0$ are continuous, and let $U(x,y,\alpha) = \widetilde{U}(x,y,\alpha)/(x-\alpha)^{\lambda}$, with $0 < \lambda < 1$, be a solution of $L(u) = 0$ for all (x,y) in R, wherever $\alpha_0 \leq \alpha < x$. Let U be such that $\widetilde{U}$, $\widetilde{U}_x$, $\widetilde{U}_y$, $\widetilde{U}_{xy}$, $\widetilde{U}_{\alpha}$, $\widetilde{U}_{\alpha x}$, $\widetilde{U}_{\alpha y}$, $\widetilde{U}_{\alpha xy}$ are continuous on the 3-dimensional region consisting of all (x,y,α) with (x,y) in R and $\alpha_0 \leq \alpha \leq x$. Then

$$u(x,y) = \int_{\alpha_0}^{x} \frac{\widetilde{U}(x,y,\alpha)}{(x-\alpha)^{\lambda}} f(\alpha)\, d\alpha$$

is, for an arbitrary once continuously differentiable function $f(\alpha)$, a solution of $L(u)$ in R. Throughout the discussion, α is a parameter and α_0 is a constant. (ASTIA abstract)

A RAYLEIGH-RITZ PROCEDURE GIVING UPPER AND LOWER BOUNDS FOR EIGENVALUES, by H. F. Weinberger. Sept. 1954, 30p. (Technical note no. BN-41) ([AF]OSR-TN-54-264) (AF 18(600)573) AD 44269 Unclassified

Presented at meeting of the Amer. Math. Soc., Laramie, Wyo., Aug. 31-Sept. 3, 1954.

If A and P are positive self-adjoint elliptic differential operators with A of higher order than P, the Rayleigh-Ritz method gives upper bounds for the eigenvalues of $Au = \lambda Pu$. If another such eigenvalue problem, $Bv = \mu Qv$, where B has the same principal part as A and Q is of the same order as P, can be solved and if its eigenfunctions are used in the Rayleigh-Ritz method, the error in the upper bounds for the λ_k is explicitly bounded. The error bound can be made arbitrarily small by using enough eigenfunctions. The eigenvalues of any sufficiently regular ordinary differential operator as well as many partial differential operators may be approximated in this way. (Contractor's abstract)

ON THE SINGULAR CAUCHY PROBLEM FOR A GENERALIZATION OF THE EULER-POISSON-DARBOUX EQUATION IN TWO SPACE VARIABLES, by J. B. Diaz and G. S. S. Ludford. Oct. 1954, 25p. incl. refs. (Technical note no. BN-34) ([AF]OSR-TN-54-280) (AF 18(600)573) AD 44333 Unclassified

Also published in Ann Mat. Pura Appl., Series IV, v. 38: 33-50, 1955.

An existence and uniqueness theorem is presented for the singular Cauchy problem for the nonhomogeneous Euler-Poisson-Darboux equation in 2 space variables, $u_{xx} + u_{yy} - u_{tt} - \frac{k}{t}u_t = f(x,y,t)$, $t > 0$, $k > 0$, $u(x,y,o) = u_t(x,y,o) = 0$. The solution of this problem is used to prove, by Picard's method of successive approximations, an existence and uniquesness theorem for the following singular Cauchy problem:

$u_{xx} + u_{yy} - u_{tt} - \frac{k}{t}u_t - h(x,y,t)u = 0$, $t > 0$, $k > 0$,

$u(x,y,o) = g(x,y)$, $u_t(x,y,o) = 0$.

ON AN INEQUALITY OF FEJÉR AND RIESZ, by A. Huber. Dec. 1954, 29p. refs. (Technical rept. no. BT-45) ([AF]OSR-TN-54-341) (AF 18(600)573) AD 49708 Unclassified

Also published in Ann. Math., v. 63: 572-587, May 1956.

The following theorem by Fejér and Riesz (Math. Zeitschr., v. 11: 305-314, 1929) and some of its extensions are generalized. Suppose the function $f(z)$ is regular analytic on $|z| \leq 1$. Then the inequality $\int_{-\pi}^{\pi} |f(e^{it})|^{\lambda} dt \geq 2 \int_{-1}^{1} |f(\rho, e^{i\theta})|^{\lambda} d\theta$ holds for any θ $(0 \leq \theta \leq 2\pi)$ and arbitrary $\lambda > 0$. Equality is attained if and only if $f \equiv 0$. The constant 2 is the best possible. The main result of the generalization is also stated as a theorem. Let the function $u(z)$ be defined on the closed unit circle $|z| \leq 1$ as a difference of 2 subharmonic functions $u(z) = u_1(z) - u_2(z)$. Suppose that $u_2(|\zeta| < 1) = \alpha < \infty$, where $u_2(e^{i\zeta})$ denotes the meas-

ure associated with $u_2(z)$. Then the inequality $\int_{-\pi}^{+\pi} e^{u(e^{it})} dt \geq 2\cos(\frac{\pi\alpha}{2}) \int_{-1}^{1} e^{u(\rho e^{i\theta})} d\rho$ holds for any θ ($0 \leq \theta < 2\pi$). Equality holds if and only if $0 < \alpha < 1$ and $u = \log |F^1(z)[F(z)]^{-\alpha}(1-F^2(z))^{\alpha-1}| + C$, where $F(z)$ denotes any conformal transformation of $|z| < 1$ onto itself which maps the diameter $(e^{i\theta}, -e^{i\theta})$ on the real axis; C is an arbitrary real constant. The integrals of the theorem do not necessarily exist under the given hypothesis, but the proof implies that if the integral on the left exists then so does the integral on the right and the inequality holds.

INEQUALITIES FOR CERTAIN EIGENVALUES OF A MEMBRANE (Abstract), by L. E. Payne. [1954] [1]p. (AF 18(600)573) Unclassified

Presented at meeting of the Amer. Math. Soc., Laramie, Wyo., Aug. 31-Sept. 3, 1954.

Let D be a closed domain with boundary C in the xy plane and let u(x, y) satisfy the differential equation, $\Delta u + ku = 0$ in D, (where k is a positive constant) and either (1) $u = 0$ on C or (2) $\partial u/\partial n = 0$ on C. We denote the eigenvalues in case (1) by $\lambda_1 \leq \lambda_2 \leq \lambda_3 \leq \ldots$, and in case (2) by $0 = \mu_1 \leq \mu_2 \leq \mu_3 \leq \ldots$. It has been shown by Szegö (Jour. Rat. Mech. and Analysis, v. 3: 354, 1954 that $\mu_2 \leq p\lambda_1$, where p is the constant giving equality if D is a circle. In this article, we obtain for a convex domain D the following inequalities: (3) $\mu_2 \leq \lambda_1 - \frac{2}{(\rho h)_{max}}$ and (4) $\mu_3 \leq \lambda_1 - \frac{(\sqrt{2}-1)}{(\rho h)_{max}} \leq \lambda_1$, where ρ is the radius of curvature of C, and the value of h at any point P on C is the distance from an arbitrary origin inside D to the line tangent to C through P. THE ELASTIC SPINDLE UNDER CONCENTRATED TORQUES APPLIED AT THE POLES, by L. E. Payne. Mar. I955, 8p. refs. (Technicat note no. BN-49) ([AF]OSR-TN-55-74) (AF I8(600)573) AD 58484 Unclassified

Atso pubtished in Jour. Science and Engineering, v. I: 37-42, Jan. I957.

The problem of an etastic spindte subjected to 2 concentrated couptes apptied at the potes is considered. The introduction of dipolar coordinates permits a convenient representation for the stress function in terms of Legendre functions. Simpte expressions for the stress function and the stresses are obtained, and the nonvanishing component of the displacement is catcutated for the case of the sphere.

ON A REGULAR CAUCHY PROBLEM FOR THE EULER-POISSON-DARBOUX EQUATION, by R. M. Davis. Apr. 1955, 47p. incl. diagr. refs. (Technical note no. BN-50) ([AF]OSR-TN-55-104) (AF 18(600)573) AD 61001 Unctassified

Atso published in Ann. Mat. Pura Appl., v. 42: 205-226, 1956.

The n-dimensional Eu[illegible] Poisson-Darboux equation (EPD equation) is given

$L_x[u] = u_{x_o x_o} - \sum_{i=1}^{n-1} u_{x_i x_i} + \frac{k}{x_o} u_{x_o} = 0$, where

$x = (x_o, x_1, \ldots, x_{n-1})$ denotes a point in a space-time of n-dimensions, and where k is any real number, $-\infty < k < \infty$. This equation yields the wave equation as a special case for $k = 0$. In this study, the solution of a regular Cauchy problem for the EPD equation with initial conditions

$u(t_o, x_1, \ldots, x_{n-1}) = f(x_1, \ldots, x_{n-1})$ and

$u_x(t_o, x_1, \ldots, x_{n-1}) = 0$ is found. To obtain the solution, the method of Marcel Riesz, developed only for self-adjoint differential equations is extended to cover the non self-adjoint EPD equation. This method of solution involves constructing a function $V^\alpha(x,y)$ depending on a parameter α such that $M_y[V^{\alpha+2}] = V^\alpha = L_x[V^{\alpha+2}]$, where M is the adjoint operator to L, and such that $V^\alpha(x,y)$ and its first derivatives vanish on the characteristic cone with vertex x. A MAXIMUM PROPERTY OF CAUCHY'S PROBLEM, by H. F. Weinberger. Apr. 1955, 12p. refs. (Technical note no. BN-51) ([AF]OSR-TN-55-110) (AF 18(600)573) AD 62165 Unclassified

Also published in Ann. Math., v. 64: 505-513, Nov. 1956.

It is shown that if the coefficients of the hyperbolic equation $M[u] + eu \equiv (au_x)_x - (bu_y)_y + (cu)_x + (du)_y + eu = 0$ satisfy certain inequalities, and if the Cauchy data u and $\frac{\partial u}{\partial y}$ are nonpositive on an initial arc, then u is nonpositive in the domain of influence of the initial arc. It follows that the Riemann function is nonnegative, and hence that for fixed Cauchy data, u decreases as $M[u] + eu$ increases. An application to ordinary differential equations results in the generalization of a theorem of Bochner on double eigenfunction expansions. (Contractor's abstract)

MULTIVALUED FUNCTIONS IN GENERALIZED AXIALLY SYMMETRIC POTENTIAL THEORY, by L. E. Payne. May 1955, 18p. (Technical note no. BN-52) ([AF]OSR-TN-55-146) (AF 18(600)573) AD 66847 Unclassified

Also published in Estratto dagli Ann della Scoula Normale Superiore (Pisa), v. 10: 135-145, 1956.

A representation is obtained for the many-valued function conjugate to the Neumann function for a half plane. This Neumann function is identified as the potential of a source ring, and the conjugate function is identified as the stream function for the same ring. Toroidal coordinates are introduced to obtain a representation of the stream function as a sum of 2 terms. The first term is an arc cotangent a multivalued quantity which displays the cyclic nature of the stream function; the second term is single-valued and vanishes at the branch point. This latter quantity is written as an integral or as a sum of Legendre functions. The solution for the stream function of the source disk is represented in the same manner. New representations for the stream function for a vortex ring to the potential of a source ring are presented. The stream function for a source disk can be represented as the sum of the stream function for a source ring and a quantity which is related to the potential of a vortex ring. The analytical character of all of these functions is exhibited.

Also published in Communications on Pure and Appl. Math., v. 9: 471-478, Aug. 1956.

A proof is given of the following theorem: suppose that the function $w(x_1, x_2, \ldots, x_n)$ is harmonic of order p (p is a positive integer) in a region G in n-dimensional space, the boundary of which contains an open subset S of the hyperplane $x_1 = 0$, and that w/x_1^{p-1} assumes the boundary value 0 on S; then w can be continued analytically across S into the reflected domain G* by the relation $w(-x_1, x_2, \ldots, x_n) = \sum_{k=0}^{p-1} \frac{(-x_1)^{p+k}}{(k!)^2} \Delta^k \left(\frac{w(x_1, x_2, \ldots, x_n)}{x_1^{p-k}} \right)$.

As an application, the following Phragmen-Lindelöf type of theorem is obtained: suppose that $w(x)$ is harmonic of order p throughout the half-space $x_1 > 0$ and that w/x_1^{p-1} assumes the boundary value 0 on $x_1 = 0$, then $w = o(|x|^p)$ implies $w \equiv 0$.

THE THICK ELASTIC SPHERICAL SHELL UNDER CONCENTRATED TORQUES, by J. H. Bramble. July 1955, 17p. (Technical note no. BN-54) ([AF]OSR-TN-55-249) (AF 18(600)573) AD 69583 Unclassified

In this study, a thick elastic spherical shell subjected to concentrated torques at the end points of a diameter is considered. It is proved that the solution is determined uniquely, and an explicit expression is derived for it. Extensive use is made of the fact that the stress function is closely related to an axially symmetric harmonic function, defined in a 7-dimensional space.

SOME RESULTS ON GENERALIZED AXIALLY SYMMETRIC POTENTIALS, by A. Huber. Oct. 1955, 15p. incl. refs. (Technical note no. BN-58) ([AF]OSR-TN-55-366) (AF 18(600)573) AD 74510 Unclassified

Also published in Proc. Conference on Differential Equations, Maryland U., College Park (Mar. 17-19, 1955), 1956, p. 147-155.

Some properties of the solutions of the elliptic partial differential equation $L_k[u] \equiv \sum_{i=1}^{n} \frac{\partial^2 u}{\partial x_i^2} + \frac{k}{x_n} \frac{\partial u}{\partial x_n} = 0$,

where k a real constant, are discussed. The method of generating solutions is given by 2 principles. (1) Let k be a positive integer, then the function $u(x_1, x_2, \ldots, x_n)$, defined in a subregion of the half-space $x_n > 0$, is a solution of $L_k[u] = 0$ if and only if the function $W(\xi_1, \xi_2, \ldots, \xi_{n+k}) \equiv v(\xi_1, \xi_2, \ldots, \xi_n, 1)$

$\sqrt{\xi_n^2 + \ldots + \xi_{n+k}^2}$) is harmonic in the corresponding domain in (n+k)-dimensional space. (2) If u is a solution of $L_k[u] = 0$ in a region G not intersecting with $x_n = 0$, then the function $v = ux_n^{k-1}$ satisfies $L_{2-k}[v] = 0$ and vice versa.

TWO INEQUALITIES FOR EIGENVALUES OF MEMBRANES, by L. E. Payne and H. F. Weinberger. Nov. 1955, 15p. (Technical note no. BN-65) ([AF]-OSR-TN 55-420) (AF 18(600)573) AD 77324 Unclassified

The first part proves the following isoperimetric inequality. Let R be an N-dimensional region. Let μ_2 be the second (first nonzero) eigenvalue of the problem $\Delta u + \mu u = 0$ on R with the boundary condition $\partial u/\partial n = 0$. Let μ_2^* be the second eigenvalue for the same problem in the N-sphere of the same N-volume as R. Then $\mu_2 \leq \mu_2^*$. The second part deals with the problem $\Delta u + \lambda u = 0$ with the boundary condition $\partial u/\partial n + ku = 0$, $k \geq 0$. Lower bounds for the lowest eigenvalue of this problem on a 2- or 3-dimensional region R are given in terms of k, and the maximum length of line segments in R parallel to the coordinate axes. The inequalities become equalities for rectangles and rectangular parallelopipeds. Similar lower bounds are given for the second eigenvalue when R is symmetric with respect to the coordinate axes or planes. (Contractor's abstract)

PROOF OF AN EXISTENCE AND UNIQUENESS THEOREM OF PICARD FOR A NON-LINEAR HYPERBOLIC PARTIAL DIFFERENTIAL EQUATION, BY MEANS OF AN ANALOGUE OF CAUCHY'S POLYGON METHOD, by R. H. Moore. Jan. 1956, 19p. (Technical note no. BN-67) (AFOSR-TN-56-41) (AF 18(600)-573) AD 80553 Unclassified

Following the general method used in proving the existence and uniqueness of the solution of the Cauchy problem for the first order ordinary differential equation by means of Cauchy polygons of approximation, this study considers the existence and uniqueness of the solution of an analogous boundary value problem for a second order hyperbolic partial differential equation by means of approximate solutions which are essentially surfaces of approximation. As in the method for the ordinary equation, a set of convergence inequalities is first obtained, and then it is shown, by means of these inequalities, that the sequence of approximate solutions defined converges uniformly to a unique solution of the hyperbolic equation. ON THE ITERATED WAVE EQUATION, by D. Krahn. May 1956, 29p. (Technical note no. BN-73) (AFOSR-TN-56-239) (AF 18(600)573) AD 88359 Unclassified

Also published in Nederl. Akad. Wetensch. Proc., Indag. Math., Ser. A, v. 60: 492-505, 1957.

A theorem on the decompositions of the general solution of the iterated wave equation is established in terms of solutions of the Euler-Poisson-Darboux equation. A particular decomposition is then chosen to solve a Cauchy problem for the equation $L_o^n(w) = 0$, where $L_o^n \equiv \left(\frac{\partial^2}{\partial n_1^2} + \frac{\partial^2}{\partial n_2^2} + \ldots + \frac{\partial^2}{\partial n_v^2} - \frac{\partial^2}{\partial t^2}\right)^n$ and w is the solution of the equation $L_o^n(w) = 0$, with initial conditions on the boundary $t = 0$. Application of essentially the same techniques is briefly shown for solution of the more general equation $\prod_{i=1}^{n} \left(a_i^2 \frac{\partial^2}{\partial t^2} - \Delta\right) W = 0$. INEQUALITIES FOR EIGENVALUES OF SUPPORTED AND FREE PLATES, by L. E. Payne. June 1956, 25p. refs. (Technical note no. BN-75) (AFOSR-TN-56-281) (AF 18(600)573) AD 89491 Unclassified

The eigenvalues in the vibration and buckling problems for a supported or free plate were bounded in terms of the eigenvalues in the corresponding fixed or free membrane problems. Eigenvalues of the fixed membrane are monotone with region, while those for the plate problems considered are not. Under certain symmetry conditions, one can obtain a lower bound for the first nonzero eigenvalue in the free membrane problem which involves only the geometry of the region. There are also inequalities which involve the geometry of the plate and the eigenvalues of membranes having the same shape as that of the plate.

UPPER AND LOWER BOUNDS FOR EIGENVALUES, by J. B. Diaz. June 1956, 47p. refs. (Technical note no. BN-74) ([AF]OSR-TN-56-283) (AF 18(600)-573) AD 89493 Unclassified

Published in Proc. Symposia in Appl. Math. of the Amer. Math. Soc., Chicago, U., Ill. (Apr. 12-13, 1956), New York, McGraw-Hill Book Co., Inc., Vol. VIII, Calculus of Variations and Applications, 1958, p. 53-78.

An account is given of the underlying ideas of the Raleigh-Ritz and the Weinstein methods for the approximation of upper bounds and lower bounds of eigenvalues, respectively. For definiteness, attention has been focussed on a particular differential problem, that of a vibrating clamped plate which was originally utilized by Weinstein (Mémorial des Sciences Mathématiques, v. 88, 1937) in developing his method. In addition, almost all of the relevant differentiability hypotheses required of the "arbitrary" functions occurring in the discussion have been omitted. The eigenvalues are supposed to be defined by means of certain variational problems, and the question of the equivalence between these problems and the corresponding differential problems is not analyzed. The variational problems are used in Section 2 as a basis for all later considerations. In Section 3, the Raleigh-Ritz method is considered, and in Section 4, the Weinstein method is treated.

NEW ISOPERIMETRIC INEQUALITIES FOR EIGENVALUES AND OTHER PHYSICAL QUANTITIES, by L. E. Payne. [1956] [12]p. incl. refs. (AF 18(600)-573) Unclassified

Presented at Symposium on Partial Differential Equations, California U., Berkeley, June 20-July 1, 1955.

Published in Trans. Symposium on Partial Differential Equations, California U., Berkeley (June 20-July 1, 1955), N. Y., Interscience Publishers, Inc., 1955, p. 233-244.

Published in Communications on Pure and Appl. Math., v. 9: 531-542, Aug. 1956.

Isoperimetric inequalities, which include any inequality connecting two or more physical quantities associated with the same region, are derived for the eigenvalues of certain classical plate and membrane problems where the displacement is considered to satisfy a certain differential equation in a plane domain D with boundary C in the x, y-plane. The problem of Stekloff is then considered in an infinite three-dimensional region D* which lies exterior to the closed surface C*; isoperimetric inequalities are obtained for the first and second eigenvalues. Inequalities for certain other physical quantities are derived in order to establish some of the eigenvalue relationships obtained. The eigenvalue problems considered include (1) $\Delta u + \lambda u = 0$ in D, $u = 0$ on C, the classical membrane problem; (2) $\Delta^2 w + \Lambda \Delta w = 0$ in D, $w = \frac{\partial w}{\partial n} = 0$ on C, as well as (3) $\Delta^2 \zeta + \mu \Delta \zeta + b\zeta = 0$ in D, (b= const. > 0), $\zeta = \frac{\partial \zeta}{\partial n} = 0$ on C, buckling problem for a clamped plate; (4) $\Delta^2 \varphi - \Omega \varphi = 0$ in D, $\varphi = \frac{\partial \varphi}{\partial n} = 0$ on C, as well as (5) $\Delta^2 \psi - a\Delta\psi - \Gamma\psi = 0$ in D (a const. > 0), $\psi = \frac{\partial \psi}{\partial n} = 0$ on C, both vibration problems for a clamped plate; and (6) $\Delta \chi = 0$ in D, $\frac{\partial \chi}{\partial n} = k\chi$ on C*, $\chi = 0(R^{-1})$ as $R \to \infty$, the Stekloff problem, Δ denotes the Laplace operator, $\vec{n}$ denotes the outward normal from D (or D*) on C (or C*), $R^2 = x^2 + y^2 + z^2$, and λ, Λ, Ω, Γ, u, and k are constants (eigenvalues) to be determined.

ON THE RATIO OF CONSECUTIVE EIGENVALUES, by L. E. Payne, G. Pólya, and H. F. Weinberger. [1956] [10]p. (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under [AF 18(600)573] Unclassified

Published in Jour. Math. and Phys., v. 35: 289-398, Oct. 1956.

The eigenvalues considered are those in the three problems for a two-dimensional domain D with boundary C, and

$\Delta u + \lambda u = 0$ in D, $u = 0$ on C,

$\Delta\Delta u - \mu u = 0$ in D, $u = \partial u/\partial n = 0$ on C,

$\Delta\Delta u + \nu\Delta u = 0$ in D, $u = \partial u/\partial n = 0$ on C.

Let λ_n, μ_n, ν_n be the eigenvalues in these problems respectively. It is proved that

$$\lambda_{n+1} \leq \lambda_n + 2(\lambda_1 + \cdots + \lambda_n)/n,$$

$$\mu_{n+1} \leq \mu_n + 8(\mu_1 + \cdots + \mu_n)/n,$$

so that $\lambda_{n+1} \leq 3\lambda_n$, $\mu_{n+1} \leq 9\mu_n$. The method (selection of appropriate trial-functions) is not so successful for (3), in which it is proved only that $\nu_2 < 3\nu_1$. A proof of $\lambda_2 + \lambda_3 \leq 6\lambda_1$ is also sketched. (Math. Rev. abstract)

THE STRUCTURE OF TURBULENCE, by T. Theodorsen. May 1954, 18p. illus. diagrs. (Technical note no. BN-31) ([AF]OSR-TN-54-131) (AF 18-(600)893) AD 33852 Unclassified

The theory of turbulence is based on the existence of a unique and universal turbulent structure previously introduced. The theory prescribes the existence of an oriented array of bent-vortex formations which are arranged so that work is continually transferred from the main flow to the primary disturbance, and from this primary structure to an external array of secondary structures. The process continues until the smallest existing subdivision is reached. The characteristic structure is referred to as the horseshoe. Each horseshoe is attached to one of the preceding order in such a way as to exert the greatest energy extraction so that a number of horseshoes is created at the expense of the energy contained in the larger order horseshoe. The theory is neither homogeneous nor isotropic because of the oriented structures, and it is considered probable that real turbulence is associated with a shear force and vice versa. The treatment is restricted to shear turbulence in full equilibrium. Experimental verification has been obtained by other researchers on the physical appearance of the proposed turbulent structure.

DISCRETE VORTICES IN THE TRANSITION RANGE OF FLOW IN A PIPE, by J. R. Weske. Feb. 1955, 14p. illus. diagrs. refs. (Technical note no. BN-47) ([AF]OSR-TN-55-37) (AF 18(600)893) AD 54115 Unclassified

Experimental results are presented of the action of 3-dimensional discrete vortices of the Theodorsen-horseshoe-vortex type on the flow in a 6-in. -id, 68-ft long straight tube. The flow, though distorted by the vortices, remained laminar around the vortex filaments and throughout their core up to Re = 4000. The vortex motion itself appeared to be stable and ultimately died down under the effect of viscosity. The travel of vortex centers normal to the direction of mean flow is regarded as being the most significant feature of the motion. Discussions are given of the Magnus effect, momentum drag, effects near the roots of the horseshoe vortices, effects in plan view of the vortex filament, and viscous effects. The observed behavior of horseshoe vortices stretched in a shear flow may be explained by the relative motion between the vortex and the ambient fluid which is caused by the Magnus effect and momentum transfer.

THE EFFECT OF STRETCHING OF A VORTEX CORE, by J. R. Weske. Aug. 1955 [20]p. incl. illus. diagrs. (Technical note no. BN-57) ([AF]OSR-TN-55-282) (AF 18(600)893) AD 71270 Unclassified

The investigation concerns the core of a straight vortex which is simplified by assuming that it extends to a definite radius within which the rotation is constant. The vortex field surrounding the core is irrotational, and the effects of viscous action and of compressibility between the initial and final states are disregarded. The results show that backflow occurs in the core as the stretching exceeds a certain value. The resulting flow in an annular region close to the center of the core becomes radially unstable. Experimental evidence is presented to show that the backflow actually occurs. (ASTIA abstract)

EXPLANATION OF THE OCCURRENCE OF A LIFT-FORCE ON AN OBJECT PLACED IN VORTEX, by D. F. Gates. [Mar. 31, 1955] 5p. illus. (AF 18(600)893) Unclassified

An experiment was conducted on reproducing a vortex in a cylindrical bottle by means of water jets directed tangentially along the bottle wall. A golf ball of density greater than water is supported near the vortex midpoint of the vortex axis. A guide wire attached to the ball is inserted in a vertical tube allowing the ball to move axially upward but preventing radial motion. From the pressure relationships in the vortex and the axial variation of the core radius, an axial static pressure gradient was established. From the pressure relationships in the vortex and the axial variation of the core radius, the presence of an axial static pressure gradient was established. If a solid body is placed in a region of the vortex in which this axial pressure gradient exists, a pressure force is exerted upon the body in the direction of lower pressure. If the core radius below the object is larger than the above, then there is an upward force or "lift." The existence of a lift force is thus explained. (Contractor's abstract)

A METHOD FOR THE MEASUREMENT OF THE FLOW OF AIR BY MEANS OF SERIES OF ELECTRIC SPARKS, by H. J. Bomelburg. Feb. 1955 [39]p. incl. illus. diagrs. (Technical note no. BN-68) ([AF]OSR-TN-56-38) (AF 18(600)893) AD 80549 Unclassified

MDU. 10:006 - MDU. 11:004

A technique has been developed in which series of electric sparks of low current are used to render visible the flow of air. Sparks traversing the air at very high frequency produce visible successive-displacement profiles, photographic records of which furnish detailed information. The method is applicable to both subsonic and supersonic flow. The technique has been investigated in detail. Its merits and limitations are compared with other methods. Photographs are presented to illustrate possible applications. (Contractor's abstract)

THE EFFECT OF STRETCHING OF A VORTEX-CORE, by J. M. Burgers. Aug. 1956, 22p. incl. diagr. (Technical note no. BN-80) (AFOSR-TN-56-376) (AF 18(600)893) AD 95812 Unclassified

General relations are established for axially symmetrical nonviscous, rotational flows between converging or diverging meridional streamlines when initially the axial velocity is constant, the radial velocity zero and the radial distribution of peripheral velocity is known. The equations are solved in detail for numerical evaluation for the particular case of a vortex core with solid body rotation, either contained in a duct or surrounded by a potential vortex. A theoretical treatment is given of the problem of stability connected with this type of flow. (Contractor's abstract)

LAMINAR FLOW OF AN ELECTRICALLY CONDUCTING INCOMPRESSIBLE FLUID IN A CIRCULAR PIPE, by S. I. Pai. 1954, 2p. incl. diagrs. ([AF]OSR-TN-54-93) (AF 18(600)993) Unclassified

Published in Jour. Appl. Phys., v. 25: 1205-1207, Sept. 1954.

As an aid in understanding magnetohydrodynamics, the exact solution of the steady laminar flow of an electrically conducting, viscous and incompressible fluid in a circular pipe under an external radial magnetic is presented. Three typical velocity distributions for laminar steady flow in a circular pipe under the influence of different strength magnetic fields are plotted.

HYPERSONIC VISCOUS FLOW OVER AN INSULATED WEDGE AT AN ANGLE OF ATTACK, by S. I. Pai. Oct. 1954, 21p. diagrs. (Technical note no. BN-42) ([AF]OSR-TN-54-321) (AF 18(600)993) AD 47552 Unclassified

Previous work by Pai (Jour. Aeronaut. Sciences, v. 20: 502-504, July 1953) is extended by a detailed calculation of the hypersonic viscous flow over an insulated wedge at an angle of attack by a generalized von Kármán integral method for the boundary-layer equations of a compressible fluid. Both the interactions of the shock wave and of the expansion wave with boundary-layer flow over the wedge are investigated in the strong interaction region. The results are combined to give the over-all effects on the skin friction and the pressure distribution of the wedge. Consideration is given only to those cases where the shock is attached to the wedge. The analysis shows that the interaction phenomenon increases both the pressure on the surface of the wedge and the skin friction of the wedge.

MAGNETOHYDRODYNAMICS AND MAGNETOGASDYNAMICS, by S. I. Pai. Sept. 1955, 33p. refs. (Technical note no. BN-59) ([AF]OSR-TN-55-347) (AF 18(600)993) AD 74432 Unclassified

The fundamental equations of magnetofluiddynamics are derived. For incompressible fluid magnetohydrodynamics, the important parameters are the Reynolds number R_e, the magnetic pressure number R_H, which is the ratio of magnetic pressure to dynamic pressure, and the velocity number R_v, which is the ratio of the fluid velocity to the characteristic velocity of which the magnetic field is moving through a conductor. Some exact solutions and properties of the equations of magnetohydrodynamics are given. Stability of laminar flow and turbulence in magnetohydrodynamics are briefly reviewed. Finally, some magnetohydrodynamic experiments are described. For compressible fluid, magnetogasdynamics, the important parameters are still R_e, R_H and R_v plus other well known parameters of ordinary gas dynamics such as Mach number, Prandtl number and ratio of specific heats. Both the waves of small amplitude, Alfven's waves in compressible fluid, and shock waves in magnetogasdynamics are discussed. (Contractor's abstract)

ON THE SIMILARITY SOLUTION OF LAMINAR BOUNDARY LAYER WITH HYPERSONIC VARIABLE FREE STREAM, by S. F. Shen. Oct. 1955, 18p. incl. refs. (Technical note no. BN-60) ([AF]OSR-TN-55-362) (AF 18(600)993) AD 76253 Unclassified

For arbitrary Prandtl number and the power index of

the viscosity-temperature relation, certain "similar solutions" of the boundary-layer equations are shown to exist, provided that errors of the order $O(M_1^{-2})$ may be tolerated, M_1 being the Mach number at the outer edge of the boundary layer. The admissible pressure gradients are of the same types as those for the "similar solutions" of incompressible boundary layers. Application to the "strong-interaction" problem of a flat plate in a hypersonic stream is discussed. (Contractor's abstract)

LAMINAR JET MIXING OF TWO COMPRESSIBLE FLUIDS, by S. I. Pai. Oct. 1955 [30]p. incl. illus. diagrs. (Technical note no. BN-63) ([AF]OSR-TN-55-406) (AF 18(600)993) AD 79701 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 23: 1012-1018, Nov. 1956.

This study is concerned with a steady 2-dimensional laminar flow of a jet of a combustible gas mixture which is injected into and mixed with a uniform stream of another gas which is the combustion product of the combustible mixture. The problem involves 5 unknowns (temperature, density, concentration, and 2 velocity components) which are related through 5 equations: the equations of state, continuity, diffusion, motion, and energy. Detailed discussions are given of the following special cases: (1) jet mixing of a compressible fluid in which the concentration is a constant; (2) isothermal jet mixing of 2 compressible fluids in which 2 gases mix at a low Mach number without a chemical reaction; and (3) isovel jet mixing in which 2 streams of different gases of the same velocity but different temperature mix.

INSTRUMENT TO STUDY RELAXATION RATES BEHIND SHOCK WAVES, by E. L. Resler, Jr. and M. Scheibe. [1955] [7]p. incl. illus. diagrs. [AF 18(600)993] Unclassified

Published in Jour. Acoust. Soc. Amer., v. 27: 932-938, Sept. 1955.

An instrument is described which combines the schlieren technique, a photomultiplier tube and an oscilloscope in a manner that enables one to measure the density distribution behind shock waves (in gases) produced in a shock tube. From these measured distributions one can determine the way in which the gas or gases relax to equilibrium and the time it takes to reach equilibrium after the gas's enthalpy is increased suddenly a calculable amount in passing through the shock wave. The theory of the instrument is discussed and its predicted performance verified experimentally by measuring vibrational heat capacity relaxation times behind shock waves in CO_2 containing water vapor. The instrument in the reported tests demonstrated a sensitivity sufficient to record a change in atmospheric density of 1/2% over 1-mm distance and a space resolution of the density in the shock tube of 1/10 mm corresponding to times of the order of 1/10 μsec. ON RELAXATION EFFECTS IN SHOCK WAVES IN GASES, by P. E. Stepanov, tr. by B. [B.] Cary. July 1956 [19]p. incl. diagrs. (Technical note no. BN-76) (AFOSR-TN-56-309) (Trans. of Zhur. Eksper. Teoreticheskoi Fiziki, v. 17: 377-385, 1947) (AF 18-(600)993) AD 94843 Unclassified

The possibility of using a shock wave for the investigation of the rate of the redistribution of energy between translational and rotational degrees of freedom is analyzed in the instance of a shock wave in H_2 where the usual ultracoustic method becomes impracticable owing to the slowness of the corresponding relaxation time, 10^{-7} sec, and the necessity of resorting to very high frequencies. The shock wave is composed of 2 regions, one of a width corresponding to the gas-kinetic time of free path, being the seat of redistribution of energy among the translational degrees of freedom, the other, being the scene of passage of energy from translational to rotational degrees of freedom, of a width corresponding to the time lag of that passage. Formulas are derived for the structure of a shock wave with relaxation permitting calculation of the translational-rotational relaxation time from the width of the 2nd region and the pressure increase therein. These determinations will give the heat capacity of the rotational degrees of freedom.

CONCERNING THE STABILITY OF SHOCK WAVES, by S. P. D'iakov, tr. by B. [B.] Cary. Aug. 1956 [14]p. incl. diagrs. table. (Rept. no. BN-68) (AFOSR-TN-56-406) (Trans. of Zhur. Eksper. Teoreticheskoi Fiziki, v. 27: 288-295, 1954) (AF 18-(600)993) AD 96214 Unclassified

In this translation, the problem of the stability of shock waves in an arbitrary medium has been examined. Conditions for the instability of shock waves are found, which if satisfied, result in an exponential growth of the disturbances with time. The original phenomenon discovered is the spontaneous radiation of sound by the shock wave; conditions which determine the possibility of its occurrence are considered. Examples are given of the shapes of Hugoniot adiabatics in which it is possible for the conditions of instability and spontaneous radiation of sound to be fulfilled. It is shown in which media the fulfillment of these conditions is to be expected.

PHASE RELATIONS IN ISOTROPIC TURBULENCE, by R. Betchov. Aug. 1954, 36p. tncl. table, refs. (Technical ncte no. BN-40) ([AF]OSR-TN-54-254) (AF 18(600)1014) AD 42070 Unclassifted

Certain relations between the spectrum of a turbulent function, and that of the square of the function depend upon phase correlations between the vartous Fourier components. The case of uncorrelated phases can be treated with a suitable hypothesis, and studied experimentally with electronic noises. Experiments with tsotroptc turbulence show that phase correlations affect only the high frequency end of the spectrum. Phase correlations tn tsotropic turbulence are associated with a certain type of pulse, easily observed tn a phase space. Comparisons between turbulence and electronic notse tndicate that energy transfer and vorticity production are highly tntermittent processes. These results suggest some hypothesis on the mechantsm of energy transfer and vorticity production. (Contractor's abstract)
