Water-tank observation of the flow phenomena associated with boundary-layer transition has confirmed that a 2-dimensional discrete vortex line, which is considered to be the consequence of an amplified perturbation wave, has a strong tendency in shear flows to form a 3-dimensional vortex loop with a marked transverse wave length. The formation and development of the vortex loop are found to be the essential features preceding the origination of a turbulence spot, which takes place near the top of the vortex loop and near the outer edge of the boundary layer, and the guiding principle of laminar-to-turbulent transition not only in boundary layers but in wakes and in jet boundaries as well. As an application, an efficient turbulence-stimulation device is proposed. (Contractor's abstract)

AN EFFICIENT TRIPPING DEVICE, by F. R. Hama. Oct. 15, 1956, 2p. illus. (AF 18(600)1014) Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 236-237, Mar. 1957.

Investigations on transition from laminar to turbulent flow have revealed that the formation and development of a 3-dimensional vortex loop are the essential features preceding the genesis of a turbulent spot. As an application of this confirmation, a proposed turbulence-stimulation or "tripping" device, for use in wind-tunnel or towing-tank model tests, is described. A sketch of the device shows a row of thin triangular patches pasted on a flat plate. Streamlines near the triangle are diagrammed, indicating that a spiral motion inherent to a 3-dimensional vortex loop will be produced. In addition, because of converging stream lines near the bottom corner of 2 adjacent triangles, the fluid velocity close to the surface will be increased, giving an efficient vortex which sheds even better than a 2-dimensional trip. This arrangement generates 3-dimensional vortex loops directly with more efficiency in shedding, and for this reason appears to give a simple yet better way of tripping laminar boundary layers than any other known stimulation device. An experimental test indicated that the triangular-patch device is far superior to a 2-dimensional trip. Comparative flow pattern photographs of the test results are presented.

THREE-DIMENSIONAL VORTEX PATTERN BEHIND A CIRCULAR CYLINDER, by F. R. Hama. Oct. 15, 1956, 2p. illus. (AF 18(600)1014) Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 156-157, Feb. 1957.

A study was made of the 3-dimensional vortex pattern behind a circular cylinder in a towing tank, 2-ft wide, 2-ft deep and 12-ft long. The circular cylinder, a .25-in. outside diameter brass tube 20-in. long, is submerged horizontally at the mid-depth of the water. Red dye is leaked slowly through a row of small holes in the cylinder. The row of holes is located approximately 120°, measured from the foward stagnation point so that only one side of the vortex sheets is observed from above the plane of the vortex sheet. Results of the observations are presented in photographs taken at Reynolds numbers of 117, 190, and 313. At the lowest Reynolds number (stable range), the vortices are shed regularly without showing much 3-dimensionality except for a slight long-range deformation which is rather attributable to persistent large-scale disturbance in still water. Reasonably good 2-dimensionality was obtained consistently. When the Reynolds number is increased to about 200 (transition range), the 3-dimensionality is seen to appear violently. Flow phenomena in the irregular range in which the Reynolds number exceeds approximately 300, look much the same as those behind a trip wire on a flat plate; the vortex line being shed by the circular cylinder becomes wavy almost immediately, develops further apparently in the shear layer, and then breaks down into turbulent motion. The appearance of the 3-dimensionality, and its importance in creating the local transition into turbulent motion are therefore confirmed in the wake behind a circular cylinder. These processes, thus, are considered to be the guiding principle of transition phenomena not only in jet boundaries and boundary layers, but also in wakes.

STUDIES IN NON-EQUILIBRIUM CHEMICAL KINETICS. I. THE RELAXATION OF A SYSTEM OF HARMONIC OSCILLATORS, by E. W. Montroll and K. E. Shuler. Mar. 1956 [38]p. incl. diagrs. refs. (Technical note no. BN-70) (AFOSR-TN-56-108) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600) 1315 and Atomic Energy Commission) AD 82504 Unclassified

Also published in Jour. Chem. Phys., v. 26: 454-464, Mar. 1957.

As part of an investigation of non-equilibrium phenomena in chemical kinetics, a theoretical study has been made

of the collisional and radiative relaxation of a system of harmonic oscillators contained in a constant temperature heat bath and prepared initially in a vibrational non-equilibrium distribution. An exact solution has been obtained for the general relaxation equation applicable to this system; expressions have been derived for the relaxation of initial Boltzmann, Poisson, and σ-function distributions, and for the relaxation of the moments of the distributions. Using the latter result, explicit expressions are given for the relaxation of the internal energy of the system of oscillators and for the time dependence of the dispersion of the distributions. THEORY OF THE VIBRATIONAL RELAXATION OF DIATOMIC MOLECULES, by E. W. Montroll. Nov. 1956 [12]p. (Technical note no. BN-85) (AFOSR-TN-56-507) (AF 18(600)1315) AD 110322 Unclassified

This report discusses the manner in which systems of polyatomic molecules initially in a non-equilibrium vibrational state relax to their stationary states. Initial non-equilibrium distributions arise during the formulation of molecules and upon passage of shock waves through a gas composed of polyatomic molecules. The theory of dissociation of polyatomic molecules is discussed as a type of random walk process. (Contractor's abstract)

NOTE ON THE RELATION OF ISOTOPIC SPINSPACE TO SPACETIME, by R. L. Ingraham. Nov. 1956 [10]p. (Rept. no. BN-89) ([AF]OSR-TN-56-570) (AF 18(600)1315) AD 110391 Unclassified

Also published in Phys. Rev., v. 106: 595-597, May 1, 1957.

The customary form of physical space as the direct product of space-time and isotopic spin space can be replaced by a certain fusion of these 2 spaces into 1 space if the group from the Lorentz group is widened to the conformal space-time group which endows particles with an intrinsic finite size. It is shown that the familiar space-time transformations continue to induce their familiar Dirac spinor transformations, while the new space-time transformations in general induce isotopic spin transformations as well. The detailed correspondence is worked out for a theory of T = 1 bosons coupled to T = ½ fermions. (Contractor's abstract)

SCATTERING OF LOW VELOCITY MOLECULAR BEAMS IN GASES, by E. A. Mason. May 12, 1956, 35p. incl. diagrs. tables, refs. (Rept. no. IMP-OSR-1; AFOSR-TN-56-208) (AF 18(600)1562) AD 87522 Unclassified

Also published in Jour. Chem. Phys., v. 26: 667-677, Mar. 1957.

A large number of partial and total molecular scattering cross sections have been calculated numerically for molecules obeying an exp-six potential, consisting of an exponential repulsion term and an inverse sixth power attraction term. The tabulations cover a wide range of scattering angles, energies, and potential parameters, and can be used to obtain information about intermolecular forces from the results of experiments on the scattering of low velocity molecular beams in gases. The calculations are classical throughout, and quantum effects are ignored, but an approximate formula is given for estimating where the classical calculations break down in any particular case. The use of the tables is illustrated by a comparison with Knauer's results on the scattering of beams of H_2 in Hg vapor. (Naturwissenschaften, v. 21: 366, 1933; Zeitschr. Physik, v. 90: 599, 1934). A THEOREM OF MYERS, by W. Ambrose. Nov. 9, 1956 [4]p. [AFOSR-TN-56-552] (AF 18(603)91) AD 110371 Unclassified

Also published in Duke Math. Jour., v. 24: 345-348, Sept. 1957.

Myers theorem has been approved which states that if the mean curvature of a complete Riemannian manifold M is bounded below by a positive number, the M is compact. A variant with a weaker assumption that the integral of the mean curvature of the tangential direction is infinite along all geodesic rays emanating from fixed point of M is proved. M is a completely connected C^{∞} Riemannian manifold of dimensions $d \geq 2$.

A STUDY OF GUST ENTRY OF SWEPTBACK WINGS, by T. H. H. Pian and H. Ashley. May 1954 [31]p. incl. diagrs. refs. [AFOSR-TN-54-116] (AF 33(038)-7267 and AF 33(600)961) AD 42902 Unclassified

The lift and moment growths on a swept wing upon entering a sharp-edged gust are determined by strip theory and by a "semi-three-dimensional" theory. The latter is based on the calculation of lift distribution of an infinite swept wing penetrating a gust front. This unsteady-flow problem is shown to be equivalent to a steady-flow problem involving an infinite swept wing with an angle-of-attack discontinuity at a spanwise station. Results indicate that, according to the improved theory, the airloads build up faster than what is shown by strip theory. (Contractor's abstract)

THE STATISTICAL THEORY OF SIZE AND SHAPE EFFECTS IN FATIGUE, by F. A. McClintock. Nov. 4, 1954, 15p. diagrs. ([AF]OSR-TN-54-351) (AF 18-(600)895) AD 51990 Unclassified

Also published in Jour. Appl. Mech., v. 22: 421-426, Sept. 1955.

Fatigue specimens are considered in which the stress amplitude is constant with respect to time but falls off parabolically along the length of the specimen from the point of maximum stress. From assumptions regarding the local variability in the strength of the material, equations are derived relating the scatter in cycles to failure to the scatter in position of failure. The effect of specimen size is determined for these two types of scatter, as well as for the average life. It is found that the shape of the distribution function does not seriously affect the relation between scatter in cycles to failure and scatter in position of failure. The size effect, however, is markedly influenced by the shape of the distribution function. A modification is suggested to make the results applicable to tests to determine the endurance limit, where the stress amplitude is a variable. (Contractor's abstract)

A CRITERION FOR MINIMUM SCATTER IN FATIGUE TESTING, by F. A. McClintock. Nov. 29, 1954 [17]p. incl. diagrs. tables. ([AF]OSR-TN-55-1) (AF 18(600)-895) AD 68081 Unclassified

Also published in Jour. Appl. Mech., v. 22: 427-431, Sept. 1955.

When a number of fatigue tests are run on specimens with a longitudinal radius of curvature, there results a scatter in both the number of cycles to failure and the position of failure. A previous statistical analysis showed that if the variations in life are due solely to local inhomogeneities in the specimen, then there is a definite relation between the scatter in position of failure and the scatter in the number of cycles to failure. If the scatter in life significantly exceeds that corresponding to the scatter in position of failure, then there is some factor other than local inhomogeneities contributing to the scatter in life. Such other factors can be eliminated by improving the experimental technique. The usefulness of this criterion is illustrated by its application to crack detection tests on polycrystalline ingot iron. (Contractor's abstract)

VARIABILITY IN FATIGUE TESTING: SOURCES AND EFFECT ON NOTCH SENSITIVITY, by F. A. McClintock. May 25, 1955 [15]p. incl. tables, refs. ([AF]OSR-TN-55-186) (AF 18(600)895) AD 71738 PB 120014 Unclassified

Presented at International Union of Theoretical and Appl. Mech. Colloquium on Fatigue, Stockholm (Sweden), May 1955

Rough limits are obtained for the effect of various testing variables on fatigue life. Experimental data support the theoretical relation between scatter in position of failure and scatter in life due to local variations in strength: $K_{\log N}/2.3S_m a)_z^2 = 1$. From a statistical analysis taking into account the stress gradient normal to the surface, an estimate of notch insensitivity is obtained. Data from 75ST6 aluminum alloy indicate that it is unlikely that notch insensitivity results from statistical effects alone. (Contractor's abstract)

RESEARCH ON MINIMUM SCATTER IN FATIGUE TESTING, by F. A. McClintock. Final research rept. Dec. 28, 1955, 3p. (AFOSR-TR-56-3) (AF 18(600)895; continued by AF 18(600)957) AD 83283 Unclassified

The research project results show that for fatigue specimens in which the stress is assumed to vary with longitudinal distance z and depth y according to $S = S_m(1 - az^2 - gy)$, the mean and standard duration of the life and position of failure have been calculated for a class of distribution functions representing the strength of the differential elements comprising the specimen. These theoretical results provide a method for checking whether the variability in life at constant stress, or the variability of the rupture stress in the case of Prot testing, arises solely from that due to local inhomogeneities within the material or also arises in part from extraneous factors associated with specimen preparation and testing technique. These theoretical results provide a framework for estimating how much of the size effect arises from statistical causes. An approximate application of the results to notched specimens is suggested. THE GROWTH OF FATIGUE CRACKS UNDER PLASTIC TORSION, by F. A. McClintock. Feb. 17, 1956 [25] p. incl. illus. diagrs. tables, refs. (AFOSR-TN-56-277) (AF 18(600)957) AD 89487 Unclassified

Also published in Proc. International Conference on Fatigue of Metals, London (England), Sept. 1956, p. 538-542.

Theoretical and experimental studies were made of the growth of cracks in bars subjected to fully plastic cycles of torsion. Rules were postulated which state: (a) cracks always tend to grow toward the center of the remaining section, which is that point most distant from all present boundaries; and (b) a branch crack grows as above, but more slowly. Crack propagation and fracture are essentially dependent on the size of the specimen as opposed to yielding where size effects are of secondary importance. In the case of 2 geometrically similar specimens subject to the same nominal (large) strain amplitude, cracks progress across the larger one in fewer cycles. Rectangular specimens (7/32 in. x 7/16 in.) of precipitation hardening 7075 T6 Al alloy were subjected to reversed shear strains of constant amplitude and sectioned for examination of crack patterns. The development of fatigue cracks under fully plastic torsion, which is predicted from a knowledge of the strain distribution around the crack, was in general accord with experimental results. (ASTIA abstract)

ELASTIC-PLASTIC STRESS AND STRAIN DISTRIBUTIONS AROUND SHARP NOTCHES UNDER REPEATED SHEAR, by F. A. McClintock and J. A. H. Hult. Apr. 12, 1956, 11p. incl. diagrs. (AFOSR-TN-56-278) (AF 18(600)957) AD 89488 Unclassified

The elastic-plastic stress and strain distributions around sharp notches were obtained for pure shear, which is the limiting case of a very shallow notch in a specimen subjected to torsion. A small region at the tip of a fatigue crack is sujected to plastic flow caused by the intensity of the stress. Plasticity equations are solved for a material with a shear modulus G and yield stress in shear of k. The shear strain γ is formulated for a distance r beyond the end of a sharp notch, with zero flank angle and depth c in a region subjected to a nominal shear stress very much smaller than the yield stress, by the equation $\gamma = C\tau_\infty^2/r\,kG$. The analysis analysis shows that: (1) the strain at a sharp, zero-angle notch under plastic flow is greater than that for a purely elastic material by the factor $(\tau_\infty^2/k)\sqrt{2c/r}$ at relatively low stresses, and is still greater at higher stresses; (2) the angle subtended by the region of infinite strain becomes smaller as the notch angle increases; (3) the strain amplitude under repeated loading depends on the stress range but not on the mean stress; and (4) the strain concentration becomes insensitive to the notch angle at high stresses.

APPLICABILITY OF PISTON THEORY TO THE FLOW AROUND WINGS IN UNSTEADY MOTION, by E. L. Mollo-Christensen and H. Ashley. June 6, 1954, 3p. incl. illus. table. [AF 18(600)961] Unclassified

Published in Jour. Aeronaut. Sciences, v. 21: 779-781, Nov. 1954.

It has been observed that the pressures on a body which suddenly starts moving in a compressible fluid depend, at the first instant, only upon the local normal velocities of the surface (Two-dimensional Unsteady Lift Problems in Supersonic Flight, by M. A. Heaslet and H. Lomax, NACA rept. no. 945, 1949). This information can be applied to rapidly oscillating bodies, considering the frequency of oscillation as the primary variable, rather than the time-constant of the motion. It is shown that such a simplification of the problem of finding the pressures on oscillating wings can be deduced directly from small disturbance considerations, and criteria for the applicability of the simplified theory can be obtained in the process. The general expression for the pressures

on an oscillating wing is developed, and the results of sample calculations for "piston theory" are compared to results of more exact theory. Piston theory proves to be more accurate, the higher the Mach number, but the order of accuracy persists down to $M_1 = 10/7$ for $k > 2$, where k = reduced frequency.

AN APPROXIMATE AERODYNAMIC THEORY FOR GUST ENTRY OF SWEPT WINGS, by H. Ashley. Dec. 1954, 63p. incl. diagrs. tables, refs. (MIT Fluid Dynamics Research Group rept. no. 54-1) ([AF]OSR-TN-55-32) (AF 18(600)961) AD 55743 Unclassified

The lift and moment growths on a swept wing entering a sharp-edged gust are determined by a "semi-3-dimensional" theory, based on calculating the lift distribution of an infinite swept wing penetrating a gust front. This unsteady flow problem is shown to be equivalent to steady flow over an infinite swept wing with discontinuous angle of attack. Results indicate that the new theory predicts a more rapid buildup of gust loading than conventional strip theory at subsonic speeds. Details of lift and moment are given for subsonic flight, and for supersonic flight with both supersonic and subsonic leading and trailing edges. (Contractor's abstract)

UNSTEADY FLOW AROUND THIN WINGS AT HIGH MACH NUMBERS, by M. T. Landahl. June 1955, 20p. incl. diagrs. (MIT Fluid Dynamics Research Group rept. no. 55-3) ([AF]OSR-TN-55-245) (AF 18(600)961) AD 71949 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 24: 33-38, Jan. 1957.

The perturbation velocity potential for unsteady flow around thin wings is expanded in a series of M^{-2}, taking into account linear and second-order terms in perturbation velocities. The first terms for the pressure are seen to be in agreement with those predicted by the Hayes-Lighthill piston theory. The additional terms provide an accuracy sufficient for engineering purposes down to $M \approx 2$. This solution cannot be used in the hypersonic region, and is also restricted to low reduced frequencies.

UNSTEADY LAMINAR BOUNDARY LAYERS, by M. Finston. June 1955, 19p. incl. diagrs. refs. (MIT Fluid Dynamics Research Group rept. no. 55-4) ([AF]OSR-TN-55-466) (AF 18(600)961) AD 84887 Unclassified

Equations are presented describing motion of a viscous fluid. The unsteady boundary-layer equations are compared with the linearized flows. The high-frequency perturbations on an existing boundary layer are shown to be independent of the main flow and relatively insensitive to curvature of adjacent surfaces. An explanation is advanced for these phenomena by using exact solutions to Rayleigh's problem and related classical examples.

PARAMETRIC STUDIES OF VISCOUS AND NON-VISCOUS UNSTEADY FLOWS, by M. T. Landahl, E. L. Mollo-Christensen, and H. Ashley. Apr. 1955, 94p. incl. diagrs. tables, refs. (MIT Fluid Dynamics Research Group repl. no. 55-1) ([AF]OSR-TR-55-13) (AF 18(600)961) AD 64033 Unclassified

A systematic study is made of the circumstances under which the differential equations governing motion of viscous and nonviscous gases can be simplified by eliminating or linearizing various terms. In the nonviscous case, a complete classification of small disturbance potential flow problems is constructed by means of series expansions involving all important dimensionless parameters. Parametric ranges are found within which mathematical reductions are permissible, and the order of magnitude of the numerical error made in each of these is estimated. The multiplicity of parameters prevents exhaustive classification of viscous flows, but several interesting simplifications are presented.

MIT. 06:007 - MIT. 06:011

including linearized cases with differential equations of diffusion type. Solutions are derived for 2 of the simpler problems identified in the parametric analysis. The first concerns the emission of sound from a wire heated by alternating current, and qualitative comparisons are made with the data from an elementary experiment. The second is "piston theory" for wings moving at high frequencies or Mach numbers. Certain relatively easy computations are shown to compare favorably with more exact 2- and 3-dimensional results, and the application to flutter prediction is discussed. (Contractor's abstract)

ON APPROXIMATE SOLUTIONS FOR THE COMPRESSIBLE FLOW AROUND OSCILLATING THIN WINGS, by M. T. Landhal, H. Ashley, and E. L. Mollo-Christensen. Mar. 14, 1955, 2p. incl. illus. [AF 18-(600)961] Unclassified

Published in Jour. Aeronaut. Sciences, v. 22: 581-582, Aug. 1955.

A thin wing with root semichord b = 1 oscillating in a free stream of velocity U = 1 with reduced frequency of $k = \omega b/U$, ω being the circular velocity, is considered. An equation is given for which exact solutions can be obtained only in special cases, e.g., the 2-dimensional supersonic case. By neglecting one or several terms, however, simple solutions can be procured. Three approximations are discussed which are applicable for different ranges of k and M.

FORCES AND MOMENTS ON OSCILLATING SLENDER WING-BODY COMBINATIONS AT SONIC SPEED, by M. T. Landahl. Feb. 1956, 42p. incl. diagrs. (MIT Fluid Dynamics Research Group rept. no. 56-1) ([AF]OSR-TN-56-109) (AF 18(600)961) AD 82505 Unclassified

It is shown that, under certain conditions, the linearized equations of motion are valid for treating the lifting, unsteady, transonic flow around slender configurations of finite thickness. On this basis, a method of solution is proposed which is valid for low combinations of aspect ratio and reduced frequency of oscillation. The method is an extension of the iterative method of Adams and Sears (Jour. Aeronaut. Sciences, v. 20: Feb. 1953), and is applied in detail to a wing-body configuration. The stability derivatives are calculated and simple formulas are given for the influence of the body. It is found that, except for very slender configurations ($A < 1$), the slender-body theory alone is inadequate for calculation of damping derivatives. The effect of the body is to decrease the damping moment in pitch and this effect is important in case of a delta wing. (Contractor's abstract)

A STRIP THEORY FOR OSCILLATING THIN WINGS WITH SUBSONIC LEADING AND SUPERSONIC TRAILING EDGES, by M. T. Landahl. Mar. 1956, 19p. incl. illus. tables, refs. (MIT Fluid Dynamics Research Group rept. no. 56-2) (AFOSR-TN-56-155) (AF 18-(600)961) AD 86315 Unclassified

A strip theory is presented for calculation of forces and moments on an oscillating wing having subsonic leading and supersonic trailing edges. The theory is valid when the reduced frequency, based on the wing semi-span and the velocity of sound, is large. Tables for forces and moments on a streamwise strip are given. STRONG SHOCK WAVES IN POLYATOMIC GASES, by I. Greber. May 1956, 22p. incl. diagrs. refs. (MIT Fluid Dynamics Research Group rept. no. 56-3) ([AF]OSR-TN-56-310) (AF 18(600)961) AD 94845 Unclassified

A summary is presented of a brief survey concerning the literature of strong shock waves. Of the 23 published- and report-literature references treated, which range in time from 1922 to 1955, 22 are in English and 1 is in German. Primary attention is placed on the structure of strong shock waves in a polyatomic gas, particularly air, and the generation of strong shock waves in shock tubes. The increase of shock strengths obtainable from simple configurational modifications of the basic shock tube are shown. (Contractor's abstract)

THE FLOW AROUND OSCILLATING LOW-ASPECT RATIO WINGS AND WING-BODY COMBINATIONS AT TRANSONIC SPEEDS, by M. T. Landahl. [1956] 6p. diagrs. refs. (AFOSR-TN-56-445) (AF 18(600)961) AD 96970 Unclassified

Also published in Proc. Ninth International Congress of Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956), v. 3: 103-112, 1957.

Theoretical results on the unsteady transonic flow

around thin, low-aspect-ratio wings and wing-body combinations are presented. First the problem of linearization of the equations of motion is considered. It is shown that linearization is possible provided the reduced frequency of oscillation is large compared to a certain parameter involving the thickness ratio and aspect ratio of the wing. This requirement automatically makes any upstream influence vanish, even when the free stream is slightly subsonic and thus considerably simplifies the analysis. The linearized solution for the perturbation velocity potential is obtained through expansion in terms of aspect ratio or reduced frequency. Two different methods are used, one which is valid for wings of delta type and the other for rectangular wings. The methods are applicable both for rigid and elastic oscillations of the wings, so that they can be used for three-dimensional flutter calculations. In the case of a wing-body combination the different terms in the expansion of the solution are found by use of the theory of conformal transformation. Some numerical results are given and compared with those of earlier, simpler theories. It is found that three-dimensional flow effects are very important. Dynamic stability derivatives are also calculated, and it is shown that the damping in pitch can vanish for certain wings and wing-body combinations. The interference effect of the body is to decrease the damping. Means are suggested for modifying the planform so as to provide a substantial increase in the damping. (Contractor's abstract)

MEASUREMENTS OF THREE-DIMENSIONAL BOUNDARY LAYERS ON WINGS, by P. H. Winter. Mar. 1955, 30p. incl. illus. diagrs. (MIT Fluid Dynamics Research Group rept. no. 55-2) ([AF]OSR-TN-55-133) (AF 18(600)1306) AD 64034 Unclassified

A description is given of a preliminary experimental investigation of 3-dimensional boundary layer flow on a 45° sweptback, infinite, flat-plate wing. A probe mounting with 3° of freedom in translation and 1° of freedom in rotation in a plane parallel to the wing surface controlled from outside the tunnel was designed and built. Measurements of profiles were taken at a Reynolds number of 3.3×10^5. At zero incidence, the profiles satisfied approximately the 7th power law, but the boundary-layer thickness was appreciably greater than for the equivalent 2-dimensional boundary layer. At incidence, the free stream was nearly parallel, the flow in the core of the boundary layer appeared to turn upstream near the leading edge, and to sweep outward further downstream. (Contractor's abstract)

VISCOUS FLOWS NEAR SIDE EDGES AND LEADING EDGES, by L. Trilling. June 1955, 64p. incl. diagr. refs. (MIT Fluid Dynamics Research Group rept. no. 55-4) ([AF]OSR-TN-55-220) (AF 18(600)1306) AD 70112 Unclassified

The solution is given of the Navier Stokes equations for the unsteady motion of a viscous incompressible fluid past a parabolic cylinder parallel to its generatrices, and of the linearized Oseen equations for the steady flow past a quarter infinite thin flat plate whose edges are respectively parallel and perpendicular to the direction of undisturbed motion. In the second problem, the convection velocity is the constant free stream velocity; the no-slip conditions are applied on the plate surface, and the vorticity vanishes in the plane of symmetry off the plate surface. The pressure and skin friction on the plate are computed; the pressure vanishes and the skin friction has an inverse square root singularity along both edges; its strength remains constant along the leading edge, decreases as an inverse quarter power of distance downstream from the leading edge along the side edge, and depends on the direction of approach in the neighborhood of the corner. PHOTOEMISSION FROM SILVER INTO AgCl, KBr, NaCl AND NEW BANDS OF PHOTOSENSITIVITY IN AgCl, by M. A. Gilleo. Oct. 1952, 40p. incl. diagrs. refs. (Technical rept. no. 54) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) U24896 Unclassified

Also published in Phys. Rev., v. 91: 534-542, Aug. 1, 1953.

The work required to move an electron from a metal into an insulator has been investigated photoelectrically. The work function thus found was about 4.3 ev for Ag evaporated in vacuo on KBr (Fowler plot) as well as on NaCl (threshold wavelength). The photoelectrons become trapped in these crystals at vacant anion sites and may be released by F-band illumination. For Ag on AgCl a work function of 1.1 ev is measured at the low temperatures used to freeze out ionic conductivity. In AgCl seven new bands of photoconductive response were found; the optical absorption was too small to be measured directly. These bands have a half width of ca 0.2 ev at 90°K and are bleached by irradiation. The 4400, 5000, 5700, 6600, and 7500A bands increase in intensity with an increasing supply of electrons provided by photoelecIric emission and behave analogously to the F bands of the alkali halides. The 4800 and 9200A bands are favored by a scarcity of electrons and may correspond to trapped holes. Photosensitivity in all these bands can be created by irradiation in the intrinsic optical-absorption edge of AgCl at low temperature. They may not be characteristic of a perfect crystal. The intrinsic band-like photoconductive response of AgCl and the absorption edge on which it occurs shift toward shorter wavelengths with decreasing temperature. The maximum of response which appears with decreasing wavelength may arise from a bimolecular recombination of charge carriers released by light. The absorption edge steepens as it shifts toward shorter wavelengths with decreasing temperature. (Contractor's abstract)

ELECTRICAL AND OPTICAL PROPERTIES OF RUTILE SINGLE CRYSTALS, by D. C. Cronemeyer. [1952] [11]p. incl. diagrs. table, refs. (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) Unclassified

Published in Phys. Rev., v. 87: 876-886, Sept. 1, 1952.

Clear, synthetic rutile (TiO_2) single crystals have been investigated by electrical and optical methods. It seems possible to correlate the high temperature conductivity (E_G = 3.05 ev) with the threshold of optical absorption at low temperatures (3.03 ev) and with the maximum of the photoconductivity (3.00 - 3.03 ev). This evidence indicates an energy gap ca 3.05 ev for rutile as an insulator. Semiconducting rutile, prepared by hydrogen reduction at temperatures $\leq$ 800°C, shows a blue color arising from an optical absorption maximum at ca 1.7μ (0.73 ev). Conductivity-temperature plots for slightly reduced specimens indicate an optical activation energy of 0.68 ev. A theoretical calculation for the ionization of the first electron from an oxygen vacancy indicates 0.74 ev as the expected value, in good agreement with the experimental results. At room temperature the mobility of electrons in slightly reduced single crystals is ca 10^{-4} m^2/v-sec. Strongly reduced rutile is opaque; a comparison of electron concentrations calculated from weight loss and Hall coefficient data shows that for samples in which the electron concentration is $10^{26}/m^3$, all contribute to conduction at room temperature. BEHAVIOR OF SLOW ELECTRONS IN POLAR CRYSTALS, by E. P. Gross. Dec. 1952, 40p. incl. diagrs. refs. (Technical rept. no. 55) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 6048 Unclassified

The effective mass of slow electrons in polar crystals is investigated using the continuum model of Pekar and Frölich, Plezer and Zienau. The Hamiltonian is studied in a Fock representation so that effects of several quanta can be assessed. The calculations show that the effective mass is larger than that predicted by the one quantum solution, but that the effective mass is still small for weakly polar crystals. For excess electrons in strongly polar crystals many quantum contributions must be included and the present method is inappropriate. It is uncertain whether the effective mass is small in this case. Holes in polar crystals appear to satisfy the conditions for the validity of the theory of Landau and Pekar which predicts a high effective mass. (Contractor's abstract)

THE GROWING OF LEAD TITANATE CRYSTALS

AND SOME OF THEIR PROPERTIES, by H. H. Rogers. Dec. 1952, 17p. incl. illus. diagrs. refs. (Technical rept. no. 56) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 4803 Unclassified

Small, high-purity, single crystals of lead titanate were grown from a melt consisting of TiO_2 and an excess of PbO. The preparation of a large single crystal by the Bridgman-Stockbarger method is described. Its subsequent fracturing on cooling is interpreted by visual observation and by x-ray measurements. The chemical reactivity of $PbTiO_3$ is discussed and data on the thermal dissociation into PBO vapor and by x-ray measurements. $PbTiO_3$ appears to be the only stable compound in the system PbO-TiO_2. The chemical reactivity of $PbTiO_3$ is discussed on data on the thermal dissociation into PbO vapor and solid TiO_2 are given. $PbTiO_3$, as expected, is piezoelectric at room temperature, has the domains characteristic of a ferroelectric substance, and, in addition, undergoes a reversible color change from red to yellow when cooled through the Curie point (ca 490°C). The density of a cracked crystal, measured at 25°C, proved to be 7.96 g/ml, or 99.2% of x-ray density. The birefringence at 25°C has been measured as a function of wavelength (at 5800A, $^{n}max^{-n}min = 0.011$). (Contractor's abstract)

TABLES OF DIELECTRIC MATERIALS, VOLUME IV, by [A. von Hippel]. Jan. 1953, 138p. incl. diagrs. tables. (Technical rept. no. 57) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 5843 Unclassified

This work in its present form summarizes the measurements of the Laboratory for Insulation Research at M. I. T. on the complex permittivity (dielectric constant and loss tangent) and the complex permeability of important dielectrics made in this country. They are intended to aid government agencies, engineers and manufacturers in the proper application of dielectrics and in the development of better products. Volume IV reports on about 250 new materials; simultaneously, it has taken over and amplified the measurements given in the previous volumes as far as they still are of special interest. A number of materials now not in production have been retained for this reason but are indicated as "discontinued." The total number of materials included amounts to over 600. AN X RAY DIFFRACTION STUDY OF BARIUM TITANATE, by H. T. Evans, Jr. Jan. 1953, 35p. incl. illus. diagrs. tables, refs. (Technical rept. no. 58) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 4273 Unclassified

An x-ray diffraction investigation was carried out in an attempt to determine in detail the atomic positions and temperature motions in the crystal structure of the tetragonal ferroelectric form of barium titanate. The basic experimental data used in the analysis consisted of the integrated intensities of 99 Bragg reflections of the type (hk0). The intensities were carefully measured by means of a scanning technique using a Geiger counter assembly especially designed for this study, a small (0.1 mm) untwinned single crystal, and MoKα radiation. The intensities were corrected for absorption and secondary extinction effects determined by special techniques worked out for this particular crystal. The search for a structure which will adequately account for these data was carried out by the methods of trial and error and least-squares analysis. A model was finally defined in terms of 3 structure and 9 anisotropic temperature parameters. It was found that in the general intensity function for all reflections there is an interaction between the structure parameter of an atom (displacement along the tetragonal axis) and the temperature motion of the atom in this direction. Therefore, in order to determine the value of one from the observed intensity data, it is necessary to assume a fixed value for the other. Consequently, within a rather wide range, it is not possible to determine uniquely the structure of tetragonal barium titanate. Certain temperature parameters do not interact with other parameters, and these are uniquely determined. From these, reasonable values have been assigned to the other temperature motions, and the structure consistent with these assumptions determined. The reliability factor R for this structure is 0.0367. These results are compared with those published by other workers. (Contractor's abstract)

THE LOW-TEMPERATURE TRANSITION IN MAGNETITE, by S. C. Abrahams and B. A. Calhoun. Feb. 1953, 4p. incl. tables. (Technical repl. no. 61) (Bound with its Technical repl. nos. 60-63; AD 6191-AD 6094) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 6192 Unclassified

Also published in Acta Crystallographica, v. 6: 105-106, Jan. 10, 1953.

Magnetite was shown to transform from the cubic to the orthorhombic system at temperatures below 119°K. The thermal expansion coefficient of the c axis became negative below 119°K, and at about 95°K there was no appreciable difference in the spacing of (440) and (008). The dimensions of the magnetite unit cell were measured at 295°, 128°, and 78°K and the resulting volumes were 591.4, 589.1, and 589.6 A^3, respectively. From these data and the c axis length at 108°K, the coefficients of thermal expansion above and below the transition were calculated.

A GRAPHICAL METHOD OF EVALUATING CERTAIN CRYSTALLOGRAPHIC STRUCTURE FACTORS, by H. J. Grenville-Wells. Feb. 1953, 14p. incl. illus. table. (Technical repl. no. 65) (Bound with its Technical rept. nos. 64-66; AD 6195-AD 6197) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 6196 Unclassified

Also published in Jour. Appl. Phys., v. 25: 485-490, Apr. 1954.

A graphical method is described for evaluating structure factors of the form

$$F(hk) = \sum_{0}^{n} f_r(hk)\cos 2\pi(hx_r + ky_r)$$ and electron density

expressions of the form $\rho(X, Y) = \Sigma_H \Sigma_K F(hk)\cos 2\pi(hX + kY)$. The method depends upon the fact that if in a 2-dimensional [001] projection of a unit cell the normal to the planes (hk0) is graduated with the appropriate cosine function giving the phases of points along the normal, then a circle, having its center at (X/2, Y/2) and passing through the origin will cut the normal to F(hk0) at the value of cos 2π(hx + ky). The practical limitations and general utility of the construction are discussed. (ASTIA abstract)

INHOMOGENEITY OF THALLIUM HALIDE MIXED CRYSTALS AND ITS ELIMINATION, by A. Smakula, J. Kalnajs, and V. Sils. Mar. 1953, 20p. incl. illus. tables, refs. (Technical rept. no. 67) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 8948 Unclassified

Also published in Jour. Opt. Soc. Amer., v. 43: 698-701, Aug. 1953.

A study was made of the optical inhomogeneity of prisms used in IR spectroscopy, which are cut from mixed crystals of thallium halides. The cause of the defect was determined to be the use of incorrect minimum melting points of the compositions from which the crystals were grown. The freezing points of thallium halides and the minimum freezing points of the binary systems (TlCl with TlBr and TlI) were determined by cooling the melted samples and measuring the temperature with an Fe-Constantan thermocouple. The freezing points were higher than those of Moenkemeyer (Neves Jahrb. Mineral. Geol. Pal. 22, Beilage-Band, 1906). Crystals of binary systems were grown on the basis of the new data, and the greatest deviation of the lattice constant along the crystal length was determined to be more than 5×10^{-5}. These results show that the optical inhomogeneity was caused by the incorrect composition of the melt. The refractive index variation in the new crystals was less than 1×10^{-5}.

ELECTRICAL CONDUCTIVITY OF MAGNETITE AT LOW TEMPERATURES (Abstract), by B. A. Calhoun. [1953] [1]p. (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under [N5ori-07801]) Unclassified

MIT. 08:018 - MIT. 08:020

Presented at meeting of the Amer. Phys. Soc., Cambridge, Mass., Jan. 22-24, 1953.

Published in Phys. Rev., v. 90: 374, Apr. 15, 1953.

The electrical conductivity of synthetic magnetite single crystals, has been measured from room temperature to 40°K. Below the transition at 119°K, the activation energy decreases from 0.11 ev (90-78°K) to 0.061 ev (52-40°K). The conductivity below the transition is isotropic when the samples are cooled in a demagnetized state. Samples cooled through the transition in a magnetic field sufficient to saturate and then demagnetized show an anisotropic conductivity. The conductivity depends on the orientation of both the sample and the magnetic field. Verwey and his co-workers (Jour. Chem. Phys., v. 15: 181, 1947) suggested that the transition resulted from an ordering of the ferrous and ferric ions in the octahedral sites and proposed an ordered structure of orthorhombic symmetry. The observed anisotropy of the conductivity agrees with this model. (Contractor's abstract)

Published in Jour. Amer. Ceramic Soc., v. 36: 204-206, June 1953.

The catenary curve was analyzed to find the dimensions at which a self-supporting arch can be obtained. For kiln construction, a height-to-base ratio of 1 to 1 was found to be advisable. Detailed construction data was given for a kiln with a 0.5-cu ft chamber. A parallel heating element system with a low-voltage, high-ampere power circuit is described, and the advantages of the arrangement are noted. Excellent temperature uniformity is reported, and 1400°C can be attained at a rate of 65°C per hour with 3-kw power input. An atemized cost of construction is also given. (Contractor's abstract)

MAGNETIC AND ELECTRIC PROPERTIES OF MAGNETITE AT LOW TEMPERATURES, by B. A. Calhoun. July 1953. 49p. incl. diagrs. tables, refs. (Technical rept. no. 68) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under N5ori-07801 and N5ori-07858) AD 15523 Unclassified

Also published in Phys. Rev., v. 94: 1577-1585, June 15, 1954.

The low-temperature transition in magnetite, according to Verwey, is due to the ordering of the ferrous and ferric ions in the octahedral interstices of the spinel lattice. This arrangement would require a symmetry change from cubic to orthorhombic. X-ray diffraction indicates and electric conductivity and magnetization measurements confirm that the transition leads to an orthorhombic structure. An external magnetic field applied while cooling through the transition establishes a preferred orientation for the c axis throughout the whole crystal. Below the transition this c axis can be switched to a new direction by a strong magnetic field, a process involving a cooperative rearrangement of the ferrous ions in new sites and relatively large changes in dimensions. In stoichiometric, synthetic, single crystals the transition occurs at 119.4°K and is marked by an abrupt decrease in the conductivity by a factor of 90 in a temperature interval of 1°. No thermal hysteresis is observed. The conductivity of a crystal cooled in a strong magnetic field is anisotropic below the transition as given by the relation $\sigma = A + B(1 + \cos^2\theta)$, where θ is the angle between the c axis and the direction of measurement. The ratio $B/(A + B)$ increases rapidly as the crystal is cooled to 90°K, indicating a progressive increase in the long-range order. The c axis is the direction of easy magnetization below the transition, and the anisotropy energy is very much larger below than above; the anisotropy constants have been determined at 85°K. A NOMOGRAM FOR EVALUATING THE TEMPERATURE FACTOR, by H. J. Greenville-Wells. [1953] [2]p. incl. diagr. (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) Unclassified

Published in Acta Crystallographica, v. 6: 665-666, July 10, 1953.

The nomogram evaluates the expression

$$\exp[(-2B \sin^2\theta)/\lambda^2] = f_t/f_o,$$

where the symbols have the usual significance. It has four scales, A, B, C, and D. A and D are logarithmic scales with 1 cycle = 10 in.; they are equidistant from C, which is the logarithmic scale having 2 cycles = 10 in. required for multiplication. The B scale, which is a linear inch scale, is antilogarithmic against the A scale. An example of the use of the nomogram for evaluating f_t/f_o for particular values of B and $\sin^2\theta/\lambda^2$ would be: if $\sin^2\theta/\lambda^2 = 0.04$ and B = 3, the $f_t/f_o = 0.79$.

A KINETIC APPROACH TO COLLISION PROCESSES IN GASES. I. SMALL AMPLITUDE PROCESSES IN CHARGED AND NEUTRAL ONE-COMPONENT SYSTEMS, by P. L. Bhatnager, E. P. Gross, and M. Krook. Sept. 1953, 41p. incl. illus. refs. (Technical rept. no. 69) (In cooperation with Harvard Coll. Observatory, Cambridge, Mass. under AF 19(604)146) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 17744 Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 27-28, 1953.

Abstract published in Phys. Rev., v. 93: 936, Feb. 15, 1954.

Also published in Phys. Rev., v. 94: 511-525, May 1, 1954.

This approach appears adequate for the unified treatment of the dynamic properties of gasss over a continuous range of pressures from the Knudsen limit to the high-pressure limit where the aerodynamic equations are valid. Alterations are made in the collision terms of the Boltzmann equation; each collision conserves particle number, momentum, and energy; persistence of velocities and angular dependence may be included. The approach illustrates a technique for a simple model involving the assumption of a collision time independent of velocity; this model is applied to the study of small amplitude oscillations of 1-component ionized and neutral gases. The initial value problem for unbounded space is solved by performing a Fourier transformation on the space variable and a Laplace transformation on the time variable. For uncharged gases there results the correct adiabatic limiting law for sound-wave propagation at high pressures. For ionized gases the difference in the nature of the organization in the low-pressure plasma oscillations and in high-pressure sound-type oscillations is studied. Two important cases are distinguished. If the wave length of the oscillations is long compared to either the Debye length or the mean free path, a small change in frequency is obtained as the collision frequency varies from zero to infinity. The accompanying absorption is small and reaches its maximum value when the collision frequency equals the plasma frequency. The other case refers to waves shorter than both the Debye length and the mean free path; these waves are characterized by a very heavy absorption. (For part II of this report see item no. THE CRYSTAL STRUCTURE OF BARIUM TETRASULFIDE MONOHYDRATE, by S. C. Abrahams. Sept. 1953, 25p. incl. illus. tables, refs. (Technical rept. no. 70) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 17743 Unclassified

Also published in Acta Crystallographica, v. 7: 423-429, May 20, 1954.

Barium tetrasulfide monohydrate forms piezoelectric crystals belonging to the orthorhombic system, space group D_2^3 - $P2_12_12$ with 4 molecules in the unit cell of dimensions a = 9.67, b = 7.99, c = 7.81 Å. The crystal structure was completely determined, and the values of the 17 atomic coordinates were refined by double Fourier series and least-square methods, based upon 296 terms derived from visual intensity measurements, in the 3 principal zones. The Ba atom is completely ionized, and is in ionic contact with the S atoms and the O of the H_2O molecule. The tetrasulfide ion possesses C_2 symmetry. Like the anion of Cs_2S_6 the tetrasulfide ion is non-branched and nonplanar, and also exhibits a similar alternation in bond length. Two kinds of S-S bonds are present, of length 2.02 and 2.07 A, allowing a new tentative bond-order vs bond-length curve for S to be established. (Contractor's abstract)

DERIVATION OF ATOMIC COORDINATES IN HELICAL STRUCTURES, by H. J. Grenville-Wells. Sept. 1953, 12p. incl. illus. (Technical rept. no. 71) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 19939 Unclassified

A general method is developed for obtaining the coordinates of atoms in helical structures. The helix is treated as the repetition of a structural unit by an n-fold screw axis, where n is continuously variable. The coordinates are needed in complex structures such as proteins for the calculation of bond lengths and bond angles. The specific form in which the derivation is presented was developed for the analysis of polypeptide chain helices. Graphs are given which facilitate the use of the derived expressions.

A SINGLE-CRYSTAL ADAPTOR FOR THE NORELCO HIGH-ANGLE DIFFRACTOMETER, by S. C. Abrahams and H. J. Grenville-Wells. Sept. 1953, 4p. incl. illus. (Technical rept. no. 72) (Bound with its Technical rept. no. 71; AD 19939-AD 19940) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ort-07858) AD 19940 Unclassified

Also published in Rev. Scient. Instruments, v. 25: 519-520, May 1954.

The adaptor is based on the principle of completely bathing a small single crystal in a slightly divergent collimated x-ray beam, and slowly rocking the crystal through the Bragg reflection angle while keeping the GM counter stationary at the proper 2θ angle. The normal specimen holder is replaced by a long shaft which closely fits the bronze sleeve of the diffractometer and ends in a screw on which a Supper goniometer head can be fitted. A graduated circle is attached to the other end of the shaft which is connected to a synchronous motor. The whole shaft can be translated along its length to bring the crystal into the x-ray beam. A Bodine motor is used to rotate the crystal at a constant angular velocity of 1/8° θ/min. A backstop is mounted on a sleeve which fits over the collimator shaft, and permits the counter to record spectra with angles as low as 3°2θ.

A REGULATED CONTROL SYSTEM FOR A LARGE ELECTROMAGNET, by L. E. Johnson. Sept. 1953 [41]p. incl. illus. tables, refs. (Technical rept. no. 73) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 19932 Unclassified

The system is an automatic self-correcting device which maintains the magnet current at any desired level. The design is a servomechanism which functions as a follow-up device for varying input commands. It also compensates for extraneous current fluctuations resulting from variations produced by temperature changes, generator brush noise, generator structural asymmetries, and changes in generator speed caused by variations in line voltage. The design originally incorporated a parallel-connected dual-loop design of which the L.F loop, or current stabilizer, was intended to satisfy the input requirements, while the 2 loops together would give the proper degree of stabilization. The present system however, uses only the L.F loop which compensates for the drift and small shifts in the dc value of the current at any desired level. Slow thermal drift and small dc shifts are held to within 1 part in 10^5. (ASTIA abstract)

BLEACHING OF CaF_2 CRYSTALS COLORED BY X-RAYS, by A. Smakula. Sept. 15, 1953 [2]p. incl. diagrs. (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under [N5ori-07801]) Unclassified

Published in Phys. Rev., v. 91: 1570-1571, Sept. 15, 1953.

Bleaching by light at room temperature is reported of x-ray colored CaF_2 synthetic crystals, by use of a filtered Hg lamp. Tabulated results show no apparent bleaching of the absorption bands marked 1 to 4 after 3 weeks treatment at room temperature. An exposure to light absorbed only by band 1 does not bleach this band after one hour of exposure. A five-minute exposure to light absorbed by band 2 produced a strong decrease of band 2, the other bands being unaffected; simultaneous with destruction of band 2, a new band peaking at 4850A appears. Band 2 can be restored either by heat or by light absorbed by band 1 which remains unaffected while the new band at 4850A disappears. Use of light simultaneously absorbed by bands 1 and 2 effects bleaching of both bands and formation of a new band at 4850A; both bands can be restored either thermally or by irradiation in band 1. A tentative explanation of the absorption bands is proposed.

EFFECT OF A TWO-DIMENSIONAL PRESSURE ON THE CURIE POINT OF BARIUM TITANATE, by P. W. Forsbergh, Jr. Oct. 1953, 20[1]. incl. illus. refs. (Technical rept. no. 74) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 19933 Unclassified

Also published in Phys. Rev., v. 93: 686-692, Feb. 15, 1954.

By hydraulics, a single crystal of $BaTiO_3$ in the shape of a flat circular disk was subjected to a pressure exerted on the edges. After removal of all domains that were not normal to the disk by a slight pressure, the stress system consisted of equal pressures on the 2 a axes and none on the c axis. The transition temperature increased with the square of the 2-dimensional pressure; Merz's hydrostatic pressure produced a linear drop. The free energy for the 2 dimensional and hydrostatic stress systems was obtained by using Devonshire's expansion for energy (Phil. Mag., v. 40: 1040,

1949; v. 42: 1065, 1951) and the appropriate Legendre transformation. The expansion had to be supplemented to obtain a quadratic effect. The evaluation of the effect of pressure on the transition temperature was difficult when higher terms were included, but the effect on Curie-Weiss temperature was easily determined. The linear part of the Curie-Weiss temperature shift depended only on the lower terms in the free energy expansion; it provided 2 independent relations for determining the 2g coefficients. The quadratic shift of the Curie-Weiss temperature depended on the higher terms with which the Devonshire's expansion was supplemented, and an interpretation of these higher terms gave an upward direction to the shift.

THE KINETICS OF THE HETEROGENEOUS PARA-HYDROGEN CONVERSION, by Y. L. Sandler. 1953 [2]p. (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under [N5ori-07801]) Unclassified

Published in Jour. Chem. Phys., v. 21: 2243-2244, Dec. 1953.

Heterogeneous parahydrogen conversion is asserted to follow a strict first order decay law. The observed rate is written as: $r = kN = k_3N_3$, where N is the total number of molecules present in the reaction vessel and N_3 is the number of absorbed molecules. The "true" rate constant k_3 is defined by the aforegiven equation. Like k, it generally will be a function of temperature and pressure (or coverage).

SOLUTION OF THE BOLTZMANN EQUATION FOR MAXWELLIAN MOLECULES, by E. P. Gross. [1954] [2]p. [Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force] Office of Scientific Research under [N5ori-07801] Unclassified

Published in Phys. Rev., v. 93: 347-348, Jan. 15, 1954.

The Boltzmann integrodifferential equation for monatomic gases has been studied extensively in two limiting cases, where the mean free path is small compared to the relevant lengths of the problem and where the mean free paths are large compared to a container dimension. Due to present active interest in processes occurring in rarefied gases, a method of solution is required which deals with the entire range of pressures in a unified manner and which can satisfy general microscopic boundary conditions. A method is outlined for the special case of Maxwellian molecules which repel each other with an inverse fifth-power law of force.

A KINETIC APPROACH TO COLLISION PROCESSES IN GASES, II (Abstract), by E. P. Gross and M. Krook. [1954] [1]p. (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under [N5ori-07801]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 27-28, 1953.

Published in Phys. Rev., v. 93: 936, Feb. 15, 1954.

A kinetic approach is applied to the study of the small amplitude oscillations of one-component ionized and neutral gases. The initial-value problem in unbounded space is solved in detail for a simple collision model involving the assumption of a collision time independent of velocity. For uncharged gases, there results the corrected adiabatic limiting law for sound-wave propagation at high pressures. In addition, one obtains a theory of the absorption and dispersion of sound for arbitrary pressures. For ionized gases the difference in the nature of the organization in the low-pressure plasma oscillations and in high-pressure sound-type oscillations can be studied. At high pressures it is not permissible to treat an ionized gas as a one-component system; the electron ion coupling must be studied more carefully. This kinetic approach is therefore generalized to treat many-component systems and is applied to the treatment of the oscillations of ionized gases and to the propagation of sound in mixtures of neutral gases. A STUDY ON MAGNETIC CERAMICS [Parts 1-5], by G. Economos. May 1954, 59p. incl. iltus. tables, refs. (Technical rept. no. 78) (Sponsored jotntly by Offtce of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801, N5ori-07858, and AF 19(604)458) AD 33858 Unclassifted

Also published tn Jour. Amer. Ceramic Soc., Pt. 1, v. 38: 241-244, July 1955; Pt. 2, v. 38: 292-297, Aug. 1955; Pt. 3, v. 38: 335-340, Sept. 1955; Pt. 4, v. 38: 353-357, Oct. 1955; and Pt. 5, v. 38: 408-411, Nov. 1955.

Magnetite, manganese ferrite, and magnesium ferrite together with thirteen compositions within the system Fe_2O_3-MgO-MnO were investigated. A carbonate decomposition method of obtaining a well-dispersed oxide mix of high reactivity was used. The ferrites were also prepared and fired in various controlled atmospheres. Magnesium ferrite and one complex composition (approximate mole percent: 30 Fe_2O_3: 35 MgO: 35 MnO) with a rectangular hysteresis loop characteristic were investigated in detail under a variety of ftring conditions. They showed an increase tn the tnitial permeability (μ_i) and a decrease in the coercitive field (H_c) with tncreasing peak firing temperature and ftring time. The maximum induction (B_m) tncreased, but the remanent induction (B_r) fell off when fired at 1450°C, especially for the complex composition. A similar decrease of B_r was noted by quenching from above 800°C. Oxygen loss or gain over the stoichiometrtc amount produced a loss of magnetic properties in atl the ferrttes tnvestigated (μ_i, B_m, B_r down and H_c up). Changes in the magnetic properties of the complex ferrites in the center of the system Fe_2O_3-MgO-MnO coutd be correlated to the amount and types of tons contributing magnetic momenis. X-ray and microsiructure studies aided in the tnterpretation of ihe experimenial data. (Contractor's abstract)

PROPAGATION OF WAVES IN IONIZED GASES (Absiract), by E. P. Gross and M. Krook. Preliminary rept. [t954] [1]p. [Sponsored jointly by Office of Naval ttesearch, Signal Corps, and Air Force Office of Scientific Research under N5ori-07801] Unctassified

Presented at annual meeting of the Amer. Phys Soc., Columbia U., New York, Jan. 28-30, 1954.

Published in Phys. Rev., v. 94: 778, May 1, 1954.

A theoretical study is made of the small-amplitude oscillations of a completely ionized gas as a function of pressure. At low pressures there exist two types of waves. The high-frequency electronic plasma waves (Phys. Rev., v. 75: 1851, 1864; 1949), are only slightly modified by the motion of positive ions. In addition, we find the low-frequency "plasma-ion" waves previously studied by Tonks and Langmuir (Phys. Rev., v. 33: 195, 1929). The latter are, however, undamped only when the electron temperature is considerably greater than the ion temperature. To study the effects of collisions we make use of a model for collision processes proposed earlier (Bull. Amer. Phys. Soc., v. 28: 32, 1953). It is found that the low frequency modes are increasingly damped as the pressure is raised. The high-frequency modes are also highly damped at intermediate pressure. However, at higher pressures this mode changes its nature continuously and becomes a sound wave with a propagation velocity characteristic of a mixture of gases. (Contractor's abstract)

Also published in Phys. Rev., v. 97: 395-403, Jan. 15, 1955.

Van Vleck and Weisskopf and Fröhlich have derived a microwave line shape by studying the interruption by collisions of the motion of a classical oscillator. They assume that after the instantaneous impact the oscillator variables are distributed according to a Boltzmann distribution appropriate to the value of the applied field at collision. In contrast to the earlier theory of Lorentz, they obtain the correct static polarization. The procedure involves an assumption of very large velocity during collision. This is criticized on the grounds that the duration of collision is short compared to the resonant period and energy exchanges are of the order of kT. We have derived a line-shape formula assuming that the positions are unchanged after impact. Two extreme models are studied. In one, the oscillators have a Maxwellian distribution of velocities after impact; the second is a Brownian motion treatment. The resulting line shape in both cases is that of a friction-damped oscillator. For collision frequency much less than the resonant frequency, the polarization postulated by the above authors is reached as a result of kinematic motion between collisions, and the line shapes agree with ours. However, to obtain equal line widths and peak absorptions, the collision frequency is twice as large for the present theory. For collision frequency comparable to resonant frequency a less distorted line shape results. For testing the theories, experiments on foreign-gas broadening in the microwave region at pressures of the order of an atmosphere are required. Differences between the theories are small for conditions accessible experimentally at present. (See also item no. SYR. 04:007) (Contractor's abstract)

The lattice constants of sodium, potassium, rubidium, and cesium borohydrides have been measured at 25.0°C as 6.1635 ± 0.0005, 6.7272 ± 0.0005, 7.029 ± 0.001, and 7.419 ± 0.001A, respectively. All four crystals are face-centered cubic and have the sodium chloride structure. Below the transition point (-83°C) sodium borohydride becomes tetragonal with lattice constants of a = 4.354 ± 0.005 and c = 5.907 ± 0.005A at -195°C. (Contractor's abstract)

A MAGNETO-X-RAY STUDY OF MAGNETITE AT 78°K, by S. C. Abrahams and B. A. Calhoun. July 1954, 10p. incl. illus. refs. (Technical rept. no. 82) (Bound with its Technical rept. no. 80; AD 37277) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and N5ori-07858) AD 37227(b) Unclassified

Also published in Acta Crystallographica, v. 8: 257-260, May 10, 1955.

The x-ray diffraction pattern produced by a small single crystal of magnetite after cooling through the transition at 119°K, has been examined. It is demonstrated by using orientated magnetic fields during the cooling process that up to six different domain orientations are present in the crystal at 78°K. This number of domain orientations can be produced only if the symmetry of the low-temperature phase of magnetite is orthorhombic, or lower. (Contractor's abstract)

THE CRYSTAL AND MOLECULAR STRUCTURE OF ORTHORHOMBIC SULFUR, by S. C. Abrahams. Sept. 1954, 27p. incl. illus. tables, refs. (Technical rept. no. 83) (Bound with its Technical repts. nos. 84-85; AD 45684(a)-AD 45684(b)) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 45684 Unclassified

Also published in Acta Crystallographica, v. 8: 661-671, Nov. 10, 1955.

The lattice constants of orthorhombic sulfur have been determined as a = 10.437 ± 0.020, b = 12.845 ± 0.010, and c = 24.369 ± 0.010 A. Using Mokα radiation, and both Weissenberg and precession cameras, 669 out of a possible 1049 structure factors have been measured. Warren and Burwell's approximation to the structure was refined first by double Fourier series, and then by repeated least-squares analyses using all the measured structure factors. The coordinates thus obtained, after the least-squares method had completely converged, were used in evaluating a triple Fourier series. The arithmetic mean of the coordinates obtained by the triple Fourier series and the final least-squares analysis correspond to an S_8 molecule in which the average sulfur-sulfur bond length is 2.039 ± 0.007A, the average sulfur-sulfur-sulfur bond angle is 107°41 ± 39' and the average dihedral angle is 99°44' ± 48'. There are no unusual intermolecular contacts. The dimensions in the S_8 molecule are briefly discussed in terms of other recent determinations of sulfur compounds. (Contractor's abstract)

Also published in Zeitschr. f. Physik, v. 138: 276-283, 1954.

Synthetic CaF_2 crystals were colored by 2.5-mev electrons, Ca vapor, and low-energy electrons. Impurities and imperfections of the crystals were compared by the measurements of UV light transmission, density, and ionic conductivity and by spectroanalysis. The best crystals showed good transmission in the near and far UV, high density, and low ionic conductivity; they had a low yield of color centers. Four absorption bands located at 2.16, 3.14, 3.70, and 5.50 ev were observed. The coloration rate was higher and the absorption bands varied somewhat in spectral position and intensity. The 4 bands observed in the best crystals were caused by electrons and/or holes trapped in lattice imperfections and not by chemical impurities as was suggested by Luty (Zeitschr. Physik. v. 34: 596, 1956). (ASTIA abstract)

THE DYNAMIC BEHAVIOR OF DOMAIN WALLS IN BARIUM TITANATE, by E. A. Little. Oct. 1954, 44p. incl. illus. refs. (Technical rept. no. 87) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 45689 Unclassified

Also published in Phys. Rev., v. 98: 978-984, May 15, 1955.

The nucleation and growth of 180° and 90° domains in $BaTiO_3$ single crystals were measured with optical techniques. The creation of 180° domains proceeds by the nucleation of long thin spikes with an initial velocity along the polar axis of about 10^4 cm/sec for E=5 kv/cm. The limiting field for 180° domain growth is nearly identical with the limiting field for nucleation of a domain. The growth of 90° domains in an electric field begins by the nucleation of long thin wedges. Direct measurements of the nucleation rate as a function of time and field strength show that this rate traverses a maximum as a function of time. The maximum growth rate of a single wedge approaches asymptotically about 10^6 cm/sec with increasing field strength. The interaction of 90° and 180° domains were also investigated. Observations showed that 90° walls may form head-to-head or tail-to-tail configurations which can only be switched by the intermediate formation of 180° domains. The free energy for rotation of the polar axis through 90° was calculated, and an approximate value for the energy of a 90° wall was derived. (ASTIA abstract)

THE SYNTHESIS OF FERRITES AND PREPARATION OF COBALT-FERRITE CRYSTALS, by D. G. Wickham. Oct. 1954, 51p. incl. diagrs. tables, refs. (Technical rept. no. 89) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801, and [Wright Air Development Center. Electronic Components Lab.] under AF 33(616)2191) AD 47112 Unclassified

A new method is developed for the preparation of magnesium, manganese, cobalt, nickel, and zinc ferrites, based on the thermal decomposition of the mixed precipitates of ferrous oxalate dihydrate with the analogous compounds of magnesium, manganese, cobalt, nickel, and zinc. Evidence is presented to show that ferrous oxalate dihydrate forms mixed crystals (solid solutions) with the other oxalates of the series. The ferrites are prepared from these mixed crystals at relatively low temperatures and with greater convenience in comparison with methods previously used. The purity of the ferrite products is established by x-ray and chemical analysis. An x-ray diffraction

MIT. 08:047 - MIT. 08:049

study of the oxalate dihydrates shows that the compounds of manganese, cobalt, nickel, and zinc possess crystal structures very similar to that of ferrous oxalate dihydrate, which is found to be orthorhombic (space group, Fmm2). Lattice parameters for ferrous oxalate are directly measured, those for the other oxalates and mixed crystals are computed. A high temperature furnace, utilizing a molybdenum wire heating element, is designed and constructed for the purpose of growing single crystals of the ferrites from the melt by the Bridgman method. The operation of the furnace is tested in attempts to prepare single crystals of cobalt ferrite. The results of these experiments show that single crystals can be obtained by the method used, but in order to prepare crystals of the composition given by the formula, $CoFe_2O_4$, an oxygen pressure surrounding the melt considerably higher than one atmosphere will be required, and some provision to prevent the loss of cobalt oxide by evaporation will be necessary. THE ORIENTATION OF ELECTRIC-BREAKDOWN PATHS IN ALKALI HALIDE SINGLE CRYSTALS, by M. E. Caspari. Nov. 1954, 55p. incl. diagrs. tables, refs. (Technical rept. no. 90) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 49542 Unclassified

Also published in Phys. Rev., v. 98: 1679-1691, June 15, 1955.

Experiments were conducted to establish the breakdown-path directions in some alkali haldie crystals over a wide temperature range under controlled field conditions prior to breakdown. Independence of the dc breakdown strength of NaCl in homogeneous fields on the direction of the applied field was confirmed for liquid N temperature. Experiments on the orientation of the breakdown paths in NaCl at room temperature with various electrode shapes and immersion media revealed the existence of 3 different types of breakdown paths: anodic, cathodic, and homogeneous field paths. Breakdown leading to anodic paths is initiated by prebreakdown discharges at the anode and is produced by highly inhomogeneous starting fields. The paths are precisely orientated with respect to the crystallographic axes of the crystal. Cathodic breakdown paths are initiated directly at the cathode in point-plane electrode systems with the point as cathode; their direction difference differs from those of anodic paths. Breakdown paths produced in homogeneous fields follow the direction of the applied field. Experiments on NaCl, NaBr, KBr, RbCl, and RbI from -160° to 325°C under reproducible field conditions confirm the findings of Davisson (Phys. Rev. v. 70: 685, 1946; v. 73: 1194, 1948) that the anodic path directions follow the sequence: random → '100' → 'ttt' → 'tt0' with increasing temperature. While the random → 't00' transition takes place gradually over a range of more than 100°C, the [100] → [110] transition in K and Rb salts is sharp. Mechanical deformation has little effect on the path directions. (ASTIA abstract)

PREBREAKDOWN CURRENT AND NOISE IN INSULATORS, by D. A. Powers and T. Suita. Jan. 1955, 12p. incl. diagrs. refs. (Technical rept. no. 91) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 54505 Unclassified

Also published in Jour. Appl. Phys., v. 26: 1244-1247, Oct. 1955.

Haworth and Bozorth (Physics, v. 5: 15, 1934), as well as von Hippel (Phys. Rev., v. 54: 1096, 1938), many years ago observed that the prebreakdown current in dielectrics may be accompanied by characteristic noise phenomena of a not clearly established origin. Lately, several scientists have ascribed this noise to impact ionization in the dielectric and deduced the number and height of these avalanches from it. This interpretation appears very doubtful, because the onset of impact ionization in the presence of field emission should normally lead to breakdown. To clarify the situation, the present authors have investigated the origin of the noise and its frequency spectrum in some detail. The finding is that most of the noise is due to surface discharges and can be eliminated by special types of electrodes and careful experimentation. The remaining noise has a frequency spectrum with the highest amplitudes at very low frequencies; it falls rapidly to the Johnson noise level in the measuring resistor at about 10^4 cps. This noise apparently originates from fluctuations in the field emission current. (Contractor's abstract)

PRECISION DETERMINATION OF LATTICE CONSTANTS WITH A GEIGER-COUNTER X-RAY DIFFRACTOMETER, by A. Smakula and J. Kalnajs. Feb. 1955, 28p. incl. diagrs. tables, refs. (Technical rept. no. 92) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under N5ori-07801 and Watertown Arsenal Ordnance Material Research Office under DA 19-020-ord-3429) AD 56364 Unclassified

Also published in Phys. Rev. v. 99: 1737-1743, Sept. 15, 1955.

It is shown that the Geiger-counter x-ray diffractometer can be used for precision determination of lattice

constants. The zero point of the goniometer (determined by two methods) and the position of the diffraction lines (2θ) have been obtained with an accuracy of ± 0.001°. The temperature was kept constant by a special unit within 0.05°C. An investigation of the systematic errors has been made, which shows that the extrapolation of lattice constants vs $\cos^2\theta$, according to Wilson's equation, is permissible and the vertical divergence error, as computed by Eastabrook, lies up to 2θ = 165°, within the limits of error, and may be neglected. The lattice constants of Al, Ag, Ge, Si, CaF_2, CsI, TlCl, and TlBr, determined by extrapolation, are in good agreement with published data. The limiting factor in the accuracy of the lattice constants determination is not in the error of the diffractometer, but in the x-ray wavelength. (Contractor's abstract)

CONDUCTION AND BREAKDOWN IN HEXANE, by W. B. Green. Mar. 1955, 38p. incl. diagrs. refs. (Technical rept. no. 93) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 57124 Unclassified

Also published in Jour. Appl. Phys., v. 26: 1254-1264, Oct. 1955.

Conduction currents in hexane were studied as a function of spacing, metal, and heat-treatment of the electrodes over the field-strength range from 0 to 250 kv/cm. Exposure to γ rays increases the current in a way that indicates a decrease of the effective work function. The most important factor determining the currents appears to be the surface layer on the cathode. As the voltage increases from zero, positive ions accumulate in front of the cathode and set up an intense local field which induces field emission. The size of the local field depends on the number of ions arriving per second and on the thickness, homogeneity, and conductivity of the surface layer. For some electrodes, the current increases with gap width for constant field, but change of current with gap width is an electrode property. In one case the current was measured up to breakdown (1060 kv/cm).

INFRARED SPECTRA OF FERRITES, by R. D. Waldron. Mar. 1955, 22p. incl. diagrs. tables, refs. (Technical rept. no. 94) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 59713 Unclassified

Also published in Phys. Rev., v. 99: 1727-1735, Sept. 15, 1955.

The infrared spectra of 7 ferrites of the formula MFe_2O_4, where M designates a divalent metal, are presented and analyzed. Electronic absorption was observed in the visible and near-infrared regions. Two absorption bonds arising from interatomic vibrations were measured and force constants calculated for the stretching of bonds between octahedral or tetrahedral metal ions and oxide ions. These force constants are in agreement with the elastic and thermodynamic properties of these compounds and are sensitive to the distribution of metal ions between the alternate sites. The integrated vibrational bond intensities were measured; they are compatible with predominantly ionic bonding for these structures. (Contractor's abstract)

Also published in Phys. Rev., v. 99: 1747-1750, Sept. 15, 1955.

The densities of Si, Al, CaF_2, CsI, Ge, TlCl, TlBr,

MIT. 08:054 - MIT. 08:056

and SiO_2 (quartz) have been computed from lattice constants and molecular weights obtained from International Atomic Weights, and compared with the densities as determined by hydrostatic weighing of large crystals. The hydrostatic density of Ge proves too large by 0.0019 0.00193. This discrepancy disappears when the mass-spectroscopic atomic weight is used for the density calculations. Also for Si, Al, and CaF_2 a better agreement results with mass-spectroscopic atomic weights. From this series of measurements it is concluded that the mass-spectroscopic atomic weights are more reliable than the officially accepted ones. From measured densities and lattice constants of Si, Al, CaF_2, and Ge, Avogadro's number is obtained 6.02368×10^{23} $mole^{-1}$. The relative density defects for these samples of Si, Al, CaF_2, and Ge proves to be negligible within the limit of the measurements ($< 5 \times 10^{-6}$). These crystals are considered the most perfect that we have obtained up to the present time. A somewhat higher relative density defect in quartz (11×10^{-6}) may be caused by uncertainty of the data used for the computation of the density and that for CsI (13×10^{-6}) by Rb contamination. TlCl and TlBr show the greatest relative density defects, 43×10^{-6} and 40×10^{-6}, respectively. These crystals may contain vacancies or dislocations in the order of $\sim 5 \times 10^{18}$/cc, as is known also for the silver halides. (Contractor's abstract)

DIELECTRIC SPECTROSCOPY OF FERROMAGNETIC SEMICONDUCTORS, by A. von Hippel, W. B. Westphal, and P. A. Miles. July 1955, 117p. incl. diagrs. refs. (Technical rept. no. 97) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and Wright Air Development Center. Electronics Components Lab. under AF 33(616)2191) AD 68767 Unclassified

Also published in Rev. Modern Phys., v. 29: 279-307, July 1957.

A broad-band dielectric spectroscopy of the ferrites is attempted. The objective of such a research is defined, the language of dielectric spectroscopy is formulated and the experimental techniques from dc to the ultraviolet are described. Sections 3-11 discuss the physics of the situation, outlining the existing information on the frequency dependence of ferromagnetic response, and reformulating in our language the gyroscopic effects in magnetization phenomena, the behavior of domain walls, and the possible resonance and relaxation-type responses that may be expected in polarization and magnetization processes. The criteria for distinguishing between these responses are considered. Measurements in the optical and infrared ranges show the contributions to the low-frequency dielectric constant of the electronic and atomic polarizabilities, the latter showing sensitivity to cation distribution in ferrites. Conductivity measurements at microwave frequencies indicate a loss mechanism differing from the normal semiconducting behavior observed at lower frequencies. Boundary-layer effects predominate in the kilocycle range. The magnetization, in contrast, varies with frequency only in the electrical range. Two main dispersion regions can be distinguished and the uncertainty of their interpretation as domain-wall or spin-orientation processes is partly resolved by evidence from the nickel-zinc ferrite system and from temperature and time effects. Dielectric spectroscopy, as a mode of thinking, can obviously contribute much to the perception of ferromagnetic effects and of their appraisal in proper perspective. (Contractor's abstract)

PULSE-VOLTAGE STUDIES ON THE CONDUCTIVITY OF ELECTROLYTES AND SEMICONDUCTORS, by F. R. Kotter. July 1955, 45p. incl. illus. diagrs. refs. (Technical rept. no. 98) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 67868 Unclassified

Equipment was developed for the study of conductivities and of deviations from Ohm's law in highly conducting systems. A differential pulse transformer bridge similar to that of Gledhill and Patterson (Jour. Phys. Chem., v. 56: 999, 1952) was built for Wien-effect measurements. Preliminary measurements at field strengths up to 10^5 v/cm with 3-μsec rectangular-voltage pulses on aqueous $MgSO_4$ solutions (0.0002 to 0.004M) showed departures from ohmic behavior about 50% larger than predicted by the Onsager-Wilson Theory (H. S. Harned and B. B. Owen, The Physical Chemistry of Electrolytic Solutions, N. Y., Reinhold, 1950, p. 95-114). Contrary to the predictions of the Onsager theory for weak electrolytes, measurements on acetic acid (0.0006 to 0.3N) showed a dependence on concentration. Four-terminal equipment was used with 10-μsec voltage pulses in preliminary studies on solids (magnetite, Se, and Ag_2HgI_4). Significant departures from ohmic behavior were observed with field strengths of the order of 10^3v/cm.

FERROMAGNETIC AND FERROELECTRICS, by A. von Hippel. Aug. 1955, 43p. incl. diagrs. refs. (Technical rept. no. 99) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 71382 Unclassified

A comparison between ferromagnetics and ferroelectrics is given that intends to place these states of spontaneous order into clearer perspective by emphasizing their analogies and differences. Magnetization and

polarization by uncoupled moments leads to the Curie law. The introduction of a long-range feedback coupling produces the Curie-Weiss law; and the concept of an "inherent" ordering temperature sets both laws in a mutual relation. However, it becomes apparent that the long-range dipole forces of permanent moments cannot account for the creation of the observed long-range order. They have to be replaced by a short-range ordering forces, because the magnetic moments are too weak and the electric moments too strong. The formation of the ordered state is followed in more detail in the examples of nickel, barium titanate and magnetite. The domain status of the ordered state and its response to "effective" fields requires an analysis of the domain walls and of the distortion caused by walls in the crystal lattice. On the basis of domain rotation and the domain-wall nucleation and motion, the dynamics of the ordered state is considered as shaped by anisotropy, resonance and relaxation effects, fabrication parameters, and the short-range order of the material. FIELD EMISSION FROM METALS INTO ALKALI HALIDE CRYSTALS, by M. Geller. Oct. 1955, 31p. incl. diagrs. tables, refs. (Technical rept. no. 100) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 76994 Unclassified

Also published in Phys. Rev., v. 101: 1685-1693, Mar. 15, 1956.

Experimentation on (1) the transient photocurrents associated with the movement of photoelectrons in additively colored alkali halide crystals and (2) the accompanying growth of positive space charge at the cathode with subsequent field emission was extended from room temperature to low temperatures, and the theory was expanded to include the final photocurrents produced by the space-charge-enhanced field. The field strength at the cathode was derived and correlated to the final current density by means of measurements of the initial current, its time constant, and the final current. Fowler-Nordheim plots yielded a straight line, but the order of magnitude of the calculated field and the apparent work function were too small to be reasonable. The work function exhibited a dependence on light intensity. The decrease of the photocurrent from room temperature to -130°C by a factor of only 2 was attributed to the lowered mobility of the electrons in the crystal. An analysis of final photocurrent-vs-voltage curves for various metals and composite surfaces indicated that the photocurrent was controlled by the ionized F centers in a thin surface layer of the crystal, and that the image forces of these centers created the high fields which were required for the emission.

MOLECULAR ENGINEERING, by A. von Hippel. Oct. 1955, 22p. incl. refs. (Technical rept. no. 101) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 76993 Unclassified

Also published in Science, v. 123: 315-317, Feb. 24, 1956.

A discussion is presented on the concept of molecular engineering and the necessity of a transition from the phenomenological approach to matter to such a concept. In cases of great complexity, empirical experimentation may be more suitable than scientific analysis and synthesis, but the shift will be to molecular engineering as knowledge and experience increase. The concept is applied to the problem of developing aircraft materials capable of withstanding temperatures of 1000°F caused by friction. An academic environment incorporating areas for fundamental research, discussion of practical implications and long-range applications, and prototype development is recommended.

DEVELOPMENT OF THE VIBRATING-COIL MAGNETOMETER AND ITS APPLICATION TO MAGNETITE, by D. O. Smith. Nov. 1955, 77p. incl. diagrs. refs. (Technical rept. no. 102) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 80347 Unclassified

Also published in Rev. Scient. Instruments, v. 27: 261-268, May 1956.

Also published in Phys. Rev., v. 102: 959-963, May 15, 1956.

A vibrating-coil magnetometer was used to measure the isothermal M-H curves of magnetite at atmospheric pressure in the principal crystallographic directions from room temperature to the Curie point. Near the Curie point, the magnetizing field required to create a single domain was less than 100 amp/m which provides an unambiguous experimental determination of the spontaneous magnetization in this critical region. In the neighborhood of the Curie point, the M-H curves are very nonlinear; replotting the data in the form of H-T curves at constant magnetization shows that in this region the magnetic energy can be expressed as $U_M = -\mu_o WM^2/2$ where W is a constant, H is the applied field, and M is the volume magnetization. These results suggest that the classical work of Weiss and Forrer (Ann. Phys., v. 5: 153, 1926) on nickel

should be repeated with the use of a single crystal to eliminate domain effects.

CONTROLLED FIELD EMISSION IN HEXANE, by W. B. Green. Nov. 1955, 16p. incl. diagrs. refs. (Technical rept. no. 103) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801 and Army Ordnance. Diamond Ordnance Fuze Labs. under DAI-49-186-502-ord(P)-334) AD 80348 Unclassified

Also published in Jour. Appl. Phys., v. 27: 921-925, Aug. 1956.

The current-voltage relationship for dielectric liquids consists of two portions, usually in superposition; at lower voltages a current of ions flows; at higher voltages, field emission sets in. The field emission current depends on the material of the cathode, but not simply on its work function. The current may be altered by changing the thickness of the cathode surface layer or the gas adsorbed upon the surface. When the ion content of the liquid is raised, not only the ionic current, but also the field-emission portion of the current increases. Controlled field-emission currents have been produced. PREBREAKDOWN CURRENT STUDIES IN COMPRESSED NITROGEN, by N. L. Allen. Apr. 1956, 24p. incl. diagrs. tables, refs. (Technical rept. no. 107) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 99321 Unclassified

A description is given of a vessel containing an electrode system for measurement of prebreakdown currents in compressed gases. Auxiliary equipment includes a pressure intensifier and a manganin-wire pressure gauge. A highly stablized high-voltage supply allows measurements to be made very close to breakdown. Values of the ionization coefficient η and regeneration coefficient Υ are given for pressures between one and four atmospheres and the variation of Υ in this region is discussed in detail. Difficulties encountered at higher pressures and suggestions for future experiments are outlined. (Contractor's abstract)

THE CRYSTAL STRUCTURE OF DIPHENYL SULFOXIDE, by S. C. Abrahams and H. J. Grenville-Wells. May 1956, 20p. incl. diagrs. tables, refs. (Technical rept. no. 105) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 95350 Unclassified

Also published in Acta Crystallographica, v. 10: 417-422, June 10, 1957.

Diphenyl sulfoxide forms monoclinic crystals, space group $P2_1/n$, in a cell with lattice constants a = 8.90 ± 0.02, b = 14.08 ± 0.03 and c = 8.32 ± 0.02A, and β = 101°7' ± 10', containing four molecules. The crystal structure has been solved by a combination of isomorphous replacement and trial and error methods. Refinement of the atomic parameters was effected by the use of double Fourier series, followed by least-squares analysis of a set of 664 independent structure factors. This partially complete set of three-dimensional structure factors was derived by visual intensity measurement. The final coordinates lead to bond lengths of 1.47 ± 0.016A for sulfur-oxygen, 1.76 ± 0.015A for sulfur-carbon and 1.40 ± 0.008A for carbon-carbon, and bond angles of 106°10' ± 40' for carbon-sulfur-oxygen, 97°19' ± 58' for carbon-sulfur-carbon and 119°27' for sulfur-carbon-carbon. The dihedral angle between the normals to the planes of the aromatic rings is 75°50' ± 58', and between the plane of each ring and the common carbon-sulfur-carbon plane is 81°54' ± 40'. An intermolecular contact of 3.36A satisfying the formal requirements of a C - H ...O bond occurs in this crystal. In considering the stereochemistry of subgroup VI_b of the periodic table, there is a special importance in a study of these atoms when chemically linked to three other atoms. The early debates on the possibility of planarity in the three sulfur bonds in the sulfoxide group were largely ended by the optical resolution of unsymmetrical sulfoxides by Harrison, Kenyon

and Phillips (1926). This work clearly demonstrated that the three bonds could not be coplanar, but left the precise arrangement undetermined. Recent studies of the molecular constants of several simple sulfoxides has entirely confirmed the pyramidal form of these bonds. The present study of the simplest aromatic sulfoxide was undertaken in order to throw further light on the stereochemistry of the sulfoxide group, and also for comparison with similar molecules lacking the oxygen atom.

INFRARED-ABSORPTION STUDIES ON BARIUM TITANATE AND RELATED MATERIALS, by J. T. Lasi. May 1956, 38p. incl. diagrs. tables, refs. (Technical rept. no. 106) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under N5ori-07801) AD 96171 Unclassified

Presented at meeting of the Amer. Phys. Soc., Eugene, Ore., June 21-23, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 255, June 21, 1956.

Also published in Phys. Rev., v. 105: 1740-1750, Mar. 15, 1957.

The infrared-absorption spectrum of $BaTiO_3$ has been measured for thin single crystals and for powder samples dispersed in pressed KBr disks. Absorption bands for single-crystal samples occur at 495 cm^{-1} and at ca 340 cm^{-1}, arising from normal vibrations of the TiO_3 group. A third vibration, a motion of Ba against the TiO_3 group, occurs below the experimentally accessible range. A frequency of about 225 cm^{-1} is expected for this vibration on the basis of a comparison of the specific heat contributions of the observed bands with the measured low-temperature specific heat. Measurements were made on the 495 cm^{-1} band over a wide temperature range. As the crystal changes from the cubic to the tetragonal, orthorhombic, and rhombohedral structures, there occurs band splitting which can be related to the change of crystal symmetry. The spectra of the perovskite titanates, $SrTiO_3$, $PbTiO_3$, and $CaTiO_3$, and the perovskite niobates, $KNbO_3$ and $NaNbO_3$, have been found to be similar, in general features, to that of $BaTiO_3$. The slight differences in band frequency and structure can be related to differences in unit-cell size and symmetry. Integrated band intensities have been found to be in reasonable agreement with measurements on other oxide systems that have vibrations in this spectral region. (Contractor's abstract)

THE INFRARED SPECTRA OF HDO IN WATER AND IONIC SOLUTIONS, by R. D. Waldron. May 1956, 18p. incl. diagrs. tables, refs. (Technical rept. no. 108) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 100917 Unclassified

Also published in Jour. Chem. Phys., v. 26: 809-814, Apr. 1957.

The IR spectra of HDO in H_2O and saturated metal-halide solutions were investigated for studying the interactions between ions and solvent molecules and the nature of H bonding in aqueous systems. The fundamental and overtone bands of the OH and OD streiching vibrations are shifted to lower frequencies and the bending vibration is shifted to higher frequencies in passing from the gaseous to the liquid state. Similar shifts occur for the metal-halide solutions; the magnitudes of these are sensitive to the anion species but relatively independent of the cations. The frequency shifts for ionic solutions increase in the order I^-, Cl^-, and F^-, with the shift in ion-free H_2O about equal to that for Cl^-. The vibrational anharmonicity of the OH stretching vibration in solution was almost independent of the frequency shift and only slightly larger than the gas value. The dependence of frequency shift on the shortening of H bonds (volume contraction) and H-bond energy gave qualitative agreement with other systems previously investigated.

SINGULAR POTENTIALS IN QUANTUM MECHANICS, by F. L. Scarf. June 1956, 48p. incl. diagrs. refs. (Technical rept. no. 109) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under N5ori-07801) AD 100919 Unclassified

Many physical systems are characterized by attractive potential energies which become infinite in such a way that $\lim_{r \to 0} r^2 V(r) < 0$. For example, magnetic, spin-orbit, polarization and many exchange forces are all approximately described (at large distances) by these so-called singular potentials for which ordinary methods of solving Schrödinger's equation are insufficient. In this paper the general problem of solving the quantum-mechanical wave equations for singular potentials is reinvestigated. It is shown that a set of orthogonal states states with complex energy eigenvalues $(E_n = W_n + \frac{1}{2} i \Gamma_n)$ is obtained. In general, this is interpreted in the following way: W_n is the most probable position of the energy level for various kinds of

MIT. 08:067 - MIT. 09:001

potential cut-offs and Γ_n is a measure of the probable error. The virial theorem and the W. K. B. method are used to explain the physical basis of these results. (Contractor's abstract)

WIDE-BAND HIGH-PRESSURE DIELECTRIC CELL, by M. G. Vallauri and P. W. Forsbergh, Jr. Oct. 1956, 8p. incl. diagrs. (Technical rept. no. 110) (Sponsored jointly by Office of Naval Research, Signal Corps, [Air Force Office of Scientific Research] and Ordnance Materials Research Office under [N5ori-07801] AD 114705 Unclassified

Also published in Rev. Scient. Instrument, v. 28: 198-199, Mar. 1957.

A quartz and metal seal capable of holding compressed gases at 1500 atm forms the tapered, coaxial transition leading from a standing-wave detector or from a bridge, into a coaxial condenser. The continuity of characteristic impedance through the seal is sufficiently good to allow accurate measurement of dielectric constant and loss in compressed gases and liquids from low frequencies to 3000 mc (λ_0 = 10 cm) in a single cell. The performance is illustrated with isotherms of the dielectric constant of N_2O through the critical point. Organic sealing materials are not used. The unit promises to be satisfactory for a wider temperature range than is reported here.

ELECTRIC BREAKDOWN AND CONDUCTION THROUGH MYLAR FILMS, by Y. Inuishi and D. A. Powers. Dec. 1956, 19p. incl. illus. (Technical rept. no. 112) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under [N5ori-07801] and DAI-49-186-502-ord(P)-334) AD 120218 Unclassified

Also published in Jour. Appl. Phys., v. 28: 1017-1022, Sept. 1957

Studies of dc breakdown on Mylar film show that defects cause a decrease in dielectric strength with decreasing film thickness at room temperature but not at -180°C. The breakdown at defects is associated with moisture content. Using self-healing electrodes to eliminate weak areas, a dc electric strength of 6 mv/cm is found, independent of film thickness. Prebreakdown current measurements indicate ionic currents which are fairly uniform throughout a sample, and field emission currents localized at incipient breakdown points. Breakdown probably occurs as a result of local heating due to the field emission currents. (Contractor's abstract)

MACH NUMBER MEASUREMENTS IN HIGH-SPEED WIND TUNNELS, by J. A. F. Hill, J. R. Baron, and L. H. Schindel. Jan. 1956, 121p. incl. diagrs. tables, refs. (Technical rept. no. 145) (AFOSR-TR-56-7) (AF 18(603)4) AD 81540 Unclassified

Presented at Eighth meeting of the Wind Tunnel and Model-Testing Panel of AGARD, Rome (Italy), Feb. 1956.

The report discusses the measurement of subsonic and supersonic Mach numbers in air from the point of view of calibration measurements of an empty wind tunnel, of measurements of local Mach numbers at points in the flow field around a model, and of simulating free flight Mach numbers in the presence of wind-tunnel wall interference. The sensitivity of various parameters to change in Mach number is evaluated and instruments and techniques are discussed. The Mach number is related to various measurable properties by assuming certain properties. Errors are due to departures from the assumed properties (perfect gas, etc.) and the interference of the probe.

ON THE EVALUATION OF INTEGRALS OF THE TYPE $f(\tau_1, \tau_2, \ldots, \tau_n) = \frac{1}{2\pi i} \int F(s) e^{W(s, \tau_1, \tau_2, \ldots, \tau_n)} ds$ AND THE MECHANISM OF FORMATION OF TRANSIENT PHENOMENA. PART 2a. AN ELEMENTARY INTRODUCTION TO THE THEORY OF THE SADDLE-POINT METHOD OF INTEGRATION, by M. V. Cerrillo. May 3, 1950, 74p. incl. diagrs. (Technical rept. no. 55:2a) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) AD 47792 Unclassified

This report is concerned with the ideas that serve as a foundation for the "Saddlepoint Method of Integration." This method is also known by other names; particularly, as the "Method of Steepest Descent" and the "Method of the Points of Stagnation." The method and ideas presented here will serve as an introductory presentation to a more complete theory of integration which will be discussed in subsequent reports of this series. The material covers the following condensed description: (a) definition and properties of saddlepoints of different orders; (b) basic procedure of integration through saddlepoints of the second order; (c) definition of the family of integral approximations of the resonant type. The pole, zero, and dipole solutions; (d) integration in the case of composite behavior; (e) introduction to the idea of "Generating Function" associated with second-order saddlepoints. The Fresnel solid; (f) the case of saddlepoints of higher order and the theory of transition for saddlepoints of the third order; (g) zero, pole, and dipole types of integral; (h) the Airey-Hardy type of "Generating Function." The corresponding generating solid; (i) the mixed type of integral and composition of solutions; and (j) a few comparative typical solutions for transitions of higher order corresponding to the pole, zero, and dipole cases. The manuscript was originally written for use in certain applications in circuit theory. Because of this objective some specific terminology was used: "resonant transients," "transitional transients," etc. This nomenclature is, of course, not quite suitable for other applications of the method of integration. It is therefore advised that the reader disregard the terms "resonant and transitional transients" and use instead the terms "second-order, third-order solutions. (Contractor's abstract)

PERIODIC SAMPLING OF STATIONARY TIME SERIES, by J. P. Costas. May 16, 1950, 7p. incl. diagrs. (Technical rept. no. 156) [Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100 and W36-039-sc-32037] U11612; ATI-83682 Unclassified

When measuring the mean or average value of a random time function by periodic sampling some error is to be expected since only a finite number of samples are taken. An expression for the mean-square error of a sample mean is derived. The variation of error with changes in total sampling time and spacing between samples is discussed. An expression for the error involved in determining the mean by continuous integration is derived and the concept of sampling efficiency is introduced. A brief discussion of the probability of error is presented. (Contractor's abstract)

MICROWAVE DETERMINATIONS OF AVERAGE ELECTRON ENERGIES AND THE FIRST TOWNSEND COEFFICIENT IN HYDROGEN, by L. J. Varnerin, Jr. and S. C. Brown. May 24, 1950, 14p. incl. diagrs. refs. (Technical rept. no. 158) [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100 and W36-039-sc-32037] U13444; ATI-83681 Unclassified

A microwave method of measuring the average energy of electrons in a gas in the presence of a dc field has been developed through a measurement of the ratio between the electron diffusion and mobility. By solving for ac and dc distribution functions it is found possible to compare quantitatively the effective ac ionization coefficient and the first Townsend coefficient in hydrogen. It is then possible to calculate the first Townsend coefficient from ac breakdown data in hydrogen and these values are compared with previously determined values. Measurements of average energy have been made and values calculated from theory compared with previous measurements of average energy. All measurements are in substantial agreement with each other

MIT. 10:005 - MIT. 10:009

and with the theoretically determined values. (Contractor's abstract)

SHORT-TIME AUTOCORRELATION FUNCTIONS AND POWER SPECTRA, by R. M. Fano. June 6, 1950 [5]p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-100 and W36-039-sc-32037]) U13567; ATI-198559 Unclassified

Also published in Jour. Acoust. Soc. Amer., v. 22: 546-550, Sept. 1950.

The reciprocal relations between autocorrelation functions and power spectra, known as Wiener's Theorem, are extended in a modified form to the case of experimental results obtained by means of filters with finite time constants. If the short-time autocorrelation function $\varphi_t(\tau)$ and power spectrum $G_t(\omega)$ are properly defined, it is found that

$$\varphi_t(\tau) = \frac{e^{a|\tau|}}{2\pi} \int_{-\infty}^{\infty} G_t(\omega) \cos\omega\tau \, d\omega$$

$$G_t(\omega) = \int_{-\infty}^{\infty} e^{-a|\tau|} \varphi_t(\tau) \cos\omega\tau \, d\tau$$

where $1/a$ is a time constant. These equations may be used to relate the autocorrelation-function representation of a speech wave to the corresponding spectrographic representation. (Contractor's abstract)

AN ANALOG DEVICE FOR SOLVING THE APPROXIMATION PROBLEM OF NETWORK SYNTHESIS, by R. E. Scott. June 8, 1950, 47p. incl. illus. diagrs. refs. (Technical rept. no. 137) [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100] U14032; ATI-92381 Unclassified

An analog device has been developed which can solve the approximation problem of network synthesis with sufficient accuracy for most network problems. The complex frequency plane is represented by a conducting sheet of Teledeltos paper. The zeros and poles of the rational function are represented by positive and negative currents introduced into the plane. The voltage along the $j\omega$ axis in the plane represents the logarithm of the magnitude of the rational function. This voltage is scanned by a commutator at 10 cps and displayed upon the face of a CRT. The locations of the poles and zeros for a desired function are obtained by a cut and try process. A comparison of calculated and observed results shows that the accuracy of the device is 1-5% for the logarithm of the magnitude of the network function, and 3-15% for the phase, depending upon the particular function which is being solved. This accuracy is adequate for most network problems. A complete analysis is included of the errors introduced by the finite size of the plane, the finite size of the current and voltage probes, and the finite series impedance of the current sources. AMPLIFIERS WITH PRESCRIBED FREQUENCY

CHARACTERISTICS AND ARBITRARY BANDWIDTH, by J. G. Linvill. July 7, 1950, 61p. incl. diagrs. refs. (Technical rept. no. 163) [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100] U15596 Unclassified

The amplifier chain, a cascade connection of amplifier tubes connected by 2-terminal or 2-terminal-pair interstages, is the basic component of the amplifiers designed. Shunt capacitance in the interstages imposes a limit on the amplification per stage over a prescribed band of frequencies. The limit of amplification per stage is inversely proportional to the bandwidth. The method of design of amplifier chains presented leads to simple interstages which are economically close to the maximum in performance for the shunt capacitance present. The interstages used are simple-tuned circuits or double-tuned circuits. The technique of design of the amplifier chains is related to the stagger-tuning technique invented by Wallman. The characteristics of individual stages are nonuniform but the stages in a chain complement each other to provide an acceptably uniform characteristic. In the design procedure one chooses the amplification function for the chain being designed, according to a flexible technique presented in technical report no. 145 (TIP U11490), such that prescribed frequency characteristics are approximated. The amplification functions so chosen are suitable to be identified with realizable networks. This step is the key of the whole design process. Single amplifier chains become ineffective as amplifiers when the bandwidth becomes so broad that the amplification per stage approaches 1. When amplifiers are to amplify such broad bands of frequencies that this situation arises, more than 1 amplifier chain is used. The chains amplify different subbands and are connected in parallel at the input and output. The amplification functions of the individual chains are also chosen that the chains, when connected in parallel, give a desired characteristic. A summary of the pertinent characteristics of the distributed amplifier (invented by Percival), which is capable of amplifying over bands greater than those for which single amplifier chains are useful, permits a comparison with the parallel-chain amplifier. The parallel-chain amplifier is more economical in tubes and the design is more flexible. The frequency selectivity of the parallel-chain amplifier is affected by nonuniform changes in the tube characteristics; a properly designed distributed amplifier has a frequency selectivity not altered by changing transconductances of the tubes. DETERIORATION OF OXIDE-COATED CATHODES UNDER LOW DUTY-FACTOR OPERATION, by J. F. Waymouth, Jr. July 20, 1950, 15p. incl. diagrs. tables. (Technical rept. no. 159) [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100 and W36-039-sc-32037] U12316; ATI-85018 Unclassified

The behavior of oxide cathodes coated on a Ni alloy containing about 0.1% Si has been investigated under 100% and zero duty-factor operation. The operation of these cathodes at zero duty-factor was found to be highly favorable to the development of a high resistance in a layer of Ba_2SiO_4 located at the interface between the oxide and the core. The layer itself was present not only in cathodes that had aged without electron emission and had developed interface resistance, but also in cathodes that had aged with electron emission and had not developed interface resistance. A model is presented to account for the experimental observations. Evidence is also presented which shows that there may exist an "active" Ni alloy that does not lead to undue interface resistance formation. (Contractor's abstract)

AMPLITUDE MODULATION OF SYNCHRONIZED MICROWAVE OSCILLATORS, by W. P. Schneider and E. E. David, Jr. July 25, 1950, 23p. incl. illus. diagrs. refs. (Technical rept. no. 166) (Sponsored jointly by Signal Corps, Office of Naval Research, [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U17066; ATI-103041 Unclassified

It can be shown that 2 push-pull frequency-modulated oscillators, both synchronized by the same RF signal, can be arranged so that their combined output contains the side bands of ordinary amplitude modulation. Linearity of the scheme is excellent even for high modulation indices. The bandwidth is somewhat less than the AM bandwidth of the oscillators themselves; it is about 3 mc at X-band. Experimental work with the system indicates that it has characteristics suitable for microwave relay and possibly low-power broadcast applications. (Contractor's abstract)

MICROWAVE SPECTRUM OF PHOSPHINE, ARSINE AND STIBINE, by C. C. Loomis and M. W. P. Strandberg. July 31, 1950, 20p. incl. tables, refs. (Technical rept. no. 167) [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100 and W36-039-sc-32037] U12314; ATI-84984 Unclassified

The microwave spectrum of the mono-deuterated phosphine (PH_2D), arsine (AsH_2D), and stibine (SbH_2D) has been measured. Although a supposedly pure sample of stibine was prepared, phosphine and arsine proved to be major impurities. They were separated from the sample; the microwave spectrometer was used to

MIT. 10:013 - MIT. 10:015

monitor the distillation process. The quadrupole fine structure associated with the absorption transitions for AsH_2D is used to illustrate the special assumptions which may be made with these molecules having an axis of charge symmetry. These assumptions allow one to rotate the coordinate system from the charge-symmetry axes to the inertial axes without thereby adding unknown cross derivatives to the descriptions of the dyadic ∇E_{zz}. Interpretation of the spectrum of SbH_2D is more complicated. It is not found possible to fit the theory to the observed lines without making use of the second-order order perturbations due to a nearby level of different symmetry but of the same J. This perturbation involves the cross derivatives which had previously been assumed to be zero. With the assumption of cross derivatives approximately 1% of the diagonal terms, the theory fitted experiment within the experimental error. In order to measure the electric dipole moment of arsine and stibine a slight extension is made to the theory of asymmetric tops in a uniform electric field. The ground-state inversion splitting is determined to be less than 0.5 mc/sec for all three molecules. (Contractor's abstract)

LIMITS FOR THE DIFFUSION THEORY OF HIGH-FREQUENCY GAS DISCHARGE BREAKDOWN, by S. C. Brown and A. D. MacDonald. Aug. 3, 1950, 10p. incl. diagrs. refs. (Technical repl. no. 132) [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100 and W36-039-sc-32037] U10088; ATI-71878 Unclassified

A study is made of the limits within which diffusion phenomena control the breakdown of a HF discharge. The discussion is based on proper variables for dimensional analysis, using the parameters $p\Lambda$, $p\lambda$, and $E\Lambda$, where p is the pressure, Λ the characteristic diffusion length, λ the wave length of the excitation, and E the breakdown electric field. The limits of applicability of the diffusion theory are found to be a uniform field limit, a mean free path limit, and an oscillation amplitude limit. Within these limits, a single function for the effective breakdown voltage, $E\Lambda$, and the energy per mean free path, E/p, correlated the breakdown voltages for all published data tested, covering a wave-length range from 10 to 17,000 cm. THEORY OF NONLINEAR TRANSDUCERS, by H. E. Singleton. Aug. 12, 1950, 47p. incl. diagrs. tables, refs. (Technical repl. no. 186) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U16903; ATI-96271 Unclassified

Transducers are classified according to the manner in which they make use of storage to control their output. The state of a transducer is specified by the position of a point in multidimensional space. The system function of the transducer is then determined by attaching to each state point a set of numbers or probabilities characteristic of the output for the corresponding state. The technique of synthesizing nonlinear transducers is considered, and standard forms for synthesizing the various kinds of transducers are obtained. It is shown that a necessary and sufficient condition for an invariant finite-state transducer to be capable of synthesis in terms of a finite number of linear elements and rectifiers is that the state-defining regions be bounded by hyperfine surfaces. It is found that any nonlinear system function is determined by certain higher-order autocorrelation functions of the input and cross correlations between the input and output. The problem of optimum design of nonlinear filters is discussed. It is shown that if the probability distributions of noise and signal are Gaussian, the optimum mean-square filter is linear. For finite-state filters, the criterion of minimizing the probability of error is employed. The problem is to specify optimum boundaries for the state-defining regions and to obtain specific design equations. Several examples of filter design are given, including an application to the radar search problem. (Contractor's abstract)

Massachusetts Inst. of Tech. Research Lab. of Electronics, Cambridge.

TRANSIENT STARTING OF A MAGNETRON AS DESCRIBED BY THE INHOMOGENEOUS VAN DER POL EQUATION, by E. E. David, Jr. Aug. 16, 1950, 14p. incl. illus. diagrs. (Technical repl. no. 168) (Sponsored jointly by Signal Corps, Office of Naval Research, [Air Force Office of Scientific Research] under DA-36-039-sc-100 and W36-039-sc-32037) U18525; ATI-111108 Unclassified

The solution to the inhomogeneous Van der Pol equation specifies the operation of a nonlinear oscillator perturbed by an external signal of similar frequency. The steady state behavior of such an oscillator was first quoted by Van der Pol himself and is in agreement with other literature in the field. In this study, approximate and differential analyzer solutions are used to investigate the frequency and phase transients during starting, and distortion of the build-up envelope by the exciting signal. Results are essentially in agreement with results indicated in technical rept. no. 100 (TII' U8967), although details are different because reactive electronic beam-loading is neglected here. (Contractor's abstract)

A NOTE ON THE BEHAVIOR OF MUTUALLY COUPLED OSCILLATORS, by E. E. David, Jr. Aug. 16, 1950, 15p. incl. diagrs. (Technical rept. no. 169) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U17791; ATI-109131 Unclassified

The operation of an arbitrary number of oscillators mutually coupled into an arbitrary number of loads is discussed. By utilizing the oscillator Rieke diagrams, the scattering equations of the interconnecting network, and the constraints furnished by passive loads, the behavior of such a system may be predicted. Two simple, but practically important cases are discussed: (1) two oscillators operating into a matched parallel junction, and (2) the dual of this arrangement. The operation of these systems is critically dependent upon the oscillator spacing relative to the interconnecting network, although the tolerances on these spacings are not severe. Dissimilarities between the oscillators are not important. (Contractor's abstract)

MIT. 10:017

Massachusetts Inst. of Tech. Research Lab. of Electronics, Cambridge.

A STUDY OF SPEECH PROBABILITY DISTRIBUTIONS, by W. B. Davenport, Jr. Aug. 25, 1950, 76p. incl. illus. diagrs. refs. (Technical rept. no. 148) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U16015; ATI-101290 Unclassified

The problem of measuring a probability concerning a random time function is shown to reduce generally to that of measuring a time average. A study is made of the error due to averaging over only a finite interval of time. A description is given of apparatus, which, with pulse techniques, can measure certain probabilities concerning the instantaneous amplitude and the zero-crossing periods of any time function whose statistics lie in the range of the voice wave statistics. Measurements of the first probability distribution density of the speech-wave instantaneous amplitude for several speakers indicate that this distribution varies exponentially for large value of amplitude. Small but definite increases in conditional probability were noted for delay times of the order of magnitude of the pitch period. These measurements were of the stationary, or long time, speech statistics. Most of the measurements were made on substantially undistorted speech; some were made to show qualitatively the effect of reflections. (Contractor's abstract)

Massachusetts Inst. of Tech. Research Lab. of Electronics, Cambridge.

SERVOMECHANISM SYNTHESIS THROUGH POLE-ZERO CONFIGURATIONS, by J. G. Truxal. Aug. 25, 1950, 101p. incl. diagrs. refs. (Technical rept. no. 162) [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100] U15904; ATI-96270 Unclassified

A servomechanism synthesis procedure based on manipulation of pole-zero configurations permits simultaneous control over system response in both the frequency and time domain. In addition, this synthesis procedure is based on several important relationships between pole-zero locations and various criteria of system performance (e.g. error constants or the effect of corrupting signals). The synthesis procedure starts with the selection of an over-all system function meeting performance specifications in both the time and frequency domains and simultaneously resulting in physically realizable compensation networks. From the over-all system function the open-loop transfer function is determined by a simple graphical procedure, and the final step in the design is the determination of compensation networks. AXIALLY SYMMETRIC ELECTRON BEAM AND MAGNETIC FIELD SYSTEMS, by L. A. Harris. Aug. 29, 1950, 77p. incl. illus. diagrs. refs. (Technical rept. no. 170) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U17398 Unclassified

The theory of longitudinally uniform and axially symmetric electron beams focused by a uniform axial magnetic field is presented. It is assumed that the axial velocity is common to all electrons and that they do not cross each other radially. The radial electric, magnetic, and centrifugal forces are balanced if the proper relation between the magnetic field at the cathode and that in the uniform beam is satisfied. This balance is due to the rotation of electrons around the axis brought about by their crossing magnetic field lines. A general graphical method is presented for obtaining the potential distribution required for the design of hollow beams. The necessity of bringing the beam through a transition region where electrons acquire their angular velocity restricts the problem to 2 categories in which the cathode is either in a uniform magnetic field or in a magnetically shielded region. Special cases are the solid beam, the hollow beam with uniform radial charge density, the hollow beam between coaxial electrodes at the same potential, and the hollow beam inside an outer electrode only. Of interest is the

MIT. 10:020 - MIT. 10:023

case of a hollow beam focused with a magnetic field in the cathode region only. Explicit design equations are presented for all cases. The possible effects of incidential ionization are briefly considered. Experimental results confirm the theory qualitatively and to a considerable extent quantitatively and indicate the importance of the cathode flux condition and the need for a good method of bringing the beam through the transition region. A NEW METHOD OF ESTIMATING PREOSCILLATION NOISE IN A PULSED OSCILLATOR (MAGNETRON), by E. E. David, Jr. Aug. 30, 1950, 3p. incl. diagr. (Technical rept. no. 173) [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100]
U14696; ATI-92489 Unclassified

Starting-time jitter in pulsed magnetrons is throught to be caused principally by a corresponding initial RF amplitude jitter resulting from preoscillation noise. The initial amplitude (Ao) and the nose envelope were assumed to have a Rayleigh distribution, and the built-up was assumed to commence exponentially. Measurements of the time jitter were extrapolated to compute the amplitude variations and subsequently the rms preoscillation noise. Values 100 db above that expected from a temperature-limited diode carrying the same current and about 20 db greater than that found by static measurements were obtained for the QK-61 magnetron. The large value may be attributed to the low magnetic field (1400 gauss) used with this magnetron and the larger plate voltage (1050 v) present during the transient as opposed to the static measurement.

THE QUANTUM THEORY OF ANTIFERROMAGNETISM, by R. J. Harrison. Aug. 31, 1950, 31p. incl. diagrs. refs. (Technical rept. no. 172) [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100]
U14693; ATI-92490 Unclassified

Recent neutron diffraction experiments on antiferromagnetic crystals at low temperatures indicate the existence of a long range correlation in direction of the spin magnetic moments. Although the Ising model predicts such a correlation, a consideration of the uncertainty relationships for spin shows that in the correct quantum description of an antiferromagnet, the ordering cannot be the simple type given by this semiclassical model. The problem of determining the lowest quantum state of an antiferromagnet is much the same as the quantum chemical problem of determining the state of a large molecule. The short range correlation of spin moments is measured by a quantity called the "bond order" in molecular problems. This assumes its maximum in the lowest eigenstate. In an attempt to make progress in solving the general quantum mechanical problem, a new method of approximation has been developed and applied to the linear antiferromagnetic chain. The spin eigenfunction is expanded in terms of a set of "valence bond spin functions," grouped according to "degree of excitation." The amplitudes for each excitation are determined by the solution of an infinite set of linear difference equations. (Contractor's abstract)

A SIMPLIFICATION OF THE HARTREE-FOCK METHOD, by J. C. Slater. Sept. 28, 1950 [5]p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-100]) U16598; ATI-158493 Unclassified

Also published in Phys. Rev., v. 81: 385-390, Feb. 1, 1951.

It is shown that the Hartree-Fock equations can be regarded as ordinary Schrödinger equations for the motion of electrons, each electron moving in a slightly different potential field, which is computed by electrostatics from all the charges of the system, positive and negative, corrected by the removal of an exchange charge, equal in magnitude to one electron, surrounding the electron whose motion is being investigated. By forming a weighted mean of the exchange charges, weighted and averaged over the various electronic wave functions at a given point of space, we set up an average potential field in which we can consider all of the electrons to move, thus leading to a great simplification of the Hartree-Fock method, and bringing it into agreement with the usual band picture of solids, in which all electrons are assumed to move in the same field. We can further replace the average exchange charge by the corresponding value which we should have in a free-electron gas whose local density of actual charge is at the position in question; this results in a very simple expression for the average potential field, which still behaves qualitatively like that of the Hartree-Fock method. This simplified field is being applied to problems in atomic structure, with satisfactory results, and is adapted as well to problems of molecules and solid. (Contractor's abstract)

Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100]
U14660; ATI-92487 Unclassified

A semiclassical approach is used to develop a simple expression for the centrifugal distortion correction in asymmetric top molecules. The general expression for the shift of any given energy level involves 5 experimentally determined distortion coefficients and a knowledge of the dependence of the term value as a function of asymmetry. A useful simplified expression for the frequency correction in $\Delta J = 0$ transitions involves only 2 effective rigid rotor parameters and 4 distortion coefficients. The method is applied to the microwave spectrum of $H_2C^{12}O$; the results show excellent internal consistency. The resulting rigid rotor parameters are: a = 282,106 mc/sec, b = 38,834 mc/sec, and c = 34,004 mc/sec. The electric dipole moment is determined to be 2.31 ± 0.04 debye and the line breadth parameter as 97 ± 10 microns Hg per mc/sec. (Contractor's abstract)

CENTRIFUGAL DISTORTION IN ASYMMETRIC MOLECULES. II. HDS, by R. E. Hillger and M. W. P. Strandberg. Oct. 5, 1950, 15p. incl. diagr. tables. (Technical rept. no. 180) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100)
U61362; ATI-123918 Unclassified

Also published in Phys. Rev., v. 83: 575-581, Aug. 1, 1951.

A perturbation method for relating the theory of centrifugal distortion in asymmetric top molecules to observed microwave Q branch, a- or c-type transitions, is presented. The formula for the distortion correction is expressed in terms of the total angular momentum, J, the symmetry axis momentum of the nearest symmetric top, K, and five distortion constants. The formula yields a satisfactory fit to the observed spectrum of HDS ($K \simeq -0.5$). The electric dipole moment is determined as 1.02 ± 0.02 debye. The inertia defect and distortion constants are calculated. The effective structure for the HDS molecule so determined is in agreement with infrared determinations. (Contractor's abstract)

AREA DISPLAYS OF THE ELECTRICAL ACTIVITY OF THE HEART, by S. Goldman, W. F. Santelmann, Jr. and others. Nov. 15, 1950, 11p. incl. illus. diagrs. (Technical rept. no. 121) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U15144 Unclassified

The method of electronic mapping or area display was used to obtain information about the movement of electrical potentials in the heart as projected on the surface of the chest. Sixteen electrodes connected to a CRT were placed in an ordered array on the chest, with a small square marked on the screen of the tube corresponding to each electrode. The light intensity of each square was made proportional to the instantaneous voltage of its electrode by electronic means. The subject was placed on a cot inside a wire-mesh grounded cage and had an added ground attached to his arm. Moving pictures were made of the area display on the CRT and were subsequently shown in slow motion. These pictures indicated the location and sequences or paths of activity of the P, QRS, and T waves in normal and abnormal heart functions.

THE MICROWAVE SPECTRA OF THE DEUTERO-AMMONIAS, by M. T. Weiss and M. W. P. Strandberg. Dec. 18, 1950, 16p. incl. tables. (Technical rept. no. 183) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-100 and W36-039-sc-32037]) ATI-118355 Unclassified

Also published in Phys. Rev., v. 81: 286, Jan. 15, 1951 (Letter-to-the-editor).

Also published in Phys. Rev., v. 83: 567-575, Aug. 1, 1951.

Measurements of the inversion-rotation spectra of the deutero-ammonias have been made in the 4000 mc/sec

region. Fifty lines of NH_2D and NHD_2 have been measured and identified by means of the Stark effect. As expected, the results show that for these molecules, only simultaneous rotational and inversion transitions could be observed. Thus, corresponding to each $J_\tau - J_\tau$, transition two absorption lines could be observed, separated by either twice the rotational energy separation or twice the inversion splitting of the levels involved. From the observations the inversion splittings of the partially deuterated molecules could be calculated and were found to be in good agreement with the Dennison and Uhlenbeck inversion doubling theory. Thus, the inversion splittings for the ammonia molecules are approximately as follows: 24,000 mc/sec for NH_3; 12,000 mc/sec for NH_2D; 5,000 mc/sec for NHD_2; 2000 mc/sec for ND_3. The results are also in agreement with the structural parameters of ammonia as given by Herzberg. The sign of the nuclear quadrupole coupling constant was also measured and found to be negative, as expected. The centrifugal distortion for both rotation and inversion states has been experimentally determined. (Contractor's abstract)

ROTATIONAL MAGNETIC MOMENTS OF $^1\Sigma$ MOLECULES, by J. R. Eshbach and M. W. P. Strandberg. Jan. 9, 1951, 20p. incl. diagr. tables, refs. (Technical rept. no. 184) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U19568; ATI-118356 Unclassified

Also published in Phys. Rev., v. 85: 24-34, Jan. 1, 1952.

The molecules considered have zero total orbital and zero total spin angular moments. The magnetic moment due to the free rotation of a $^1\Sigma$ polyatomic molecule is calculated, using the equation for the magnetic moment of a system of particles

$$\vec{m} = \frac{1}{2c} \sum_i e_i(\vec{r}_i \times \vec{v}_i)$$

where c is the particular axis of inertia fixed in the molecule and e_i is the charge, $\vec{r}_i$ the position vector, and $\vec{v}_i$ the velocity vector of the i^{th} particle. The $\vec{v}_i$'s are derived from the rotational problem. The theory of the rotational magnetic moment in $^1\Sigma$ molecules is applied to describe experiments on the Zeeman effect for a linear rotor, OCS, and a symmetric top, NH_3. (TIP abstract)

THE APPROXIMATION WITH RATIONAL FUNCTIONS OF PRESCRIBED MAGNITUDE AND PHASE CHARACTERISTICS, by J. G. Linvill. Jan. 19, 1951, [11]p. incl. diagrs. (In cooperation with Bell Telephone Labs., Inc.) [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100 and W36-039-sc-32037] U23852 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 40: 711-721, June 1952.

A successive-approximations method is applied to the selection of network functions having desired magnitude and phase variation with frequency. The first approximation, the first set of pole and zero locations, can be selected on the basis of known solutions to similar problems or through use of a set of curves. In succeeding approximations the pole and zero locations are adjusted to decrease the deviation of the earlier approximations from the desired characteristics. The process adjusts the magnitude and phase characteristics simultaneously. Its flexibility permits accommodation of practical constraints not possible with other methods. (Contractor's abstract)

EXPERIMENTAL STUDY OF NONLINEAR DEVICES BY CORRELATION METHODS, by L. Weinberg and L. G. Kraft. Jan. 20, 1951, 29p. incl. illus. diagrs. refs. (Technical rept. no. 178) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U20643; ATI-128339 Unclassified

The autocorrelation method was applied in determining the power density spectra for the output of 2 nonlinear devices, the linear 9005 tube and the square-law 1N48 crystal diode. The characteristic-function method is discussed for obtaining the output autocorrelation function of nonlinear circuits. In the experimental setup, a 6D4 gas triode was employed as the primary white noise generator. Monitoring of the rectifier input and the rectifier bias voltages was accomplished by use of thermocouple and dc meters, respectively. The resonant frequency of the band-pass filter was 23 kc. The sine-wave generator was also set to this frequency. Autocorrelation curves of the rectifier input, with and without the sine wave present, were obtained for Q values (60, 25, 8.8) of the resonant circuit. Autocorrelation curves of the rectifier output were also obtained. The results for the autocorrelation functions were compared with the theoretically calculated curves. (TIP abstract)

SUBCARRIER MODULATION OF A REFLEX

MIT. 10:037 - MIT. 10:040

KLYSTRON, by J. Jensen. Jan. 26, 1951, 15p. incl. diagrs. refs. (Technical rept. no. 187) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U18786; ATI-113039 Unclassified

A method of modulating a reflex klystron is reported whereby the message to be transmitted is modulated on a subcarrier, which in turn modulates the klystron through its repeller. Of the resulting frequency spectrum only a narrow band, which contains the message, is transmitted. The message was found to be contained in a frequency band centered locally about the first microwave side bands, and in certain cases also about the microwave carrier. A theoretical analysis seems to indicate that the distortion introduced by transmitting only one of these local frequency bands can be made as small as desired under proper operating conditions, dependent upon the modulation index of the frequency-modulated klystron output. The power output obtainable by this method is considered, since the possibility of modulating microwave frequencies at high-power levels is the main reason for studying this problem. The power output of a Si crystal modulator may be exceeded under certain conditions. Experimental data confirm the analytical results within the limits of accuracy of the equipment.

SIGNAL-TO-NOISE RATIO IN CORRELATION DETECTORS, by R. M. Fano. Feb. 19, 1951, 13p. incl. refs. (Technical rept. no. 186) (Sponsored jointly by Signal Corps; Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U17068; ATI-103043 Unclassified

A discussion is presented of the operation in the presence of noise of a correlation detector consisting of a multiplier followed by a low-pass filter. It is shown that in the most favorable cases the output S/N power ratio is proportional to the corresponding input ratio and to the ratio of the signal bandwidth to the bandwidth of the low-pass filter. EXTENSION OF THE MICROWAVE SPECTRUM OF ND_2H, by K. A. Sawyer and J. D. Kierstead. Feb. 19, 1951, 5p. incl. tables. (Technical rept. no. 188) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U18585; ATI-113038 Unclassified

Extension of the investigation of the deutero-ammonias down to the 4,000 mc/sec region produced many inversion-rotation spectrum lines of ND_2H. Selection rules, molecular constants, and equations employed by Weiss (The Microwave Rotation-Inversion Spectra of the Deutero-Ammonias, Doctoral Thesis, Physics, M.I.T. 1950) were found to be reliable with the exception of the need for a slight modification of the constants developed for the Sheng, Barker, and Dennison (Phys. Rev., v. 60: 786, 1941) type inversion equation. Frequencies in this region may serve other purposes than that of investigating the ND_2H molecule. The lines are of sufficient intensity to provide a good frequency check in this region. Inasmuch as a mixture of the ammonias is easily prepared and the combined spectrum covers the whole microwave region, the deutero-ammonias are exceptionally useful for this purpose. With the use of this energy region for commercial microwave relay systems these frequencies may have value for stabilization purposes. Frequencies in this region are being considered by NBS for use in an atomic clock, a clock controlled by constant absorption frequencies. (Contractor's abstract)

A SHORT-TIME CORRELATOR FOR SPEECH WAVES, by P. E. A. Cowley, R. M. Fano, and B. L. Basore. Feb. 26, 1951, 21p. incl. illus. diagrs. (Technical rept. no. 174) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U65644; ATI-162764 Unclassified

A short-time correlator for speech waves is described. This equipment is designed to analyze speech of a quality suitable for toll-telephone circuits. The analysis carried out is a thirteen-point approximation to the short-time autocorrection function which is presented as a display on a cathode-ray tube. The design is discussed in some detail and circuit diagrams of the equipment are presented. The equipment is considered suitable for any application where autocorrection or cross correlation functions of audio waveforms are desired to a moderate accuracy. Some experimental results are also included in this report of short-time correlation patterns of speech sounds, sinusoids, noise, and combinations of these waveforms.

INTERFERENCE FILTERING, by J. P. Costas. Mar. 1, 1951, 45p. incl. diagrs. tables, refs. (Technical rept. no. 185) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U20628; ATI-128340 Unclassified

The problem of filtering a number of channels of information for the best recovery of one particular channel message is considered. Each channel is assumed to carry a message and a disturbance function, and correlation is assumed to exist between all possible pairs of message and disturbance functions. Exact solutions are obtained for filtering with long delay, and expressions for the irremovable filtering error are derived. The synthesis of optimum linear filters by approximation methods is considered. A method of approximation which tends to minimize the filtering error for a given allowable network complexity is given and detailed examples in the use of the method for the general solution of the multiple time series problem are presented. Multichannel filtering techniques may be applied to the problem of detection of amplitude-modulated signals. Adjacent channel interference situations are examined in detail for both double- and single-side-band signals. Experimental results verify the theoretical conclusions. (Contractor's abstract)

A measurement S/N ratio is defined as the reciprocal of a normalized rms measurement error. This ratio is evaluated for the general continuous correlator and for the general sampling correlator. The limiting behavior of the S/N ratio is studied for several specific cases. The continuous correlator cases considered are those where the averaging filter is: (a) a perfect integrator, and (b) an RC low-pass filter. The sampling correlator special case considered is that where the sampling is done periodically. (Contractor's abstract)

THE MICROWAVE SPECTRUM OF KETENE, by H. R. Johnson and M. W. P. Strandberg. Mar. 15, 1951, 20p. incl. illus. diagrs. refs. (Technical rept. no. 192) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U20019; ATI-123911
Unclassified

Also published in Jour. Chem. Phys., v. 20: 687-695, Apr. 1952.

The microwave absorption spectra of the $H_2^1C_2^{12}O^{16}$, $H^1D^2C_2^{12}O^{16}$, and $D_2^2C_2^{12}O^{16}$ ketene molecules were studied. The lines were identified by the Stark effect, intensity, and frequency. The reciprocal moments of inertia were calculated for each, and the centrifugal-distortion theory of Hillger and Strandberg (Technical rept. no. 177; item no. MIT. 10:028) was verified for both Q ($\Delta K_{-1} = 0$, $\Delta J = 0$) and R ($\Delta K_{-1} = 0$, $\Delta J = +1$) branches. The equilibrium structure was calculated from the moments of inertia extrapolated to zero centrifugal distortion. Comparison with data from other methods indicated an increased accuracy for the structure as well as the dipole moments which are determined from the Stark effect. Intensities of satellites of the lightest molecule corresponding to the lowest 3 vibrational fundamentals were also measured, and changes in the average reciprocal moments determined. Calculated vibrational frequencies differed from values reported by infrared workers. Further measurement of the D_2C_2O spectrum was recommended for a more complete check on the centrifugal-distortion theory applied to a molecule with both Q and R branch transitions. Actual calculation of the coefficients from the vibrational fundamentals seemed possible for ketene because of its symmetry.

AN ELECTRONIC CORRELATOR, by T. P. Cheatman, Jr. Mar. 28, 1951, 87p. incl. illus. diagrs. refs. (Technical rept. no. 122) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U18523; ATI-112708
Unclassified

The role and application of correlation functions in the statistical theory of communication is described in terms of the important basic properties of autocorrelation and crosscorrelation functions. An electronic correlator constructed on the basis of (a) utilizing pulse-sampling techniques and (b) multiplication in time-amplitude coordinates is described in detail. General criticisms and suggestions for improvements, based on experience gained from the application of the correlator to several problems, are given. Some additional methods of computing correlation functions are outlined and discussed. The experimental application of the electronic correlator is illustrated by several studies that are concerned with the detection, analysis, or filtering of a desired signal in noise. SIMPLIFIED FM TRANSIENT RESPONSE, by W. L. Hatton. Apr. 23, 1951, 7p. incl. diagrs. (Technical rept. no. 196) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U20023; ATI-123916 Unclassified

The response of a single tuned circuit to a driving current having a sudden jump in frequency is calculated. It is found that the rise time and overshoot depend upon the size of the frequency jump and the position of the initial and final frequencies with respect to the center frequency of the tuned circuit. The slowest rise occurs when the jump is very small and near the center frequency. The rise time is then the same as in the case of double-side-band AM. Larger jumps and decentering of the driving frequencies result in shorter rise times and possibly larger overshoots. FM compares favorably with double-side-band AM.

IBM punched-card machines were employed in an analysis of the congestion at a single landing strip when aircraft are scheduled to arrive in sequence but fail to meet such schedules according to certain simple deviation statistics assumed to have a finite spread. Numerical results for the distribution of the resulting stack and total delays are presented. The former are compared with those which arise from the more random Poisson arrival distribution. The amounts of congestion and stack delay are considerably smaller under the new conditions, particularly when the traffic is heavy. A significant range of the parameters was covered by the numerical analysis. A quantitative relation is established between the time-keeping errors of the aircraft en route to an airport and the resulting terminal congestion and delay. The results may be applied to problems of en route control. (TIP abstract)

Also published in Phys. Rev., v. 84: 944-949, Dec. 1, 1955.

The spectrograph used by O'Bryan and Skinner (Phys. Rev., v. 45: 370, 1934) to study the emission bands of metals was modified by replacing the photographic plates with a photomultiplier detector. Samples were prepared by evaporating a pure coat of the metal onto the targets in a high-temperature furnace; the targets were bombarded with electrons of 300 to 500 ev energy at currents of 2 to 6 ma. Transitions of the valence electrons into the ionized 3p state of the atom produced the radiation. A spectrum curve was recorded in 5 min at bombarding power approximately 0.01 as great as that required with the photographic plates. The emission bandwidths for K and Ca, respectively, were 1.9 and 3.0 ev compared with 3.6 and 5.0 ev predicted from theoretical calculations. Sample purity was the limiting factor in emission-band accuracy; emission edges were as sharp as those observed for Al. Reliability of the emission curves was mainly determined by the depth of penetration of the bombarding electrons. A bombarding potential of 300 v or higher was required for K and Ca. Chemical activity did not appear to be a decisive factor in determining resistance to oxide contamination. Results indicated that the present theories give an inadequate picture of the electronic structure of metals of the third period. A bibliography is included relating to the electronic structure of solids, high-vacuum spectroscopy, and experimental techniques.

COMMUNICATION AND LEARNING IN TASK ORIENTED GROUPS, by L. S. Christie, R. D. Luce, and J. Macy, Jr. May 13, 1952, 251p. incl. illus. diagrs. tables, refs. (Technical rept. no. 231) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) AD 16785
Unclassified

This study presents an account of the principal theoretical and experimental developments of the

"Group Networks Lab." at M. I. T. during the period of Aug. 1949 to Apr. 1952. The following are presented: Chap. 1. Task-oriented groups are discussed generally and definitions are introduced to isolate variables which were experimentally manipulated. Chap. 2. A general description of the experimental techniques is given. Chap. 3. The statistical behavior of individual message destination choice is coupled with communication network properties to account for the observed statistics of group performance. Emphasis is placed upon the learning which occurs during trials. Chap. 4. Individual decision latency is shown to be approximately exponential. A simple theory relates group latency to individual, and these results are used to explicate other experiments for which less complete data are available. Chap. 5. Attention is turned to noise in the coding-decoding of messages. Group errors are simply explicable in terms of a measure of noise. A mechanism, redundancy, is demonstrated to account for a decrease in noise. In turn, redundancy is related, imperfectly, to several network properties. Chap. 6. Questionnaire attitudinal data are presented and for some questions a high correlation with network properties is demonstrated. A factor analysis yields four orthogonal factors for the questionnaire used. Appendix 1. Detailed descriptions of specific experiments are presented. Appendix 2. An electrical device which controls and records a class of communication experiments is described. Appendix 3. A human group interpretation of the classical electrical network equations is shown to have very limited applicability. Appendix 4. Some mathematical results on network topology and their experimental implications are recounted. (Contractor's abstract)

EXPERIMENTAL STUDY OF OPTIMUM FILTERS, by C. A. Stutt. May 15, 1951, 127p. incl. illus. diagrs. (Technical rept. no. 182) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U17505 Unclassified

A study was made of the use of mean-square-error (mse) criterion in network and communication-theory problems. It concerned the development of a time-domain technique for use in Wiener's theory for the linear system, and the compilation of experimental data on the performance of optimum-mean-square (oms) filters on certain idealized problems. One part of the design technique is a specification of the impulse response of oms filters, and is pointed towards interpreting this response directly in terms of experimental correlation data. The method hinges on a time-domain solution of the Wiener-Hopf integral equation. A second part is devoted to a laboratory scheme of synthesis for this response. A flexible network, based on the convolution integral, is described. The device incorporates a delay line having multiple taps with provision for linearly combining the voltage of each tap into a common output. The transient voltage evoked in this circuit can be shaped by independent adjustment of the taps. The delay-line network is shown to be useful in the evaluation of Fourier transforms and convolution integrals and as an information storage device. Problems, especially adapted to the mse theory, and equipment for their study in the laboratory are described, and experimental results on the performance of oms filters and a Butterworth-type filter are presented. These results include values of the mse, noise-to-signal ratio, and pictures of pertinent wave forms. These experiments indicate that the mse network specifications may be used advantageously as standards in conventional designs, that oms designs are relatively noncritical, and that the theory needs strengthening by the inclusion of some interpretation of what is objectionable in an error function.

ELECTROMAGNETIC WAVE PROPAGATION ON HELICAL CONDUCTORS, by S. Sensiper. May 16, 1951, 119p. incl. diagrs. refs. (Technical rept. no. 194) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U69327
ATI-194313 Unclassified

The results of a theoretical investigation of the properties of the natural waves or "free modes" which propagate along infinite helical conductors are reported. The sheath model which replaces the helix by an anisotropic cylindrical sheet is considered. The higher modes are investigated, and it is found that several waves per mode can exist. The significance of these waves in terms of inward and outward traveling waves from a source is shown. The manner in which the characteristics of these waves change as the parameters of the system are altered is discussed. A more physically realistic model of the helix than the sheath model is analyzed. The exact formulation shows the existence of bands where free mode waves are not permitted. The cases of a single wire helix wound with a very narrow tape and a very wide tape for which reasonably valid approximations can be made are analyzed, and the solutions are obtained. The usual low frequency behavior predicted by the sheath model and the anomalous behavior of the propagation constant in the region where the circumference of the helix is approximately equal to a wavelength result from these solutions. The problem of multiwire helices is considered, and the manner in which the sheath helix model is obtained as the number of wires becomes infinite is shown. The integral formulation of the small wire helix problem yields results essentially identical to those obtained by means of the methods and approximations indicated above. This formulation allows a solution for the infinite driven helix to be obtained, and although this is not completely evaluated, the free mode portion is extracted. (Contractor's abstract)

PRE-EMPHASIZING VIDEO SIGNALS, by W. L. Hatton. May 23, 1951, 16p. incl. illus. diagrs. (Technical rept. no. 202) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U20020; ATI-123909 Unclassified

In considering the feasibility of using FM for TV picture transmission, an effort was made to adapt pre- and de-emphasis networks for obtaining all the noise-reduction benefits of FM. The application of pre-emphasis similar to that for audio waves to the video produced overshoot of the order of 300% for a single rapid white-to-black transition. Analysis of the overshoot caused by an input of the Kallman stretch function (Proc. Inst. Radio Engineers, v. 33: 169, Mar. 1945) by graphical convolution indicated that the principal problem exists at the rapid white-black or black-white transitions. A system of clipping after pre-emphasis was proposed, and comparisons were made of a facsimile-system transmission with and without clipping. The clipping produced some degradation of quality in large transitions, but the overall picture was fairly acceptable. A second method was proposed which spread out the overshoot by phase distortion. An approximate method was used to investigate the effect of this method. In a preliminary test, poor results were obtained which were attributed to improper network approximation.

DETERMINATION OF AXIAL FIELD STRENGTH IN A LINEAR ACCELERATOR CAVITY, by L. C. Maier, Jr. and J. C. Slater. May 31, 1951, 5p. incl. diagrs. (Technical rept. no. 205) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U19802; ATI-123914 Unclassified

Two experimental methods are described for finding the accelerating field E in the MIT linear accelerator. These methods were used to check a numerical factor a in Slater's formula for E in terms of input power per unit length, unloaded Q of the accelerator cavity, and wave length (Rev. Mod. Phys., v. 20: 473, 1948). One method is based on measuring the power leaking out of a hole in the cavity wall at the point where the field is to be determined. This method yielded a value of 0.51 for a compared with the theoretical value 0.48. The other method based on the perturbation of the resonant frequency of the cavity by a small conducting sphere located on the axis gave a value of 0.474. (TIP abstract)

ELECTROMAGNETIC RESONANT BEHAVIOR OF A CONFOCAL SPHEROIDAL CAVITY SYSTEM IN THE MICROWAVE REGION, by J. C. Simons and J. C. Slater. May 31, 1951, 3p. (Technical rept. no. 206) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100 and W36-039-sc-32037) U19803; ATI-123913 Unclassified

The resonance of a small spheroid in a larger confocal spheroidal cavity is investigated. The resonant frequencies and the ratio of contributions to the Q of the inner and outer conductors are computed for different values of the parameters. This problem is used to approximate the case of a thin needle-like antenna in a large cavity. The needle if thin enough shows a greatly enhanced magnetic field on its surface when the cavity is tuned to the resonant frequency defined by the needle. At resonance most of the cavity loss is located at the surface of the needle and depends on the needle material. This property may be used as a means of measuring the surface impedance of the needle material.

INTERACTION OF MODES IN MAGNETRON

OSCILLATORS, by R. R. Moats. June 25, 1951, 54p. incl. diagrs. tables, refs. (Technical rept. no. 171) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U21245; ATI-134862
Unclassified

The magnetron is discussed in terms of its properties as a feed-back oscillator in order to show that nonlinear circuit theory may be applied in analyzing mode interactions. The problems under study concern mode selection or the establishing of oscillation in the desired mode stability in either pulse or CW magnetrons. The interaction of modes in a nonlinear feed-back oscillator with 2 resonances was examined. The development established that large-amplitude oscillation in one mode tends to suppress oscillation in other modes. This supports the mode-competition theory advanced by Rieke (Microwave Magnetrons, M. I. T. Rad. Lab. Series 6, McGraw-Hill, 1948). These theoretical observations were supported directly by measurement of the loading effect of an oscillating mode in a magnetron upon small-amplitude externally supplied oscillations in another mode; they were also supported indirectly by observation of the performance of several different types of magnetrons.

A HIGH VACUUM RECORDING SPECTROGRAPH FOR THE STUDY OF RADIATION FROM SOLIDS IN THE 100-800 A RANGE, by E. R. Piore, G. G. Harvey and others. June 29, 1951 [5]p. incl. illus. diagrs. tables. (Sponsored jointly by Signal Corps, Office of Naval Research and [Air Force Office of Scientific Research] under [DA 36-039-sc-190 and W36-039-sc-32037]) U23078; ATI-149627 Unclassified

Also published in Rev. Scient. Instruments, v. 23: 8-12, Jan. 1952.

The two-meter grazing-incidence vacuum spectrograph used by O'Bryan and Skinner for the study of the emission bands of solids has been rebuilt to operate with improved sensitivity and speed. The major modification is the replacement of the photographic plate by a Be - Cu photomultiplier which is designed to traverse the Rowland circle, giving a continuous record of the photon-counting rate as a function of wavelength. With the photomultiplier it is possible to take as many separate curves as desired, subject to x-ray target condition, without opening the spectrograph, which is normally evacuated to better than 10^{-5} mm Hg. In addition, the sensitivity is increased about a thousand-fold, i.e., with a photographic plate, the target current and voltage needed are 10-100 ma and about 3000 v for a one- to three-hour exposure. Using the photomultiplier, however, these values may be reduced to 2-3 ma and 300-500 v respectively, and the complete emission band may be recorded in five minutes. The results for aluminum are in excellent agreement with the results of previous authors. (Contractor's abstract)

PROPAGATION OF DISTURBANCES IN ACCELERATED ELECTRON STREAMS. I. ONE-DIMENSIONAL ACCELERATED STREAMS, by L. D. Smullin. July 12, 1951, 6p. (Technical rept. no. 207) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U20024; ATI-123910 Unclassified

Also published in Jour. Appl. Phys., v. 22: 1496-1498, Dec. 1951.

The propagation of small sinusoidal modulations in the infinite, parallel-plane diode was studied. A second-order differential equation was obtained for the alternating convection current. Solutions were found in closed form for the cases of a drift-stream, space-charge-limited acceleration, and acceleration with an arbitrary current density less than the space-charge-limited value. MICROWAVE DETERMINATION OF THE PROBABILITY OF COLLISION FOR SLOW ELECTRONS IN GASES, by A. V. Phelps, O. T. Fundingsland, and S. C. Brown. July 23, 1951, 9p. incl. diagrs. (Technical rept. no. 211) Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) U20227; ATI-123920
Unclassified

A microwave method is outlined for determining the collision probability for momentum transfer for electrons in thermal equilibrium with a gas. An integral equation is developed which gives the ratio of the resistive and reactive components of the microwave conductivity in terms of the collision frequency for electrons with the gas atoms. Two appropriate solutions are given for the collision frequency as a function of electron energy. An experimental procedure is described in which the conductivity ratio is determined from the shift in the resonant frequency and the change in conductance of a resonant cavity. Measurements are made during the decay of a pulsed discharge after the electrons have cooled to the gas temperature. For electrons having a mean energy of 0.039 ev the following results were obtained for P_c at 1 mm Hg pressure in units of cm^2/cm^3: He, 19; Ne, 3.3; A, 2.1; Kr, 54; Xe, 160; H_2, 46; and N_2, 15.

DETERMINATION OF FIELD STRENGTH IN A LINEAR ACCELERATOR CAVITY, by L. C. Maier, Jr. and J. C. Slater. Aug. 2, 1951 [6]p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-100) ATI-163260
Unclassified

Also published in Jour. Appl. Phys., v. 23: 78-83, Jan. 1952.

One theoretical and two experimental methods are described for finding the accelerating field in the M.I.T. linear accelerator cavity, in terms of the input power. One of the experimental methods is based on measuring the power leaking out through a calibrated hole in an end wall closing the cavity, the hole being located where the field strength is to be determined. The other method is based on the resonant frequency of the cavity by a small conducting sphere located on the axis. All three methods of determination check satisfactorily. In terms of the resulting relations, we discuss the probable field actually existing in the accelerator under operating conditions. (Contractor's abstract)

THE FLOW OF SCHEDULED AIR TRAFFIC (II), by R. B. Adler and S. J. Fricker. Aug. 13, 1951, 50p. incl. diagrs. tables. (Technical rept. no. 199) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100 and Cca-26152) U19805; ATI-123915
Unclassified

IBM punched-card analysis was used in a study of scheduled air traffic problems under the following conditions: (a) a single en-route control point rescheduled the aircraft, and (b) the control point attempted to keep each plane on its original schedule. In both cases, moderate control reduced the frequency of long slack delays for heavy traffic but had little effect on light traffic. In case (a) the total time-keeping error statistics were not greatly altered by the control, since slack delay was traded for added artifical en-route delay. In case (b), however, the en-route-deviation distribution was reduced as well as the slack delay. A less rigid schedule without en-route control was approximately equivalent to en-route-deviation statistics acting upon a rigid schedule. The slacking caused by a sudden terminal shutdown is illustrated in a severely

idealized case. The effect of a delayed feedback which eventually stops the flow of traffic to the terminal was included. Long stack delays, which can not be accounted for in terms of reasonable en-route-deviation distributions, may be caused by the shutdown. The conditions for this latter occurrence were regarded as relatively rare. (See item no. MIT. 10:046 for Part I) (TIP abstract)

SPECTROSCOPY OF THE SOLID STATE: POTASSIUM AND CALCIUM, by R. H. Kingston. Aug. 27, 1951 [6]p. incl. diagrs. tables. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-100]) ATI-149239 Unclassified

Also published in Phys. Rev., v. 84: 944-949, Dec. 1, 1951.

Utilizing the techniques by O'Bryan and Skinner for the study of the emission bands of metals, it has been possible to determine the structure of the conduction bands of the metals, potassium and calcium. The spectrograph used utilizes a photomultiplier in place of a photograph plate, thus enabling higher sensitivity and ease of operation. The particular radiation studied is produced by transitions of the conduction electrons into the ionized 3p state of the atom. The limiting factor in the accuracy of the emission band obtained in this way is the purity of the sample studied. The contamination of the surface of an evaporated sample affects the resultant curve mainly as a result of insufficient penetration of the electrons, since the photon absorption is negligible at depths required to produce radiation representative of the pure bulk metal. The results for potassium and calcium at temperatures between 25°C and 100°C are not in good agreement with previous theoretical calculations. The experimental values of band width are 1.9 and 3.0 ev, respectively, compared with the theoretical calculations of 3.6 and 5.0 ev. (Contractor's abstract)

STATISTICAL ERRORS IN MEASUREMENTS ON RANDOM TIME FUNCTIONS, by W. B. Davenport, Jr., R. A. Johnson, and D. Middleton. Aug. 29, 1951 [12]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-100]) U23524 Unclassified

Published in Jour. Appl. Phys., v. 23: 377-388, Apr. 1952.

The statistical errors in time-average measurements of various properties of (stationary) random time functions are analyzed for their dependence on the averaging interval, the method of averaging, and the statistics of the particular time function under observation. The specific averaging processes considered here are: (1) the continuous time average

$$\left(\frac{1}{T}\int_0^T Z(t)dt\right);$$

(2) the summation (by discrete sampling techniques)

$$\left(\frac{1}{N}\sum_{n=1}^{N}(nT_o)\right);$$ and (3) the smoothing

accomplished by various low-pass filters (for example, a dc meter). Here Z(t) may represent the output of a linear or non-linear device. As a particular example, the measurement of the power in a random noise voltage of bandwidth ω_F is analyzed in detail. The expected root-mean-square error approaches asymptotically the value $(K/\omega_F T)^{1/2}$, where K is some numerical constant, depending on the device in question. For (1) and (2) T is the total observation time, while for (3) it is proportional to a relevant time constant of the low-pass filter. A short discussion of the relative merits of correlators and spectrum analyzers is included, together with a brief treatment of the distribution function of the error in the measurement.

NEW SYNTHESIS PROCEDURES FOR REALIZING TRANSFER FUNCTIONS OF RLC AND RC NETWORKS, by L. Weinberg. Sept. 15, 1951, 105p. incl. illus. refs. (Technical rept. no. 201) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 2227 Unclassified

Also published in part in Jour. Appl. Phys., v. 24: 776-779, June 1953.

Synthesis procedures that realize practical RLC and RC networks are presented. The RLC networks are practical in that they contain no mutual inductance and no perfect coils (every inductance has an associated series resistance). New techniques employed in the procedures are discussed in detail and applied to various synthesis problems. Included among the procedures for synthesizing RLC networks are those for realizing unbalanced structures and lattices whose arms possess identical poles. Reduction of the lattices to unbalanced forms is considered; if real transformers are allowed (transformers with winding resistance, magnetizing inductance, and a coupling coefficient smaller than one), then the lattice realization for a transfer admittance is always reducible. Unbalanced networks are realized by the RC synthesis procedure. The number of elements required is smaller than that required by the Guillemin method (A Summary of

MIT. 10:067 - MIT. 10:070

Modern Methods of Network Synthesis; Advances in Electronics, vol. III, Academic Press, New York, 1951) of RC synthesis. Two new synthesis procedures ars presented for realizing a Darlington network (Jour. Math. Phys., v. 18: 257-353, 1939) without any ideal or unity-coupled transformers, whsre a Darlington network is considered to be composed of lossless elements plus only one resistanc. In one of the procedures, the single resistance appears not as a termination but within ths network.

AN FM-AM MULTIPLIER OF HIGH ACCURACY AND WIDE RANGE, by R. Price. Oct. 4, 1951, 15p. incl. diagrs. refs. (Technical rept. no. 213) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) U20226; ATI-123921 Unclassified

This multiplier employs combined frequency and amplitude modulation to obtain nearly faithful multiplication with minimum space requirements. With a fixed dc signal on either input, linearity of the output with the other input is within 1 or 2%. The range in output product is 2500:1, the output for maximum input signals of 1.4 v in the FM channel and 3.6 v in the AM channel being 0.07 v. Frequency response is excellent from dc up to 5 kc in either channel. At 10 kc there is about 7° phase shift in the AM channel, with the same performance in the FM channel if the AFC phase-correcting unit is used. Total chassis space is about 1.5 sq ft.

RESPONSE OF NONLINEAR DEVICES TO A PULSED SIGNAL AND GATED NOISE, by D. B. Armstrong. Oct. 5, 1951, 15p. incl. diagrs. (Tschnical rept. no. 214) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) U20879; ATI-13087 Unclassified

The analysis of the performance of nonlinear devices in the presence of signals and noise is extended to the case in which the excitation consists of a pulsed signal and gated noise. The idealized assumption is made that the pulses are rectangular. The general method of analysis (Quart. Appl. Math., v. 5: 445, 1947) involved determining the autocorrelation function of the response of the nonlinear device in terms of the parameters specifying the applied excitation voltage. The magnitude of each line component of the output signal spectrum and the mean power spectrum of the output noise are derived from the output autocorrelation obtained. The general results are applied to a balanced diode phase-detector circuit.

PROPERTIES AND TABLES OF THE EXTENDED AIRY-HARDY INTEGRALS, by M. V. Cerrillo and W. H. Kautz. Nov. 15, 1951, 61p. incl. diagrs. tables. (Technical rept. no. 144) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-[100]) AD 126183 Unclassified

There are three basic Airy-Hardy functions. They are denoted by: $Ah_{1,3}$, $Ah_{2,3}$, $Ah_{3,3}$. The first index refers to the particular function; the second index expresses the order of the saddlepoint associated with the function. Definitions, series representations, and properties are given in this report. The connections of these functions with the methods of integration are supplied in Appendices I and II. The functions $Ah_{\nu,3}$, $\nu = 1, 2, 3$, correspond to the so-called pure transitions. The function $Ah_{1,3}(s)$ has been tabulated for complex values of the argument **s**. This function represents a surface over the s-plane. Radial cross sections have been computed for angular arguments in steps from 0° to 180° and for $|s|$ in the range from zero to 4. Twenty-seven tables give $|Ah_{1,3}(s)|$, $\arg\{Ah_{1,3}(s)\}$, $\mathrm{Re}\{Ah_{1,3}(s)\}$, and $\mathrm{Im}\{Ah_{1,3}(s)\}$. Plots of this function are provided in the graph of the cross sections of each of the functions above. Several isometric plots of the corresponding surface are also given. The aim of the computations given in this report is to show an over-all behavior of the functions indicated above, rather than to produce a detailed evaluation of those functions. Only the function $Ah_{1,3}$ was tabulated. There are simple connecting relations between this function and $Ah_{2,3}$ and $Ah_{3,3}$ that permit a rapid computation for $Ah_{2,3}$ and $Ah_{3,3}$ from the tables of $Ah_{1,3}$. Mixed transitions of third order require some other functions, $\Phi_{\nu,p}(B)$ and $\Phi_{\nu,o}(B)$, which appear when the saddle-point of third order runs over or in the vicinity of a pole or a zero of the integrand. These functions can be expressed as the integrals or derivatives, respectively, of the $Ah_{1,3}$ functions. A simple numerical integration of differentiation can be performed from $Ah_{1,3}$, and the evaluation of $\Phi_{1,p}(B)$ and $\Phi_{1,o}(B)$ obtained without much effort. SYNTHESIS OF RC TRANSFER FUNCTIONS AS UNBALANCED TWO TERMINAL-PAIR NETWORKS, by B. J. Dasher. Nov. 20, 1951, 48p. incl. diagrs. refs. (Technical rept. no. 215) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) U20880; ATI-130386 Unclassified

A new general method for synthesizing RC transfer functions is based on an extension of Brune's procedure (Jour. Math. Phys., v. 10: 191-236, 1930-31) for the synthesis of driving-point impedances. Canonical sections are used for controlling transmission zeros in much the same way as they are used by Darlington (Jour. Math. Phys., v. 18: 257-353, 1939) in synthesizing lossless 2 terminal-pair networks. The following theorem is proved: given a function $F_1(\lambda)$ of suitable degree, realizable as an RC function or admittance, it is always possible to design an unbalanced 2 terminal-pair network that (a) produces a transmission zero or single pair of conjugate zeros at any given point or points, respectively, not in the right half-plane; and (b) produces the prescribed function $F_1(\lambda)$ when terminated in a second function $F_2(\lambda)$, also RC, the degree of which is less than the degree of $F_1(\lambda)$. The networks obtained take the form of ladder networks cascaded with bridge sections similar to the twin-T null network. The zero sections are obtained one at a time, each by a single application of the theorem, and this process is repeated until the original function is completely developed. When used in combination with existing synthesis techniques, the method provides a highly flexible procedure which allows limited control over impedance levels and insertion loss.

THE MAGNETIC MOMENT OF K^{40} AND THE HYPERFINE STRUCTURE ANOMALY OF THE POTASSIUM ISOTOPES, by J. T. Eisinger, B. Bederson, and B. T. Feld. Dec. 6, 1951. 9 p. incl. diagrs. tables.

MIT. 10:075 - MIT. 10:077

refs. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100 and W36-039-sc-32037] U23053; ATI-158905 Unclassified

Published in Phys. Rev., v. 86: 73-81, Apr. 1, 1952.

The nuclear magnetic moment and atomic hyperfine splitting of the rare K^{40} isotope have been measured by the atomic beam magnetic resonance technique. Detection of K^{40} atoms, from a source of normal potassium, was achieved by employing a conventional surface ionization detector as the ion source for a mass spectrometer, and by utilizing an electron multiplier to count the K^{40} ions. By measuring the frequencies of appropriate lines in the Zeeman pattern, the nuclear moment was redetermined with higher precision than that of previous measurements, to be $\Delta\nu$ = 1285.790 ± 0.007 mc/sec. The ratio of the nuclear g factors of K^{39} and K^{40} was measured directly by observing, in the same homogeneous magnetic field, H, the frequencies of two lines (a doublet) in the Zeeman spectrum of each isotope. The doublet separation of these lines is, in each case, proportional to $2\ g I\mu_0 H$, so that the ratio of the doublet splittings yielded directly $|g(K^{40})/g(K^{39})|$ = 1.24346 ± 0.00024. From these results and from the previously measured $\Delta\nu(K^{39})$, the hyperfine structure anomaly of these K isotopes is $\{[2I(K^{40})+1]g(K^{40})\Delta\nu(K^{39})/[2I(K^{39})+1]g(K^{39})\Delta\nu(K^{40})\}-1$ = (0.466 ± 0.019) percent. The theory of the hyperfine structure anomaly, as developed by A. Bohr and V. F. Weisskopf, has been applied to the interpretation of this result. The predictions of a number of specific models, previously suggested to account for the observed nuclear g factors, have been compared with this experiment and with previous results on the anomalies for the Rb and the abundant K isotopes. The "asymmetric core" model of A. Bohr gives the best over-all agreement, mainly on the basis of the K^{41}-K^{39} anomaly. In general, all models which are, in their essential features, based on the independent-particle model with spin-orbit coupling, give predictions in fair qualitative agreement with the experiments. The contribution of K^{40} to the hfs anomaly seems, however, to be (fortuitously) insensitive to the differences between the models investigated. (Contractor's abstract)

THERMIONIC EMISSION FROM OXIDE-COATED TUNGSTEN FILAMENTS, by C. P. Hadley. Dec. 11, 1951, 25p. incl. diagrs. refs. (Technical rept. no. 218) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 6945; ATI-158301 Unclassified

Also published in Jour. Appl. Phys., v. 24: 49-52, Jan. 1953.

A study of the filaments cataphoretically coated with alkaline earth oxides revealed that emission from the oxide-coated filament was not influenced by the variation of work function with crystallographic direction of the base metal. The apparent deviation of thermionic electrons from Maxwell-Boltzmann statistics was interpreted as due to a potential drop through the coating. This interpretation led to a method for studying the resistive properties of the coating.

A NEW "DOUBLE RESONANCE" METHOD FOR INVESTIGATING ATOMIC ENERGY LEVELS. APPLICATIONS TO Hg^3P_1, by J. Brossel and F. Bitter. Dec. 17, 1951 [9]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA-36-039-sc-100 and W36-039-sc-32037]) U23088; ATI-160286 Unclassified

Also published in Phys. Rev., v. 86: 308-316, May 1, 1952.

Excitations of atoms in a vapor by polarized light produces unequal population of the magnetic sublevels of the excited state. The emitted optical resonance radiation is therefore partly polarized. The application of radiofrequency or microwave fields at a magnetic resonance frequency will induce transitions between sublevels of the excited state. The degree of polarization of the emitted optical resonance radiation is altered when the magnetic resonance condition is fulfilled. As suggested by Brossel and Kastler, this effect may be used to reveal the structure of the energy level. A detailed theory applicable to, and experiments on the $^3P_1$ state of all the isotopes of mercury are reported. The results obtained indicate that double resonance phenomena constitute a valuable new tool for investigating the structure of atomic energy levels. The mean life of the $^3P_1$ state is shown by observations on the resonance line widths to be 1.55×10^{-7} sec for all the isotopes. The g factor of the $^3P_1$ state for isotopes with zero spin, measured in terms of the proton g factor, is 1.4838 ± 0.0004. (Contractor's abstract)

THE NUCLEAR MAGNETIC MOMENT OF S^{33} FROM MICROWAVE SPECTROSCOPY, by J. R. Eshbach, R. E. Hilliger, and M. W. P. Strandberg. Dec. 20, 1951, 18p. incl. diagrs. tables, refs. (Technical rept. no. 224) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) U23505; U24932 Unclassified

Also published in Phys. Rev., v. 85: 532-539, Feb. 15, 1952.

The magnetic dipole moment of the S^{33} nucleus was determined by means of the Zeeman effect on the hyperfine pattern of the $J = 1 \rightarrow 2$ rotational absorption of the molecule $O^{16}C^{12}S^{33}$ at about 24,020 mc/sec. The result is $\mu(S^{33}) = +0.633 \pm 0.010$ nuclear magnetons. The sign of this moment was determined by means of circularly polarized microwave radiation with σ-type Zeeman observations. The frequencies of all of the componenis of the hyperfine pattern were measured. All fit the nuclear electric quadrupole coupling theory to within $\pm$ 0.01 mc/sec. The measured value for eqQ of the S^{33} nucleus in $O^{16}C^{12}S^{33}$ is $eqQ(O^{16}C^{12}S^{33}) = -29.07 \pm 0.01$ mc/sec. (Contractor's absiract)

POSITIVE IONS IN THE AFTERGLOW OF A LOW-PRESSURE HELIUM DISCHARGE, by A. V. Phelps and S. C. Brown. Jan. 3, 1952, 8p. incl. diagr. refs. (Technical rept. no. 220) (Sponsored joinily by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) U22086; U23523; ATI-149713 Unclassified

Also published in Phys. Rev., v. 86: 102-105, Apr. 1, 1952.

The production and loss of He^+ and He_2^+ ions in the afterglow of a low-pressure He discharge were studied by using a mass spectrometer to analyze the positive ions and resonant-frequency shifts in the microwave cavity containing the discharge to determine the electron density. The change of positive-ion and electron densities with time is explained by considering 3 dominant processes in the afterglow: production of He^+ ions and electrons by collisions between metastable-atom pairs, ambipolar diffusion of the ions and electrons, and He^+ to He_2^+ ion conversion by 3-body collisions with neutral atoms. The time constants for the electron-density decay at low pressures yielded 560 sq cm/sec for the ambipolar diffusion coefficient for He^+ ions and a frequency of 65/sec for He^+ to He_2^+ conversion; both were calculated at 1-mm pressure and 300°K. The He^+ mobility coefficient of 14 sq cm/v-sec at 300°K and 760-mm pressure obtained from the measured ambipolar diffusion coefficent agreed satisfactorily with the value of 12 sq cm/v-sec calculated using the quantum mechanical interaction of the He^+ ion and the neutral He atom.

PROBE STUDIES OF ENERGY DISTRIBUTIONS AND RADIAL POTENTIAL VARIATIONS IN A LOW PRESSURE MERCURY ARC, by R. M. Howe. Jan. 18, 1952, 27p. incl. diagrs. tables. (Technical repi. no. 221) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) U22883; ATI-158168
Unclassified

Probe studies were made of the electron-energy distributions in the plasma of the low pressure Hg arc in order to obtain improvemenis over Killian's (Phys. Rev., v. 35: 1238, 1930) original determinations of radial variations of plasma potential and density in a cyclindrical discharge. The electron-energy measuremenis showed depletions from a Maxwellian distribution in the high-energy range. Coupling effects beiween adjaceni probes were investigaied and found to be small but in the proper direction for agreemeni with the Langmuir-Tonks theory. Drift-curreni distortion of the random electron-energy disiributions was measured with a bidirectional probe and compared with theory. A multisection probe exiending from iube axis to iube wall allowed a determination of radial poiential and densiiy variations. Resulis over a pressure range from 3.4 to 3.5 μ showed good agreemeni with the ambipolar diffusion theory based on cumulative ionization. A direci calculation of ionization raie in the plasma was made from the ionizaiion probabiliiy for a 1-step ionizing process: comparison of this calculation with the observed ionizaiion raie ai 1.7 μ indicaied that the ionization is half direci, half cumulative. For higher arc pressures cumulative ionization evidently predominates.

jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100 and W36-039-sc-32037] U23076; ATI-158904 Unclassified

Also published in Phys. Rev., v. 85: 1051, Mar. 15, 1952.

The absorption of polarized resonance radiation by a vapor produces unequal populations of the magnetic sublevels of the excited state, and also of the ground state after re-emission. Kestler has suggested that, as a consequence of these facts, polarized light may be used to orient nuclei. An experimental demonstration of this effect was attempted, and yielded a negative result. Further experimentation is under way in an attempt to isolate the reasons for the negative results reported.

METHODS OF MEASURING THE PROPERTIES OF IONIZED GASES AT HIGH FREQUENCIES. I. MEASUREMENTS OF Q, by S. C. Brown and D. J. Rose. Jan. 22, 1952, 17p. incl. diagrs. (Technical rept. no. 222) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) U22085; ATI-149714 Unclassified

Also published in Jour. Appl. Phys., v. 23: 711-718, July 1952.

Experimental methods for obtaining the Q of both high- and low-Q resonant cavities were investigated in connection with determining the practical measurements necessary in establishing the properties of ionized gases at microwave frequencies. The lumped circuit representation of a cavity was introduced. The system under analysis consisted of a cavity and part of the input line to which the cavity is coupled by loops through vacuum-tight, glass seals. The calculations apply explicitly to the usual case in which the cavity terminates the line. Relationships were derived for determining the impedance, the Q, and the resonant wave length of the cavity system from measurements of the voltage distribution on the line terminated by the cavity. The measurements involve determining the position of the voltage minima and the VSWR in db as functions of λ. Three Q-measuring procedures using the relationships derived are outlined: a resonance-curve method, a phase-curve method, and a technique employing an RF impedance bridge. The effect of introducing a steady-state discharge into the cavity is also considered.

METHODS OF MEASURING THE PROPERTIES OF IONIZED GASES AT HIGH FREQUENCIES. II. MEASUREMENT OF ELECTRIC FIELD, by D. J. Rose and S. C. Brown. Jan. 22, 1952, 8p. incl. diagrs. (Technical rept. no. 223) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) U22070; ATI-151187 Unclassified

Also published in Jour. Appl. Phys., v. 23: 719-722, July 1952.

Three general procedures are outlined whereby the electric field is determined in terms of the incident power on the cavity and the standing-wave pattern on the input line. The procedures designated for high Q_L cavities are the cavity mode method which is applied when the field configuration can be readily computed and the tuning-rate method which is applicable when the cavity has a complicated shape. For cases where the cavity Q is very low, a 4-terminal network method is proposed which is subject to the restriction that the region of the discharge is small compared to λ. A discussion is given on converting incident-power measurements at frequencies other than the cavity resonant frequency to equivalent ones at resonance. (TIP abstract)

THE MAGNETIC MOMENT AND HYPERFINE STRUCTURE ANOMALY OF K^{40}, by J. T. Eisinger and B. Bederson. Jan. 28, 1952, 32p. incl. illus. diagrs. refs. (Technical rept. no. 212) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) U24409; ATI-170042 Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Oct. 24-27, 1951.

Abstract published in Phys. Rev., v. 85: 716, Feb. 15, 1952.

The ratio of the nuclear gyromagnetic ratios of K^{40} and K^{39} was measured by an atomic-beam, magnetic-resonance method using a high-resolution RF spectrometer. The average value for the ratio was -1.24346 ± 0.00024. The nuclear moment of K^{40} was measured independently of this ratio by determining the applied magnetic field and mean frequency of the K^{40} doublet and applying the Breit-Rabi formula. The value obtained was -1.2964 ± 0.0004 mm. The gyromagnetic ratio of K^{40} was then calculated to be 0.32410 ± 0.00010. The hyperfine separation, $\Delta\nu$, of K^{40} was determined from the maximum mean frequency

of the doublet to be 1285.790 ± 0.007 mc. Results are compared with pertinent theoretical formulas and values obtained by other experimenters; they give support to nuclear models based on the independent particle model with spin-orbit coupling.

AN ANALOGUE ELECTRONIC CORRELATOR, by J. F. Reintjes. Feb. 1952, 11p. incl. illus. diagrs. tables. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-100] and W36-039-sc-32037) U23054; ATI-149624 Unclassified

Also published in Proc. National Electronics Conferences, v. 7: 390-400, Feb. 1952.

In recent years widespread attention has been given to the application of statistical methods to the solution of electrical-communications problems. Involved in the statistical approach is a need for a machine capable of evaluating correlation functions of random electrical phenomena. An electronic device for evaluating correlation functions is described. The machine is capable of providing 110 points on the correlation curve of signals having frequency components in the range between 500 c/sec and 100 kc/sec. Operation is based upon the principle of discrete sampling of the input signal, in pairs, at periodic intervals. The delay, multiplication, and integration processes involved in the computation are carried out, for each pair of samples, through use of pulse techniques. The pulses used for multiplication and integration are derived from the signal amplitudes, which are stored as charges on capacitors rather than in binary form. In the design of the machine emphasis has been placed upon simplicity, stability, and portability. Included in the paper is a discussion of principles of operation, details of circuitry, and examples of experimental data taken from the machine.

RESOLUTION AND SENSITIVITY OF MICROWAVE SPECTROGRAPHS (Abstract), by H. R. Johnson. [1952] [1]p. (Sponsored jotntly by Signal Corps, Offtce of Naval Research, and [Air Force Offtce of Scientific Research] under [DA 36-039-sc-100])
Unclassifted

Presented at meeting of the Amer. Phys. Soc., Berkeley, Calif., Dec. 27-29, 1951.

Abstract published in Phys. Rev., v. 85: 764, Feb. 15, 1952.

Obtaining narrow lines tn mtcrowave spectroscopy ts tmportant, since tt determines whether or not fine structure can be resolved and the accuracy with which tt can be measured. Sensitivity determines whether or not weak lines can be observed at all. A Stark modulation spectrograph has been used in the laboratory for over a year; tn K-band it yields line half-widths at half intensity of 50 kc/sec and has a limiting sensitivity of 10^{-8} cm^{-1} with a Stark cell 1-m long and a 5-sec time constant. The factors responsible for this line width will be discussed, and an equation from which the ultimate sensitivity of our Stark spectrographs can be predicted will be presented. This discussion will include the effect of detector crystal noise and Stark modulation frequency. It will be shown that for most purposes a Stark modulation frequency of about 6 kc/sec is optimum, and that the generally accepted expression for optimum cell length is incorrect for our spectrographs. The optimum length is greater by a calculable factor that is typically about 5 or 10. (Contractor's abstract)

AN EXPERIMENTAL STUDY OF SPEECH-WAVE PROBABILITY DISTRIBUTIONS, by W. B. Davenport, Jr., Apr. 8, 1952 [10]p. incl. illus. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-100]) U23863; ATI-171078 Unclassified

Also published in Jour. Acoust. Soc. Amer., v. 24: 390-399, July 1952.

Measurements were made of the first-probability distribution and of various conditional probability distributions of the speech wave instantaneous amplitude. Results obtained for several speakers indicate that the first-probability distribution varies exponentially with large values of amplitude and that increases in the conditional probabilities are noted for delay times of the order of magnitude of the pitch period. Measurements were also made of the first-probability distribution of the duration of the speech-wave zero-crossing periods, and of the auto-correlation function of clipped speech. These measurements were of the stationary, or "long-time," speech-wave probability distributions. Most of the results are for speech waves recorded in an anechoic chamber. Some results are included for voices recorded in a live studio. (Contractor's abstract)

NETWORK SYNTHESIS FOR SPECIFIED TRANSIENT RESPONSE, by W. H. Kautz. Apr. 23, 1952, 177p. incl. illus. tables, refs. (Technical rept. no. 209) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 13984 Unclassified

Three methods of solution are presented for the synthesis of finite, lumped-parameter networks for the case in which the desired behavior is prescribed in terms of transients. In the time-domain solution, the desired response is approximated by means of a finite sum of damped exponentials or sinusoids. The Laplace transform of this sum yields a ratio of polynomials in the frequency. The method combines flexibility and generality with a minimum of computational work. Certain time-frequency-domain relationships are derived which result in an approximate frequency domain solution. For this solution, continued-fraction expansions are utilized. The third method of solution combines both time- and frequency-domain approximations. The given response is first approximated in terms of intermediary functions, called constituent transients; each constituent transient is then transformed and a second approximation is made by frequency-domain expansions. The flexibility of this solution results from the fact that the approximation is carried out in two steps and that the intermediary functions are chosen to be the most convenient type for a given problem. Examples are presented which illustrate the extent of applicability of each method. (ASTIA abstract)

CRYSTALLOGRAPHIC VARIATIONS OF FIELD EMISSION FROM SINGLE TUNGSTEN CRYSTALS, by M. K. Wilkinson. May 7, 1952, 18p. incl. illus. diagrs. tables, refs. (Technical rept. no. 228) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 3315 Unclassified

A photometric method is described for measuring field-emission electron currents quantitatively as a function of the crystal crystallographic directions found in a single crystal emission point. A projection tube was used so that the state of contamination of the cathode would always be known from the pattern which was obtained on the phosphor. The study was made by photometering the light output along the various crystallographic directions. Slopes of the field-emission characteristics for the different crystallographic directions showed relative magnitudes of the work functions. The photometric data indicated that the dark spots on a field-emission pattern of clean tungsten are caused by the difference in the work functions of the crystallographic directions. Moreover, with a reasonable assumption of the electric field distribution around the surface of the point cathode, the data are in agreement with the theoretical equation. To insure the required constancy of the electron emission for measurement, it was necessary to maintain a supervacuum. The vacuum attained was better than 10^{-12} mm.

PROPAGATION OF AN ELECTROMAGNETIC WAVE ALONG A HELIX SURROUNDED BY A RESISTANCE SHEATH, by A. Tonning. May 13, 1952, 11p. incl. illus. (Technical rept. no. 232) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 12907 Unclassified

The problem is considered of wave propagation along a helix when losses are present; the problem arises in connection with the design of broadband traveling-wave tubes. Due to imperfect matching; a part of the wave will be reflected at the output end of the tube. To reduce the amplitude of the reflected wave and avoid oscillations, it is convenient to surround the helix by a sheath of glossy material. The effect of this resistance sheath on the phase velocity of the wave and the resulting attenuation is calculated. Only the case when no electron beam is present is treated. The introduction of losses in this way reduces the phase velocity, and the amount of this reduction approaches zero for very high and very low frequencies. (Contractor's abstract)

SIGNAL-TO-NOISE RATIOS IN BANDPASS LIMITERS, by W. B. Davenport, Jr. May 29, 1952, 18p. incl. diagrs. (Technical rept. no. 234) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) U24044; ATI-165501 Unclassified

Also published in Jour. Appl. Phys., v. 24: 720-727, June 1953.

A general analysis is made of the relations between output signal and noise powers and input signal and noise powers for bandpass limiters having odd symmetry to their limiting characteristics. Specific results are given for the case where the limiter has an n-th root characteristic, and they include the ideal symmetrical limiter (or clipper) as a limiting case. This analysis shows that for the output signal-to-noise power ratio is essentially directly proportional to the input signal-to-noise power ratio for all values of the latter. The result is due to the bypass characteristics rather than to the symmetrical limiting action. (Contractor's abstract)

THE M. I. T. LINEAR ELECTRON ACCELERATOR, by P. T. Demos, A. F. Kip, and J. C. Slater. May 31, 1952, 23p. incl. illus. diagrs. refs. (Technical rept. no. 203) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100; W36-039-sc-32037; and N5ori-07806) U20229; ATI-123992 Unclassified

The M.I. T. linear electron accelerator consists of a circular wave guide fitted with uniformly spaced irises, and sustains a standing-wave, transverse magnetic π-mode oscillation at a resonant frequency of 2800 mc/sec. The phase velocity is equal to that of light. Electrons are injected into the accelerating tube at an energy of 2 mev by a Van de Graaff generator. Acceleration up to an energy of at least 18 mev has been obtained by using the 21-ft length of the accelerator. Peak accelerated currents of the order of 10 ma, and average currents of the order of 1 μa, are obtained. The accelerator is fed by 21 tunable magnetrons (Raytheon RK5586), phased in synchronism. The principles of design, constructional features, and operation are discussed. The accelerator is being used for nuclear experimentation. (Contractor's abstract)

RF PHASE CONTROL IN PULSED MAGNETRONS, by E. E. David, Jr. [1952] 17 p. incl. illus. diagrs. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-100 and W36-039-sc-32137]) U23885 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 40: 669-685, June 1952.

A description is given of the behavior of a magnetron oscillator started in the presence of an externally applied rf exciting signal whose frequency is not greatly different from the unperturbed steady-state frequency of the magnetron. Two points of view are presented: first, quasi-steady-state starting is assumed, and a differential equation representing the system within this limitation is derived. Solutions obtained specify the phase of the oscillator as a function of time subsequent to starting. Second, the inhomogeneous Van der Pol equation is used to describe the system. The oscillator is represented as a parallel RLC circuit shunted by a negative, nonlinear conductance. Approximate analytical and differential analyzer solutions of this equation are used to investigate the frequency and phase transients during starting and distortion of the build-up envelope by the exciting signal. The initial conditions for both equations are established in terms of the exciting signal-to-preoscillation noise ratio. Results of the two analyses are essentially in agreement; details of the solutions are different since reactive beam loading has been neglected in the latter case. The phase transient initiated during starting may have a duration which is long compared to the build-up time of the rf voltage on the magnetron anode. Preoscillation conditions which fix the initial phase play an important part in determining the phase for a considerable time subsequent to starting. Other influencing factors include the oscillator tuning relative to the injected frequency; the value of a coefficient directly related to the injected power and the natural frequency of the oscillator cavity, and inversely to the power output and coupling Q; and design parameters determining the rf rise time. Certain aspects concerning the rational expansion of transfer and positive-real functions are discussed. The results are a partial conclusion extracted from a study of the foundation of network theory, particularly in connection with the problem of network synthesis. A set of integral representations for Laplace transforms is established. These integrals express the necessary and sufficient condition for the existence of transfer functions. Fundamental aspects of the rational expansion of transfer functions are discussed, and 2 methods of construction are presented. The integral representations serve as the mathematical tools for the construction of such rational expansions. The general discussion is systematically supported by an integral representation along a particular contour.

Also published in Phys. Rev., v. 87: 676-677, Aug. 15, 1952.

The atomic beam magnetic resonance method has been applied to the measurement of the hfs interaction in the ground state of the radioactive nuclide Cs^{134}. A 200-millicurie sample of $(Cs^{134})_2 CO_3$ was prepared by neutron irradiation in the Brookhaven pile, yielding a ratio of Cs^{134} to Cs^{133} of 1 to 6000 in the sample. A directional oven of special design was used to produce the atomic beam of cesium, which after being ionized at the hot wire detector was analyzed with a mass spectrometer having an enrichment factor of 2000 per mass number at the mass 134 position.

ON THE ANOMALOUS SPIN GYROMAGNETIC RATIO OF THE ELECTRON (Abstract), by J. G. King and V. Jaccarino. [1952] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-100]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1952.

Published in Phys Rev., v. 87: 228, July 1, 1952.

The anomalous spin gyromagnetic ratio of the electron has been obtained from observations of the Zeeman effect of the hyperfine structure interaction in the $P_{3/2}$ and $P_{1/2}$ states of atomic Cl^{35}, using the interaction constants previously determined by the authors. From 8 independent measurements of the atomic g_j values in fields up to 500 gauss a mean value of $g_s = 2$ (1.00121 ± 0.00010) was computed. This value of g_s for a closed shell minus an electron agrees with both theoretical and experimental values obtained for a closed shell plus an electron. (Contractor's abstract)

PRECISION MEASUREMENTS OF THE hfs OF Rb^{85} AND Rb^{87} (Abstract), by B. Bederson and V. Jaccarino. [1952] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under [DA 36-039-sc-100]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1952.

Published in Phys. Rev., v. 87: 228-229, July 1, 1952.

Using an atomic beam method we have obtained high precision measurements of the Rb^{85} and Rb^{87} hfs interaction energies ($h\Delta\nu$). The first-order field independent transitions ($F = 3$, $m_F = 0 \leftrightarrow F = 2$, $m_F = 0$) and ($F = 2$, $m_F = 0 \leftrightarrow F = 1$, $m_F = 0$) for Rb^{85} and Rb^{87}, respectively, were observed in a magnetic field of approximately 0.4 gauss and when corrected to zero field yield the following values: $\Delta\nu$ (Rb^{85}) = 3035.735 ±

0.002 mc/sec and $\Delta\nu(Rb^{87}$ = 6834.7005 ± 0.0011 mc/sec. The above transitions were positively identified by observing the frequencies and widths of all allowed $|\Delta F = \pm 1$ transitions. Factors influencing the ultimate accuracy of $\Delta\nu$ determinations (Doppler broadening, resonance widths, stability of rf sources, frequency measurement techniques, etc.) will be discussed and a comparison made of the above data with recent high field measurements. The results of more accurate measurements will be given at this time. (Contractor's abstract)

THE RESISTANCE MINIMUM IN MAGNESIUM AT LOW TEMPERATURES (Abstract), by H. E. Rorschach, Jr. and M. A. Herlin. [1952] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-100]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1952.

Published in Phys. Rev., v. 87: 193, July 1, 1952.

The electrical resistivities of three very pure magnesium samples from different sources have been measured from 1 to 40°K by an improved mutual inductance method. All samples exhibit a minimum, although the effect is much more pronounced in one which is believed to contain more impurity than the others. Above 20°K, all of the resistivity curves can be well represented by a power law $\rho = \rho_r + aT^b$ with b equal to approximately 3.5. However, Matthiesen's rule does not hold, since at least two of the curves intersect. (Contractor's abstract)

A PHASE PRINCIPLE FOR COMPLEX-FREQUENCY ANALYSIS AND ITS IMPLICATIONS IN AUDITORY THEORY, by W. H. Huggins. Aug. 12, 1952 [8]p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-100]) AD 12368 Unclassified

Also published in Jour. Acoust. Soc. Amer., v. 24: 582-589, Nov. 1952.

A filtering scheme that utilizes the phase-frequency characteristic of a filter is shown to have certain advantages for analyzing signals, such as speech, which are produced by shock or noise excitation of a physical system having one or more resonances. The phase principle is shown to be particularly well suited to neural mechanisms of inhibition and facilitation, and evidence is presented that such a principle may be used by the ear to achieve its analysis of the sound that it receives. ON BASIC EXISTENCE THEOREMS IN NETWORK SYNTHESIS. IV. TRANSMISSION OF PULSES, by M. V. Cerrillo and E. F. Bolinder. Aug. 15, 1952, 168p. incl. diagrs. tables, refs. (Technical rept. no. 246) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 45533 Unclassified

This report is the fourth in a series of reports on basic existence theorems in network synthesis. The parameter representation of the time and frequency domain functions derived in earlier reports in the series has been used for an investigation of the delicate problem of transmission of narrow pulses through finite passive networks. The report starts by stating and proving the necessary and sufficient condition for a transfer function to be rational. A simple and computationally appropriate relationship between the parameter function $U(0, \lambda)$ and the time function, which eliminates the integration, is then established by means of the so-called corner theorems. Due to discontinuous time derivatives, the Stieltjes integral representation has to be used. The $U(0, \lambda)$ function is then approximated in such a way that the famous phenomenon of "ringing" is completely controlled. A rational transfer function is obtained from the approximated U function by means of an interpolation procedure. Some illustrative examples are given. The important question of minimum number of elements is treated in connection with the correlation of the number of extremal points of the U function and the number of poles of a rotational transfer function. Finally, rational approximations of transfer functions are obtained by means of a powerful nonlinear process of summability which contains the Padé summability as a special case. POWER GAIN IN FEEDBACK AMPLIFIERS, by S. J. Mason. Aug. 25, 1952, 15p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-100]) AD 16449 Unclassified

An analysis is presented of the effect of the terminating impedance upon the power gain and stability of a feedback amplifier. The optimum passive source and load impedances which would give maximum power gain at

MIT. 10:115 - MIT. 10:118

every real frequency were obtained for a 2-terminal pair filter chosen to represent an arbitrary amplifier. However, these values were obtained subject to the specified stability margin $|T/(1-T)| = m \leq M$, where T represents the loop gain of the feed-back diagram and M is the value of the upper bound determined by practical considerations such as design tolerances. The entire analysis is also applicable to the problem in which admittances take the place of impedances. In addition, mechanical, electromechanical, and other classes of linear active systems fall within the scope of the analysis.

A RECEIVER DESIGN FOR REJECTING INTERFERENCE, by R. A. Paananen. Sept. 22, 1952, 85p. incl. illus. diagrs. tables, refs. (Technical rept. no. 245) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 28467 Unclassified

This report concerns the application of a wideband, interference-reducing theory to FM broadcast receiver design. In the first part, the space link between the transmitter and receiver is examined, with discussions of FM coverage and expected interference in a given area. This material allows the determination of some of the receiver parameters, such as selectivity and spurious responses. The second part of the report pertains to the receiver itself. Various selectivity configurations are compared, with special attention to an approximation method useful in filter amplifier design. General material relevant to crystal limiter performance is presented, and a limiter coefficient is defined. The results of a fairly complete testing of this unit are also included, together with an evaluation of the design and operating differences between this and a typical narrow-band receiver. AN INDUCTION METHOD OF MEASURING ELECTRICAL RESISTIVITY, by H. E. Rorschach, Jr. and M. A. Herlin. Oct. 12, 1952, 23p. incl. illus. table. (Technical rept. no. 125) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under DA 36-039-sc-100) AD 20074 Unclassified

A method is described for measuring the electrical resistivity of a cylindrical specimen of metal. The specimen is mounted at the center of a pair of concentric coils whose complex mutual inductance is measured. The field equations for this geometry are solved so that mutual inductance values may be used to yield resistivity values. Calculations are made for the mutual inductance of (1) a finite core in a finite cylinder and (2) an infinite core in an infinite cylinder. The sensitivity of the resistivity-measuring system is also calculated. The method is considered useful for low-temperature measurements because (1) the specimen requires no electrical or other connections, and (2) the sample size and shape are convenient for preparation and for other measurements.

NOISE FIGURE OF TRAVELING-WAVE TUBES, by C. F. Muehe, Jr. Oct. 16, 1952, 38p. incl. illus. diagrs. tables, refs. (Technical rept. no. 240) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 28574 Unclassified

This report describes experiments primarily designed to measure the noise in electron beams and traveling-wave tubes at 3000 mc/sec. Since it was desirable to know the dc conditions in the electron beam, the radial positive ion flow and the beam diameter were measured along the beam. Measurement of the radial positive ion flow shows that the beam was fully neutralized by positive ions over all but a few centimeters of length near

the anode. An analysis was made of the electron trajectories, and from measurements of beam shape the fact of full ion neutralization was confirmed. With full ion neutralization there is considerable spiraling of the electrons and hence a dc velocity spread in a beam from a converging beam gun. For large magnetic fields this velocity spread causes an increase in the minima of the noise-current curve which is confirmed by experiment. Next a double velocity jump was tried, since this is supposed to reduce the noise in the beam. It was found that the maxima of the noise-current curve could be reduced, but the minima were increased, and no success was achieved in reducing the noise figure of a traveling-wave tube with this device. Finally, the noise current in an electron beam and the noise figure of a traveling-wave tube were measured under the same conditions; first with a converging beam electron gun, then with a parallel beam gun. The noise figures predicted from the noise-current curves agreed quite well when a correction was made for the nonzero minima of the noise-currect curves. Finally, it was shown experimentally that a beam from a parallel beam gun is quieter than the same beam from a converging beam gun. (Contractor's abstract)

NOISE ANALYSIS OF A FINITE ELECTRON GUN IN AN INFINITE MAGNETIC FIELD, by H. E. Rowe. Oct. 24, 1952, 45p. incl. diagrs. tables, refs. (Technical rept. no. 239) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-100]) AD 221425 Unclassified

A theoretical study of the noise behavior of a finite electron beam in an infinite magnetic field was made to determine the effects of the finite diameter of the beam and the transverse vartations in the velocity and current density modulation on the noise behavior of an electron beam, using the method presented by Parzen for the analysis of the gun region. The presence of the higher axially-symmetric modes results in a finite standing-wave ratio of noise current in the drift space as measured by a cavity moving along the beam, as low as 10 db in some cases, as well as a behavior of partition noise which is, at least qualitatively, in agreement with that observed experimentally. (Contractor's abstract)

AN OUTLINE OF A THEORY OF SEMANTIC INFORMATION, by R. Carnap and Y. Bar-Hillel. Oct. 27, 1952, 48p. incl. diagrs. table. (Technical rept. no. 247) (In cooperation with Chicago U., Ill.) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100) AD 10117 Unclassified

The theory of information emphasizes semantic aspects which are deliberately neglected in prevailing communication theory. This theoretical restraint results in misapplications. The information carried by a sentence within a given language system is treated as being synonymous with the sentence content, normalized in a certain way. The amount of semantic information is explicated by various measures of this content, all based on logical probability functions ranging over the contents. Two major types of amount of information were investigated; one is additive with respect to sentences whose contents are exclusive, and the other is additive with respect to sentences which are inductively independent. The latter is formally analogous to the customary information measure function. The concepts of information and information measures were believed to be of value in various theories including those for the design of experiments and for testing. An extension of the use of the concepts to take into account the linear arrangements of the individuals is outlined.

AN ELECTRON-BEAM TUBE FOR ANALOG MULTIPLICATION, by E. J. Angelo, Jr. Oct. 27, 1952, 41p. incl. illus. refs. (Technical rept. no. 249) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 11807 Unclassified

Also published in Rev. Scient. Instruments, v. 25: 280-284, Mar. 1954.

An electron-beam tube developed for providing accurate, high-speed, analog multiplication was subjected to static and dynamic tests. The maximum errors in multiplication under static conditions were approximately 2% of the maximum product; the output voltage corresponding to the maximum product was 3 v. Under the conditions of the dynamic tests, the tube performance was limited by stray capacitance shunting the output circuit; accordingly, with a sinusoidal output voltage the half-power point was at 70 kc. Further measurements showed that flat response up to 100 kc should be obtained by reducing the impedance level of the output circuit. The tube multiplies in the following manner. A circular electron beam of relatively large diameter and with uniform current density is projected through a conventional beam-deflection system upon a metallic target consisting of 4 quadrants that are insulated from one another. From the 4 currents collected by the target an output current is obtained that is proportional to the product of the 2 deflecting voltages. The accuracy of multiplication depends primarily upon the uniformity of the current distribution in the beam when it reaches the target; linearity of deflection and accuracy of target construction are significant but not critical. Consideration is also given to the problem presented by positive ions created from residual gas in the tube.

PHYSICAL LIMITATIONS ON ANTENNAS, by J. Ruze. Oct. 30, 1952, 85p. incl. illus. (Technical rept. no. 248) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 62351 Unclassified

Investigation of the physical realizability of a specified radiation polar diagram from an antenna aperture of a finite size is presented in three related parts: (1) Limitations Imposed by Aperture Distribution Errors. Deviations from the theoretical aperture distribution caused corresponding deviations from the desired polar diagram. Systematic and random errors are involved, the latter forms a statistical problem. A theory is formulated for their treatment for both the discrete and the continuous aperture. For the continuous aperture it is necessary to introduce the concept of a correlation interval. The effect of aperture errors on the antenna gain and on the realizability of low side lobes is examined. Experimental work on a broadside array and on a "randomly" distorted parabolic mirror provides a verification of the theory. (2) Limitations Imposed by the Synthesis Procedure. In the antenna synthesis problem we are required to determine an aperture distribution of a specified finite width whose radiation pattern approximates the desired one. Existing synthesis procedures are examined with particular interest in the nature of the optimization condition. Two procedures are suggested for approximating a function in an approximating a function in an approximate Chebyshev sense. (3) Limitation Imposed by the Aperture "Q". It is shown by direct integration of the aperture Poynting vector that those field components with spatial variation of a period smaller than a wavelength contribute essentially reactive power. They increase the Q of the aperture and impose a limitation on the practically obtainable polar diagrams. (Contractor's abstract)

SECOND-SOUND VELOCITY BELOW 1°K AS A FUNCTION OF PRESSURE, by V. Mayper, Jr. and M. A. Herlin. [Nov. 24, 1952] [2]p. incl. diagr. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100] AD 12367 Unclassified

Presented at ONR GE Cryogenics Conference, Schenectady, N. Y., Oct. 6, 1952.

Also published in Phys. Rev., v. 89: 523-524, Jan. 15, 1953.

Previous findings on the velocity of second sound in liquid helium II along the vapor pressure line seem to confirm a predicted approach of c_2 to the constant $c_1/\sqrt{3}$ which is based on the proposal that the liquid should approach an ideal phonon gas at low temperatures. Specific heat measurements, showing a T^3 dependence for C_v below ~0.6°K, also indicates that excitations of the liquid are due solely to phonons at low temperatures; some discrepancies are noted between the two sets of measurements with second-sound velocities departing radically from the phonon-gas model above ~0.35°K instead of 0.6°K of the specific heat measurements. Measurements by the pulse method now in progress are reported both at vapor pressure and at higher pressure. Results at vapor pressure are in reasonably good agreement with the previous specific heat data, at least above 0.3°K; the extrapolated value for c_2 is 155 m/sec. No trace of previously-reported rise in velocity at lower temperatures was found at vapor pressure but at higher pressure results tend to indicate the low temperature rise in velocity to be a real phenomenon, becoming more apparent at higher pressure. Values at each pressure for c_2 at a temperature just below that of the sharp drop in c_2 are about 10% higher than $c_1/\sqrt{3}$ for that pressure. Data at 14.2 atmospheres shows the low temperature rise to apparently begin before the sharp rise at intermediate temperature is complete. At the very lowest temperatures, velocities have risen to near c_1. A possible explanation of this behavior is presented.

ELECTROMAGNETIC WAVES IN PERIODIC STRUCTURES, by L. Stark. Dec. 9, 1952, 41p. incl. diagrs. tables, refs. (Technical rept. no. 208) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 25740 Unclassified

The two problems under study are (1) the propagation

constant in iris-loaded wave guides of standard cross section, and (2) the use of an interleaved-fin structure as a slow-wave circuit for traveling wave amplifiers. In the first case an attempt is made at unification by presenting a result which is common to all standard types of wave-guide cross sections and which is general to the extent that the loading irises can be taken to be infinitely thin. The result is expressed as a quotient of infinite sums whose terms depend upon the field distribution in the aperture. The result can be solved to a quasi-stationary approximation, and in the case of a rectangular guide, the series can be virtually summed so that the result is useful in practice. The second problem is considered for the case of either open or closed lateral boundaries, and the structure is considered as a folded rectangular wave guide with either open-circuited or short-circuited side walls. The discontinuity at each bend of the folded guide is accounted for by an equivalent network. Although most of the theory neglects beam transmission holes, experiments indicate that the propagation constant is negligibly affected by even relatively large holes. The degree to which the circuit couples to a given beam is calculated from the field distribution in a model.

A METHOD OF WIENER IN A NONLINEAR CIRCUIT, by S. Ikehara. Dec. 10, 1952. 22p. incl. illus. refs. (Technical rept. no. 217) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 1800 Unclassified

The Wiener method (M.I.T. Radiation Lab. rept. no. 129) is discussed which is to solve for the voltage across a nonlinear device in terms of the entire random voltage and then to get statistical averages, on the assumption that the current-voltage function of the nonlinear element and the system transfer function are given. A case is treated in which random voltage passes through a filter before entering the circuit. Explicit formulas depending only on the assumptions can be given for the moments of all orders of the voltage across part of the circuit, and similarly, for its frequency spectrum. The method of computation explicitly requires the use of the Wiener theory of Brownian motion (Acta Math., v. 55: 117, 1930 and Amer. Math. Soc., Colloquium Publications XIX, Chap. 9, 1934).

A FIVE-CHANNEL ELECTRONIC ANALOG CORRELATOR, by M. J. Levin and J. F. Reintjes. [1953] [10]p. incl. illus. table. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-100]) AD 10280 Unclassified

Also published in Proc. National Electronic Conference, v. 8: 647-656, Jan. 1953.

Recent applications of statistical theory to communication problems require the evaluation of the correlation functions of electrical phenomena. Most exciting correlators consume considerable time in computing these functions, since they are capable of obtaining only one point of the curve at a time. More rapid evaluation of correlation functions would extend the usefulness of these techniques. This paper describes an electronic analog correlator which computes five points of a correlation curve simultaneously. The correlator obtains these points from the actual time series under consideration within 2 to 30 sec and displays them in the form of spot displacements on the face of a cathode-ray tube. Input signal frequencies from 200 cps to 500 kcps are handled accurately. Values of delay between adjacent points ranging from 1 to 400 μsec are available.

MIT. 10:130 - MIT. 10:133

The equipment utilizes pulse-circuits techniques for the computing circuits. The correlator is especially useful for the study of time series whose characteristics change with time. Results of brief studies of some of these nonstationary series are presented.

HEAD-END DESIGN FOR FM TUNERS. A DETAILED ANALYSIS OF THE PROBLEMS ASSOCIATED WITH THE DESIGN OF FM TUNER HEAD-ENDS, WITH PRACTICAL SOLUTIONS, by H. H. Cross. 1952 [7]p. incl. illus. table, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 52543 Unclassified

Also published in TV and Radio Engineering, v. 23: Feb.-Mar. 1953.

The design of signal-frequency and frequency-changing sections of narrow-band VHF superheterodyne receivers for the FM broadcast band is analyzed. It is shown that since, noise factor varies inversely as the power efficiency of the input network, any finite -Q input network must compromise between noise factor and selectivity. For a given number of tuned circuits, the best arrangement is one which utilizes one tuned circuit for the input network and the rest to obtain interstage selectivity. Mixer operation is considered, and the optimum adjustment is found to be relatively low oscillator injection combined with RF gain sufficient to make the amplifier input noise one to ten times the power of the noise generated in the mixer tube. Tuners built in accordance with these principles are described briefly. Experimental data show that their performances compare favorable with those of medium-frequency receivers.

SYNTHESIS OF TRANSFER FUNCTIONS WITH POLES RESTRICTED TO THE NEGATIVE REAL AXIS, by L. Weinberg. 1953 10 p incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039 sc 100) Unclassified

Published in Jour. Appl. Phys., v. 24: 207 216, Feb. 1953.

A procedure for the synthesis of general RC transfer functions by means of unbalanced networks is described. The transfer function need not be minimum phase but may have zeros anywhere in the complex plane except on the positive real axis. Use is made of the technique of zero shifting as in the Guillemin procedure; but the additional use of a network theorem divides the desired network into 2 parts, with a consequent reduction of the problem to 2 simpler problems. Zero shifting can now be performed in 2 directions from within the total network. The theorem plus a method of using fewer paralleled ladders yield a final network with fewer ladders and fewer elements than that given by the Guillemin procedure. In the illustrative example given, 26 elements are used, whereas the Guillemin procedure would use 66. (Contractor's abstract)

FEEDBACK THEORY. I. SOME PROPERTIES OF SIGNAL FLOW GRAPHS, by S. J. Mason. Feb. 2, 1953, 25p. incl. illus. (Technical rept. no. 153) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100) AD 11294 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 41: 1144-1156, Sept. 1953.

The fundamentals are presented of flow-graph topology, which exposes the structure (Gestalt) of the functional relationships associated with a signal flow graph. The latter is interpreted as a signal transmission system in which each node is a repeater station. The station receives signals via incoming branches, combines the information, and transmits the result along each out going branch. The manipulative techniques are shown by which flow graphs may be transformed or reduced, thereby solving or programming the solution of the accompanying [illegible]ations. Illustrative examples are given. Spec[illegible]tion to linear flow graphs yields results which are useful for the discussion of the general theory of feedback in linear systems, as well as for

the solution of practical linear analysis problems.

SYNTHESIS OF UNBALANCED RLC NETWORKS, by L. Weinberg. [1953] [7]p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-100]) Unclassified

Published in Jour. Appl. Phys., v. 24: 300-306, Mar. 1953.

A method is demonstrated for synthesizing an unbalanced RLC network with lossy coils, i.e., each inductance has an associated series resistance. The network realizes a minimum phase transfer function whose numerator and denominator are of degree not higher than the third and fourth, respectively, and whose poles and zeros may lie anywhere in the left half of the complex frequency plane. It is shown that in many cases higher degree functions may be realized as one network. For a transfer function of arbitrary degree, factoring into component transfer functions is carried out, each components having the above characteristics; the components are then realized separately and isolated from each other by vacuum tubes supplying gain. The method makes use of the following new features: (1) A breakdown of a Hurwitz polynomial into two Hurwitz polynomials so that a division by one of them yields a sum of unity plus a positive real RLC function, each of whose partial-fraction terms (complex poles taken in pairs, or course) is positive real. (2) An application of a network theorem which divides the desired network into two networks, thus simplifying the synthesis problem. (3) A method of zero shifting to any point in the left half-plane with at least one pair of complex poles. A further advantage of the procedure is that the network may be designed to possess input and output shunt capacitances so that tube capacitances may be automatically provided for. HYPERFINE STRUCTURE AND NUCLEAR MOMENT RATIOS OF THE STABLE BROMINE ISOTOPES, by J. G. King and V. Jaccarino. Mar. 26, 1953 7 p. incl. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-100) AD 44506 Unclassified

Presented at meeting of the Amer. Phys. Soc., Durham and Chapel Hill, N. C., Mar. 26-28, 1953.

Also published in Phys. Rev., v. 94: 1610-1616, June 15, 1953.

The hyperfine structure of the $^2P_{3/2}$ state of atomic Br^{79} and Br^{81} was investigated by the atomic-beam magnetic-resonance method. The ratio of the magnetic dipole interaction constants a^{81}/a^{79} is 1.07794 ± 0.00001, and the ratio of the electric quadrupole interaction constants b^{79}/b^{81} is 1.9707 ± 0.00003. Applying the results of recent theoretical calculations by Sternheimer, Koster, and Feld, the following values of nuclear quadrupole moments were computed: $Q^{79} = 0.335 \times 10^{-24} cm^2$, $Q^{81} = 0.280 \times 10^{-24} cm^2$. IF AND DETECTOR DESIGN FOR FM. PART I. EXAMINATION OF TYPICAL CONDITIONS UNDER WHICH RECEIVERS MUST OPERATE. VARIOUS EFFECTS OF INTERFERENCE. PART II. PERFORMANCE REQUIREMENTS FOR THE IF SECTION, AND DESIGN PROCEDURE INVOLVED. LIMITER CHARACTERISTICS. PART III. LIMITERS CONCLUDED. THE FREQUENCY DETECTOR. COMPLETE TUNER CIRCUIT DIAGRAM AND CONCLUDING REMARKS, by R. A. Paananen. [1953] [23]p. incl. illus. refs. (Parts 1, 2, and 3 of its Rept. on IF and Detector Design for FM, AD 52544; Pt. 1, AD 52544(a); Pt 2, AD 52544(b); Pt. 3, AD 52544(c)) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 52544 Unclassified

Also published in TV and Radio Engineering, Pt. 1, v. 23, Apr.-May 1953; Pt. 2, v. 23, June-July, 1953; Pt. 3, v. 23, Aug.-Sept. 1953.

This paper concerns the application of a wide-band, interference-reducing theory to FM broadcast receiver design. The first part concerns the space link between the transmitter and receiver, with regard to wave propagation, coverage, and interference. This material facilitates specification of some receiver characteristics, such as selectivity and spurious responses. The second part pertains to receiver design, beginning with a chapter on IF amplifiers. Various selectivity configurations are compared, with special attention given to an approximation method useful in filter design. Overloading, phase-shift distortion, and detailed design are also covered. The section on limiters contains general material relevant to crystal limiter performance, defines a limiter coefficient, and discussed the 6BN6 tube as a limiter. A ratio detector circuit is evolved in the next section, and data are given from experiments on a 100 kc detector. Wiring data for the receiver and the results of tests on the complete unit are then given. The final sections concern possible improvements as well as an evaluation of the design and operating differences between this receiver and a typical narrow band unit.

METHODS OF MEASURING THE PROPERTIES OF IONIZED GASES AT HIGH FREQUENCIES. IV. A NULL METHOD OF MEASURING THE DISCHARGE ADMITTANCE, by L. Gould and S. C. Brown. Apr. 8, 1953 [4]p. incl. diagrs. (Technical rept. no. 256) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 52553 Unclassified

Also published in Jour. Appl. Phys., v. 24: 1053-1056, Aug. 1953.

The admittance of a gas discharge may be obtained from measuring the ratio of the transmitted power through a microwave cavity to the incident power as a function of signal frequency near the cavity resonance. The method involves balancing the transmitted and incident signals to zero at the cavity resonance after they have passed through two separate receiving systems. When the signal frequency is changed, an attenuator is used to rebalance the two signals. The change in frequency from resonance and the corresponding change in attenuation gives the necessary data which will plot as a straight line whose slope yields the desired information. MICROWAVE SPECTRUM OF THE WATER MOLECULE, by D. W. Posener. May 14, 1953, 156p. incl. tables, refs. (Technical rept. no. 255) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 14660 Unclassified

The centrifugal distortion theory applicable to the H_2O molecule and its isotopic modifications was rederived. Rotational constants and distortion parameters were calculated for the H_2O, D_2O, and HDO molecules by a utilization of the theory with infrared data; the resulting theoretical transition frequencies were compared with those observed in the microwave region. Theoretically calculated parameters were employed to obtain Q-branch frequencies in HDO; a relationship was established between the theoretical and observed values. The comparison indicated that the theoretical distortion corrections represented true conditions; a simple variation of the effective moments provided reasonable agreement with experiment. The parameters accounted for the known $|\Delta J| = 1$ transitions in HDO. The validity of the Hillger-Strandberg-Kivelson-Wilson approximation for calculating the Q-branch frequencies in HDO is discussed. The effective reciprocal moments of inertia for HDO are: a = 7.0396 ± 0.0005 x 10^5 mc/sec, b = 2.7360 ± 0.0005 x 10^5 mc/sec, and c = 1.9186 ± 0.0005 x 10^5 mc/sec with K = 0.6841 ± 0.0002. The new transitions observed in the microwave spectra of D_2O and HDO are: D_2O $2_{20} \rightarrow 3_{13}$, 10,919.39 ± 0.05 mc/sec; HDO $8_{45} \rightarrow 8_{44}$, 24,844.77 ± 0.05 mc/sec; HDO $10_{56} \rightarrow 10_{55}$, 8836.95 ± 0.1 mc/sec; and HDO $11_{57} \rightarrow 11_{56}$, 22,581.1 ± 0.2 mc/sec. A line at 26,880.38 ± 38 ± 0.05 mc/sec was identified as the $6_{24} \rightarrow 7_{17}$ transition of HDO.

M-EMISSION BANDS OF THE TRANSITION METALS IN THE SOLID STATE, by E. M. Gyorgy. May 25, 1953, 34p. incl. diagrs. tables, refs. (Technical rept. no. 254) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 28470
Unclassified

M-emission bands of Cr, Mn, Fe, Ni, and Cu were studied with a modified vacuum spectrograph which employed the grazing-incidence Rowland mounting with a movable photodetector capable of measuring radiation intensities in the range of 50-800 A. The spectra discussed were produced by transitions of valence electrons in the excited $3\,P_{3/2,\ 1/2}$ states of the atom. An explanation of several of the observed features of the bands is permitted by assuming (1) the observed bands represent only the density of d-type electrons; or (2) an appreciable part of the experimental bands is due to the conduction electrons. The emission process and some aspects of background radiation are discussed. Experimental emission curves, emission edges, emission bandwidths, and electron distribution curves are included for the metals studied.

A COMPUTER FOR SOLVING INTEGRAL FORMULATIONS OF ENGINEERING PROBLEMS BY METHODS OF SUCCESSIVE APPROXIMATIONS, by J. M. Ham. May 28, 1953, 54p. incl. illus. diagrs. tables, refs. (Technical rept. no. 241) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 28573
Unclassified

Variational methods of successive approximations for solving the linear operational equation $P\alpha + \beta = 0$ are examined, where P is an n x n matrix, β is a known vector, and α is an unknown vector. The equation is used to represent linear simultaneous equations, integral equations, and boundary value problems in differential equations. The variational principle informing the methods of solution is that of associating with the basic equation a scalar-valued functional $W(\alpha)$ that attains its extrema when the equation is satisfied; $W(\alpha)$ defines a surface over the n-space of the operator P. In this space the solution sequences $\alpha_0, \alpha_1, \ldots, \alpha_m$ generated by relaxation and classical iterative methods describe particular types of vector trajectories that terminate under the extrema of $W(\alpha)$. It is concluded that small and relatively simple special-purpose computers designed for use by the research worker can contribute significantly to the effective application of methods of successive approximations. The design and application of such a computer is described. The internal operations are in part digital and in part analog. The major mathematical function performed by the machine is that of transforming an n-vector by an n x n matrix. A 40-vector may be so transformed in approximately 40 sec. The machine carries 9 binary digits. The machine is effective for evaluating integral transformations such as Fourier, correlation, and convolution integrals.

THE USE OF FREQUENCY MODULATION FOR TELEVISION TRANSMISSION, by R. D. Stuart, L. B. Arguimbau and others. July 6, 1953, 25p. incl. illus. (Technical rept. no. 259) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 18975 Unclassified

Investigations were made of FM television transmissions. A facsimile system having an 1800-c AM carrier was detected, and the video wave form was used to frequency modulate a 14-kc carrier. A signal which was acoustically delayed 25 msec and a direct signal were added to simulate multipath transmissions. Doubleside-band operation was used over a bandwidth equivalent to 5 mc for a 140-mc carrier. Interfering signals up to 70% of the desired signal were investigated. The tests were made with a 3-element Butterworth filter having 3-db points at the equivalent of 140 ± 2.5 mc. The test signal was frequency modulated with a trapezoidal wave having a rise time equivalent to 0.08 μsec. The investigations indicated that under multipath-transmission conditions, the stronger signal may capture in an FM system even in the presence of strong interference. The characteristic ghost of spike interference was present, and its repetition rate depended on the frequency, with the bandwidth the same as the highest components of the transmitted wave form, the spike frequency fell in a region of the spectrum containing picture information. Effective filtering in the latter case appeared difficult; pre-emphasis simplified but did not solve the problem. The use of wider bandwidths for effective interference reduction was considered possible.

HYPERFINE STRUCTURE OF IODINE (Abstract), by J. G. King, H. H. Stroke, and V. Jaccarino. [1953] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-100]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 30-May 2, 1953.

Published in Phys. Rev., v. 91: 476, July 15, 1953.

The atomic beam magnetic resonance method was used to investigate the $^2P_{3/2}$ atomic ground state of the stable isotope of iodine. From observations of the Zeeman frequencies in a known weak magnetic field, the value of 5/2 ħ for the nuclear spin I was verified. Further work is in progress to determine the nuclear magnetic dipole and electric quadrupole interaction constants. There has been considerable interest in the hyperfine structure of iodine for some time because of the possible existence of a nuclear magnetic octupole interaction. (Contractor's abstract)

A "MAGNETIC SCANNING" METHOD FOR INVESTIGATING HYPERFINE STRUCTURE AND ISOTOPE SHIFT, by F. Bitter, H. H. Plotkin and others. [1953] 1 p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-100]) Unclassified

Published in Phys. Rev., v. 91: 421, July 15, 1953.

A new technique for observing hyperfine structure and isotope shift in absorption lines is applied to a study of the resonance lines of vaporized natural Hg isotopes as well as the radioactive Hg^{197}. The 2537A radiation emitted axially from a Hg^{198} lamp in a magnetic field, and passed through a quarter wave plate and Nicol

prism to obtain one of the two σ-components of the normal Zeeman triplet, provides a variable-frequency monochromatic light source for selective excitation of components of the entire hyperfine structure pattern of the resonance line of natural Hg; fields up to 10,000 gauss vary the frequency, while resonance radiation intensity is observed with a photomultiplier. Computation of frequency from the magnetic field was in good agreement with previous findings but anomalous results were found for intensities. Observation of small samples of Hg^{197}, produced from deutron-bombarded gold showed in addition to the normal five hyperfine components of the natural Hg spectrum, presumably due to contamination, several new components whose intensity changed with time. It was not possible to identify these lines in our preliminary experiments, but the results seem at present to be compatible with the spin assignments of the shell model, and of experiments on γ-emission, namely f3/2 for the isomeric state and f/2 for the ground state. Further experiments attempting to identify the various newly discovered lines are also in progress.

MEASUREMENT OF THERMAL DIFFUSIVITY OF MAGNESIUM AT LOW TEMPERATURES BY VARIABLE STATE TECHNIQUES (Abstract), by S. Waldron and M. A. Herlin. Apr. 30, f953 [f p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc f00) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 30-May 2, f953.

Published in Phys. Rev., v. 9f: 447, July f5, f953.

The measurement of thermal properties of metals at low temperatures by a pulsed and a sinusoidal heating of a rod of the metal has been investigated. The pulse measurements are shown to be seriously limited by the thermal resistance of the heater-to-sample interface. The sinusoidal measurements, however, are able to yield the thermal diffusivity (ratio of thermal conductivity to specific heat) and thus form a convenient method of obtaining this quantity. The method has been applied to magnesium, whose specific heat is known. Two samples have been investigated, one of high purity, and one containing sufficient manganese impurity to show a pronounced electrical resistance minimum. The thermal conductivity derived from these results shows the normal linear variation with temperature at low temperatures for the pure sample, but a nonlinear variation in the direction expected from the electrical conductivity anomaly for the impure sample. Both samples show the characteristic maximum at higher temperatures. (Contractor's abstract)

NUCLEAR RESONANCE LINE STRUCTURE IN HD AND MOLECULAR SHIELDING IN HD, H_2, AND D_2 (Abstract), by T. F. Wimett. [f953] [f]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-f00]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 30-May 2, f953.

Published in Phys. Rev., v. 9f: 478, July f5, f953.

Line splitting in both the proton and deuteron magnetic resonances in HD was predicted by Ramsey and Purcell and has been observed by means of the radio-frequency pulse technique and also by a line broadening measurement. We will report a measurement of this splitting by the direct recording of the lines obtained in a nuclear resonance absorption experiment of very high resolution. As measured at f5 kilogauss, the splitting observed was $\sigma = 42.7 \pm 0.7$ cycles. By comparing the ratio of proton and deuteron resonance frequencies in HD with that observed in a mixture of H_2 and D_2 gases, the following difference between the molecular shielding factors for H_2 and D_2 was obtained: $\sigma D_2 - \sigma H_2 = (0.65 \pm 0.59) \times f0^{-7}$. The difference in the shielding fields in D_2 and HD was obtained by measuring the shift between the deuteron resonance in D_2 from that in HD using a single sample containing both gases. The following result was found: $\sigma D_2 - \sigma HD = (0.48 \pm 0.32) \times f0^{-7}$. (Contractor's abstract)

A simple high temperature microwave spectrograph was built. Four rotational transitions in $K^{39}Cl^{35}$ and two in $K^{39}Cl^{37}$ were observed. Those in $K^{39}Cl^{35}$ agree with the same transitions observed by Stitch, Honig, and Townes. Rotational constants agree within experimental error with those found by molecular beam methods. The Stark patterns for the transitions J 2 → 3, v 0 in $K^{39}Cl^{35}$ and J f → 2, v 0 in $Na^{23}Cl^{35}$ were studied. From these the electric dipole

MIT. 10:153 - MIT. 10:156

moments of $K^{39}Cl^{35}$ and $Na^{23}Cl^{35}$ were determined. (Contractor's abstract)

THERMOMECHANICAL EFFECT IN LIQUID HELIUM II TO 0.9°K (Abstract), by D. H. Rogers and M. A. Herlin. [1953] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research and [Air Force Office of Scientific Research] under [DA 36-039-sc-100]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 30-May 2, 1953.

Published in Phys. Rev., v. 91: 489, July 15, 1953.

The thermomechanical pressure in liquid helium II has been measured as a function of temperature difference and ambient temperature to slightly below 0.9°K ambient. The full thermomechanical pressure as given by the London equation is observed. At the lower temperature limit the phonon contribution to the entropy is over half of the total entropy, indicating that the phonons contribute to the thermomechanical pressure reversibly as has been observed for the higher temperature excitations. A nonlinear dependence of thermomechanical pressure on temperature difference has been found to be completely explained by the change of entropy with temperature, substantiating the assumption of reversibility. It has been found possible to sustain a fairly large temperature difference across the filter element even at the low temperature end of the observed range without introducing irreversible effects. ULTRASONIC MEASUREMENTS IN LIQUID HELIUM (Abstract), by C. E. Chase. [1953] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-100]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 30-May 2, 1953.

Published in Phys. Rev., v. 91: 489, July 15, 1953.

Measurements of the velocity and absorption of ordinary sound in liquid helium were made in the temperature range from 0.85°K to the normal boiling point, using a pulsed ultrasonic technique at frequencies of 2, 6, and 12 mc/sec. The velocity measurements indicate the absence of detectable dispersion over this frequency range. The attenuation measurements disclose a very rapid rise in the attentuation below 1.6°K. Above 1.2°K quantity α/ω^2 is independent of frequency; a marked departure from this behavior at lower temperatures indicates the presence of relaxation effects. These results are in qualitative agreement with the theoretical predictions of Khalatnikov, whose calculations are based on the assumption of finite relaxation times for the processes leading to a change in the number of elementary excitations present in the liquid. NETWORK SYNTHESIS BY IMPULSE RESPONSE FOR SPECIFIED INPUT AND OUTPUT IN THE TIME DOMAIN, by F. Ba Hli. July 31, 1953, 65p. incl. diagrs. refs. (Technical rept. no. 261) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 51989 Unclassified

A solution to the general problem of synthesis in the time domain is presented: given an arbitrary time function as the specified input to an electrical network and another such time function as the desired output, a design procedure is offered for a network for obtaining the required relationship. These arbitrary time functions may be prescribed either graphically, or as analytic functions, or merely as sequences of values at stated intervals of time. The specified input-output pair is reduced to a single function which is known as the impulse response of the network by a simple, straightforward, synthetic division procedure. The physical realizability of the network is tested by two, easy-to-apply, criteria in the time domain that are the analogs of the Hurwitz test used on functions of s. Then three original methods are presented for calculating the network system function directly from the impulse response in the time domain. All three methods offer the advantages of being simple and computationally rapid. Moreover, it is possible to get rational function approximations to transcendental network system functions by an algebraic method which yields great economy of network elements with good tolerances in the time domain.

POWER GAIN IN FEEDBACK AMPLIFIERS, by S. J. Mason. Aug. 25, 1953, 13p. incl. illus. (Technical rept. no. 257) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 31774 Unclassified

Also published in I. R. E. Trans. of Professional Group on Circuit Theory, v. CT-1: 20-25, June 1954.

A linear transistor model (or other linear

two-terminal-pair device) is imbedded in a lossless passive network N and the properties of the complete system, as measured at two specified terminal pairs, are described by the open-circuit impedances Z_{11}, Z_{12}, Z_{21}, Z_{22}. The quantity

$$U = \frac{(Z_{21} - Z_{12})^2}{4(R_{11}R_{22} - R_{12}R_{21})}$$

where R_{jk} is the real part of Z_{jk}, is defined as the unilateral gain of the transistor. Quantity U is independent of the choice of N and is (consequently) invariant under permutations of the three transistor terminals and also under replacement of the open-circuit impedances by short-circuit admittances. If U exceeds unity at a specified frequency, then N can always be chosen to make R_{11} and R_{22} positive and Z_{12} zero at that frequency. Quantity U is identifiable as the available power gain of the resulting unilateral structure. An arbitrary coupling network may be decomposed into a portion that accomplished unilateralization and a remaining complementary portion that provides feedback around the unilateralized structure. Such decomposition brings some of the methods of elementary feedback theory to bear upon nonunilateral circuit problems and offers a viewpoint from which signal flow and power flow can be simply related. INFORMATION FLOW IN TASK-ORIENTED GROUPS, by R. D. Luce, J. Macy, Jr. and others. Aug. 31, 1953, 95p. incl. diagrs. tables. (Technical rept. no. 264) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 49440 Unclassified

Chapter I: A nonaction-quantized group experiment in which the subjects were conditioned in one communication network and tested in another is described. The difficulties of this general information flow problem are pointed out. Chapter II: The group results for time, number of messages, content of messages, and errors are presented. It is shown that interesting carry-over effects occur; that the dominant effect is that of the present communication network. Chapter III. Individual decisions are characterized in terms of conditional probabilities for certain ambiguous and unambiguous conditions, but the determinants of behavior in the ambiguous situations are not well understood. Chapter IV: It is shown that individual decision times and probabilities of decision are not directly interdependent; that both depend on the information state. The exponential distribution is again found adequate for individual decisions and it is shown that the decision rate is nearly content for serial decisions. Chapter V: Subjects' knowledge of the network and their attitudes toward experiences in the groups are examined and previous network experience are given. Chapter VI: Conclusions from this and previous studies are drawn, and generalizations are made concerning future developments and applications. (Contractor's abstract)

COMPUTATIONAL TECHNIQUES WHICH SIMPLIFY THE CORRELATION BETWEEN STEADY-STATE AND TRANSIENT RESPONSE OF FILTERS AND OTHER NETWORKS, by E. A. Guillemin. [Sept. 2, 1953] [20]p. incl. illus. (Technical rept. no. 268) (Sponsored jointly Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 55312 Unclassified

Also published in Proc. National Electronic Conference, v. 9: 513-532, Feb. 1954.

In some wave filter applications it is significant to determine the transient response for the contemplated excitation as well as to control the pertinent sinusoidal steady-state transmission and rejection properties. In others it may be necessary to consider simultaneously the tolerance specifications on the transient response as well as on the steady-state frequency response of the filter in its design. The difficulty involved in handling such specifications lies primarily in finding a reasonably simple way (computationally as well as logically) of correlating tolerances or errors in the time domain with their counterparts in the frequency domain. Formally, this correlation is expressible through use of the Laplace transform; but from the standpoint of computational ease and interpretive clarity this mathematical relationship leaves much to be desired. The method proposed in this paper effects the desired correlation without integration, and in many

cases the pertinent results can be written down by inspection. While not an exact method, it is a very much better approximation than some other approximate procedures that have previously been proposed. The same techniques also make possible easy computation of the minimum phase associated with a specified magnitude vs frequency variation. From this can be obtained a relatively simple and direct way of computing transient response from a specified gain or loss characteristic that is as accurate as need be and one in which the appropriate asymptotic character of the filter characteristic is properly taken into account. STATISTICAL THEORY APPLIED TO COMMUNICATION THROUGH MULTIPATH DISTURBANCES, by R. Price. Sept 5, 1953, 70p. incl. diagrs. refs. (Technical rept. no 266; Lincoln Lab. tech. rept. no. 34) (In cooperation with M. I. T. Lincoln Lab. under AF 19(122)458) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-100) AD 28497 Unclassified

This work is concerned with the synthesis and evaluation of integrated communication systems constructed specifically to perform in the presence of channel disturbances of the form encountered in multipath propagation. In the communication system considered, information is conveyed from source to user by encoding it into electrical symbols at the transmitter and decoding it at the receiver. Statistical theory, including information theory, is used throughout the paper. Gross aspects of multiple-mode propagation in ionospheric scattering are discussed, and previous efforts to improve systems affected by these disturbances are reviewed. System capacities are computed for the transmission of band-limited white Gaussian signals through fixed multiple-mode disturbances, and the optimum spectral distribution of transmitter power is found. In general, presence of additional paths does not upset the message-handling capabilities of the channel if suitable wide-band signals are used. Quasi-stationary path fluctuations are considered, and a technique for measurement of the multipath characteristic by the receiver is suggested. Capacities are found for slow path delay fluctuations. Single-mode scatter propagation is considered as a complex multiplicative Gaussian process. The probability computing receiver is found analytically, and a physical realization is developed for small signal-to-noise ratios. Lower bounds to system capacity are found for a binary transmission through scatter. Incidental results are system capacities for a related multiplicative channel, and the capacity for a binary transmission through white Gaussian noise. (Contractor's abstract)

Also published in Phys. Rev., v. 93: 84-93, Jan. 1, 1954.

This paper deals with the spatial distributions of the charged particles, space-charge fields, and voltages in certain types of gas discharge plasmas and with the rate of ionization necessary to maintain the plasma in a steady state. In gas discharge plasmas with very low charge densities, the charged particles diffuse freely in directions perpendicular to the applied electric field because the space-charge field is negligible. At high charge densities, the space-charge field saturates and gives rise to a combination of diffusive and mobility flow termed ambipolar. The transition between these limits is examined theoretically for the case of plasmas maintained through ionization by electron impact. The ionization frequency per electron, one of the principle parameters of the transition, can be re-expressed in terms of an effective diffusion coefficient; it falls from a high value at the free diffusion limit to a low value at the ambipolar limit as the electron density increases over many orders of magnitude. The transition is accompanied by changes in the charge distributions and by the development of a positive ion sheath. The current equations determining the process are examined, and approximate solutions are obtained. Second approximations are obtained for the case where the ratio of electron to ion energies is much greater than unity. Machine solutions are presented both for the above case and for an isothermal plasma in which this ratio equals unity. An application to the afterglow is shown. (Contractor's abstract)

Also published in Jour. Math. and Phys., v. 33: 194-198, July 1954.

Bott and Duffin's result has been arrived at by the continuation of the Brune synthesis procedure. This provides an alternative proof to that of Bott and Duffin for the existence of a network configuration without an ideal transformer for any positive real function. This method of approach suggests a more unified synthesis procedure: first follow the Brune synthesis procedure. If a Brune cycle with an ideal transformer is confronted, convert that cycle into a cycle without a transformer. Numerical values of the elements of the latter cycle are found in terms of elements of the corresponding Brune cycle.

Also published in Phys. Rev., v. 93: 965-969, Mar. 1, 1954.

A beam of high energy electrons, injected into the plasma of a dc discharge from an auxiliary electron gun, excited oscillations in the plasma at the plasma electron oscillation frequency given by the Tonks-Langmuir equation. A movable probe showed the existence of a standing wave patterns of the oscillatory energy in the region of the plasma in and around the electron beam. Nodes of the patterns coincided with the electrodes which limited the region of the plasma traversed by the beam. The standing wave patterns were independent of the frequency of the oscillation. At any particular frequency, the standing wave was determined by the thickness of the ion sheaths on the bounding electrodes. The mechanism of the energy transfer from the electron beam to the oscillation of the plasma electrons was established as a velocity-modulation process by the detailed behavior of the frequency of oscillation and the transitions in the standing-wave patterns as the sheath thickness was varied. Experimental attempts to produce plasma oscillations as predicted by Bohm and Gross proved to be fruitless. (Contractor's abstract)

Also published in Jour. Franklin Inst., v. 257: 161-190; 275-303, Mar.-Apr. 1954.

An orderly procedure is developed by which the requirements of a sequential switching circuit (one with memory) can be reduced to the requirements of several combinational switching circuits (those without memory). Important in this procedure are: (1) the flow table: a tabular means by which the requirements of a sequential switching circuit may be stated precisely and by which redundancy in these requirements may be recognized and eliminated; and (2) the transition index: a new variable which indicates the stability (or lack of stability) of a switching device. The role of those switching devices which are not directly controlled by the input of a sequential switching circuit is investigated thoroughly. The resulting philosophy, which is exploited in synthesis procedures for circuits using either relay or vacuum-tube switching devices, is valid for circuits using other devices as well. A TIME-GATED AMPLITUDE QUANTIZER FOR NEURAL SIGNALS. AN APPLICATION TO ELECTRIC SIGNALS FROM THE AUDITORY NERVOUS SYSTEM, by K. Putter. Jan. 13, 1954, 41p. incl. illus. diagrs. table, refs. (Technical rept. no. 275) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607) AD 37045 Unclassified

Equipment is described which was designed specifically to aid in the first stages of the analysis of data obtained in electrophysiological experiments with acoustic stimuli. The time-gated amplitude quantizer (TGAQ) automatically quantizes the amplitudes of preselected portions of the signals and makes possible a partial analysis during the course of the experiment. Quantization is achieved by an electromechanical method. The TGAQ is sufficiently flexible to select and quantize signals present at cortical and peripheral locations of the auditory nervous system. The TGAQ may be modified to accept responses to stimuli other than single clicks. The TGAQ model was used in a number of experiments dealing with peripheral responses. A comparison of visual quantization and TGAQ quantization is given.

MICROWAVE MEASUREMENT OF THE VELOCITY DEPENDENCE OF THE COLLISION CROSS SECTION OF SLOW ELECTRONS IN HELIUM (Abstract), by L. Gould. [1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Oct. 22-24, 1953.

Published in Phys. Rev., v. 93: 648, Feb. 1, 1954.

A microwave method previously reported for determining the collision probability for momentum transfer of slow electrons has been modified so that a variation in average electron energy from 0.012 to 3 electron volts may be obtained. Measurements of the ratio of the real to the imaginary part of the complex conductivity, using a null method, are made in the afterglow of a pulsed discharge. The average electron energy is varied by applying a microwave electric field in the afterglow, and, under appropriate assumptions, the average energy is determined theoretically from this field. Measurements from 0.012 to 0.052 electron volt are also obtained by varying the gas temperature from 95°K to 400°K. The value of the collision probability in helium is 18.3 ± 2% from 0 to 0.75 electron volt and increases slowly to a peak value of 19.2 ± 2% at 2.2 electron volts. (Contractor's abstract)

STARK EFFECT IN THE MICROWAVE SPECTRA OF KCl AND NaCl, by P. A. Tate and M. W. P. Strandberg. Feb. 8, 1954 [4]p. incl. diagr. table, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-42607]) AD 44508 Unclassified

Also publtshed in Jour. Chem. Phys., v. 22: 1380-1383, Aug. 1954.

Some further lines in the microwave spectrum of KCl have been observed at frequencies predicted by the rotational constants given by recent molecular beam work. Measurements have been made on the Stark patterns of the $J = 2 \rightarrow 3$, $v = 0$ line of $Na^{23}Cl^{35}$. The dipole moments of these molecules have been determined to be 10.1 ± 0.2 Debye units for KCl and 8.5 ± 0.2 Debye units for NaCl. The KCl value is in fair agreement with the results of molecular beam investigations. (Contractor's abstract)

PHASE STABILIZATION OF MICROWAVE OSCILLATORS, by M. Peter and M. W. P. Strandberg. Feb. 25, 1954, rev. May 6, 1955, 5p. incl. illus. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) AD 102871 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 43: 869-873, July 1955.

A circuit has been developed with which microwave oscillators may be phase-locked to weak but stable reference signals. The circuit was operated with S-band oscillators (707B klystron; 2C37 triode oscillator) and a 2K50 K-band klystron. It is possible to lock a microwave oscillator directly or through a cascade of such circuits to a quartz-stabilized oscillator. The statistical theory of random noise is used to obtain an analysis of the stabilizing effect of the circuit, and the power spectrum of the stabilized microwave source is calculated. The scheme can also be applied in divider operation. Modifications are discussed. A modified circuit that uses carrier-suppressed modulation of the reference signal has also been realized. In another circuit, the oscillator frequency is converted by means of a stable reference, and compared with a second reference that can be of low frequency and tunable. These latter circuits allow elimination of the excess noise introduced by crystal diodes. In the original straight dc circuit this noise cannot be eliminated, but calculation shows that its influence on the output power spectrum is very small. (Contractor's summary)

SYNTHESIS WITHOUT IDEAL TRANSFORMERS, by F. M. Reza. Mar. 3, 1954 [1]p. incl. diagr. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) AD 44501 Unclassified

Also published in Jour. Appl. Phys., v. 25: 807-808, June 1954.

Regarding a synthesis procedure suggested by Bott and Duffin that avoids mutual couplings in the realization of the driving-point impedance functions, it was found that: (a) a direct continuation of the Brune synthesis procedure leads to a result identical with that obtained by Bott and Dufftn; (b) each element of the Bott and Duffin structure (referred to here as a "conversion cycle") can be solely described in terms of the elements of the corresponding Brune cycle and a constant k, which also appears in the same Brune cycle. The conversion cycle contains two remainder functions that are explicit functions of the elements of the same Brune cycle; and (c) it is also possible to find an equivalent structure for the Brune cycle in the form of an unbalanced bridge. This is an improved conversion cycle as it presents one element less per cycle than the original Bott and Duffin structure. This bridge conversion cycle provides a method of avoiding mutual couplings without undergoing much additional computation. Once the Brune synthesis is accomplished, the bridge conversion cycle follows directly.

EQUIVALENT CIRCUIT FOR A PASSIVE NONRECIPROCAL NETWORK, by H. A. Haus. Mar. 25, 1954 [3]p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607] AD 80342 Unclassified

Also published in Jour. Appl. Phys., v. 25: 1500-1502, Dec. 1954.

An equivalent circuit is proposed for a linear, passive, nonreciprocal, four-terminal network. It introduces an ideal amplifier and phase shifter. It is shown that the proposed equivalent circuit has certain advantages over equivalent network representation that use gyrators. In particular, standard measuring techniques used on reciprocal networks lead directly to the determination of six elements of the equivalent circuit. One additional measurement gives the remaining two parameters.

Also published in Proc. Symposium on Information Networks, Polytechnic Inst. of Brooklyn, N. Y., Apr. 12-14, 1954, p. 291-307.

The applicability is demonstrated of modern statistical theory of information to those systems which process data which have been coded into some discontinuous form. Such systems include, among others, communication channels with pulse modulated signals, digital computers and switching control circuits. Particular attention is given to those systems which have a "memory," i.e., systems which may be conditioned so that their present behavior is modified by their past history.

ON WIENER FILTERS AND PREDICTIONS, by Y. W. Lee. 1954 11 p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under [DA 36-039-sc-42607]) AD 76834 Unclassified

Also published in Proc. Symposium on Information Networks, Polytechnic Inst. of Brooklyn, N. Y., Apr. 12-14, 1954, p. 19-29.

The Wiener theory of filtering and prediction is based upon the minimum mean square error criterion. This paper presents the theory under the minimum integral square crosscorrelation error criterion. An interesting point in the new criterion is that it involves the same autocorrelation and crosscorrelation functions as in the original Wiener theory, and no higher order correlations. Another matter under consideration is the generalization of the filter and predictor formulas for the inclusion of certain problems which are more complicated than simple filtering and prediction.

FINE STRUCTURE OF POSITRONIUM (Abstract), by R. Weinstein, M. Deutsch, and S. [C.] Brown. [1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under [DA 36-039-sc-42607]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Columbia U., New York, Jan. 28-30, 1954.

Published in Phys. Rev., v. 94: 758, May 1, 1954.

Experiments on the Zeeman splitting of the 1^3S state of positronium (Phys. Rev., v. 85: 1047, 1952) have been extended, using higher RF power, and improved control of the magnetic field. The reduction of the three quantum annihilation at resonance ranged from 5 to 20 percent and agreed with the theoretically expected quenching within the experimental uncertainty. The width of the resonance at half maximum, ΔH H $\simeq 4 \times 10^{-3}$, agrees with the annihilation width broadened by a doppler effect due to a kinetic energy of the order of 1 ev. The position of the resonance was found to be independent of the nature and pressure of gas in the cavity. He, A, Kr, and CF_2Cl_2 were used at pressures between 1.3 and 4.3 atmospheres. The singlet triplet splitting of the ground state, calculated to order α^2 from the Zeeman splitting, is $\Delta W = 2.03350 \pm 5$ mc, compared with a theoretical value (Phys. Rev., v. 86: 257, 1952) of 2.03370 mc. (Contractor's abstract)

ULTRASONIC MEASUREMENTS IN MAGNETICALLY COOLED LIQUID HELIUM, by C. E. Chase and M. A. Herlin. [May 19, 1954] [2]p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) AD 44504 Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Also published in Phys. Rev., v. 95: 565-566, July 15, 1954.

Measurements were made of the velocity and attenuation of ordinary (first) sound in liquid helium between 0.1°K and 1°K, at 12.1 mc/sec. These temperatures were produced by adiabatic demagnetization of ferric ammonium alum from a starting temperature near 0.9°K, produced by a large oil diffusion pump. Since helium was admitted by an arrangement of concentric thin-walled stainless-steel cones (originated by Dr. J. Ashmead, Mond Laboratory), the demagnetization chamber could be isolated or placed in direct communication with the bath. Warmup times approximating one hour were obtained. The velocity remains essentially constant below 1°K at 240 ± 5 m/sec. Although the inherent difficulty of a fixed path length makes it less accurate than the earlier 239 ± 2 m/sec found above 0.85°K, the value shows that no gross changes occur. The attenuation passes through two clearly resolved maxima slightly below 1°K, falls smoothly toward zero as absolute zero is approached. This agrees qualitatively with Khalatnikov's theory which explains the anomalously high absorption of helium in terms of two relaxation times resulting from elastic interactions of phonons with phonons and of phonons with rotons. MIT. 11:024 - MIT. 11:027

Use of a combination of microwave spectroscopic and molecular beam techniques produces about a six-fold reduction in the Doppler width of a molecular absorption line by utilizing the effect of matter on the electromagnetic radiation. The high resolution of molecular beam experiments afforded by the interaction of the radiation field and the transverse molecular beam is thus made available for microwave spectroscopic use. An exploratory study of the ammonia inversion absorption transition for the rational state J = 3 is reported wherein K = 3 was observed with the microwave radiation propagated transverse to the beam of ammonia molecules. Conventional means were used to detect and display the radiation. Because of the resulting narrow line-width the microwave was swept in saw-tooth fashion only over a region 80 kc/sec wide, centered at about 23870 mc/sec. Figures are included showing the absorption signal of the ammonia inversion lines (J = 3, K = 3) as observed transverse to the ammonia molecular beam. Further development and use of the procedure is discussed.

HYPERFINE STRUCTURE OF I^{127}. NUCLEAR MAGNETIC OCTUPOLE MOMENT, by V. Jaccarino, J. G. King and others. [1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42697]) AD 44505 Unclassified

Also published in Phys. Rev., v. 94: 1798-1799, June 15, 1954.

The hyperfine structure of the atomic $^2P_{3/2}$ ground state of the stable isotope of iodine has been studied by the atomic-beam magnetic-resonance method. Mathematical analysis shows the measured intervals as not fitted by dipole and quadrupole-like interactions alone. A mathematical expression for energy levels is given which includes magnetic dipole, electric quadrupole, and magnetic octupole terms. Matrix elements of the dipole and quadrupole moment operators, nondiagonal with respect to J for a given F, are calculated by use of second-order perturbation theory. With the effects of these perturbations by the neighboring $^2P_{1/2}$ fine-structure level included, the measured zero-field intervals are found to be:

Uncorrected

$F=4 \leftrightarrow F=3$: 4226.172 ± 0.015 mc/sec;
$F=3 \leftrightarrow F=2$: 1965.884 ± 0.010 mc/sec;
$F=2 \leftrightarrow F=1$: 737.492 ± 0.008 mc/sec;

Corrected

$F=4 \leftrightarrow F=3$: 4226.161 ± 0.015 mc/sec,
$F=3 \leftrightarrow F=2$: 1965.895 ± 0.010 mc/sec,
$F=2 \leftrightarrow F=1$: 737.492 ± 0.008 mc/sec.

Experimental values for each of the three intervals were obtained by observing transitions for which $\Delta F = 1$, in the region of zero external magnetic field. The corrected intervals give the following values for the interaction constants:

a = 827.265 ± 0.003 mc/sec,
b = 1146.356 ± 0.010 mc/sec,
c = 0.00245 ± 0.00037 mc/sec (att errors rms). From this vatue of c the nuctear magnetic octupote moment is calculated: $(1/2\ (5_z{}^3-3_{zr}{}^2)\ divM)_{I,I} = +0.3\mu_n \times 10^{-24}$ cm^2. This result is not inconsistent either in magnitude or sign with the expected octupote moment of lodine.

SIMPLIFIED LCAO METHOD FOR THE PERIODIC POTENTIAL PROBLEM, by J. C. Slater and G. F. Koster. [1954] [32]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) Unclassified

Published in Phys. Rev., v. 94: 1498-1529, June 15, 1954.

The LCAO, or Bloch, or tight binding, approximation for solids is discussed as an interpolation method, to be used in connection with more accurate calculations made by the cellular or orthogonalized plane-wave methods. It is proposed that the various integrals be obtained as disposable constants, so that the tight binding method will agree with accurate calculations at symmetry points in the Brillouin zone for which these calculations have been made, and that the LCAO method then be used for making calculations throughout the Brillouin zone. A general discussion of the method is given, including tables of matrix components of energy for simpte cubic, face-centered and body-centered cubic, and diamond structures. Applications are given to the results of Fletcher and Wohlfarth on Ni, and Itowarth on Cu, as illustrations of the fcc case. In discussing the bcc case, the splitting of the energy bands in chromium by an antiferromagnetic alternating potential is worked out, as well as a distribution of energy states for the case of no antiferromagnetism. For diamond, comparisons are made with the calculation of Herman, using the orthogonalized plane-wave method. The case of such crystals as InSb is discussed, and it is shown that their properties fit in with the energy band picture. (Contractor's abstract)

CONDUCTION ELECTRON SPIN RESONANCE ABSORPTION IN SODIUM (Abstract), by I. H. Solt, Jr. and M. W. P. Strandberg. [1954] [1]p. (Sponsored jointly by Signat Corps, Office of Navat Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, and May 1, 1954.

Published in Phys. Rev., v. 95: 607, July 15, 1954.

In order to understand more ctearly the uegree of spin-orhit coupling experienced by the conduction electrons in metals, an accurate measurement has been made of the g value of the spin resonance absorption in sodium. Colloidal suspensions of sodium particles (less than 4 microns in size), ultrasonically dispersed in paraffin wax, were tnvestigated at 9000 mc/sec. The measured g values are g = 2.0012 ± 0.0002 at 300°K and 78°K, and g = 2.0014 ± 0.0002 at 4°K. These values disagree outside the range of experimental error with the value of 2.0019 calculated by Yafet (Phys. Rev., v. 85: 478, 1952). Line-shaped and line-width measurements were also made. The observed line shape was asymmetric and could be explained as the sum of the reat and imaginary parts of the susceptibility where the tmaginary part had a Lorentz shape. The line width at the half power points of the imaginary part of the susceptibility was 11.5 gauss at room temperature and decreased linearly with temperature. This corresponds to a relaxation time of about 5 x 10^{-9} sec at room temperature. (Contractor's abstract)

EFFECTS OF THE DEVIATION OF O_2 FROM HUND (b) (Abstract), by M. W. P. Strandberg and M. Tinkham. [1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) Unclassified

Presented al meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, and May 1, 1954.

Published in Phys. Rev., v. 95: 623, July 15, 1954.

The rotational Hamiltonian of the oxygen molecule, including lhe spin-spin interaction, is not exactly diagonal in the Hund (b) representation (J^2, J_z, K^2, S^2) where $J = K + S$. Hence K is not a good quantum number, and three poinls should be made. First, the intensities of the oxygen spin triplel spectrum at 5 mm are not exact as given by Van Vleck. He has used the matrix elemenls of S_z in the Hund (b) represenlation rather than in lhe representation which diagonalizes the Hamiltonian. Thus inference of the breadths of the oxygen lines from the observed pressure and intensity, using the Van Vleck formulas, is only approximate. Exact calculation shows that such a procedure will overestimate the actual line width for low K lransitions. Second, lines "forbidden" under the previous analysis now become allowed. For example, the three lowest frequency lines corresponding to changes in $K = 1 \rightarrow 3$ are predicted to be al 368,522 mc/sec, 424,787 mc/sec, and 487,274 mc/sec, wilh intensities respectively of $0.64 \times 10^{-6} cm^{-1}$, and 10^{-6} cm^{-1}, assuming the same $\Delta\nu$ as the 5-mm lines. Third, the weak field Zeeman splitlings will not exactly follow the simple vector model predictions for Hund (b). (Contractor's abstract)

THE INFLUENCE OF COVALENCE ON ION ORDERING AND DISTORTION IN SPINELS, I (Abstract), by A. L. Loeb and J. B. Goodenough. [1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, and May 1, 1954.

Published in Phys. Rev., v. 95: 616, July 15, 1954.

In previous attempts to explain the catio[n] distribution in spinel lattices on the basis of elastic and electrostatic energies, covalence was resorted to in order to account for the preference of certain cations for tetrahedral sites. A later treatment, based on the perturbation of d shells by a crystalline field due to surrounding ions, is limited by the assumption of ionic lattice elements. A mechanism based on covalent bonding due to overlap of hybrid orbitals is proposed here to predict the cation distribution and related properties of spinels. Cations in tetrahedral sites usually bond through tetrahedral sp^3 orbitals; in octahedral sites cations are bound ionically, or covalently through either octahedral d^2sp^3 or planar dsp^2 bonds. In the last case the cation is bound covalently to four oxygen ions at the corners of a square, and ionically to two oxygen ions on an axis normal to the square, so that tetragonal distortion of the lattice results. Covalence decreases the electrostatic and modifies the elastic energies. A covalence exchange mechanism is proposed for the indirect interaction between incomplete d shells. (Contractor's abstract)

Presented al meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, and May 1, 1954.

Published in Phys. Rev., v. 95: 599, July 15, 1954.

A series of sludies has been made on powdered electroluminescent phosphors. The phosphors which were of the ZnS:Cu:Pb blue-green type were excited by sharp pulse of current of the order of a microsecond in duration. The pulse of light which followed each current pulse was detected by a photomultiplier after passing through a monochromator. The decay of the light intensity was recorded for several thousand microseconds and was thus observed during a period when the plate was not being excited. The decay rate depended on the wavelength of the light, but in all cases the light fell off much slower than either a linear or bimolecular process would predict. A second current pulse applied in the same direction before the light has ceased completely results in a momentary decrease in output. This suggests that, before emission occurs, electrons must diffuse back to the emission centers from which they have been pulled by the original electric field. Irradiating the phosphor with infrared has marked effects upon its light output and this will be discussed. (Contractor's abstract)

MICROWAVE SPECTRUM OF OCS (Abstract), by M. Peter and M. W. P. Strandberg. [1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research,

and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, and May 1, 1954.

Published in Phys. Rev., v. 95: 622, July 15, 1954.

The $J = 1 \rightarrow J = 2$ transition of OCS has been studied with a microwave spectroscope designed for high sensitivity and high resolution. The line $v_3 = 1$ has been found at 0.85 ± 0.1 mc/sec above the $v_1 = 2$ line. This is the frequency predicted with the α_3 value determined from infrared spectra by Thompson, and agrees with his value within his limits of error. Several quadrupole components of OCS_{33} in the states $v_1 = 1$; $v_2 = 1$; $l = \pm 1$; and $v_2 = 2$ have also been measured and analyzed. (Contractor's abstract)

Published in Phys. Rev., v. 95: 607, July 15, 1954.

A study has been made of the paramagnetic resonance absorption in diluted single crystals of ammonium chrome alum at room temperature. Work was done at X, S, and K band and at various orientations of the crystal. These data have been checked with the theoretical predictions of line intensity and position (based on the assumption that the chromium ion is in an electric field of trigonal symmetry). Paramagnetic resonance spectra of single ammonium chrome alum crystals at 77°K have been studied in an attempt to explain the anomalous two splittings of the ground state. (Contractor's abstract)

THE PHENOMENA OF PLASMA RESONANCE (Abstract), by K. S. W. Champion and S. C. Brown. [1954] 1 p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, and May 1, 1954.

Published in Phys. Rev., v. 95: 634, July 15, 1954.

Plasma resonance is associated with the transmission of externally applied high-frequency electromagnetic waves through a plasma. Two types of resonance will be discussed. The first impedance resonance, occurs when the E field at a point has a relative maximum. The second, dielectric resonance, occurs when the dielectric constant is zero at the point considered. Impedance resonance occurs when $ne^2/m\varepsilon_0\omega^2 = 1$ and dielectric resonance when $ne^2/m\varepsilon_0(v_c^2 + \omega^2) = 1$, where n represents the electron density and v_c the electron collision frequency. At low pressures, when $v_c^2 << \omega^2$, the two types of resonance coincide, but they differ at high pressures. Impedance resonance corresponds to greatest ionization and excitation rates. Above dielectric resonance the transmitted electromagnetic waves are strongly attenuated and there is a reflected wave. A special tunable 100 mc/sec resonance cavity was designed so that discharges above plasma resonance could be produced in relatively large volumes. Discharges were obtained which, under the appropriate conditions, exhibited the properties of impedance and dielectric resonance. (Contractor's abstract)

SELECTION RULES IN THE MICROWAVE MAGNETIC RESONANCE SPECTRUM OF OXYGEN (Abstract), by M. Tinkham and M. W. P. Strandberg. [1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, and May 1, 1954.

Published in Phys. Rev., v. 95: 622-623, July 15, 1954. 1954.

The X band paramagnetic resonance spectrum of molecular oxygen consists of about 120 lines of observable intensity for magnetic fields below 12 kilogauss. Forty of these lines have been identified by rather tedious calculations. To aid in identifying the others, a circularly polarized radiation field in the cavity containing the sample gas has been used. This field is provided by exciting the two degenerate orthogonal TE_{111} modes in a cylindrical cavity 90° out of phase. This field configuration gives pure circularly polarized radiation only along the axis. Averaging H^2 over the cavity, 52% is circular in one sense, 4% is circular in the other sense, and 44% is axial. Comparison of the two observed spectra with the two senses of rotation unambiguously separates $\Delta M = \pm 1, 0$ transitions. The results are that approximately 95 lines have $\Delta M = +1$, the rest have $\Delta M = -1$. The absence of $\Delta M = 0$ lines

is consistent with detailed calculations which show that their intensities should be down by a factor of at least 100. Another result of the identification is that about two-thirds of the lines observed have the "forbidden" $\Delta J = \pm 2$. They are allowed here because J is not a good quantum number in the presence of the magnetic perturbation. (Contractor's abstract)

SYNAPTIC TRANSMISSION, by W. S. McCulloch, P. D. Wall and others. Progress rept. for 1953-1954. Aug. 4, 1954, 33p. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) AD 40853 Unclassified

Studies were undertaken to determine if the known properties of peripheral nerve are sufficient to account for some phases of synaptic transmission under the geometrical conditions known to exist. A cat was anesthetized with Dial-Urethane (0.6 cc/kg IP) a tracheal cannula was installed, and artificial respiration was established. The spinal cord was transected at the first cervical vertebra. Heating lamps which were controlled by a subscapular thermistor maintained the body temperature at 38° ± 0.1°C. The lumbar enlargement was exposed and covered with mineral oil which was aerated with 95% O and 5% CO_2. The fifth and sixth dorsal roots on one side were severed about 8 cm from the cord and placed on bipolar electrodes for test and conditioning stimulation, respectively. Supramaximal shocks of 0.1-msec duration were delivered every 2 sec through isolating transformers. Records of potentials throughout the transverse plane in the ipsilateral half of the spinal cord a few mm rostral to the fifth lumbar were obtained through microelectrodes (10-μ Pt wire) which were coated with a thin layer of glass and sharpened. About 1500 recordings were obtained. The existence of a conditioned block in primary afferent fibers within the cord was shown by (1) source-sink maps within the cord and (2) direct records of conducted volleys in the thoracic dorsal columns. A new method which was devised for tracing the anatomical course of axons up to their terminals involved local antidromic stimulation of the collaterals. This antidromic stimulation was used to measure the threshold change of collaterals caused by activity in the collaterals or neighboring fibers.

MICROWAVE DETERMINATION OF THE PROBABILITY OF COLLISION OF ELECTRONS IN HELIUM, by L. Gould and S. C. Brown. [1954] [7]p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) AD 44502 Unclassified

Also published in Phys. Rev., v. 95: 897-903, Aug. 15, 1954.

A previously reported microwave method for determining the collision probability for momentum transfer of slow electrons has been modified so that a variation in average electron energy from 0.012 ev to 3 ev may be obtained. Measurements of the ratio of the real part to the imaginary part of the electron conductivity are performed in the afterglow of a pulsed helium discharge in a microwave resonant cavity. The average electron energy is varied by applying a microwave electric field in the afterglow and, under appropriate assumptions, the average electron energy is determined theoretically from this field. Measurements are also obtained by varying the gas temperature from 77°K to 700°K. The value of the collision probability for momentum transfer in helium is 18.3 ± 2% cm^2/cm^3 per mm Hg from 0 to 0.75 electron volts and increases slowly to a peak value of 19.2 ± 2% at 2.2 ev.

WAVE FUNCTIONS FOR IMPURITY LEVELS, by G. F. Koster and J. C. Slater. [1954] [10]p. incl. diagrs. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-42607] Unclassified

Published in Phys. Rev., v. 95: 1167-1176, Sept. 1, 1954.

The calculation of impurity levels in crystals is set up in terms of a linear combination of Wannier functions. The coefficients of this linear combination are shown to satisfy a set of difference equations. These difference equations are solved for two simple linear chain impurity problems. The difficulties encountered in solving the difference equations are explored on the basis of these examples and a general method of solving difference equations arising from impurity calculations is presented. This method seems to have advantages over previous methods of solving the impurity problem in crystals. (Contractor's abstract)

NOISE IN ONE-DIMENSIONAL ELECTRON BEAMS, by H. A. Haus. Sept. 9, 1954 [12]p. incl. diagrs. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-[42607]) AD 96415 Unclassified

Also published in Jour. Appl. Phys., v. 26: 560-571, May 1955.

A generalized theory of noise in one-dimensional electron beams is developed with the aid of the theory of four-terminal networks. No specific assumptions are made as to the input noise velocity and current modulations and their correlation at the potential minimum. The ensuing theory is simpler and more general than the corresponding theories used in the past. Transformations are discussed of the standing wave of the meansquare noise current in drift regions by means of "lossless beam transducers." It is shown that such transformations can be reduced to the formalism of conventional impedance transformations. Expressions are derived for the minimum obtainable noise figures of a velocity-jump amplifier, a klystron, and a traveling wave tube. It is proved that these expressions present an ultimate limit for the noise figures of the respective tubes with regard to transformations by beam transducers with and without loss. THEORY OF SCATTERING IN SOLIDS, by G. F. Koster. [1954] [8]p. incl. diagr. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) Unclassified

Published in Phys. Rev., v. 95: 1436-1443, Sept. 15, 1954.

The scattering of an electron by an imperfection in a lattice is set up in terms of a linear combination of the Wannier functions associated with the lattice. The difference equations which the coefficients of the Wannier functions satisfy are discussed in the light of simple examples. A Green's function formulation of the difference equations is then introduced which leads to the proper asymptotic behavior of the scattered wave. This approach avoids many of the unwarranted assumptions usually made in the discussion of scattering in solids.

TRANSATLANTIC FREQUENCY-MODULATION EXPERIMENTS, by L. B. Arguimbau, J. Granlund and others. Sept. 20, 1954, 49p. incl. illus. (Technical rept. no. 278) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607) AD 54506 Unclassified

This report describes a series of three transatlantic frequency-modulation experiments that were conducted in 1950, 1951, and 1953. The purpose of the first test was to investigate the possibility of establishing a radio link of local broadcast quality over an ionospheric path by using a special frequency-modulation receiver particularly designed to combat two-signal and two-path interference. The desired audio-quality was not achieved in this test. An attempt was made in the second test to improve the quality of the received program by using a type of nonlinear filter; in the third, by using a highly directive antenna; but even with the aid of these devices, broadcast quality was not achieved. The failure of the frequency-modulation system is explained in terms of the complexity of the ionospheric path. This complexity is illustrated in a series of pictures of patterns received during pulsed-carrier transmissions. A system called frequency-shift modulation, which should be capable of providing high-quality transmission through a dispersive medium, such as the ionosphere, is described in the appendix. Also published in I. R. E. Trans. of Professional Group on Information Theory, PGIT-4: 29-37, Sept. 1954.

MIT. 11:046 - MIT. 11:048

Some simple constructive procedures are given for coding sequences of symbols to be transmitted over noisy channels. A message encoded by such a process transmits a positive amount of information over the channel, with an error probability which the receiver may set to be as small as it pleases, without consulting the transmitter. The amount of information transmitted is less than the channel capacity, so the procedures are not ideal, but they are quite efficient for small error probabilities. It is shown that there exist codes of the same error-free character which transmit information at rates arbitrarily near the channel capacity. (Contractor's abstract)

PRINTED MICROWAVE SYSTEMS, by M. Schetzen. Sept. 30, 1954, 39p. incl. diagrs. tables, refs. (Technical rept. no. 289) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607)
AD 66376 Unclassified

The results of a theoretical and experimental investigation of the free modes that propagate on the strip transmission line are reported. A Fourier integral solution is obtained for the free modes. Since the integrals must be solved by numerical methods, approximate equations for the phase velocity, attenuation, and the characteristic impedance are developed for the "two-conductor" H-E mode. It is shown that a static assumption for the H-E mode is good only as a first approximation. In the course of the discussion, it is proved that the only free modes that may exist on any n-conductor system of arbitrary but constant cross section in homogenous and simply connected space are TEM modes. Previously known methods for the determination of the guide wavelength and attenuation required that the standing waves of the strip transmission line be known. It was found that these could not be measured directly. Since precedent measuring methods were found to be inadequate, a new simple method for measuring the attenuation of any transmission line through a junction is presented. (Contractor's abstract)

THEORY OF THE INTERACTION OF HINDERED INTERNAL ROTATION WITH OVER-ALL ROTATIONS. I. SYMMETRIC ROTORS: METHYL SILANE, by D. Kivelson. Oct. 1954 7 p. incl. diagr. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607.) Unclassified

Published in Jour. Chem. Phys., v. 22: 1733-1739. Oct. 1954.

An approximate theory of the interactions of hindered internal rotation with over-all rotations of symmetric rotors is given. This treatment considers the interdependence of hindered internal rotation and vibrations and their effect upon the rotational energy levels. The resulting expression for the frequencies of $\Delta K = 0$, $\Delta J = 1$ transitions is:
$\nu = 2J[B_v + F_v(m|1-\cos 3\theta|m) + G_v(m|\Pi_z^2|m) + L_v K(m|\Pi_z|m)]$, where B_v, F_v, G_v, and L_v are constants independent of the rotational quantum numbers, m represents the basis that diagonalizes the Hamiltonian corresponding to pure internal rotation, Π_z is the internal angular momentum operator, and θ is the angle of internal rotation. Procedures for evaluating $(m|1-\cos 3\theta|m)$ and $(m|\Pi_z^n|m)$ in terms of a parameter α are given. This theory has been applied to the $J = 0 \rightarrow 1$ transitions of methyl silane. The parameters B_v, F_v, G_v, and α were obtained empirically and were then used to calculate frequencies. The agreement between observed and calculated values was quite good. Furthermore, the anomalous ordering of the lines observed by Lide and Coles is explained by these calculations. Assuming a cosine potential, the barrier height V_0 is proportional to the parameter α. The value of V_0 was set at 558 cm^{-1} + 17 cm^{-1}. The constant B_v, which is the rotational constant in the ground torsional state for the limiting case of $V_0 = 0$, is 10985.79 mc/sec and 9636.50 mc/sec for CH_3SiH_3 and CH_3SiD_3, respectively. HELICAL COUPLING SYSTEM, by A. J. Lichtenberg. Oct. 6, 1954, 27p. incl. diagrs. table, refs. (Technical rept. no. 290) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607)
AD 63865 Unclassified

A theory of power coupling between concentric, contrawound sheath helices has been presented by Kompfner and further amplified by Wade. In Section I of this report a modification of this theory is presented in the light of experimental results, in order to give a more accurate picture of the conditions for complete power transfer from one helix to the other. From the assumption of a sheath helix in free space, a beat wavelength is determined. Correction factors are applied to this result to account for the fact that an actual wire helix is used, and to account for the presence of an environment other than free space. The validity of these correction factors is examined by comparison with experimental results. In Section II the problem of matching a helix to a coaxial line is investigated. A procedure is developed by which the impedance of a helix within a shield may be matched to a coaxial line. With these data and the material developed in Section I, a complete coupling, capable of use on a traveling-wave tube or backward-wave

oscillator, is designed and tested. (Contractor's abstract)

EXCITATION OF CIRCULAR POLARIZATION IN MICROWAVE CAVITIES, by M. Tinkham and M. W. P. Strandberg. Oct. 28, 1954, rev. Jan. 21, 1955 [5]p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) AD 76341 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 43: 734-738, June 1955.

The usefulness of exciting a single circulatory-polarized mode in a microwave cavity is indicated. A matrix method is presented then for the analysis of the operation of various components, such as transition pieces and differential phase shifters on waves propagating in waveguides with two degnerate orthogonal modes. This method is applied to describe three distinct systems for generating the desired circular polarization in a cavity that is coupled directly to the side wall of a waveguide. The final system, which involves a minimum of critical adjustments, is described in more detail and its performance is indicated. It is shown that purely circular radiation can be set up along the axis of the cavity. However, the largest preponderance of one rotating mode over the other which can be set up, if one averages over the entire cavity volume, is 11.5 to 1. This value is obtained with the TE_{11_n} modes. (Contractor's summary)

LIMITATIONS ON THE NOISE FIGURE OF MICROWAVE AMPLIFIERS OF THE BEAM TYPE (Abstract), by H. A. Haus. [Nov. 1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607) Unclassified

Presented at joint meeting of I. R. E. Professional Group on Electron Devices and Working Group on Microwave Tubes, Symposium on Fluctuation Phenomena in Microwave Sources, New York, Nov. 18-19, 1954.

Published in I. R. E. Trans. of Professional Group on Electron Devices, v. ED-1: 238-257, Dec. 1954.

An analysis based on one-dimensional, single-velocity assumptions leads to the result that all microwave amplifiers of the beam type (such as traveling-wave tubes, velocity jump amplifiers, klystrons, and the like) have a minimum obtainable noise figure of the form

$$F_{min} = 1 + \frac{2\pi}{kT} K(S_o - \pi_o) \quad (1)$$

where S_o and π_o are parameters of the beam noise e expressed in terms of the noise fluctuations at a cross section slightly beyond the potential minimum in the electron gun, T is the temperature of the circuit, and K is a constant of the particular structure employed. Expression (1) holds for any optimized noise-reducing scheme. It includes, for instance, a prehelix that is excited by the noise in the beam and feeds into the main helix of a traveling-wave tube in an attempt to cancel part of the noise in the beam. The dependence of the constant K upon the particular structures used will be discussed. (Contractor's abstract)

Published in I. R. E. Trans. of Professional Group on Electron Devices, v. ED-1: 168-183, Dec. 1954 (Title varies).

Measurements of microwave noise have been made on electron beams formed by several different guns. They include parallel beam guns with cathode emersed in the magnetic field and converging flow guns with cathode outside the magnetic field. In general, two regions of behavior have been noted: one in which the noise current density varies sinusoidally with distance; one in which the noise current increases rapidly with distance. The latter behavior has been called the growing noise wave. The way in which these two different noise regimes respond to various parameters will be described. (Contractor's abstract)

OPTICAL STUDIES OF RADIOACTIVE MERCURY, by F. Bitter, S. P. Davis and others. [1954] [9]p. incl. illus. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, [Air Force Office of Scientific Research, and Atomic Energy Commission under [DA 36-039-sc-42607]) Unclassified

Published in Phys. Rev., v. 96: 1531-1539, Dec. 15, 1954.

A technique has been developed for studying the hyperfine structure of the resonance radiation of mercury. A single Zeeman component of the 2536A line of Hg^{198} is used as a variable-frequency monochromatic light source, and the field strength applied to the arc lamp to produce resonance absorption in a resonance lamp as a measure of the resonance frequency. Natural mercury, and radioactive mercury produced by bombarding gold with 15-mev deuterons were investigated in this way and also (by means of an echelle spectrograph) in the emission spectrum of an electrodeless discharge. Several observed lines have not been conclusively identified. The magnetic moment of Hg^{197} is 4 percent greater than that of Hg^{199}. The isotope shift of isotopes with even mass number decreases with decreasing mass number. This effect may be due in part to the increasing quadrupole moment with neutron deficiency in these isotopes. (Contractor's abstract)

AN APPROXIMATION METHOD WITH RATIONAL FUNCTIONS, by N. DeClaris. Dec. 30, 1954, 27p. incl. diagrs. refs. (Technical rept. no. 287) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607) AD 63864 Unclassified

A general method is developed for finding functions of a single complex variable s, which approximates an assigned network characteristic, within the special class of functions realizable as networks of linear lumped parameter elements. The method is based upon an interpolation technique with a series of general rational functions on the unit circle of the z-plane. A number of transformations that map the interval of interest of the s-plane into the unit circle of the z-plane are discussed. A great advantage of this method is that it allows one to preassign the pole location of the desired rational function anywhere in the left-half of the s-plane. Following a formal mathematical treatment, procedures are outlined for three cases of approximation in both the frequency and the time domain. A number of examples illustrate the wide range of applicability.

The Dynamic Analysis and Control Lab. (D. A. C. L.) at M. I. T. demonstrated another usefulness of simulation techniques by applying the D. A. C. L. Generalized Computer to a problem in electron optics. Standard D. A. C. L. analogue computing components were employed, together with an electrolytic tank, to

generate electron trajectories directly at speeds of the order of 1 in./sec. With minor setup changes, the same equipment was used to map the electrostatic field in the tank.

STUDIES ON THE NATURE OF REFLEX INHIBITION PRODUCED BY THE INTERACTION OF VOLLEYS RUNNING IN NEIGHBORING DORSAL ROOTS, by B. Howland, J. Y. Lettvin and others. [Jan. 1954] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607; and in part by the Bell Telephone Labs., Inc. and the Teagle Foundation) Unclassified

Published in Jour. Neurophysiol., v. 18: 1-17, Jan. 1955.

Dorsal roots L_6 and L_5 were stimulated in such a way that a volley in one inhibited the motor response to a volley in the other. With multiple microelectrode placements, the potential changes were measured and the current distribution calculated in a cross section of the cord traversed by these dorsal root fibers. This enabled the intramedullary course of afferent impulses to be followed. It was shown that, after stimulus of L_6, test volleys in L_5 failed to invade collaterals of the primary axons. It is concluded that one type of inhibition involves blocking afferent nerve impulses before they have reached the region of cells. (Contractor's abstract)

TWO BITS WORTH OF INFORMATION THEORY (Abstract), by R. M. Fano. [Jan. 1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039 sc 42607) Unclassified

Presented to the AIEE Technical Group on Communication (Boston Section), Boston, Mass., Jan. 4, 1955.

The process of communication plays a predominant role in most human activities. Information theory has provided a new and powerful way of analyzing communication problems such as those that arise in the study of languages, hearing, and vision, as well as those arising in the design of electrical communication systems. After a brief presentation of the basic concepts of information theory, a number of illustrative examples selected from recent research in various fields will be discussed. (Contractor's abstract)

HIGH-FREQUENCY GAS DISCHARGE PLASMA IN HYDROGEN, by D. J. Rose and S. C. Brown. [Jan. 13, 1955] [7]p. incl. diagrs. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) AD 106988 Unclassified

Also published in Phys. Rev., v. 98: 310-316, Apr. 15, 1955.

The high-frequency electric field required to maintain a hydrogen plasma has been measured as a function of pressure and plasma electron density. A theory of the plasma based on a solution of the Boltzmann transport equation has been developed to predict this field; it agrees satisfactorily with experiment. The theory has no adjustable parameters, and uses only the probabilities of collision, excitation, and ionization of the gas by electrons, and the ionic mobility. (Contractor's abstract)

VELOCITY ANALYSIS OF THERMIONIC EMISSION FROM SINGLE-CRYSTAL TUNGSTEN, by A. R. Hutson. Jan. 13, 1955 [13]p. incl. illus. tables, refs. (Technical rept. no. 260) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607) AD 68083 Unclassified

Also published in Phys. Rev., v. 98: 889-901, May 15, 1955.

A 180° magnetic velocity analyzer tube has been used to observe the energy distributions of the thermionic emission from various crystallographic directions of a single-crystal tungsten filament. The distributions were the same in all of the directions and were not Maxwellian. An energy-dependent reflection coefficient for the tungsten surface, previously proposed by Nottingham, is capable of explaining the shape of the distributions quite well. The tube permitted measurements of the differences between the true work-functions of the various directions. The changes of true work functions with temperature between 1700°K and 2000°K were also measured for all directions except the (110). The non-Maxwellian character of the energy distributions and the temperature variations of the work functions can largely explain the discrepancy between the emission constant, A 120, of Richardson's equation and the Richardson plot emission constants obtained for the various directions of a tungsten crystal by Nichols and by Smith. THEORY OF HYPERFINE STRUCTURE I, by C. Schwartz. [1955] [16]p. incl. diagrs. table, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-42607]) Unclassified

Published in Phys. Rev., v. 97: 380-395, Jan. 15, 1955.

Considering the classical electric and magnetic interactions between atomic electrons and the nucleus, a representation is arrived at of the hyperfine interactions in terms of a multipole expansion of the field potentials. Treating these noncentral interactions in first order perturbation theory, the form can be given of the general interval structure and analyzed for the multipole interaction constants using Racah coefficients. Pertinent matrix elements for a single valence electron are calculated relativistically. Some second order terms of the dipole and quadrupole interactions are calculated as they affect the interpretation of the first order octupole interaction. Also, the effect of some electronic configuration interactions is quantitatively considered. Finally the value of nuclear magnetic octupole moments expected according to different models are calculated and compared with the experimental data thus far collected. Generally the measured octupole moments are in as good agreement with the values predicted by the single-particle shell model as are the corresponding dipole moments. (Contractor's abstract)

TIME-DOMAIN COMPENSATION FOR CLOSED-LOOP SYSTEMS BY A DELAY LINE METHOD, by Y.-C. Ho. Jun. 17, 1955. 33p. incl. illus. diagrs. tables, refs. (Technical rept. no. 288) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607) AD 85767 Unclassified

This report presents a new approach to the synthesis and analysis of closed-loop systems in the time domain. In general, it investigates the effect of the discrete filter

$$D(s) = \sum_{k=0}^{n} a_k e^{-skT} = a_0 + a_1 e^{-sT} + \ldots + a_n e^{-snT}$$

in compensating for feedback systems, and its resultant transient response. First the generality, simplicity, and flexibility of the discrete filter are demonstrated. The properties of D(s) when cascaded with other elements are then studied in both the time and the frequency domain. The procedure for designing D(s) to compensate a given system is carried out entirely in the time domain. It is based on the "reshaping of the open-loop impulse response of the system." Saturation and other constraints can be taken into account during the determination of D(s). The procedure is iterative and is carried out graphically in terms of the time functions involved; it is simple, effective, and down-to-earth. The basis of this method is analyzed in terms of servo and network theory. Several methods are presented for calculating the closed-loop response of the compensated system. A specific example is designed according to the procedure and its transient response calculated. The results agree well with similar ones obtained by computer simulation. An actual experimental servo system was designed on this basis. The realization of a practical D(s) for servo systems is discussed; several methods of doing this are presented. The performance of the experimental system further verifies the validity of this approach. (Contractor's abstract)

THEORY OF THE FINE STRUCTURE OF THE MOLECULAR OXYGEN GROUND STATE AND THE MEASUREMENT OF ITS PARAMAGNETIC SPECTRUM, by M. Tinkham and M. W. P. Strandberg. Feb. 1, 1955 [30]p. incl. diagrs. tables, refs. (Technical rept. no. 281) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-42607; continued by DA 36-039-sc-64637) AD 63863 Unclassified

Also published in Phys. Rev., v. 97: 937-966, Feb. 15, 1955.

Part I. Theory of the Fine Structure of the Molecular Oxygen Ground State: A rather complete solution for the fine-structure problem in the oxygen molecule is given in the framework of the Born-Oppenheimer approximation. The reduction of the effect of the electronic state on the fine structure to an effective Hamiltonian, involving only the resultant electronic spin in addition to rotational and vibrational quantum numbers, is demonstrated. In this Hamiltonian the parameters λ and α measure the effective coupling of the spin to the figure axis and the rotational angular momentum, respectively. The contributions to these parameters which are diagonal in electronic quantum numbers, namely λ^{-1} and α^{-1}, are evaluated by using an expression for the electronic wave function as a superposition of configurations. The second-order contributions of spin-orbit coupling and rotation-induced electronic angular momentum to λ and α, and the electronic contribution to the effective moment of inertia are related to each other. This interrelation enables them all to be essentially evaluated experimentally. Part II. Interaction of Molecular Oxygen with a Magnetic Field: The dominant interaction of O_2 with a magnetic field is through the electronic spin magnetic moment. However, a precise comparison with experiment of the results of calculating the microwave paramagnetic spectrum, assuming only this interaction,

shows a systematic discrepancy. This discrepancy is removed by introducing two corrections. The larger is a correction for the second-order electronic orbital moment coupled in by the spin-orbit energy. The smaller is a correction for the rotation-induced magnetic moment of the molecule. Since the dependence of this contribution on quantum numbers is quite unique, this coefficient can also be determined by fitting the magnetic spectrum. A new result is the rotational magnetic moment of -0.25 ± 0.05 nuclear magnetrons per quantum of rotation. Knowledge of this moment allows the electronic contribution to the effective moment of inertia to be determined. Theoretical intensities of a number of the microwave transitions are calculated and successfully compared with experiment over a range of 100 to 1 in magnitude. (Contractor's abstract, modified)

CAVITIES AND WAVEGUIDES WITH INHOMOGENEOUS AND ANISOTROPIC MEDIA, by A. D. Berk. Feb. 11, 1955. 58p. incl. diagrs. (Technical rept. no. 284) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) AD 107541 Unclassified

With the advent of ferrites at microwave frequencies, the treatment of electromagnetic boundary-value problems involving anisotropic substances has become more than an academic exercise. Since exact methods of analysis often encounter formidable mathematical difficulties, it is necessary to resort to approximate calculations. Two such methods are developed. The first one is based on a mode-expansion analysis, the second on variational calculations. The former is applied to the determination of resonant frequencies and impedance matrices of cavities and to the determination of propagation constants of waveguides. The variational method is utilized in obtaining approximate expressions for resonant frequencies of cavities and for cut-off frequencies and propagation constants of waveguides. Several examples with emphasis on microwave components containing ferrites are worked out. The results indicate that it is often possible to obtain approximate, yet sufficiently accurate, solutions of problems of which the exact solutions are extremely difficult. The interesting problems of the completeness of a set of cavity modes is briefly treated in Appendix I. Several points of view are reviewed and reconciled with some modification. It appears that Slater's treatment of "empty" cavities is, for all practical purposes, complete. (Contractor's abstract)

The nature of the spin coupling in MnO is discussed, the details of the discussion being based on a very simplified three-center system. The coupling between magnetic ions whose charge densities interact with an intervening nonmagnetic ion but not directly with each other is described as the result of the polarization of

MIT. 12:005 - MIT. 12:006

the nonmagnetic ion. The configuration interaction representation of this polarization is treated by non-orthogonal orbitals, orthogonal orbitals, and by Kramers' method. These three approaches are applied to a numerical example. It is concluded that a reliable description of the simple three-center problem is more complicated than generally believed due to the importance of highly excited states of the system which have been neglected in previous treatments of the problem. INTERACTION OF MOLECULAR OXYGEN WITH A MAGNETIC FIELD, by M. Tinkham and M. W. P. Strandberg. [1955] [16]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Published in Phys. Rev., v. 97: 951-936, Feb. 15, 1955.

The dominant interaction of O_2 with a magnetic field is through the electronic spin magnetic moment. However, a precise comparison with experiment of the results of calculating the micro-wave paramagnetic spectrum, assuming only this interaction, shows a systematic discrepancy. This discrepancy is removed by introducing two corrections. The larger (~0.1 percent, or 7 gauss) is a correction for the second-order electronic orbital moment coupled in by the spin-orbit energy. Its magnitude is proportional to the second-order term μ'' in the spin-rotation coupling constant. The smaller (~1 gauss) is a correction for the rotation-induced magnetic moment of the molecule. Since the dependence of this contribution on quantum numbers is quite unique, this coefficient can also be determined by fitting the magnetic spectrum. A total of 120 X-band and 78 S-band lines were observed. The complete corrections have been made on 26 lines with a mean residual error of roughly 0.5 mc/sec. This excellent agreement confirms the anomalous electronic moment to 60 parts per million (ppm) and also confirms the validity of the Zeeman effect theory. A new result is the rotational magnetic moment of -0.25 ± 0.05 nuclear magnetons per quantum of rotation. Knowledge of this moment allows the electronic contribution to the effective moment of inertia to be determined. Making this correction of 65 ppm, and using the latest fitting of the universal atomic constants, the equilibrium internuclear distance is recomputed to be R_e = 1.2074 ± 0.00002 A. It is deduced that the magnitude of γ'', the second-order spin-orbit contribution to the coupling of the spin to the figure axis, is 465 ± 50 mc/sec, or less than one per cent of the total coupling constant γ. Theoretical intensities of a number of the microwave transitions are calculated and successfully compared with experiment over a range of 100 to 1 in magnitude. It turns out that $\Delta M = 0$ transitions are over a hundred times weaker than the $\Delta M = \pm 1$ transitions and thus are too weak to observe. Also, J breaks down as a quantum number in the presence of a magnetic field. This allows $\Delta J = \pm 2$ transitions to comprise roughly half of all lines observed. (Contractor's abstract)

AN ATOMIC FREQUENCY STANDARD (Abstract), by J. R. Zacharias, J. G. Yates, and R. D. Haun, Jr. [Mar. 1955] [2]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at the I. R. E. National Convention, New York, Mar. 21-24, 1955.

The hyperfine-structure resonance line of atomic cesium at approximately 9192.632 mc/sec has been used to stabilize the frequency of a microwave signal generator. This resonance frequency, describable as the Larmor precession frequency of the valence electron of atomic cesium in the magnetic field of the atomic nucleus, is observed by the atomic beam magnetic resonance method as a resonance curve with a half-width of approximately 200 cps. The choice of an atomic beam of cesium for this purpose was suggested by Professor I. I. Rabi sometime before 1940, but the techniques necessary to make it into a practical device have become available only in the last few years in connection with researches on rare isotopes of the alkali atoms. These techniques will be described. The atomic beam is contained in a stainless steel tube, 6 feet long and 10 inches in diameter. The atoms emerge at a temperature of about 80°C as a directed beam from 100 long canals forming the exit to a reservoir which holds the metallic cesium; they then pass through an inhomogeneous field of about 10,000 gauss/cm to produce a sideways deflection of their motion; they then pass through two cavities resonant at 9192 mc/sec and 66 cm apart; then through another inhomogeneous magnetic field similar to the first, and finally to a hot wire detector to measure the number of those atoms which have absorbed or emitted radiation in the resonant cavities. After striking the hot wire they are re-evaporated as positive ions which are accelerated to the first plate of a cascade electron multiplier. The impact of each ion results in a burst of about 10^7 electrons at the final stage of the electron multiplier, thus permitting counting of individual atoms or determining the average atom current. The resonant cavities are fed in-phase by a passive frequency tripler which receives its power from an oscillator at 3064 mc/sec. The power in the cavities is sufficient to effect absorption or stimulated emission by the atoms of the beam. Either process so changes their motion to enable them to strike the detector and be counted. The output of the detector is used in a variety of ways, one of which is to provide a voltage to lock the frequency of the oscillator to the resonance frequency of the atom. Preliminary results show that the short time stability thus obtained (for times less than 1 sec) is better than 1 part

in 10^9 and that the average stability for long times will be considerably better than this. The beam tube has run satisfactorily for periods as long as 50 days, indicating that a sealed-off tube with a life of several years should be quite possible. Commercial production of a sealed-off version of this device has been started. (Contractor's abstract)

CODING FOR NOISY CHANNELS (Abstract), by P. Elias. [Mar. 1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at the I. R. E. National Convention, New York, Mar. 21-24, 1955.

Published in I. R. E. Convention Record, Pt. IV: 37-46, 1955.

A remarkable result of Shannon's Mathematical Theory of Communication is the fact that information can be transmitted at a definite rate over a noisy channel, with as low an error probability as is desired, by properly matching the message to the noisy channel. The matching process is called "coding." The problem of designing codes for particular noisy channels is central for many applications of the theory. This paper reviews the progress which has been made in coding, especially for the noisy binary channel. Some new results will be presented on the dependence of error probability and efficiency on coding delay and equipment complexity. (Contractor's abstract)

A METHOD OF RATIONAL FUNCTION APPROXIMATION FOR NETWORK SYNTHESIS, by N. DeClaris. [Mar. 1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at the I. R. E. National Convention, New York, Mar. 21-24, 1955.

Published in I. R. E. Convention Record, Pt. II: 51-58, 1955.

A general method is developed for finding functions of a single complex variable s, which approximates an assigned network characteristic within the special class of functions realizable as networks of linear lumped parameter circuits. The method is based upon an interpolation technique with a series of general rational functions on the unit circle of the z-plane. A number of transformations that map the interval of interest of the s-plane into the unit circle of the z-plane are discussed. A great advantage of the method presented in this paper is that it allows preassigning, if so desired, the pole location of the desired rational function anywhere in the left half of the s-plane. In addition to this freedom, it also makes it possible to approximate on some contour of the complex plane the function itself rather than its modulus. Indeed, in some applications of electric circuits, one is interested in both the magnitude and phase characteristics of a network in a specified frequency interval. Following a formal mathematical treatment, procedures are outlined for three cases of approximation in both the frequency and the time domain. (Contractor's abstract)

PREDICTIVE CODING. PARTS I AND II, by P. Elias. [1955] [18]p. incl. illus. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) AD 76343 Unclassified

Also published in I. R. E. Trans. on Information Theory, v. IT-I: 16-33, Mar. 1955.

Predictive coding is a procedure for transmitting messages which are sequences of magnitudes. In this coding method, the transmitter and the receiver store past message terms, and from them estimate the value of the next message term. The transmitter transmits, not the message term, but the difference between it and its predicted value. At the receiver this error is added to the receiver prediction to reproduce the message term. This procedure is defined and messages, prediction, entropy, and ideal coding are discussed to provide a basis for Part II, which will give the mathematical criterion for the best predictor for use in the predictive coding of particular messages, will give examples of such messages, and will show that the error term which is transmitted in predictive coding may always be coded efficiently. In part I predictive coding was defined and messages, prediction, entropy, and ideal coding were discussed. In the present paper the criterion to be used for predictors for the purpose of predictive coding is defined: that predictor is optimum in the information theory (IT) sense which minimizes the entropy of the average error-term distribution. Ordered averages of distributions are defined and it is shown that if a predictor gives an ordered average error term distribution it will be a best IT predictor. Special classes of messages are considered for which a best IT predictor can easily be found, and some examples are given. The error terms which are transmitted in predictive coding are treated as if they were statistically independent. If this is indeed the case, or a good approximation, then it is still necessary to show that sequences of message terms which are statistically independent may

MIT. 12:010 - MIT. 12:013

always be coded efficiently, without impractically large memory requirements, in order to show that predictive coding may be practical and efficient in such cases. This is done in the final section of this paper. (Contractor's abstract)

THE USE OF POTENTIAL ANALOGS IN NETWORK SYNTHESIS, by R. E. Scott. [Mar. 1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at the I. R. E. National Convention, New York, Mar. 21-24, 1955.

Published in I. R. E. Convention Record, Pt. II: 2-8, 1955.

A summary is given of the use of potential analogs for synthesis in the time domain, the frequency domain, and the real-part domain. Most of the analogs discussed are based on current flow in a resistive sheet. In addition, a new device is described which combines the three types and yields essentially instantaneous curves of the gain function, the phase function, the real part, the imaginary part, and the transient response. This device can be used for network synthesis by any of the three methods and for checking the relations between them. Throughout the discussion particular attention is devoted to the use of symmetry and conformal mapping to reduce the size of physical devices and decrease the errors. (Contractor's abstract)

LINE BREADTHS IN THE MICROWAVE MAGNETIC RESONANCE SPECTRUM OF OXYGEN, by M. Tinkham and M. W. P. Strandberg. Mar. 4, 1955 [3]p. incl. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) AD 102874 Unclassified

Also published in Phys. Rev., v. 99: 537-539, July 15, 1955.

The line-breadth parameters of a number of lines of the X-band magnetic resonance spectrum of O_2 have been measured an interpreted with the aid of a previously reported theory of the spectrum. The results are that the M-dependence of the line width is negligible, and there is only a slight decrease in width with increasing K. A typical width (half-width at half-intensity) at 300°K is 2.2 (mc/sec)/mm Hg. At pressures up to 8 mm Hg, the line centers have been found to shift less than 2 percent of the line width. The average temperature dependence of the normalized line breadth parameter $(\Delta\nu/P)$ is found to be $T^{-0.75}$. This may be compared with the theoretical $T^{-0.627}$ and the $T^{-0.85}$ found by previous workers. It was found that $O_2 - N_2$ collisions were no less effective than $O_2 - O_2$ collisions in producing broadening. (Contractor's abstract)

AN EXISTENCE THEOREM FOR DRIVING POINT IMPEDANCE FUNCTIONS, by N. DeClaris. Mar. 8, 1955 [6 p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 100284 Unclassified

Also puhlished in Jour. Math. and Phys., v. 35: 83-88, Apr. 1956.

Of concern are networks of RC type except for one inductance. It is shown that the driving point impedance will have at most one pair of complex conjugate zeros and one pair of complex conjugate poles. If the real poles and zeros are arranged in order of magnitude, then no more than three zeros or three poles can occur in succession. (Math. Rev. abstract)

A STUDY OF THE MEMORY REQUIREMENTS OF SEQUENTIAL SWITCHING CIRCUITS, by D. A. Huffman. Mar. 14, 1955, 28p. incl. diagrs. (Technical rept. no. 293) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) AD 85768 Unclassified

The number of elementary binary memory devices necessary for the realization of an arbitrary asynchronous sequential switching circuit is considered. The least upper bound is discovered to be approximately equal to twice the greatest lower bound. The minimum conceivable interstate transition time for a sequential circuit is the reaction time of a single memory element. A solution which achieves this minimum time is derived and its relationship to the Hamming single-error correcting code is shown. The fundamental limitations of error correction schemes which compensate for malfunctioning of memory elements are discussed. These schemes are feasible in synchronous circuits but have slightly impaired practicability in asynchronous circuits. (Contractor's abstract)

ULTRASONIC PROPAGATION IN MAGNETICALLY COOLED HELIUM, by C. E. Chase and M. A. Herlin. [1954] [6]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Also published in Phys. Rev., v. 97: 1447-1452, Mar. 15, 1955.

Measurements have been made of the velocity and attenuation of ordinary sound in liquid helium at a frequency of 12.1 mc/sec, over the temperature range from 1°K down to 0.1°K. The velocity is essentially independent of temperature and has the value 240 ± 5 m/sec. The attenuation passes through two closely spaced maxima near 0.9°K and then falls smoothly to zero as the absolute zero is approached. These results agree qualitatively with the theoretical predictions of Khalatnikov. (Contractor's abstract)

THE OPTICAL PROPERTIES OF ATOMIC VAPORS NEAR RESONANCE, by F. Bitter. Mar. 16, 1955. 20p. incl. diagrs. tables. (Technical rept. no. 292) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) AD 66375 Unclassified

This report summarizes and amplifies well-known results in order to facilitate the design of magnetic scanning experiments and to lay the ground for a further analysis of double-resonance phenomena produced by simultaneous rf and optical resonance. The reflection, refraction, and attenuation of light incident on the plane face of a cell containing an atomic vapor are calculated for frequencies in the vicinity of an absorption frequency. The significance of the results obtained is discussed and a few numerical examples are considered. It is found that observation of the attenuation of a transmitted beam offers certain advantages over observation of scattered light in scanning experiments. (Contractor's abstract)

AN EXAMINATION OF INFORMATION THEORY, by Y. Bar-Hillel. [1955] [20]p. incl. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) AD 106989 Unclassified

Also published in Philos. Sci., v. 22: 86-105, Apr. 1955.

The so-called "theory of information" is outlined. It is implied that no direct impact on semantics is to be expected from this new science. On the other hand, however, the calculus employed in it may turn out to be a powerful tool in a number of fields including (inductive) semantics. A number of new insights into the process of communication achieved recently are cited. Their importance for semiotics is demonstrated. Clarification of a number of basic misconceptions regarding information theory is undertaken to a limited extent.

SIGNAL-FLOW-GRAPHSMANSHIP (Abstract), by S. J. Mason. [Apr. 1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at meeting of the I. R. E. Professional Group on Circuit Theory, Symposium on Signal Flow Graphs, Philadelphia, Pa., Apr. 14, 1955.

In the analysis of electronic circuits the circuit equations are often conveniently representable as a signal-flow-graph. This graph represents an abstraction of the electrical circuit model, just as the circuit model is itself an abstraction of the physical device. In the construction and manipulation of a flow graph, horrible or beautiful things can happen. Signal-flow-graphsmanship is the art of maximizing the beauty-to-horror ratio. (Contractor's abstract)

THE MINIMUM NOISE FIGURE OF MICROWAVE BEAM AMPLIFIERS, by H. A. Haus and F. N. H. Robinson. Apr. 1, 1955, rev. May 27, 1955 [11]p. incl. illus. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) AD 75635 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 43: 981-991, Aug. 1955.

A matrix description of microwave amplifiers such as klystrons, traveling wave tubes, and backward-wave amplifiers, in which an electron beam interacts with longitudinal RF fields, is developed. Certain relations between the matrix elements are derived as a consequence of the conservation of energy and these relations set a lower limit to the noise figure attainable with amplifiers of this class. It is shown that the minimum noise figure of any amplifier of this type with lossless RF structures is identical with that already found by several authors for the traveling-wave tube and is entirely determined by the noise parameters of the beam. These in turn depend only on conditions in the immediate neighborhood of the cathode. Special cases involving lossy structures are investigated and in each case the presence of loss is shown applied to calculate the minimum noise figure of a double-stream amplifier. SOME ASPECTS OF PLASMA RESONANCE (Abstract), by K. S. W. Champion and S. C. Brown. [1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637) Unclassified

Presented at Seventh Annual Gaseous Electronics Conference, New York, Oct. 14-16, 1954.

Published in Phys. Rev., v. 98: 559, Apr. 15, 1955.

The impedance (ρ) to high-frequency electromagnetic waves of any region of a plasma, divided by the wavelength, (ρ/λ) is plotted as a function $N\lambda^2$ (where n is the electron density) and $p\lambda$ (where p is the pressure). The resulting surface is of particular interest in the vicinity of plasma resonance and is important for two reasons. One is that it gives a plot of the impedance any plasma presents to the transmission of microwaves. It not only confirms the measurements of Goldstein and Makinson of the microwave impedance of dc plasma, but also indicates immediately the range over which plasma resonance properties can be used as a "microwave probe" to measure electron densities. Experimentally this technique of density measurement has been used with high-frequency discharges for the first time. The second reason for the importance of the impedance plot is that it enables the properties of microwave discharges to be predicted. In particular, more extensive calculations have been made which enable the appearance of any microwave discharge to be predicted quantitatively, provided its diameter exceeds four times its height. A "STROBOSCOPIC" APPROACH TO THE ANALYSIS OF PERIODIC AND MODULATED WAVES, by E. J. Baghdady. [May 1955] 1 p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) Unclassified

A useful approach to the Fourier analysis of modulated and periodic waves is derived from well established elementary considerations. The basic mechanism of the conventional analysis is first examined and found to lend naturally to a picture based on the fact that a

rotating phasor which represents a pure sine function may be brought to rest, relative to two orthogonal reference axes, by rotating the latter at the angular frequency of the former. Then, by determining the projections of the phasor upon the axes, it is possible to describe the phasor uniquely. Thus, to investigate the presence of a component of any specified frequency in the structure of a given sinusoid modulated in an arbitrary fashion by a general type of periodic function, it is merely necessary to imagine the orthogonal reference axes to be rotating in the positive direction at the specified angular frequency. This will reduce the instantaneous frequencies of all the spectral components, and hence of their resultant phasor, relative to the frequency of the rotating reference axes by an amount equal to the frequency of the latter. If a spectral component with the specified angular frequency is present, it will therefore be made stationary relative to the reference axes. Thus, long-time averages of the instanteous projections of the resultant phasor representing the modulated wave, upon the rotating reference axes, will yield the corresponding components of the desired spectral component, and therefore uniquely determine it. Illustrative examples are given: the theory is then shown to be formally equivalent to the standard technique of Fourier analysis and to be just a novel way to view the mechanism of this analysis. Finally, the graphical application in its most general form is described and found to circumvent possible inconveniences with the conventional approach. (Contractor's abstract)

THE TEACHING OF MATHEMATICS TO THE BLIND, by C. M. Witcher. [1955] [8]p. incl. illus. diagrs. tables. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research] under DA 36-039-sc-64637) AD 76342 Unclassified

Published in Math. Teacher, v. 48: 314-321, May 1955.

Although the use of Braille is satisfactory for beginning courses in mathematics, in the study of fractions and algebra and higher mathematics it is unsatisfactory. Some recent developments in the field of mathematics for the blind make use of an adapted abacus or soraban for numerical calculation and a practical form of circular slide rule which is suitable for fairly rapid touch reading. The latter permits the computation of powers and roots with the help of simple mental multiplication or division. In addition desk calculators and comptometers have been adapted for touch reading. A new method was developed in 1948 with the use of certain plastics and the use of cellulose acetate and a moisture-proof cellophane for a drawing media to provide for the production of diagrams and graphs, etc. A very significant developme , in the field has been the Nemeth system of Braille mathematical notation. It is simple and is quite useful in algebra and trigonometry. By the use of "level indicator" symbols it enables the blind to deal with exponents and subscripts. The system is also quite useful in vector analysis and theory of functions.

NOISE IN ELECTRON BEAMS, by C. Fried. May 2, 1955, 44p. incl. illus. diagrs. table, refs. (Technical rept. no. 294) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) AD 103532 Unclassified

This report contains an experimental investigation of beam and noise behavior in various types of electron streams. A continuous, reliable, and semi-automatic measuring technique and apparatus is described. Steady-flow and pulsed operating conditions are applied to convergent and confined flow guns. An extensive investigation of beam contour, noise standing-wave pattern, growing noise wave, and beam instability is given. The effect of magnetic field, ion neutralization, and interception current is measured over considerable operating ranges. Certain aspects of cathode temperature, type, activity, and quality of cathode are included. A low-noise three region gun is measured under steady-flow conditions. The transformation of the noise standing-wave pattern by the accelerating anodes is demonstrated. The constancy of the average of the rms noise current standing wave is verified experimentally. CARRIER EFFECTIVE MASSES IN GERMANIUM (Abstract), by J. M. Goldey and S. C. Brown. [1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 27-29, 1955.

Published in Phys. Rev., v. 98: 1192, May 15, 1955.

Current carriers in a medium make a contribution to its dielectric coefficient. An experiment, similar to those of Benedict and Shockley, which utilizes this effect has been performed to determine the effective masses of electrons and holes in germanium by measuring its microwave dielectric coefficient at several temperatures. The dielectric coefficient was determined by measuring the complex transmission coefficient for 24.15 kilomegacycle radiation through a thin slab of germanium. The values obtained for the effective masses were $M^* = (0.09 \pm 0.05) M_0$ for electrons and $M^* = (0.30 \pm 0.05) M_0$ for holes. These

MIT. 12:026 - MIT. 12:029

results are in agreement with those obtained by cyclotron resonance and magnetic susceptibility measurements, but disagree with those of Benedict and Shockley.

THE ELECTRON LOSS PROCESS IN THE HYDROGEN AFTERGLOW, by K.-B. Persson and S. C. Brown. May 19, 1955 [5]p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) AD 88739 Unclassified

Also published in Phys. Rev., v. 100: 729-733, Oct. 15, 1955.

Electron loss processes in the afterglow of very pure hydrogen have been studied by the microwave technique. The conclusion is drawn that within the error of the experiment, no electron-ion recombination is observed, and that high mode diffusion is very evident. By properly accounting for the high diffusion modes, the results are given as $D_a p = 700 \pm 50$ cm^2 mm Hg sec^{-1} with the electron-ion recombination less than 3×10^{-8} cm^{-3} sec^{-1}. Electron loss processes in the hydrogen afterglow have been studied by the microwave method by a number of workers. Although the results are related, no agreement has been achieved up to the present time as to the actual loss processes in hydrogen. In view of the result of the work presented here, it is possible to understand the disagreement between the previous investigations of the hydrogen loss processes. The main result is that, if sufficiently pure hydrogen is used, the loss process for the electrons in the ranges covered previously, as well as now, is explained by an ambipolar diffusion mechanism. If the electron-ion recombination is present, this loss process is so small that it cannot be measured with methods available at present. (Contractor's abstract)

1/F NOISE AND RELATED SURFACE EFFECTS IN GERMANIUM, by A. L. McWhorter. May 20, 1955. 112p. incl. illus. (Technical rept. no. 295; Lincoln Lab. rept. no. 80) (In cooperation with Mass. Inst. of Tech. Lincoln Lab., by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637]) AD 64023 Unclassified

By modulating the surface conductivity of germanium with external electric fields ("field effect" experiment) at sub-audio frequencies, it has been found that the capture time τ of these traps varies from spot to spot along the surface, with a distribution function for τ which is approximately proportional to $1/\tau$ up to times greater than 100 sec. The filling and emptying of the traps can alter the conductivity by producing (1) changes in the majority carrier concentration near the surface, as required to maintain charge neutrality, and (2) an injection-extraction of hole-electron pairs, due to a complex interaction between the surface recombination centers and the traps. The two processes have been analyzed and found to give a 1/f noise of the correct order of magnitude. There are two distinct types of excess reverse currents observed in p-n junctions; a water-induced leakage current, which flows externally to the germanium, and a "channel" current, which occurs whenever a strongly n- or p-type surface increases the effective rectifying area of the junction. Measurements of 1/f noise in reverse-biased p-n junctions have shown that the noise associated with the leakage current varies roughly at V^2G, where V is the applied voltage and G is the conductance of the leakage path, while the noise associated with the channel seems to vary as $I_c^2 V^{1/2}$, where I_c is the channel current. ON BINARY CHANNELS AND THEIR CASCADES, by R. A. Silverman. May 25, 1955, 9p. incl. diagrs. table. (Technical rept. no. 297) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) AD 94195 Unclassified

Also published in I. R. E. Trans. on Information Theory, v. IT-1: 19-27, Dec. 1955.

A detailed analysis of the general binary channel is given, with special reference to capacity (both

separately and in cascade), input and output symbol distributions, and probability of error. The infinite number of binary channels with the same capacity lie on doubly-branched equicapacity lines. Of the channels on the lower branch of a given equicapacity line, the symmetric channel has the smallest probability of error and the largest capacity in cascade, unless the capacity is small, in which case the asymmetric channel (with one noiseless symbol) has the smallest probability of error and the largest capacity in cascade. By simply reversing the designation of the output (or input) symbols, we can decrease the probability of error of any channel on the upper branch of the equicapacity line can be decreased and the capacity in cascade of any asymmetric channel on the upper branch can be increased. In a binary channel neither symbol should be transmitted with a probability lying outside the interval $[1/e, 1-(1/e)]$ if capacity is to be achieved. The maximally asymmetric input symbol distributions are approached by certain low-capacity channels. For these channels, redundancy coding permits an appreciable fraction of capacity in cascade if sufficient delay can be tolerated. (Contractor's abstract)

CONSTANT-RESISTANCE AGC ATTENUATOR FOR TRANSISTOR AMPLIFIERS, by C. R. Hurtig. [June 1955] [6]p. incl illus. tables. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) AD 75634 Unclassified

Also published in I. R. E. Trans. of Professional Group on Circuit Theory, v. CT-2: 191-196, June 1955.

This paper describes a unique circuit the gain of which may be varied as a function of a control current, but the input resistance of which is fairly constant over a large range of the controlled gain. A constant-resistance agc attenuator is described with these characteristics: (1) the circuit employs one junction diode and, at most 3 resistors and 2 capacitors per resistor agc stage, and is suitable for use with either triode or tetrode transistors, (2) at signal voltage levels under 1 mv, a gain variation per transistor agc stage of 50 db at 1000 cps and greater than 20 db at 10 mc may be produced by an external control voltage. The gain variation is accompanied by only slight variations in the effective input impedance of the stage, (3) the control power is dependent upon the required constancy of input resistance over the agc range, but in most cases milliwatts of control power are sufficient, and (4) a square-low device for a positive polarity input voltage is described which has an accuracy of ± 10% over a dynamic range exceeding 40 db. Polarity and frequency response limitations of this basic device are removed by a new circuit design for a balanced modulator the output of which is a linear function of both the modulating and control signals.

NOTES ON THE FLOW OF SCHEDULED AIR TRAFFIC, by R. B. Adler and S. J. Fricker. [1955] [10]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Published in I. R. E. Trans. of Professional Group on Aeronautical and Navigational Electronics, v. ANE-2: 22-31, June 1955.

Some of the effects upon air traffic of scheduling the aircraft and of controlling them en route are presented quantitatively in this report in the form of theoretical studies of four problems: (a) relations between the random en route deviations of aircraft from their schedules, and the resulting stack and total delays; (b) effectiveness of a single en route control point when 1) it reschedules the aircraft in an attempt to reduce terminal congestion; 2) it attempts to bring each plane back onto its original schedule; (c) congestion caused by relaxing the schedule; and (d) effect of a sudden shutdown of the terminal. The limiting cases of random arrival and continuous control are discussed briefly, and some aspects of multipoint discrete en route control are treated. Numerical analysis, using IBM punched-card machines, is employed extensively in problems (a)-(c). Problem (d) has been simplified enough so that purely analytic methods could be applied. It is presented merely for comparison purposes. (Contractor's abstract)

INVESTIGATIONS OF IONOSPHERIC FOWARD-SCATTER PROPAGATION AT FREQUENCIES EXCEEDfNG MUF, by W. G. Abel, J. T. DeBettencourt and others. June 3, 1955, 181p. incl. illus. tables, refs. (Technical rept. no. 262; Lincoln Lab. rept. no. 81) (In cooperation with Mass. Inst. of Tech. Lincoln Lab., AF 19(122)458) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) AD 76494 Unclassified

Results are presented of studies of ionospheric forward-scatter propagation at frequencies exceeding normal MUF in the high HF and low VHF ranges for the purpose of investigating potential point-to-point communications. Data were analyzed from about 13,000 hr of operation on frequencies of about 50 mc on circuits of about 1000 mi. Nominal 30-kw transmitters and large rhombic transmitting antennas were employed. The median received signal levels were about 100 db below free-space values. Fading during short periods in the absence of meteoric or sporadic-E enhancements was Rayleigh distributed; the fading was essentially Gaussian for periods of about 1 hr. In general, the normalized median levels were lower and the diurnal variations were less marked than those previously reported for a 773-mi path. The median levels were higher in winter and summer and lower in spring and fall. Lower levels were indicated with decreasing gun-spot activity. The vertically polarized component of the received signal was about 6 db (median) lower than the horizontally polarized component when using the 2000-ft horizontal rhombic transmitting antenna. Studies were made of off-path signal levels and measurements of cosmic noise. Preliminary analysis of pulse-transmission data for a 387-mi path indicated daytime ionospheric-scatter heights of 80 to 90 km. The level and characteristics of 27.8-mc signals are discussed. Additional measurements at 22.9 mc are described for a 1059-mi path. Observations at 21.6 mc are reported for signals received over a 997-mi path.

HYPERFINE STRUCTURE ANOMALY fN ATOMIC P-STATES, by C. Schwartz. June 10, 1955 [2]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) AD 105288 Unclassified

Also published in Phys. Rev., v. 99: 1035-1036, Aug. 1, 1955.

It is shown that, as a result of electronic-configuration mixing, there can be in principle a hyperfine structure anomaly Δ in any atomic state. This effect is calculated for Ga. Further, before a measured value of Δ can be used to study the nuclear magnetic structure through the Bohr-Weisskopf theory (C. A., v. 44, 1799c), the contribution to Δ of other mechanisms must be substracted. The net B.-W. effect in Ga is smaller than expected. Its precise value remains uncertain. (C. A., 1955:15473f)

MEASUREMENT OF SECOND-ORDER PROBABfLITY DfSTRIBUTIONS OF PfCTURES BY DIGITAL MEANS, by J. C. Stoddard. July 13, 1955, 21p. incl. illus. diagrs. tables. (Technical rept. no. 302) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637) AD 111879 Unclassified

The transmission of a picture was approached from the point of view of statistics and information theory. A picture was approximated by the processes of sampling and quantizing the video waveform that represents the intensity of the picture as it is scanned. Transmission of each sample of the picture is reduced to the problem of sending a number that indicates which of the 32 possible intensity levels occurred in that sample. Equipment that measures the second-order probability distribution of a video waveform from a facsimile transmitter by digital means was designed and built. System tests were made to permit evaluation of the potential accuracy of measurement. Although perfectly repeatable results from a known waveform

could not be obtained, measurement of the complete joint probability distribution of one picture was made by running the data until consistent results could be obtained for each set of levels. A value of entropy representing an upper bound to the information content of the picture was computed from the measured second-order probability distribution of intensity in adjacent samples. AN ANALOG CORRELATOR SYSTEM FOR BRAIN POTENTIALS, by J. S. Barlow and R. M. Brown. July 14, 1955, 41p. incl. illus. refs. (Technical rept. no. 300) (In cooperation with Massachusetts General Hospital, Boston) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under DA 36-039-sc-64637])
AD 82439 Unclassified

A description is presented of an analog correlator system for brain potentials. Brain potentials are first amplified by standard electr encephalographic equipment and then recorded on a multichannel FM magnetic tape recorder. Autocorrelation and crosscorrelation functions of the tape-recorded signals are automatically computed as the tapes are played back repeatedly by an electronic analog multiplier and integrator; a magnetic drum introduces the desired interchannel delays. Provision is also made for computation of correlation functions for signal sources other than magnetic tape (oscillators, noise generators, etc). The electrophysiological signals are taken from the amplifiers at a level of amplification sufficient to yield the desired input level to the tape recorders, for which 1 v rms of a sine wave produces 100% modulation of the FM carrier. Examples are presented of correlation functions for brain potentials and for known signals.

ELECTRONIC CONTRIBUTION TO EFFECTIVE NUCLEAR MASSES IN MOLECULES (Abstract), by M. W. P. Strandberg. Apr. 1955 [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 99: 667, July 15, 1955.

The problem of the interaction of molecular rotational and electronic states has been extensively investigated in the past. Quite briefly stated, it has been demonstrated that the molecular electrons contribute to the molecular moment of inertia tensor an amount which is directly and simply related to the molecular magnetic moment tensor. Examples of this correction have been made with the experimental results on several molecules, and the measured corrections to the principal moments of inertia arising from the molecular electrons have been discussed. A recent paper reporting the deuterium-tritium mass ratio evaluated from microwave measurements attempted a discussion of this correction without apparently realizing that it is a matter which may be reduced to measurement. The electronic correction to spectroscopic mass ratio measurements will be discussed in terms of past work. (Contractor's abstract)

EXCITED TORSIONAL STATES IN ASYMMETRIC HINDERED ROTORS (Abstract), by P. R. Swan [Jr.] and M. W. P. Strandberg. [1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 99: 667, July 15, 1955.

Investigation has been undertaken of the $J = 0 \rightarrow 1$ transition of methyl alcohol. Because of internal torsion in this type of molecule the transition is split into a series of doublets, each doublet corresponding to a particular internal torsion state. A preliminary model used was that of a rigid symmetric top attached at an arbitrary angle to a rigid asymmetric frame and allowed to rotate about its symmetry axis under the influence of a threefold cosine potential barrier. The resulting Hamiltonian was found to be incapable of predicting the torsional splitting when applied to the methyl-alcohol molecule. A semiempirical combination of Kivelson's formula for the corresponding transition in a symmetric hindered rotor with matrix elements from this methyl-alcohol Hamiltonian was found to give a close fit to the observed spectrum. An additional feature of the methyl-alcohol spectrum is the large fourth-order Stark effect of one of the lines of the $J = 0 \longrightarrow 1$ series. The Hamiltonian necessary to describe these rotation-torsion interaction effects is discussed. (Contractor's abstract)

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 99: 667, July 15, 1955.

The microwave spectrum of methyl amine exhibits hindered internal rotation of the NH_2 group with respect to the CH_3 group, as well as inversion doubling arising from the fact that there are two equally likely orientations of one NH bond with respect to the other. An approximate theory has been worked out for these two internal motions and their mutual interaction. By a suitable choice of variable the kinetic energies can be completely separated; the potential energy can be reduced to a term accounting for inversion, a term accounting for hindered internal rotation, and an interaction term. If the latter is neglected the two internal motions can be treated independently except for their interrelated dependence upon the periodic boundary conditions. The interaction term can be treated by a Van Vleck transformation. This theory is applied to methyl amine. (Contractor's abstract)

MOLECULAR-BEAM MICROWAVE-ABSORPTION SPECTROSCOPE (Abstract), by M. Peter and M. W. P. Strandberg. Apr. 1955 [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 99: 667, July 15, 1955.

A microwave absorption spectroscope has been developed, whose absorption-line half-power — half-width is determined by the average time that the molecules under observation are exposed to the microwave field. This is an improvement over the similar previous device by Strandberg and Dreicer, in which the Stark modulation frequency limited the resolution. In both devices the Doppler broadening, which limits the resolution of the usual microwave spectroscopes, is eliminated. An improvement by a factor of twelve is now obtained over such usual systems, and a half-power — half-width of 3 kc has been observed. To use such resolution it has been necessary to develop a stabilization circuit which maintains the phase of a K-band klystron to within a few degrees of the phase of some harmonic of a very stable quartz oscillator. The resolution of the present system is therefore limited only by geometry and may thereby be improved by use of longer average observation times, i.e., use of longer molecular beams. THERMODYNAMIC PROPERTIES OF CHROME ALUM (Abstract), by L. D. Jennings and M. A. Herlin. Apr. 1955 [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 99: 668, July 15, 1955.

A new method was applied to the measurement of the thermodynamic properties of potassium chromium alum in the region of temperatures reached by adiabatic magnetization curves which approach an asymptotic value at large fields characteristic of the analogous ideal paramagnetic gas at the same entropy. The entropy of the actual salt is then given as that of the ideal salt which has the same large field magnetization. The temperature of the salt is given by a method, previously described, which makes use of the deviation of the behavior of the actual salt from that of the ideal. Each adiabat is identified by T, the magnetic temperature at that entropy. Good agreement was found with other workers for T(T), but less satisfactory agreement for S(T) in the region T = 0.1 to T = 0.2. This discrepancy is attributed to a failure of the usual computation of entropy near 1°K, in the need to extrapolate the results at high magnetic fields, or to an actual difference among samples. THE CONDUCTION MECHANISM IN OXIDE COATED CATHODES, by E. B. Hensley. July 20, 1955, 5p. incl. diagrs. table, refs. (Technical rept. no. 267) (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) AD 100283 Unclassified

Also published in Jour. Appl. Phys., v. 27: 286-290, Mar. 1956.

Measurements have been made on a system composed of two parallel planar cathodes so arranged that their surfaces may be pressed together or separated by a small gap. Low field conductivity measurements show that above approximately 700°K, the conductance of the system does not depend on physical contact between the cathode surfaces; a result that is interpreted as confirmation of the theory that the high temperature conductivity of oxide cathodes is a property of the electron gas in the cathode pores. The ratio of the conductivity

to the thermionic emission was measured under conditions designed to preserve the state of activation of the cathode surface. The results of these measurements agreed with the theoretically predicted value and demonstrate that the higher values of this ratio previously reported were attributable to the fact that the surface of an oxide cathode is normally in a lower state of activation than the interior of the cathode. Also published in I. R. E. Trans. of Professional Group on Circuit Theory, v. CT-2: 347-355, Dec. 1955.

Several familiar procedures in the synthesis of driving-point and transfer impedances yield a network in the form of a cascade of two-terminal-pair networks, each of which is responsible for a set of zeros of the even part of the prescribed impedance. In each of these procedures, the computation of the typical component network begins with the determination of the equivalent T-circuit; and then a remainder function (from which other component networks are to be found) is determined by substracting the T's branch impedances (or admittances) from previously determined functions. In general, an equivalent circuit of some other configuration must be determined from the T-circuit, to achieve physical realizability. These computational procedures are laborious, and the substractions may seriously reduce accuracy. In this paper, a more direct approach is suggested. It leads to the same ultimate networks in a more logical way, and obviates much computational tedium. The general approach is developed primarily in terms of RC transfer impedances, but applications to LC networks are also included.

ON THE SCATTERING OF RADIO WAVES BY TURBULENT FLUCTUATIONS OF THE ATMOSPHERE, by F. Villars and V. F. Weisskopf. July 25, 1955 [8]p. incl. illus. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and [Air Force] Office of Scientific Research under [DA 36-039-sc-64637]) AD 94458 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 43: 1232-1239, Oct. 1955.

This paper presents a theoretical analysis of the mechanism that enables transmission of vhf-signals over distances of the order of 10^3 km. It is found that turbulent mixing, operating at the lower edge of the E layer (h = 80-90 km) produces fluctuations in electron density of sufficient intensity to account for the observed signals. The basic assumptions are the existence of a sufficiently strong gradient electron density (dN/dh cm^{-3}/km) and a reasonable level of turbulent activity.

ANALYSIS OF SIGNALS AND NOISE IN LONGITUDINAL ELECTRON BEAMS, by H. A. Haus. Aug. 18, 1955, 64p. incl. diagrs. refs. (Technical rept. no. 306) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 123164 Unclassified

The theory of signal propagation in longitudinal one-dimensional electron beams is reviewed. The kinetic power theorem is proven and used for the characterization of longitudinal-beam microwave amplifiers in terms of matrices of lossless networks. The properties of noise in electron beams are studied. The two noise parameters, invariants with regard to lossless beam transformations, are derived from a simple theorem of matrix algebra. Equivalent noise impedances are defined. As a result, noise transformations in an electron beam can be handled by conventional impedance transformation methods. The noise theory is then applied to derive the expression for the minimum noise figure of longitudinal beam tubes. Applications to practical cases are discussed.

ACTION POTENTIALS FROM THE FROG COLLICULUS (Abstract), by A. M. Andrew. [1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637; and in part by the Illuminating Engineering Research Fund (U. S.)) Unclassified

Presented at meeting of the Physiol. Soc., Dundee (Scotland), Sept. 23-24, 1955.

Micro electrodes in the colliculi (optic lobes) of pithed frogs were used to record unit action potentials from cells, in response to stimulation of the contralateral eye with light. The layer of the colliculus from which responses were obtained appears to he 0.5 mm, or, less below the surface. From a particular recording site, responses were evoked by light in a particular part of the visual field. The optimal position for a small light source could be determined with accuracy ranging from ± 5 to ± 15°. Usually both on-responses and off-responses were obtained from a recording site. Almost always the off-response was larger and had a lower threshold and shorter latency than the on-response. Typical latencies were 30 msec and 58 msec, respectively. No maintained response to steady illumination has been seen. Frequently an off-response consisted of an initial burst of activity followed by a train of impulses that sometimes lasted as long as 7 sec. Responses to a moving spot of light have been studied, using as stimulus the spot of a 2-inch cathode-ray tube moving at a selected speed from one stationary position on the screen to another. The cathode-ray tube could be placed in any position in the visual field and always faced the frog at a distance of 10 in. Some recording sites showed marked differences between the responses to movements at the same speed and along the same path but in opposite directions. The response to movement cannot be accounted for as a summation of on- and off-responses at points passed by the spot. A marked difference in the response to movement, depending on direction of travel, has been seen when the on- and off-responses were essentially the same at all points along the path of the spot. CODING FOR NOISY CHANNELS (Abstract), by P. Elias. [1955] [15]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at the Third London Symposium on Information Theory, London (England), Sept. 12-16, 1955.

Published in Proc. Third Symposium on Information Theory, Royal Institution, London (England) (Sept. 12-16, 1955), London, Butterworth's Scientific Publications, 1956, p. 61-76

This paper considers in detail the simplest kinds of noisy channels – binary channels with symmetric and independent errors. For these channels a strong version of the channel capacity theorem is proved, giving precise relations between channel capacity, rate of information transmission, decoding delay D, and error probability at the receiver. It is shown that Shannon's random message coding is essentially optimum for transmission rates reasonably near channel capacity. For low rates, however, it is possible to decrease error probability with increasing decoding delay more rapidly by design than by chance. Any

coding procedure requires codebook memories, or computers, or both, at transmitter and receiver. Random message codes require codebooks which grow exponentially in size with the decoding delay D. It is shown that random check symbol codes of various kinds can be constructed which perform just as well in terms of information rate and error probability, but which require a codebook increasing in size only linearly with D. This has not only practical but theoretical interest, since such a code is error-free. That is, the receiver can increase D and reduce error probability as much as it likes without consulting the transmitter. (Contractor's abstract)

STUDIES OF POPULATION RESPONSES IN THE PERIPHERAL AUDITORY NERVOUS SYSTEM (Abstract), by L. S. Frishkopf and W. A. Rosenblith. [1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637)
Unclassified

Presented at meeting of the Amer. Physiol. Soc., Tufts College, Medford, Mass., Sept. 6-9, 1955.

Electrical responses to auditory clicks were recorded at relatively microphonic-free locations near the round windows of anaesthetized cats. The average amplitude of N_1, the first neural component of this response, was determined in nine animals as a function of stimulus intensity over a range of 80 to 100 db. Amplitude variability was determined as a function of stimulus intensity for three animals over a similar range of stimulus intensity. In three other animals clicks were presented in a background of low intensity noise, and masked and unmasked amplitude growth functions determined. These studies were analyzed in relation to a threshold model for peripheral auditory units, a model in which threshold has a probability character. The results strongly suggest the existence of a fairly homogeneous population of sensitive units, responsive over a range of 30 to 40 db and consisting of 150 to 400 elements. A NEW METHOD FOR MEASURING THE ABSOLUTE VISCOSITY OF LIQUID HELIUM II, by H. H. Kolm and M. A. Herlin. Oct. 10, 1955 [7]p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA36-039-sc-64637]) AD 103571
Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Also published in Phys. Rev., v. 102: 607-613, May 1, 1956.

A new type of static viscometer for use in liquid helium II was developed; its inner cylinder is suspended within a rigidly fixed, coaxial outer cylinder by a servomechanically controlled magnetic bearing of the type used by Beams and others in vacuum ultracentrifuges. The inner cylinder is accelerated electromagnetically; the absolute viscosity of the medium is determined from the deceleration observed when it is permitted to coast freely. Bearing friction is negligible, and there is no inherent lower limit to the speed of this measurement. Reproducible viscosity values were obtained in gaseous helium, but 1/TS-damping from thermomechanical flow induced by eddy current heating in the rotor was observed in liquid helium II. This effect was reduced considerably by elaborate precautions for isolating the apparatus from ground vibrations. At higher speeds, the anomalous behavior was observed, which eliminates the attempted "mutual friction" explanation. The absolute viscosity increased discontinuously to a higher value as the speed increased. The observation is reproducible qualitatively, but because of vibrations, not quantitatively. EFFECTS OF STRYCHNINE WITH SPECIAL REFERENCE TO SPINAL AFFERENT FIBERS, by P. D. Wall, W. S. McCulloch and others. [1955] [12]p. incl. illus. diagr. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36 039 sc 64637) AD 88790 Unclassified

Also published in Epilepsia, Series 3, v. 4: 29-40, Nov. 1955.

Some of the literature on the basic effects of strychnine is reviewed. Experiments carried out on cats show that strychnine does not affect the excitability of the motor horn cells of the spinal cord as tested by microelectrode stimulation within the cord. It is shown that the threshold of the fibers in the terminal arborization of final afferent fibers is raised. The shape of the early components of the dorsal root potentials is changed. Findings could be explained by an increase in the height of the individual action potentials in the terminal arbors under the influence of strychnine. Strychnine spikes traveling antidromically away from strychninized nuclei of Goll and Burdach were shown to emerge from lumbar dorsal roots. The significance of these findings is discussed. A critique of strychnine neuronography in the light of recent findings is presented. (Contractor's summary)

APPLICATION OF SPACE-CHARGE THEORY TO THE DETERMINATION OF ELECTRON EMITTER PROPERTIES (Abstract), by W. B. Nottingham. Aug. 1955 [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Mexico U., Mexico City, Aug. 29-31, 1955.

Published in Phys. Rev., v. 100: 964, Nov. 1, 1955.

Basic space-charge theory depends on the simultaneous solution of three equations. These equations are: (1) Poisson's, (2) Boltzmann's density relation, and (3) the equation of current continuity. The solution of these equations applicable to parallel-plane electrodes leads to methods that also serve for coaxial cylinders. Tubes have been constructed with oxide cathodes and a ratio of radii collector to emitter of 2.5. The emitter specifications to be evaluated and reported on include the "a" constant in amp/ m^2 and the work-factor ϕ in electron volts. These constants are useful in the simplified current density expression: $a \exp(-\phi/V_T)$. The temperature expressed as V_T is T/ 11600. Also, the Richardson constants A_R and ϕ_R and the temperature coefficient of the true work-function are determined. The analysis yields a value for the true work-function of the collector. PRECISION OF MICROWAVE SPECTROGRAPHS (Abstract), by M. W. P. Strandberg and M. Peter. [1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36 039 sc 64637) Unclassified

Presented at meeting of the Amer. Phys. Soc., Mexico U., Mexico City, Aug. 19-31, 1955.

Published in Phys. Rev., v. 100: 963, Nov. 1, 1955.

Microwave molecular beam spectroscopes using either absorption or emission of radiation, or particle counting techniques, operate within the same realm of techniques. The ultimate frequency precision of each of these forms of beam spectroscopy is thus simply expressible in terms of common parameters. Then based on only the most general considerations the particle counting system has the highest probability of defining a point on the atomic or molecular resonance curve by the square root of ratio of the photon energy to the thermal noise energy kT. Practical considerations can shift this ratio many orders of magnitude either way. The microwave absorption spectroscope is unique in being able to operate without state selection and without beam flow. In this form of operation the resolution is less because of Doppler broadening. However, the over-all precision of an absorption spectrograph can be greatly increased over beam operation since the amount of active material, and hence power handling capability, can be greatly increased without the need of absurd flow handling capacity. NETWORK SYNTHESIS FOR A PRESCRIBED IMPULSE RESPONSE, by R. A. Pucel. Nov. 2, 1955, 35p. incl. diagrs. (Technical rept. no. 305) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 122939 Unclassified

Two semigraphical methods are presented for the synthesis of a linear, finite, lumped-element network in which the desired response is prescribed in the time domain. The methods are based on the approximation of the real or the imaginary part of the associated system function. In the first method, the desired real or imaginary part function is approximated in the complex-frequency plane by a sequence of impulses along a contour parallel to and to the left of the imaginary axis. In the second method, this function is approximated along the imaginary axis by a rotational fraction whose zeros and whose behavior at infinity are initially prescribed. Simple methods are proposed for the evaluation of the error committed in the time domain. Examples illustrating the two methods are given. (Contractor's abstract)

PHASE STABILIZATION OF MICROWAVE OSCILLATORS, by M. W. P. Strandberg. Nov. 30, 1955, 1p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 109228 Unclassified

Also published in Proc. Inst. Radio Engineers, v. 44: 696, May 1956.

A circuit has been developed with which microwave oscillators may be phase-locked to weak but stable reference signals. The circuit was operated with S-band oscillators (707B klystron; 2C37 triode oscillator) and a 2K50 K-band klystron. It is possible to lock a microwave oscillator directly or through a cascade of such circuits to a quartz-stabilized oscillator. The statistical theory of random noise is used to obtain an analysis of the stabilizing effect of the circuit, and the power spectrum of the stabilized microwave source is calculated. The scheme can also be applied in divider operation. Modifications are discussed. A modified circuit that uses carrier-suppressed modulation of the reference signal has also been realized. In another circuit, the oscillator frequency is converted by means of a stable reference, and compared with a second reference that can be of low frequency and tunable. These latter circuits allow elimination of the excess noise introduced by crystal diodes. In the original straight dc circuit this noise cannot be eliminated, but calculation shows that its influence on the output power spectrum is very small. (Contractor's summary)

THE CONCEPT OF THE ONE IN VOLTAGE TRANSFER SYNTHESIS, by P. M. Lewis, II. [1955] [4]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Published in I. R. E. Trans. of Professional Group on Circuit Theory, v. CT-2: 316-319, Dec. 1955 (Network Realization Issue).

The concept of the one is introduced and found to give a physical interpretation to the constant multiplier in voltage transfer synthesis. It places in evidence the constraints placed on the performance of physical systems by the configuration used in the synthesis. Several theorems are derived concerning the ultimate limits of performance obtainable when a given configuration is used to realize a given voltage transfer function. (Contractor's abstract)

THE PHONEMES OF SHILHA (Abstract), by J. R. Applegate. [1955] 1 p. (Sponsored jointly by

MIT. 12:064 - MIT. 12:066

Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at meeting of the Linguistic Soc. of Amer., Chicago, Ill., Dec. 29, 1955.

This paper presents a description of the phonology of Shilha, one of the major Berber dialects spoken in southwestern Morocco. This description is based on the analysis of the speech of several native speakers of the language. It is, primarily, a discussion of the phonemic structure of the language. Spectrographic data are used to illustrate certain features of the phonemic system which have been presented in different forms in other studies of the language and to support conclusions reached concerning these features. THE REPRESENTATION OF SOME PERIODIC STIMULI IN THE BIFREQUENCY PLANE (Abstract). by M. H. Goldstein, Jr. [Dec. 1955] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at meeting of the Acoust. Soc. Amer., Brown U., Providence, R. I., Dec. 15-17, 1955.

Published in Jour. Acoust. Soc. Amer., v. 28: 153, Dec. 1956.

Recently attention has been focused on psychophysical experiments with nonsinusoidal stimuli of a periodic nature. These studies were concerned with the "residue," the "missing fundamental" and more generally with amplitude modulated signals, bursts of noise, and repeated clicks. The results were often in contradiction with Ohm's acoustic law according to which a complex stimulus is analyzed during the listening process into its sinusoidal (Fourier) components. It appeared therefore desirable to develop a mathematical transformation that would bring to light certain aspects of these stimuli that are of importance in determining psychophysical judgments. A bifrequency transform will be presented which is a function of two variables, both of which have the dimension of frequency. One variable relates closely to Fourier frequency, the other to the time-varying envelope of the signal. The shape of the bifrequency plot of a number of auditory stimuli will be illustrated, and the method of analyzing psychophysical experiments employing these stimuli will be described. In several instances the bifrequency method makes plausible psychophysical judgments that are not predicted from Ohm's law. (Contractor's abstract)

Also published in Yale Jour. Biol. and Med., v. 28: 457-464, Dec. 1955-Feb. 1956.

A new technique is described which uses antidromic impulses generated in terminal arborizations by stimulating microelectrodes. The position of the stimulating microelectrode is determined for those points of stimulus which evoked a response recorded in a tract projecting into the stimulated area. The resolution of the technique is shown to be greatly superior to previous physiological methods which attempted to localize the ending of projection fibers. The technique is used to show the endings of the group I afferent fibers from the gastrocnemius muscle in the grey matter of the cord. The ending of the pyramidal tract in the cat is shown to be limited to a small region in the ventral part of the dorsal horn. Preliminary results on the monkey are also discussed. THEORY OF INTERNAL OVER-ALL ROTATIONAL INTERACTIONS. II. HAMILTONIAN FOR THE NON-RIGID INTERNAL ROTOR, by D. Kivelson. Dec. 1955 [6]p. incl. diagrs. table, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 85770 Unclassified

Also published in Jour. Chem. Phys., v. 23: 2230-2235, Dec. 1955.

An approximate Hamiltonian for a nonrigid internal rotor is derived. The potential energy was expanded in a Taylor's series in the displacement coordinates and in a Fourier series in the angle of internal rotation [illegible]. The Hamiltonian was transformed by a contact transformation, and a second-order Hamiltonian in which vibrations and rotations were separated was obtained. The Hamiltonian consists of terms which constitute the usual rigid internal rotational problem, of centrifugal distortion terms involving both over-all and internal angular momentum, and of terms that arise because of the repulsive nature of the barrier. These repulsive terms enter as a single term, $2JF_v(m|1 - \cos 3\alpha|m)$, in the expression for the

rotational transitions of symmetric rotors, where J is the total angular momentum quantum number and m is the pseudo-quantum number for internal rotation. The repulsive constant, F_v, is given by the relation

$$F_v = -\Sigma \tfrac{1}{2}\left[B_{xx}^{(i)} + B_{yy}^{(i)} \right] a_i^{(1)},$$

where $B_{xx}^{(i)}$ $B_{yy}^{(i)}$ is the derivative of the rigid rotor rotational constant with respect to the ith symmetry coordinate, and $a_i^{(1)}$ is one-half the displacement of the equilibrium position of the ith internal coordinate in going from $\theta = 0$ to $\theta = \pi/3$. The dependence of the barrier height upon the vibrational motion was also studied. (For Part I see item no. MIT. 11:047) (Contractor's abstract)

THEORY OF INTERNAL OVER-ALL ROTATIONAL INTERACTIONS. III. NONRIGID ASYMMETRIC ROTORS, by D. Kivelson. Dec. 1955 [8]p. incl. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 85882
Unclassified

Also published in Jour. Chem. Phys., v. 23: 2236-2243, Dec. 1955.

The theory of the interactions of hindered internal rotation with over-all rotations is extended to include nonrigid asymmetric rotors. The interdependence of hindered internal rotation and vibrations and their effect upon the vibrational energy levels is considered. An approximate over-all internal rotational wave function is discussed. Since the general energy relation involves too many parameters to compute or to fit empirically, certain special cases are discussed. (Contractor's abstract, modified)

A TRAVEL AID FOR THE BLIND (Abstract), by C. M. Witcher. [Dec. 1955] 1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637)
Unclassified

Presented at meeting of the A. A. A. S., Atlanta, Ga., Dec. 26, 1955.

The meaning of the term "adequate travel aid for the blind" based on consideration of its required performance characteristics has been previously discussed by several workers. A set of such requirements has been tentatively accepted in this laboratory to serve as the basis for the design and construction of an actual model. These are summarized in the present paper. A description of the system design aspects of the model now under construction is given, with an analysis of how this system design attempts to meet the tentatively accepted requirements. In this analysis, the travel aid is conceived as a communication system, taking in information from the environment through which the blind user moves, and transmitting it to his brain through some sensory channel which can substitute for the visual one. From this point of view, the problem presents two aspects: A, to determine the minimum necessary information which must be extracted from the environment; and B, to devise means for the most efficient use of the chosen sensory channel for transmitting this information to the user's brain. The optical system employed in the present model is considered in some detail. The principle of step-down detection is briefly reviewed, after which an analysis of detector sensitivity requirements is given. A general relation is obtained expressing the received signal power in terms of the constants of the system and a factor, f, expressing the diffuse reflectivity of the surface being viewed by the system. A Fourier analysis of the received signal is given, leading to an expression for the power spectrum. This permits some conclusions to be drawn with regard to optimum amplifier design. Also published in Jour. Acoust. Soc. Amer., v. 29: 107-116, Jan. 1957.

Results of a study of the two major cues for stop consonants are presented: the burst of the stop release and the transition of the formants in the adjacent vowel. Detailed energy density spectra of the bursts were prepared. The transitions were studied by means of sonagrams. Possible criteria for identification were developed and tested. In order to assess the efficacy of the two types of cue, preceptual tests were conducted with isolated segments that contained either stop bursts or vowel transitions alone. Common acoustical properties of bursts and formant transitions are noted; differences as well as similarities are discussed in the light of different varieties of pitch judgments. A FOURIER METHOD FOR TIME DOMAIN SYNTHESIS, by M. Strieby. [1956] [13]p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Presented at Symposium on Modern Network Synthesis, Polytechnic Inst. of Brooklyn, N. Y., Apr. 13-15, 1955.

Published in Proc. Symposium on Modern Network Synthesis, v. 5: 197-209, 1956.

The chief aspect of time domain synthesis which is considered here is that of approximating an impulse response. The specific objective is to find a function which approximates an arbitrary, transformable time function and of which the Laplace transform is a realizable function of frequency. One period of a Fourier series is used to approxmlate the desired time function. The series shows how many poles are needed in the network system function and gives one an idea of the error function to be expected. It can be adjusted to achieve a reasonable compromise hetween error and network complexity. From this a realizable system function is straightforwardly computed.

THE GYRISTOR. A TOPOLOGICAL APPROACH TO ACTIVE CIRCUIT ANALYSIS (Abstract), by S. J. Mason. [1956] [1]p. (Technical rept. no. [illegible]) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) Unclassified

Kirchhoff and Maxwell gave us topological inspection rules for evaluating the transmission of a linear bilateral branch network. A linear bilateral branch network is a connection of resistors in each of which the current is proportional to the difference of its two terminal potentials. The gyristor is a branch-like element whose current is proportional to the sum of its two terminal potentials. With (complex) resistors and gyristors one can model any lumped linear circuit, in general nonbilateral. The point is that the Kirchhoff-Maxwell rules carry over to such models without change of form, the only addition being a relatively simple algebraic sign rule for gyristors in the transmission expression. Published in Proc. Symposium on Modern Network Synthesis, v. 5: 119-144, 1956.

Driving-point and transfer problems have certain common characteristics, so that a study of one of these is in one way or another helpful in the solution to the other problem. Regarding the driving-point problem a number of realization schemes are mentioned. Stress is put on procedures which avoid mutual inductive coupling, are straightforward, and are not very tedious algebraically and numerically. In suggesting various methods simplicity is stressed more than applicability.

The isometric circle method is used to study impedance transformations through lossless exponentially tapered transmission lines. By a simple inversion in the isometric circle of the direct transformation, followed by a reflection in the symmetry line of the two isometric circles, the ratio of the input impedance and the characteristic impedance at the input of the exponential line can be obtained from the ratio of the output impedance and the characteristic impedance at the output. The three different cases: transmission in the pass-band (elliptic case), cutoff (parabolic case), and below cutoff (hyperbolic case) are studied in the complex impedance plane, the complex reflection coefficient plane (Smith chart) and on the Riemann unit sphere. The use of non-Euclidean hyperbolic geometry is briefly outlined. Finally, the extension of the method to impedance transformations through lossy exponential lines is indicated.

TRANSMISSION AND REFLECTION OF WAVES BY NONUNIFORM ONE-DIMENSIONAL MEDIA, by S. J. Mason. [1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637)
Unclassified

The propagation of a wave in a one-dimensional medium is governed by the equation

$$z \frac{d}{dx}\left(\frac{1}{z}\frac{dE}{dx}\right) = s^2 E$$

where z is the wave impedance and s is the complex frequency. In this equation we assume that the wave velocity has been normalized to unity by a properly chosen deformation of the distance scale. Let z be a known function of x in the interval from 0 to x_1 and a constant in each of the two regions lying outside this interval. Now define

$$r(x) = \frac{1}{2}\frac{d}{dx} \log$$

MIT. 12:079 - MIT. 12:081

$$f_0(s, x) = 1$$

$$f_{k+1}(s, x) = \int_0^x f_k(-s, x')\, r(x') \exp(-2sx')\, dx'$$

In terms of these defined quantities the reflection coefficient R(s) of the nonuniform region is

$$R(s) = \frac{\sum f_{2k+1}(s, x_1)}{\sum f_{2k}(s, x_1)}$$

where the summations are taken over integer values of k from zero to infinity. The reflection coefficient gives the complex amplitude of the reflected wave when a unit amplitude wave traveling in the positive x direction is incident upon the nonuniform region lying between 0 and x_1. TIME-DOMAIN SYNTHESIS BY MEANS OF TRIGONOMETRIC POLYNOMIAL APPROXIMATIONS, by M. Strieby. Jan. 5, 1956, 35p. incl. diagrs. refs. (Technical rept. no. 308) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 107542 Unclassified

The area of time-domain synthesis considered here is the process of finding the system function of a lumped-element, linear, passive, bilateral network whose impulse response approximates a prescribed function of time. Time-domain synthesis can be regarded as essentially equivalent to the design of a rotational delay-line approximant. Suppose e^{-sT^*} to be such an approximant. $H_p(s)$ is the Laplace transform of a suitably chosen semiperiodic (periodic for t greater than zero, and zero for t less than zero) trigonometric polynomial approximation of period T to the desired network impulse response that is also of duration T. Then the function $H_p(s)(1 - e^{-sT^*})$ is the desired rational system function. The first method of synthesis bases the choice of a rational delay-line approximant upon the particular impulse response that is being synthesized. Care must be taken in the selection to insure realizability of the resultant network and proper convergence of the impulse response. However, the method is straightforward and gives good results: a fairly accurate error prediction can easily be made, so that no trial and error procedure is needed. Several examples show that a close approximation to the desired impulse response is attainable with relative economy of network elements. The second of the many possible procedures based on the same underlying philosophy uses a rational delay line approximant which is independent of the function that is being synthesized. One example seems to show that this approach also produces satisfactory results. (Contractor's abstract)

A UNIFIED THEORY OF INFORMATION, by K. H. Powers. Feb. 1, 1956, 105p. incl. diagrs. refs (Technical rept. no. 311) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637 AD 99355 Unclassified

The probabilistic theory of information is extended to processes involving the most general probability distributions. A change of probability measure on an abstract space serves as the appropriate mathematical model for the fundamental information process. A unified definition for the amount of concomitant information, which takes the form of a functional of the a priori and a posteriori measures, is introduced. This definition is sufficiently general to be applied to a theory that includes both the discrete and continuous theories as special cases. The definition is applied in a study of the information associated with the realization of a stochastic process. For the evaluation of mutual information rates between stationarily correlated multivariate gaussian time series, the techniques of linear prediction are employed. A brief investigation is made of the problems of communications in the presence of noise and through linear networks. (Contractor's abstract)

A HIGH-RESOLUTION ABSORPTION SPECTROSCOPE FOR THE STUDY OF RESONANCE LINES OF RADIOISOTOPES (Abstract), by J. E. R. Young. [Feb. 1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at Spectroscopy Symposium, Argonne National Lab., Lemont, Ill., Feb. 15-16, 1956.

A unique but simple high-resolution absorption spectroscope has been built for the study of the hyperfine structure of the 2537Å mercury lines. The Zeeman effect on a cooled Hg^{198} arc gives a variable wavelength source. The two circularly polarized components are divided into separate beams, traversing the same optical system, but detected separately; thus the source line scans the absorption spectrum in two directions simultaneously as the Zeeman field is varied. The light intensity from the source is monitored both before entering, and after leaving, the quartz absorption cell, by 1P28 photomultipliers. The resultant photocurrents are accurately compared on a dc bridge which gives a value directly proportional to the transmission through the cell. The six abundant stable isotopes are readily investigated, and owing to the sensitivity of the apparatus, which will detect approximately 10^{12} atoms of mercury vapor, it is possible to investigate radioisotopes of mercury. Techniques are under development to prepare very pure samples of radio-mercury in vapor form in order to investigate their hyperfine structure with this instrument. (Contractor's abstract)

MAGNETIC SCANNING OF THE MERCURY $^3S_1$ STATE (Abstract), by H. H. Plotkin. Feb. 1956 [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at Spectroscopy Symposium, Argonne National Lab., Lemont, Ill., Feb. 15-16, 1956.

By means of an extension of the method of magnetic scanning the $^3S_1$ state of mercury was studied in samples of natural mercury, mercury enriched in the isotope Hg^{201}, and radioactive mercury produced by the bombardment of gold by deuterons. The atoms were excited into the metastable $^3P_0$ level through the absorption of 2537A radiation and subsequent collision with N_2 molecules. A variable wavelength source of 4047A radiation from a pure Hg^{198} lamp in a magnetic field was then used to excite selectively the hyperfine structure components of the 4047A line. The intensity of the re-emitted 5461A radiation was observed with a photomultiplier. The lines of the even isotopes were not resolved; all of the magnetic hyperfine structure components of Hg^{199} and Hg^{201} were separated and measured. The frequencies were found to be in good agreement with reported values. A tentative assignment of the new components which appeared in the radioactive sample results in a nuclear magnetic moment for Hg^{197} of $\mu_{197} = 1.055\mu_{199}$ and an isotope shift toward abnormally small effective nuclear radius. Other lines, presumably from an isomeric state of Hg^{197}, have not been identified (Contractor's abstract)

CENTRAL EFFECTS OF STRYCHNINE ON SPINAL AFFERENT FIBERS, by J. Y. Lettvin, W. S. McCulloch and others. [1955] [2]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637; also in part by the Teagle Foundation, National Science Foundation, and Bell-Telephone Labs., Inc.) Unclassified

Presented at 584th meeting of the Boston Soc. of Psychiatry and Neurology, May 19, 1955.

Published in Arch. Neurology and Psychiatry, v. 75: 323-324, Mar. 1956.

A stimulating microelectrode was placed in the ventral horn of a lumbar spinal segment in anesthetized curarized cats. Recordings were taken of the antidromic volley running in the group one fibers in the dorsal root and of the orthodromic volley running in the segment's ventral root. After intravenous strychnine no change was found in the threshold of the motor horn cells. The terminal arborizations of the afferent fibers showed an increase in threshold. It was shown that strychnine affects all components of the electrotonic dorsal root potentials. The earliest components believed to be due only to the passage of impulses in the primary afferent fibers were affected. In these respects, strychnine imitates post-tetanic potentiation of reflexes which is due to hyperpolarization of the stimulated fibers. No evidence could be found of a decrease of threshold of the motor-horn cells after strychnine. The nuclei of Goll and Burdach were locally strychninized and recordings were taken from the dorsal columns and lumbar dorsal roots. It was found that synchronized antidromic volleys generated in the strychninized areas ran down the dorsal columns and out of the dorsal roots. Five examples are known of strychnine failing to fire off central nerve cells, one example of transynaptic conduction of strychnine "spikes" has been shown in the sympathetic nervous system and also antidromic spike propagation in the dorsal columns. EXCITABILITY CHANGES IN ANATOMICAL COMPONENTS OF THE MONOSYNAPTIC ARC, FOLLOWING TETANIC STIMULATION (Abstract), by A. R. Johnson, P. D. Wall and others. [1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637; Bell Telephone Labs., Inc., Teagle Foundation, and National Science Foundation) Unclassified

Presented at meeting of the Amer. Physiological Soc. and Federation of Amer. Societies for Exper. Biology, Atlantic City, N. J., Apr. 16-20, 1956.

Published in Fed. Proc., v. 15: 102, Mar. 1956.

Using unanesthetized, spinal, and decerebrate cats, we have exposed nerves from individual muscles. Most experiments were carried out using the nerves to gastrocnemius. All ventral roots in the lumbar enlargement were cut. The time course of post-tetanic potentiation of a monosynaptic reflex was measured. Next stimulating monopolar microelectrodes made of 15 micron OD sharpened glass-covered platinum wire were lowered through several stations into the lumbar enlargement. These electrodes were cut off and left in the cord and their location was later shown by histological examination. The change of excitability along the intramedullary fibers was tested by stimulating locally with the microelectrodes and recording the size of the antidromic spike traveling in the relevant sensory nerve. The excitability of tetanized group I fibers from gastrocnemius is decreased for a very prolonged time from the root entrance zone to the region of their endings in the ventral horn. Relations between this depression and the increase of the monosynaptic reflex will be discussed. The excitability of the terminations of nontetanized neighboring group I fibers is not affected during the prolonged period of depression. Motor horn cell excitability was tested by direct local stimulation and was found not to be changed during the long period of post-tetanic potentiation. (Contractor's abstract)

Published in I.R.E. Convention Record, Pt. II: 26-37 1956.

A general theorem is presented that relates three arbitrary terminal-pairs of a linear circuit by means of network parameters – impedance or admittance functions. It is shown that this is a generalization of Thévinin's theorem, leading to considerable simplifications in the driving-point analysis of active networks. The class of active networks containing only one active element, or their equivalent, is considered in detail. Some properties of the driving-point impedance functions of such networks are stated in the form of existence theorems. Synthesis techniques for two particular types of active network configurations are presented and illustrated. (Contractor's abstract)

A PREDICTION THEORY APPROACH TO INFORMATION RATES, by K. H. Powers. [Mar. 1956] [8]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at I.R.E. National Convention, New York, Mar. 19-22, 1956.

Published in I.R.E. Convention Record, Pt. IV: 132-139, 1956.

Regarding a change of probability measure to be the fundamental information process, a unified definition for the amount of information resulting is introduced. This definition is sufficiently general to include as special cases both discrete and continuous theories. With the recognition of an intimate relationship between information theory and the prediction theory of Kolmogorov and Wiener, the techniques of linear prediction are employed to determine the rate at which one gaussian time function gives information about the past, present, and/or future of another similar function correlated with it. The results of this study are applied to the investigation of the processes by which information is lost in additive noisy channels as well as in linear filters and predictors. Published in I. R. E. Convention Record, Pt. 1V: 21-30, 1956.

Following the lines of the Wiener theory of experimental nonlinear system classification a theory is developed for the experimental determination of optimum time-invariant nonlinear filters. The filters are optimum in a weighted mean square sense in which the weighting function is at our disposal. An operator on the past of the input is defined in such a way that, in the experimental setup, we can take advantage of orthogonality to evaluate the classifying coefficients of the optimum system independently. This paper briefly describes the Wiener theory of nonlinear system classification and then discusses the theory and associated apparatus for the determination and synthesis of optimum nonlinear filters. TWO INVARIANTS OF NOISY LINEAR AMPLIFIERS, by H. A. Haus and R. B. Adler. [Mar. 1956] [15]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at I. R. E. National Convention, New York, Mar. 19-22, 1956.

Published in I. R. E. Convention Record, Pt. II: 53-67, 1956.

This work concerns the single-frequency noise performance of linear, active two-terminal pair networks with internal noise generators. Two parameters of any active network, expressible in terms of its impedance matrix and open-circuit noise voltages, are found to be invariant when it is imbedded in any arbitrary, lossless (reciprocal or nonreciprocal) network to produce a new two-terminal-pair system. An important class of amplifiers can be brought, by means of lossless feedback, into a unilateral form in which the open-circuit input and output impedance are guaranteed to have positive real parts. One simple interpretation of the invariants is that they determine, for this class of amplifiers, the minimum value of the expression $M = (F - 1)/(1 - 1/G)$ attainable by means of proper end-loading of the unilateralized amplifier, where F is the spot noise figure, and G is the available gain. It is shown further that the same minimum value for M can be reached, but not improved upon, by proper end-loading of the amplifier in a nonunilateral and unconditionally stable circuit connection. These results, and some others demonstrating the invariance properties of M, suggest that the quantity M be adopted, instead of the noise figure F, as a quantitative measure of amplifier noise performance. A PROBABILITY APPROACH TO CERTAIN NEUROELECTRIC PHENOMENA, by L. S. Frishkopf. Mar. 1, 1956, 74p. incl. illus. diagrs. refs. (Technical rept. no. 307) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 107077 Unclassified

When an acoustic click is presented to the ear of an anesthetized cat, an electrode, placed near the round window of the cochlea, detects a superposition of microphonic and neural components. The first neural component (N_1) represents a sum of action potentials of first-order auditory neurons. We have studied the N_1 response amplitude as a function of click intensity and observed that this "intensity function" characteristically exhibits a two-stage growth. This behavior suggests that the contributing neural elements might be usefully classified as "sensitive" or "insensitive." A model is developed in which properties of "neural units" are defined: units obey the all-or-nothing principle; the threshold of a unit is a fluctuating parameter describable by a probability density function. Populations of statistically independent identical units are postulated. The model is related to the data by defining an intensity function that depends linearly on the number of units in each population that respond. The results of two experiments are compared with the predictions of the model. First, we have studied the amplitude variability of N_1 as a function of stimulus intensity. Second, we have investigated the effect of a continuous noise background on the amplitude of the N_1 response to a click

("masking" of N_1). In both cases the data and the predictions of the model are in good agreement over the first interval of amplitude growth (the sensitive range). Over the insensitive interval the data are inconclusive. The size of the sensitive population and the characteristic rate of threshold fluctuations of a sensitive unit are estimated. It is concluded that (a) a relatively homogeneous population of neural units, characterized hy rapidly fluctuating thresholds, is responsible for the initial component of growth of the intensity function; and (b) that over the remaining interval of the intensity function a single-population hypothesis will not account for the data within the framework of the model. THEORY OF INTERNAL OVER-ALL ROTATIONAL INTERACTIONS. IV. STARK EFFECT IN NONRIGID INTERNAL ROTORS, by D. Kivelson. [Mar. 5, 1956] [2]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 129244 Unclassified

Also published in Jour. Chem. Phys., v. 26: 215-216, Jan. 1957.

When a uniform electric field is applied to a nonrigid internal rotor, the "Stark pattern" of the energy levels is dependent upon the torsional motion. This dependence enters as a centrifugal distortion interaction and by means of the so-called "repulsive effect" of the potential barrier to internal rotation. These effects are small but observable and require that appropriate corrections be made in order to obtain an accurate and meaningful dipole moment from Stark effect measurements. The theory of the Stark effect in vibrating internal rotors has been formulated in this article with particular emphasis on its application to a molecule of C_{3v} symmetry such as CH_3SiH_3. Krongelb and Strandberg have observed this effect in CH_3SiH_3. (Contractor's abstract)

VIBRATION-INTERNAL ROTATION INTERACTIONS IN MOLECULES CONTAINING A SYMMETRIC TOP GROUP, by P. R. Swan, Jr. and M. W. P. Strandberg. Mar. 22, 1956 [46]p. incl. diagrs. tables, refs. (Technical rept. no. 313) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Also published in Jour. Molecular Spectroscopy, v. 1: 333-378, Dec. 1957.

The vibration-internal rotation interactions in molecules that contain a single symmetric top are studied by means of a model consisting of two internally rigid groups that are allowed to vibrate as well as rotate relative to each other. The matrix mechanical Hamiltonian for the model is obtained and the diagonalization of the corresponding secular determinant that contains large off-diagonal terms is accomplished. An expression for the $J = 0 \rightarrow 1$, $\Delta K = 0$ transition is obtained. Numerical calculations are carried out for the case of methyl alcohol in order to compare the theory with the observed spectrum. A qualitative fit is found, the major contributions being the in-plane vibrations of the two rigid groups. The lack of detailed agreement is attributed to the neglect of those vibrations which distort the methyl group, and to insufficient knowledge concerning the infrared spectrum of the molecule. The study of nonlinearities in nature suitable for computer use has led to the cryotron, a device based on the destruction of superconductivity by a magnetic field. The cryotron, in its simplest form, consists of

MIT. 12:101 - MIT. 12:104

a straight piece of wire about one in. long with a single-layer control winding wound over it. Current in the control winding creates a magnetic field which causes the central wire to change from its superconducting state to its normal state. The device has current gain, that is, a small current can control a larger current; it has power gain so that cryotrons can be interconnected in logical networks as active elements. The device is also small, easily fabricated, and dissipates very little power.

HYPERFINE STRUCTURE BY COINCIDENCE TECHNIQUES, by L. C. Bradley, III. [1956] [1]p. incl. diagr. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 103580 Unclassified

Published in Phys. Rev., v. 102: 293, Apr. 1, 1956.

The method is based on the work of Brannen, et al. (C. A., v. 49, 12123d). A low-resolution spectrograph admits to 1 photomultiplier only right-circularly polarized light of wave length λ_1; to the other, only right-circularly polarized light of wave length λ_2. A magnetic field is applied in the direction of observation. There will be only accidental coincidences, unless a radio-frequency field causes transitions in the intermediate level between the sublevels M = ± 1/2. Thus, a rise in the coincidence rate indicates the resonant frequency. It is clear that similar, but less pronounced, effects will occur if the intermediate level possesses hyperfine-structure sublevels, between which transitions are similarly induced. A level of an ionized atom can be studied by this technique. Metastable or ground states are not accessible to this technique. (C. A., 1956:11105a)

A THEORY OF NONLINEAR SYSTEMS, by A. G. Bose. May 15, 1956, 58p. incl. diagrs. (Technical rept. no. 309) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 134905 Unclassified

The Wiener theory of nonlinear system characterization is described and some of its important concepts are discussed. Following these lines, a theory is developed for the experimental determination of optimum time-invariant nonlinear systems. The systems are optimum in a weighted mean-square sense in which the weighting function is at our disposal. The design of nonlinear systems is regarded as the problem of mapping the function space of the past of the input onto a line that corresponds to the amplitude of the filter output. By choosing a series expansion for this mapping operation that partitions the function space into nonoverlapping cells, an orthogonal representation for nonlinear systems is obtained that leads to convenient apparatus for the determination of optimum systems. General methods are described for applying this theory to the determination of systems that have a performance superior to that of given linear or nonlinear systems. A criterion is established relative to which two systems are defined as "nearly equivalent" and the approximation of nonlinear systems by linear and simple nonlinear systems is discussed. The theory is extended to include the problem of

multiple nonlinear prediction and apparatus for the determination of optimum predictors is indicated. (Contractor's abstract)

THEORETICAL LIMITATIONS ON THE NOISE PERFORMANCE OF LINEAR AMPLIFIERS (Abstract), by H. A. Haus and R. B. Adler. [June 1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at the Congrès International "Tubes Hyperfréquences," Paris (France), May 29-June 2, 1956.

This work concerns the single-frequency noise performance of linear, active, two terminal-pair networks with internal noise generators. It is shown that an adequate measure of noise performance of an amplifier must include, beside the noise figure F, the available power gain G of the amplifier. The new proposed measure is: $M = (F - 1)/(1 - 1/G)$. The significance of M shows up when the amplifier is imbedded in an arbitrary lossless network in such a way that a new two terminal-pair amplifier is obtained. This transformation leaves invariant the eigenvalues of a matrix N that is formed from the open-circuit noise voltages and the impedance elements of the amplifier. The minimum value of the noise measure M that can be achieved by such a lossless transformation is given by one of the eigenvalues of the N matrix. An important class of amplifiers can be brought, by means of lossless feedback, into a unilateral form in which the open-circuit input and output impedances have positive real parts. One way of achieving the minimum value of M is to properly mismatch the input of the amplifier in its unilateral form. Some properties of the noise measure M are presented that further recommend its use, instead of the noise figure F, as a quantitative measure of amplifier noise performance. (Contractor's abstract)

A negative resistance connected to a "suitable" resonant circuit (a current-controlled negative resistance connected to a series-tuned circuit, or a voltage-controlled negative conductance connected to a parallel-tuned circuit) constitutes an almost-harmonic oscillator. In this paper the "unsuitable" connections (a current-controlled negative resistance connected to a parallel-tuned circuit, or a voltage-controlled negative conductance connected to a series-tuned circuit) are analyzed qualitatively in terms of variables leading to a single-valued phase plane. Physical considerations, expressed in a jump condition, serve to connect different regions of analyticity of the differential

MIT. 12:109 - MIT. 12:111

equattons of lhe circuit tn this plane. The "unsuttable" connections cannot sustain almost-harmonic oscillattons, and their theorettcally possible relaxatton oscillations are unstable; they yteld bistable ctrcuits. (Contractor's abstract)

THE SYNTHESIS OF VOLTAGE TRANSFER FUNCTIONS, by P. M. Lewis, II. June 7, 1956, 105p. incl. diagrs. refs. (Technical rept. no. 314) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 133936 Unclassified

The synthesis of voltage transfer functions (E_2/E_1), in lhe form of linear, lumped, finite, passtve, bilateral networks, containing no ideal transformers or mutual coupling, is considered. The basic realizability conditions are derived and realization procedures are developed based on these conditions, showing them to be both necessary and sufficient. This particular class of networks places constraints on the allowable values of the constant multiplier in the voltage transfer function and on the positions of the transmtssion zeros in the case of grounded networks. In order to study these constraints, a new concept — the concept of the one — is introduced. This concept gives a certain physical significance to the constant multiplier which allows the basic realizability conditions to be derived in a simple fashion. These conditions are: (1) the maximum gain obtainable from a given pole-zero plot independent of configuration; (2) the maximum gain obtainable from a give pole-zero plot for a given complexity of the network configuration; (3) the maximum gain obtainable from a given pole-zero plot for a realization in terms of a symmetrical network; and (4) the general conditions under which a grounded (three-terminal) realization of any transfer function is possible Various synthesis procedures are developed based on these realizability conditions: (1) a general lattice synthesis in the two element and three element cases; (2) a general method of realizing grounded symmetrical networks, by first realizing a lattice and then unbalancing it; and (3) a general realization procedure yielding any allowable gain in both the two element and the three-element cases. MOTIONS OF IONS AND ELECTRONS, by W. P. Allis. June 13, 1956, 100p. incl. diagrs. tables, refs. (Technical rept. no. 299) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 125502 Unclassified

This report reviews the mathematical methods applicable to ionized gases. In Part I the motion of an individual electron or ion under a Lorentz force, tncluding the effects of magnetic gradients, is studted. In Part II, with the tntroductton of collistons, thts ts no longer posstble, but we can still follow the motion of an average particle. For high values of E/p, the behavtor of a swarm of parttcles ts remarkably close to the motton of the average parttcle, but for lower values of E/p other methods must be used. In Part III the Boltzmann equatton ts applied to a "Lorentzian gas," that is, to force electrons in a gas. In Part IV the equation is transformed to an integral form, the Boltzmann transport equation, so that it will be applicable to ions. The transport equation is solved exactly for the case of particles with a constant mean free time, which corresponds to the polarization force between an ion and a molecule. The consideratton of Coulomb interacltons in Part V introduces a force of so much longer range that an electron interacts simultaneously wtth a large number N of electrons and ions. The basic assumption of Boltzmann theory is then isolated, and one must use the Fokker-Planck equation, the relation of which to the Boltzmann transport equation is shown. The coefficients of the Fokker-Planck equation are derived by the method of the Rosenbluth potentials. (Contractor's abstract)

PIECEWISE-LINEAR NETWORK THEORY, by T. E. Stern. June 15, 1956, 76p. incl. diagrs. refs. (Technical rept. no. 315) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 200729 Unclassified

A systematic approach to the problems of analysis and synthesis of piecewise-linear systems that do not contain memory is presented. These systems provide a link between the general studies of nonlinear systems, examplified by the work of Wiener, Zadeh, and others, and the needs of the practical circuit designer. In the area of analysis, straightforward procedures are developed for handling resistive piecewise-linear networks. The methods are based upon an algebra of inequalities. Examples of applications to analysis are given. In the area of synthesis, techniques are developed by using diode networks for the construction of general piecewise-linear driving point functions, as well as generators of piecewise-linear voltage transfer functions of several variables. Some of the properties of nonlinear resistive networks, in general, and diode networks, in particular, are discussed. Applications of the inequality algebra to the synthesis problem are also considered. Two forms of the transfer synthesis problem are treated, arbitrary function synthesis. Examples of the practical application of the techniques that are discussed to the construction of generators of functions of one and two variables are given. (Contractor's abstract)

IMPEDANCE AND POLARIZATION RATIO TRANSFORMATIONS BY A GRAPHICAL METHOD USING THE ISOMETRIC CIRCLES, by E. F. Bolinder. [1956] [5]p. incl. diagrs. (Sponsored jointly Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 115170 Unclassified

Also published in I. R. E. Trans. on Microwave Theory and Techniques, v. MIT-4: 176-180, July 1956.

The isometric circles for the direct and inverse linear fractional transformations can be used for transformations of impedances and polarization ratios. In the loxodromic case an inversion is performed in the isometric circle of the direct transformation, followed by a reflection in the symmetry line of the two circles, and a rotation around the origin of the isometric circle of the inverse transformation. In the nonloxodromic case only the first two operations have to be applied. Three illustrative examples are given: the first shows the transformation of the right half of the complex impedance plane into the unit circle (Smith Chart); the second gives a circular geometric proof of the Weissfloch transformer theorem; the third shows an example of cascading lossless, two terminal-pair networks. MORPHOPHONEMIC CHANGE IN SIOUAN (Abstract), by G. H. Matthews. July 1956 [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc 64637, and National Science Foundation) Unclassified

Presented at meeting of the Linguistic Soc. of Amer., Ann Arbor, Mich., July 27-28, 1956.

A morphophoneme which occurs in the Siouan languages consists of from two to four allomorphophones, depending on the language. The correspondences of these allomorphophones, vowels, among both those languages which have retained the morphophoneme and those which have lost it, are different from the correspondences of the several vowels when they occur in the same environment but not as part of the morphophoneme. This infers that instead of a morphophoneme, another vowel phoneme must be reconstructured in Proto-Siouan. However, this reconstructed phoneme occurs only in a very restricted, morphologically described environment. In addition, it alters the Proto Siouan vowel from the typical Siouan one shared by most of the daughter languages. Those daughter languages differing from the typical Siouan system do so in an entirely different manner. (Contractor's abstract)

A NOTE ON THE MAXIMUM FLOW THROUGH A NETWORK, by P. Elias, A. Feinstein, and C. E. Shannon. July 11, 1956 [3]p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 127653 Unclassified

Also published in I. R. E. Trans. of Professional Group on Information Theory, v. IT-2: 117-119, Dec. 1956.

This note discusses the problem of maximizing the rate of flow from one terminal to another, through a network which consists of a number of branches, each of which has a limited capacity. The main result is a theorem: The maximum possible flow from left to right through a network is equal to the minimum value among all simple cut-sets. This theorem is applied to solve a more general problem, in which a number of input nodes and a number of output nodes are used.

THEORY AND APPLICATIONS OF FLOW GRAPHS, by C. S. Lorens. July 15, 1956, 114p. incl. diagrs. refs. (Technical rept. no. 317) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 158736 Unclassified

Three objectives were undertaken: (1) the development of a basic theory of flow graphs; (2) the extension of its known application to electrical networks; and (3) the formulation of the natural relation between flow graphs and the properties of discrete statistical systems. Part I deals with the first two objectives. Much of the linear theory of flow graphs parallels linear equation theory in such a manner that considerable meaning is given to many classical operations of formulation, inversion, and reduction. Part I covers additive functional systems; inversion; electrical network formulation; mathematical determinants; partitions and expansions of a determinant; rank, positive definite, eigenvalues, and eigenvectors; group multiplication; and transcendental equations. Part II deals with the third objective. The pictorial representation of a discrete statistical system specifies its properties. With flow graphs these properties are conveniently calculated and interpreted directly from the representative graph. The material of Part II covers recurrent events, transient systems, stationary state distributions, sensitivity and variation, generating

MAGNETIC MOMENTS AND HYPERFINE-STRUCTURE ANOMALIES OF Cs^{133}, Cs^{134}, Cs^{135}, and Cs^{137}, by H. H. Stroke, V. Jaccarino and others. July 26, 1956 [14]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 127652 Unclassified

Also published in Phys. Rev., v. 105: 590-603, Jan. 15, 1957.

The atomic-beam magnetic-resonance method was used to measure the nuclear gyromagnetic ratios and hyperfine-structure separations of the radioactive isotopes Cs^{134}, Cs^{135}, and Cs^{137}. A surface ionization detector was used. The hyperfine-structure separations were obtained by direct $\Delta F = \pm 1$ transitions near zero field. The values of $\Delta\nu$ found for the three isotopes are:

$\Delta\nu\ (Cs^{134}) = 10473.626 \pm 0.015$ mc/sec,
$\Delta\nu\ (Cs^{135}) = 9724.023 \pm 0.015$ mc/sec,
$\Delta\nu\ (Cs^{137}) = 10115.527 \pm 0.015$ mc/sec.

Pairs of transition belonging to the two different F-states, but involving the same m_F values, constitute frequency doublets separated by $2g_I\mu_o H$. From measurements of the difference frequencies of these doublets for pairs of isotopes in fields in the vicinity of 9000 gauss, the following g-value ratios were obtained:

$g_I(Cs^{135})/g_I(Cs^{133}) = 1.05820 \pm 0.00008$,
$g_I(Cs^{137})/g_I(Cs^{135}) = 1.04005 \pm 0.00008$,
$g_I(Cs^{134})/g_I(Cs^{133}) = 1.01447 \pm 0.00029$.

The hfs anomalies arising from the variation of the electron wave function over the finite distribution of nuclear magnetization were calculated from these measurements. The values found for these anomalies, defined by $\epsilon_2 - \epsilon_1 = [g_1\nu_2(2I_1 + 1)]/[g_2\nu_1 \times (2I_2 + 1)] - 1$, are:

$\epsilon(Cs^{133})\ \epsilon(Cs^{135}) = +0.057 \pm 0.009\%$,
$\epsilon(Cs^{135})\ \epsilon(Cs^{137}) = -0.020 \pm 0.009\%$,
$\epsilon(Cs^{133})\ \epsilon)Cs^{134}) = +0.169 \pm 0.030\%$.

The theory of Bohr and Weisskopf on the hfs anomalies was applied to these nuclei; the calculations are based primarily on a single-particle model with varying distributions of spin and orbital contribution to the nuclear moment. An apparent magic number effect in the anomalies was observed. (Contractor's abstract)

MICROWAVE CONDUCTIVITY OF AN IONIZED DECAYING PLASMA AT LOW-PRESSURES, by A. L. Gilardini and S. C. Brown. July 27, 1956 [6]p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 127599 Unclassified

Also published in Phys. Rev., v. 105: 25-30, Jan. 1, 1957.

Margenau's analysis for the microwave conductivity of an infinite decaying plasma in a uniform field is extended to the case of a bounded plasma in a slightly nonuniform file. It is shown that, if we assume a power expansion for the electron-collision frequency as a function of energy, the conductivity at low pressures can be computed as a function of time and position when the spatial and time variations of the density and energy moments of the electron-distribution function are known. An approximate method, based on a convenient integration of Boltzmann equation is given to compute these quantities, when inelastic collisions can be neglected. The steady-state conductivity in the late afterglow of a diffusion-controlled decaying plasma is thus explicitly determined for two experimental conditions: a plasma filling a cubic quartz bottle centered in a parallelpiped microwave cavity and a plasma filling a quartz tube of square cross section in a wave guide. The limit for the validity of the theory set by the appearance of inelastic collisions at high electric fields is investigated.

MICROWAVE DETERMINATION OF THE PROBABILITY OF COLLISION OF ELECTRONS IN NEON, by A. L. Gilardini and S. C. Brown. July 27, 1956 [4]p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 127651 Unclassified

Also published in Phys. Rev., v. 105: 31-34, Jan. 1, 1957.

The theory for computing the microwave conductivity of a plasma discussed in the previous paper (Phys. Rev., v. 105: 25-30, Jan. 1, 1957) can be used for determining the collision probability for momentum transfer of slow electrons when the conductivity ratio of a plasma is measured as a function of the applied field. The conditions required for having a pressure independent conductivity ratio and steady state electron energy for a given field are investigated. The convenience of using two independent fields for

measuring the conductivity and changing the electron energy is shown. Conductivity ratios measured in the afterglow of a pulsed discharge in a microwave resonant cavity are given for neon and neon contaminated with argon. The collision probability for momentum transfer is neon computed from these data as a function of the electron velocity joins Ramsauer's and Kollath's measurements for higher electron velocities.

ABSORPTION OF SOUND IN LIQUID HELIUM II, by W. M. Whitney. Aug. 15, 1956 [4]p. incl. diagrs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 127600 Unclassified

Also published in Phys. Rev., v. 105: 38-41, Jan. 1, 1957.

The coefficient of absorption of sound in liquid helium has been measured at a frequency of 11.8 mc/sec in the temperature range from 0.2°K to 1°K, at vapor pressure, and at 8.0, 13, and 18.3 atmospheres. Careful measurements above 0.9°K at vapor pressure reveal that the two sharp maxima observed by Chase and Herlin at the top of their absorption curve were an instrumental effect. Preliminary results at the higher pressures indicate that, if allowance is made for the pressure variation of the density and the velocity of sound, the attenuation decreases exponentially with pressure at temperatures just below 1°K. FLUCTUATIONS AND IRREVERSIBLE THERMODYNAMICS, by L. Tisza and I. Manning. [Aug. 16, 1956] 11 p. incl. refs. (Technical rept. no. 235) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 135144 Unclassified

Also published in Phys. Rev., v. 105: 1695-1705, Mar. 15, 1957.

The time dependent theory of fluctuations is based on a combined application of the phenomenological theory of dissipation and the stochastic theory of random processes. The traditional method of joining these theories into a uniform scheme proceeds by adding a random perturbation to the differential equation of the phenomenological kinetic theory (the Langevin equation in case of Brownian motion). In the present approach the problem is considered as an essentially statistical one. The role of the differential equation is to fix the form of the distribution function over the manifold of fluctuation paths in function space. The solutions of the equation constitute the most probable region in function space, and the fluctuations appear with their appropriate probabilities. The connection between the phenomenological equation and the distribution function is stipulated by means of a postulate, the essential ingredient of which is the auxilliary function recently introduced by Onsager and Machlup. This postulate is joined to the standard assumptions of the phenomenological and the stochastic theories for the derivation of the entire time-dependent fluctuation theory. The calculation of fluctuations is carried out in the temporal and the spectral descriptions. The relation of the two schemes is discussed along with the scope and limitations of the theory.

VOLTAGE-TUNED RC ACTIVE FILTERS USING JUNCTION DIODES AND TRANSISTORS (Abstract), by C. R. Hurtig. [Aug. 1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

The use of forward-biased junction diodes as the resistive parameters of RC active filters results in a voltage-tuneable filter whose complex natural frequency is a linear function, within 2 per cent, of the control voltage over a range of ten-to-one. Two examples are shown — an oscillator and a narrow-bandwidth amplifier. The fundamental limitations to linearity of the frequency control characteristic are discussed. The short-time stability of the magnitude of the complex natural frequency is limited by resistance modulation of the diodes by excess semiconductor noise to a few parts in ten thousand. The long-time stability is mainly determined by the temperature dependence (approximately -0.34 per cent per degree Centigrade) of the incremental resistance of the junction diodes. A design concept for the use of passive networks with transistor amplifiers which results in networks compatible with transistor impedances obtained with bias-stabilized connections is discussed. These networks are the reversed equivalent of those commonly used in vacuum tube circuitry. (Contractor's abstract)

THEORY OF HYPERFINE STRUCTURE II, by C. Schwartz. [Aug. 31, 1956] 11 p. incl. diagrs. tables. refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 128823 Unclassified

MIT. 12:123 - MIT. 12:124

Also published tn Phys. Rev., v. 105: 173-183, Jan. 1, 1957.

Numerical values for the 1-electron integrals of tnterest in the analysts of atomtc hyperfine structure have been calculated by using screened relativistic wave functions. Ratios of these tntegrals, representing the relativistic correction factors of Casimtr, are given to replace the older values which neglected shielding effects. The most marked changes occur tn the studies of the octopole tnteraction and hfs anomalies tn p-states. The calculated 1-electron magnetic dipole integral, when compared with the expertmental ratio. dipole hfs/nuclear moment, makes it posstble to deduce the magnitude of atomic polarization (Sternheimer) effects. In the doublet p-states that were studied, the polarization terms seem to be almost entirely of the sort discussed in an earlier paper: excitation of s-electrons. In a general discussion of polarization calculations, some explanation is given of the large correction factors for the fine structure, dipole, and quadrupole hyperfine structure that were calculated by Sternhetmer (the radial redtstribution of charge terms). It ts also suggested that large polarization corrections may be needed for the octopole interaction. (For Part I see item no. MIT. 11:061) (Contractor's abstract)

FINAL-VALUE CONTROL SYSTEMS, by R. C. Booton, Jr. [Sept. 1956] [3]p. (Sponsored jointly by Signal Corps, Offtce of Naval Research, and Air Force Office of Sctenttfic Research under DA 36-039-sc-64637) Unclassified

Presented at 1956 Symposium on Information Theory, M.I.T., Sept. 10-12, 1956.

Published in I.R.E. Trans. on Information Theory, v. IT-2: 173-175, Sept. 1956.

A final-value system controls a response variable over a time interval with the objective of minimizing some measure of the difference between a desired value and the value of the response at the final time of the interval. The ensemble of situations is considered in which the system input and the desired response are random variables that are statistically related. The response variable is constrained because of the physical limitations of the element being controlled. Earlier considerations (1) of the problem has shown that any situation in which the response is the result of a linear (possibly time variable) operation on a variable that is constrained to be less in magnitude than some allowable value can be conferred to a maximum velocity constraint situation by consideration of an extrapolated response that is velocity constrained and which equals the actual response at the final time. Earlier results (1) based upon a quasi-linearization interpretation of the optimum mean-square-error linear system with a velocity constraint suggest that a system consisting of a predictor followed by a simple nonlinear feedback system should be approximately the optimum system. The present paper discusses the optimum design problem with an arbttrary error criterion and an arbitrary ensemble of input functtons. The discussion ts restricted to the velocity constraint situation and for mathematical stmplicity the continuous time variable ts replaced by a discrete set of time values. Chotce of the system operator to mtnimize the measure of error ts shown to lead to a result that can be described in words as follows: "At each step in time the system can move the response from tts old position to a new position that can be selected from a range of values determined by the old response and by the allowable amount of movement (determined, of course, by the magnitude of the allowable velocity). For each allowable value of the new response the conditional error measure, conditional both on the input values already received and on the assumption that in the future the system will perform in an optimum manner, is computed." A RADAR DETECTION PHILOSOPHY, by W. M. Siebert. [1956] [18]p. incl. illus. (Sponsored jotntly by Signal Corps, Office of Naval Research, and Air Force Office of Sctentiftc Research under [DA 36-039-sc-64637]) AD 127078 Unclassified

Also published tn I.R.E. Trans. on Information Theory, v. IT-2: 204-221, Sept. 1956.

This paper is an attempt to present a short, unified discussion of the radar detection, parameter estimation, and multiple-signal resolution problems — mostly from a philosophical rather than a detailed mathematical point of view. The purpose is, hopefully, to make it possible in at least some limited sense to reason back from appropriate measures of desired radar performance to specifications of the necessary values of the related radar parameters. Specifically four measures of performance quality are considered: (1) the reliability of detection, (2) the accuracy with which target parameters can be esttmated; (3) the extent to which such estimates can be made without ambiguity; and (4) the degree to which two or more different target echoes can be separated or resolved. It is argued that the radar synthesis problem can be split into two more-or-less independent phases. First, adjust such parameters as those appearing in the radar equation so that the received signal energy is sufficiently large for the degree of reliability of detection desired. The required value of energy is almost entirely independent of the character of the received echo signal waveform. The second phase is, then, to select the waveform in such a way that accuracy, ambiguity, and resolution requirements are met. The limitations on what can be achieved in terms of these three quality measures are discussed in relation to an uncertainty principle. For

purposes of illustration several novel waveforms havtng unusual and useful properties are described. (Contractor's abstract)

CHARACTERIZATION OF PROBABILITY DISTRIBUTIONS FOR EXCESS PHYSICAL NOISES, by J. Hilibrand. Sept. 7, 1956, 51p. incl. illus. diagrs. tables, refs. (Technical rept. no. 276) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 149545 Unclassified

Theoretical and experimental techniques are described for charactsrizing the probability distributions of certain excess physical noises by their moments. Theoretical methods are presented for applying this "moments technique" in the time domain to random-pulse noise, and in the frequency domain to any random functions for which the momsnts exist. The frequency-domain techniqus is used for a theoretical study of the approach to a gaussian distribution of random-pulss noise that is band-limited by RC cutoffs at low and high frequencies is examined by using the time-domain technique. It is found that the approach of noise distributions to gaussian is govsrned by ths "memory" of the filter system rather than simply by its band-width. An experimsntal systsm is described for measuring the first four moments of notses in the 0.2 cps - 10 kc range. It is concluded that experimental measurements of moments are mors dsairable than direct probability denstty msasursments when the goals are: (a) to categorize broadly the form of continuous noise distributton by a small number of parameters, and/or (b) when a minimum investment of time and equipmsnt is desired. Measuremsnts on 1/f noise in germantum diodes confirm (within experimental error) that the first probabtlity dtstribution of this notse is gaussian in nature. Some effects of limited system bandwidth are illustrated by measurements on the distinctly nongaussian "avalanche" noise in silicon junction diodes. (Contractor's abstract)

THE PARAMAGNETIC RESONANCE SPECTRUM OF AMMONIUM CHROMIUM ALUM, by C. F. Davis, Jr. and M. W. P. Strandberg. [Sept. 11, 1956] [9]p. incl. diagrs. tables, refs. [Technical rept. no. 242] (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 128825 Unclassified

Also published in Phys. Rev., v. 105: 447-455, Jan. 15, 1957.

A detailed solution of the fine-structure splitting of the ground state of the chromium ion is given. This solution assumes an electric field of cubic symmetry with a small trigonal distortion and the residual spin-orbit coupling superposed. The effect of a magnetic field at an arbitrary orientation is calculated. Absorption positions and relative intensities are calculated and checked with experiment. Lines of character predominantly $\Delta S_z = 2, 3$ are shown to have sufficient $\Delta S_z = 1$ character to give the experimentally determined intensities. So-called "forbidden transitions" are accounted for quantitatively by this detailed calculation. Shapes of absorption peaks are Lorentzian for dilute specimens and Gaussian for full-strength alum. A small variation of trigonal Stark field from one paramagnetic ion to another is sufficient to account for the observed line width. (Contractor's abstract)

The design of a magnet for producing a uniform field is described. The magnet model used in the calculations is that of cylindrical cores surrounded by rims. The positions of the central pole faces and rims can be adjusted independently. A calculation, based on the assumption that the pole pieces are uniformly magnetized, shows that, for a certain positioning of the cores and rims, the z^2 and z^4 correction terms to H_z can be simultaneously canceled. Practical limitations to uniformity that result from a slight asymmetry in the geometry and from the effect of nonuniformity in magnetization because of domain structure in the iron also are discussed. BARRIER THEORY OF THE PHOTOCONDUCTIVITY OF LEAD SULFIDE, by J. C. Slater. [1956] [14]p. incl. diagrs. tables. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637] Unclassified

Published in Phys. Rev., v. 103: 1631-1644, Sept. 15, 1956.

The barrier theory of the infrared photoconductivity of PbS films is discussed, according to which the high resistance of the films arises from n-p-n barriers at the surfaces between the crystallites forming the films, the barriers being formed in the oxidizing process used in preparing the films. Under the action of light, electron hole pairs are formed, these carriers become trapped in the n- and p-type regions, respectively, the resulting charge density lowers the barriers, and hence the conductivity is increased. This theory is worked out quantitatively, and compared with experimental results of Mahlman on films of the type actually used as sensitive photoconductors. The theory shows good qualitative and quantitative agreement with experiment in numerous respects, including the explanation of the dark conductivity of the films and its dependence on temperature, the photoconductivity as a function of irradiance and temperature, the time constants involved in the rise or decay of the photoconductivity, and the short-wave limit of the photoconductivity. In working out the theory of the barrier model, we use the properties of the bulk material as determined by Petritz and Scanlon, and the properties of the films are found to be consistent with our knowledge of the behavior of the bulk material. INTERFERENCE REJECTION IN FM RECEIVERS, by E. J. Baghdady. Sept. 24, 1956, 106p. incl. diagrs. tables, refs. (Technical rept. no. 252) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 145017 Unclassified

A new role is suggested for the amplitude limiter in FM receivers. By spreading out the spectrum which is necessary for the reproduction of the FM disturbance that is caused by the interference, the limiter makes it possible for a filter to reject an important portion of this spectrum without substantially affecting the spectrum that carries the message modulation. The conditions for the success of this operation are analyzed in terms of an ideal limiter followed by an idealized filter. The variation of the required

minimum extent of linearity in the discriminator characteristic with the limiter bandwidth is determined. This is followed by a study of the effect upon the interference of a repeated cycle of amplitude limiting and spectrum filtering. The cascading of several narrowband limiters is found to be an invaluable scheme for enhancing the capture capabilities of an FM receiver. (Contractor's abstract)

FLUCTUATIONS IN NEURAL THRESHOLDS AND RELATED PROBABILITY MODELS IN THE NERVOUS SYSTEM, by L. S. Frishkopf and W. A. Rosenblith. [Oct. 1956] [16]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at the Symposium on Information Theory in Health Physics and Radiobiology (Health Physics Div.), Oak Ridge National Lab., Gatlinburg, Tenn., Oct. 19-30, 1956.

Published in Symposium on Information Theory in Biology, 1958, p. 153-168.

Over the past 25 years at least half a dozen independent investigations of the responsivity of nerve tissue have led to the conclusion that the threshold of a resting neuron fluctuates in time. This conclusion is based on the study of sensory and motor fibers, of monosynaptic arcs and neuromuscular junctions. If not a property of all nerve tissue, threshold fluctuation is a valid concept in many specific parts of the nervous system. An attempt will be made to review these studies, to find common elements among them and to specify differences. In particular it will be useful to describe the fluctuating threshold in terms of a probability distribution rather than in a deterministic way. The degree of threshold correlation among neurons of a given "pool" or population will be considered for several systems, based on available data and on theoretical considerations. Likely sources of threshold fluctuation leading to both correlated and uncorrelated variations will be discussed. A number of mathematical models based on such a probability description of neural thresholds have been developed. These models attempt to derive the response characteristics of large ensembles of neural elements from postulated properties of the thresholds of single units and of threshold interaction among several units. Each model is specific to a certain area of experimentation; common to all of them is the probability description of threshold behavior. Several of these models will be discussed and evaluated. STATISTICAL THEORIES OF RADAR SYNTHESIS, by W. M. Siebert. [1956] 10p. incl. illus. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 135148 Unclassified

Also published in Proc. National Electronics Conference, Chicago, Ill., v. 12, Oct. 1-3, 1956.

The behavior of a simple model is analyzed to determine those attributes which influence the performance with respect to various quality measures. Specifically detection reliability is shown to depend almost exclusively on the received signal energy and to be essentially independent of the transmitted waveform. On the other hand questions of accuracy, ambiguity, and resolution are determined almost entirely by the waveform and can in particular be only slightly influenced by the receiver design. The treatment is based in large part on the a posteriori probability approach of Woodward with special emphasis on the limitation imposed on simultaneous range and velocity measurements by a fundamental uncertainty principle. AN ELECTRONIC METHOD FOR DETECTING EVOKED RESPONSES OF THE BRAIN AND FOR REPRODUCING THEIR AVERAGE WAVEFORMS, by J. S. Barlow. Oct. 15, 1956 [4]p. incl. illus. (In cooperation with Mass. General Hospital, Boston.) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 139557 Unclassified

Also published in Electroencephalography and Clin. Neurophysiology Jour., v. 9: 340-343, May 1957.

An electronic method is described for detecting evoked responses of the brain and for reproducing their average waveforms. The electronic equipment utilizes a magnetic delay drum, an integrator, a timer (automatic recycling device), and a gating and storage unit. Stimuli and brain potentials are recorded simultaneously on magnetic tape from a conventional electroencephalograph and the averages of evoked responses are obtained as the tapes are played back repeatedly. By means of the magnetic drum, the stimulus artefacts can be delayed in time (+) with respect to the brain potentials. For a given setting of the magnetic drum (i.e., a given displacement of stimuli in time) the instantaneous voltage of the brain potentials corresponding to each of the stimuli is noted. An average of all such samples is obtained by a Miller integrator.

MIT. 12:136 - MIT. 12:139

and the result written out on an Esterline-Angus graphic milliammeter. The setting of the magnetic drum is then automatically changed to a new delay, the tape played through again, a new average obtained, and so on. The resulting plot of averages against the delay τ then gives the average evoked response for the particular number of stimuli chosen.

DETECTION THEORY AND PSYCHOPHYSICS, by T. Marill. Oct. 30, 1956, 72p. incl. illus. tables, refs. (Technical rept. no. 319) (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) AD 141583 Unclassified

Traditional psychophysical models and Tanner and Swets' model are critically examined. Some of the weaknesses of these models are found to be eliminable by a more sophisticated analysis in terms of detection theory. Accordingly, psychophysical methods are reexamined, and the two-category forced-choice technique is found to be particularly advantageous on theoretical grounds. Application of detection theory to the problem of auditory masking with gaussian noise as measured by this forced-choice technique leads to the mathematical derivation of the theoretical ("ideal detector") psychophysical function for this situation. Experiments using the forced-choice method with auditory signals masked by broadband gaussian noise are reported. The aim of these experiments is to determine the extent to which and the manner in which subjects differ from the "ideal detector" of detection theory. It is found that, except for being approximately 13 db less sensitive, subjects behave very much like the ideal detector – that is, in accordance with the mathematical predictions – when the signals are pure tones. Results with signals consisting of two-component tones require a somewhat enlarged model; such a model is developed. (Contractor's abstract)

A LOOK AT COMMUNICATION SYSTEMS OF THE FUTURE (Abstract), by R. M. Fano. [Nov. 1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at the New England Radio Electronics meeting, Boston, Mass., Nov. 15-16, 1956.

It has been shown that, contrary to earlier belief, the reliability of a communication system disturbed by noise can be made as perfect as desired for a fixed bandwidth, fixed signal power, and fixed transmission rate; noise sets and inherent limit to the transmission rate at which perfect reliability can be obtained but not to the degree of reliability. It has been shown further that our present utilization of communication channels is in many cases grossly inefficient. Possible future system developments will be discussed in the light of these results, together with some of the theoretical and practical problems that must still be faced in their connection. MICROWAVE DETERMINATIONS OF THE FREQUENCY OF IONIZATION AND THE COEFFICIENT OF FREE DIFFUSION IN HYDROGEN (Abstract), by M. P. Madan, S. J. Buchsbaum, and E. Gordon. [1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-64637) Unclassified

Presented at 9th annual Gaseous Electronics Conference, Westinghouse Research Labs., Pittsburgh, Pa., Oct. 31-Nov. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II. v. 2: 87, Jan. 30, 1957.

Microwave breakdown experiments yield, apart from other parameters, the ratio ν_i / D, in which ν_i is the ionization frequency and D_- is the coefficient of free diffusion for electrons. This paper describes a method for a direct determination of ν_i and D_-, utilizing an additional experimental parameter tp, where p is the pressure and t is the time for the build-up of electron density. In addition, the steady-state

breakdown fields can also be predicted. The experiment has been performed, using two TM_{010}-mode resonant cavities of different sizes. The results have been compared with the theory of Allis and Brown. By properly accounting for the space-charge effect and the nonuniformity of the electric field, the results are in substantial agreement with the theory. (Contractor's abstract)

ELECTROPHYSIOLOGICAL EVIDENCE FOR AUDITORY SENSITIZATION, by J. R. Hughes and W. A. Rosenblith. Nov. 9, 1956 [6]p. incl. illus. table. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64637]) AD 133272 Unclassified

Also published in Jour. Acoust. Soc. Amer., v. 29: 275-280, Feb. 1957.

This study was designed to investigate the properties of the first neural response (N_1) to tone-pips; the responses were recorded from the round window of the cat. Amplitude, latency, and adaptation (equilibration) curves were studied. The major part of the investigation was concerned with the effect of low-tone exposure on the amplitude of the N_1-response to tone pips. After a relatively intense exposure, the amplitude of the N_1 response, compared with the pre-exposure level, shows an initial subnormality (decreased response), a sensitization (increased response), and then a second subnormality. Sensitization was found when the exposure tone was the same, higher and lower in frequency than the basic frequency of the test tone pip. Exposure to low-frequency noise gives rise to a monotonic recovery process, i.e., a subnormality without subsequent sensitization. Contralateral effects were not detected. This sensitization of the N_1- response is compared with related psychophysical data and may be regarded as an example of post-tetanic potentiation. (Contractor's abstract)

IMPEDANCE CHARACTERISTICS OF METAL MICROELECTRODES (Abstract), by R. C. Gesteland. [Sept. 1956] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Office of Scientific Research under DA 36-039-sc-64637; and in part by National Science Foundation, Bell Telephone Labs., Inc., and Offner Electronics, Inc.) Unclassified

Presented at 8th annual meeting of the Amer. Physiol. Soc., Rochester U., N. Y., Sept. 4-7, 1956.

Published in Amer. Jour. Physiol., v. 187: 601, Dec. 1956.

Warburg's law that the impedance of a metal-electrolyte boundary varies inversely with the square root of frequency applies to a limited set of cases, few (if any) of which occur in biological science. Empirically, one can fit the behavior of most smooth-metal microelectrodes in body fluids with inverse power laws over a wide frequency range. The data presented show that these laws vary with polarizing current for the two components of impedance. The self-noise of the electrode is shown to be an index to the real component of impedance. Recording through the electrodes puts restrictions on the associated amplifier. These restrictions are discussed. (Contractor's abstract)

Presented at 8th annual meeting of the Amer. Physiol. Soc., Rochester U., N. Y., Sept. 4-7, 1956.

Published in Amer. Jour. Physiol., v. 187: 614, Dec. 1956.

Using intracellular micropipettes we have found in the cat a class of lumbar motoneurons in which the height of the antidromic response is affected systematically by orthodromic volleys. In particular, a facilitatory synaptic potential decreases the overshoot of the antidromic spike and shortens the latency of the so-called "b" spike with respect to the "a" spike. The phenomenon bears a marked resemblance to the diminution of overshoot in single muscle fibre spikes during the end-plate potential. (Contractor's abstract)

COMPARISON OF LOW GAS DENSITY FLOW VISUALIZATION TECHNIQUES, by W. B. Kunkel. Mar. 7, 1956 [12]p. (AFOSR-TN-56-426) (AF 61-(514)911) AD 96508 Unclassified

Various techniques being developed for gas-flow visualization are based on density-dependent properties other than the variation of the refractive index. They include: (1) the true absorption of suitable electromagnetic radiation; (2) the scattering and apparent absorption of electrons; and (3) the emission of electromagnetic radiation. The UV absorption technique suffers from instrumental difficulties and limited sensitivity. The afterglow techniques are easily realized and are effective for demonstration purposes.

but are not satisfactory for quantitative work. The use of an electron-beam density probe is recommended for quantitative dynamic investigations. Such a probe can be designed to scan all sizes of gas streams, and to operate with great accuracy and high sensitivity over a very wide range of gas densities.

INVESTIGATION OF SURFACE VELOCITY AND PRESSURE DISTRIBUTION ALONG CASCADE PROFILES. PART 2. A METHOD FOR VELOCITY CALCULATION AT THIN, CAMBERED CASCADE PROFILES, by H. Krüger. Feb. 27, 1954, 60p. illus. tables. (Rept. no. 2) ([AF]OSR-TN-54-80, Pt. 2) (AF 61(514)429) AD 30063 Unclassified

Vortex distributions are presented which at cascades of straight lines induce normal velocities of constant, linear, and parabolic courses over the blade length. They correspond to Birnbaum-Clauert vortex distributions at a plate, and may serve to determine velocities at thin profiles provided they can be approximated by a third-order equation. The distributions were computed by a conformal representation of the lattice of straight lines on the unit circle. The distributions for constant and linear normal velocity distributions are given in closed form, and for square normal velocity distribution, the distribution is obtained numerically by means of the Poisson integral. The vortex diagrams are used to determine velocity distributions at: (1) profiles in a straight cascade, (2) resting circular lattices flown through by a vortex and source flow originating at the center, and (3) blades of rotating circular lattices. Velocity distributions are calculated for each of these cases. (ASTIA abstract)

RESEARCH ON THE STUDY OF THE CONDITIONS SURROUNDING A BODY MOVING AT THE HIGH SPEEDS IN THE IONOSPHERE, by [F. M. Devienne]. Technical rept. Mar. 1, 1955 - Feb. 29, 1956 [39]p. incl. illus. tables. (AFOSR-TR-56-24) (AF 61(514)-818) AD 89497 Unclassified

The objectives were to study the energy exchange between a moving body and air at pressures corresponding to those of the ionosphere, and to measure the stagnation pressure. Experiments were conducted in a vacuum-tight tank 150 cm id in the pressure range 0.15 to 1 μ of Hg by means of an apparatus consisting of 2 duralumin arms capable of revolving at speeds up to 300 m/s. Temperature increase was measured easily and accurately by specially installed thermocouples for metal plate models 6 mm x 6 mm x 0.1 mm, which were fastened to one arm. Stagnation pressure was measured by micro-ionization gauges set at the end of the other arm; accurate measurement was difficult, and measurements could not be made above 150 m/s because of filament breakage. Incomplete results indicated that for temperature rise for a Ag plate in air the coefficient of accommodation is reduced when the pressure increases; and is also reduced when the speed increases, and the lower the pressure, the greater the decrease. Stagnation pressure measurements did not permit a definite conclusion as to whether the distribution of molecular velocities follows the Maxwellian law. It seemed, however, that the stagnation pressure was slightly lower than the theoretical value.

A STUDY OF INCORPORATION OF HIGH ENERGY SUBSTANCES IN CONVENTIONAL TYPE FUEL MATERIALS BY PHYSICAL INCLUSION, by D. Horvitz, F. R. Benson and others. Final technical rept. Aug. 23, 1955 - Mar. 31, 1956. Apr. 1956, 36p. incl. tables, refs. (AFOSR-TR-56-17) (AF 18-(600)1558) AD 87518 Unclassified

Efforts were directed toward synthesizing, when necessary, compounds suitable as intermolecular entrapping agents. The entrapment of H inter- and intramolecularly was investigated. The process of physical inclusion was evaluated as a means of producing improved propellant systems. Preliminary experiments in which N was physically included in quinol indicated that the equipment and techniques were satisfactory. Agitating by shaking the solutions during the inclusion process resulted in a complete and rapid entrapment of the gas. Successful attempts were made to introduce more than one molecule of N per available cavity in quinol by using higher pressures. H could not be physically included in quinol at pressures up to 1000 psi; the α-quinol structure was recovered. Mixtures of N and H at total pressures up to 1460 psi showed no evidence of H inclusion; only N was entrapped by the quinol. Experiments in which MeOH was used as the solvent and blocking agent in the presence of H at a pressure of 2500 psi likewise showed no evidence of H inclusion. Small amounts of N were included in 2,2,4-trimethyl-4-p-hydroxyphenylchroman and in hexamethylenetetramine; H could not be included. Neither N nor H was included in p-phenylenediamine, tetramethylpyrazine, and tris-(hydroxymethyl)aminomethane. H was not included in pentaerythritol, camphene, and abietic acid. Copolymerizations of divinylbenzene and diallyl maleate were conducted in N and in H at pressures up to 8000 psi. No definite evidence was obtained of any gas entrapment. Diallyl maleate was polymerized by itself under N at 8000 psi; no evidence of entrapment of N was found.

FIXED POINT PROPERTY FOR THE SPACE OF SUBSETS OF AN ABSOLUTE RETRACT, by W. L. Strother and C. E. Capel. July 1955, 1p. (Rept. no. 2) ([AF]OSR-TN-55-244) (AF 18(600)1449) Unclassified

Presented at meeting of the Amer. Math. Soc., Ann Arbor, Mich., Aug. 30-Sept. 3, 1955.

The mathematical question asked by Wojdyslawski (Fundamenta Mathematica, v. 32: 184-194, 1939),

"If X is a CAR* (= retract of a cube), is the space of closed subsets S(X) a CAR*?," has been answered in the affirmative by Strother (Fixed Points, Fixed Sets, and M-Retracts, Duke Math. Jour.) for the special case in which X is a Peano Continuum. This result is used in the present study to prove that if X is a CAR*, then S(X) has the fixed point property.

A SPACE OF SUBSETS HAVING THE FIXED POINT PROPERTY, by W. L. Strother and C. E. Capel. Aug. 1955, 5p. (Rept. no. 3) ([AF]CSR-TN-55-268) (AF 18(600)1449) AD 111085 Unclassified

Also published in Proc. Amer. Math. Soc., v. 7: 707-708, Aug. 1956.

The object of this paper is to prove that if X is a CAR* then S(X) has the fixed point property. First it will be shown that if T is a Tychonoff cube this S(T) has the fixed point property. If the space X is a CAR*, it is a retract of some cube T and hence S(X) is a retract of S(T). Thus the fixed point property in S(X) follows from that in S(T).

Let X denote a compact connected metric space. An M-arc in X is a point connected multi-valued function F:I → X. Utilizing Kelly's results on (Hyperspaces of Continuum, Trans., v. 52; 1943), indecomposable continua can be characterized as follows: A compact metric space X is indecomposable if and only if there is a pair of connected closed sets A and B in X such that for every M-arc F:I → X joining A and B there is a point a in I such that F(a) is the whole space X. Also X is a Knaster space (every subcontinua is indecomposable) if and only if M-arcs in X are unique. (Contractor's abstract)

A. D. Wallace (Bull. Amer. Math. Soc., v. 47: 757-760, 1941) has shown that if T is a tree (in a combinatorial sense) and F is a continuous, multi-valued function on T to itself, such that the image of each point is connected, then F has a fixed point. Using L. E. Ward's characterization of a tree in terms of a partially ordered space (A Note on Dendrites and Trees, Proc. Amer. Math. Soc., v. 5: 992-994, Dec. 1954), an order theoretic version of Wallace's theorem is given. (Contractor's abstract)

TRACES FOR MULTIVALUED FUNCTIONS, by C. E. Capel and W. L. Strother. July 1955, 7p. (Rept. no. 4) (AFOSR-TN-[56]-82) (AF 18(600)1449) AD 81535 Unclassified

A continuous multivalued function F: X → Y is shown to have a trace which is a continuous singled-valued function f: X → Y such that $f(x) \in F(x)$ for all x in X, when Y has a continuous partial order in which the image of each point under F has a first element. The assumption that the multivalued function is continuous is essential. The terminology is as follows: Let S(X) denote the space of nonnull, closed subsets of a compact Hausdorff space X. If $\mathbf{A} \subset S(X)$, then a continuous function s: F: $\mathbf{A} \rightarrow X$ is a selection on $\mathbf{A}$ if $s(A) \in A$, for A in $\mathbf{A}$. The idea of Michael (Trans. Amer. Math. Soc., v. 71: 152-182, 1951) that there is a selection on S(X) if X is linearly ordered in a continuous sense is extended to finding selections on subsets of S(X) when X has a continuous partial order. Then for a suitable space X, such as an n-cell or Tychonoff cube, a continuous multivalued function F: X → X, with restrictions on the image of a point such as point-convex, has a trace and hence a fixed point.

Transformations on n-Cells for Which the Images of Points are Nonacyclic Continua, Duke Math. Jour., v. 14: 689-693, 1947): Theorem. If I_n is a topological n-cell, T is a continuous multivalued transformation of I_n into a subset of itself such that for each point P of I_n, T(P) is the boundary of a topological n-cell and M_1, M_2, and M_3 are the subsets of I_n consisting of the points P which are respectively in the interior of T(P), and in the exterior of T(P), then (a) M_2 is nonvacuous and closed, (b) M_1 M_2 and M_2 M_3 are each closed, and (c) M_1 and M_3 are each open with respect to I_n. If M_1 and M_3 are each nonvacuous, then M_2 separates M_1 from M_3 in I_n. The following is an example of a continuous multivalued transformation T of a 2-cell I_2 into itself, with the image of each point being a 1-sphere, such that M_2 is null and M_1 is a single point. Using polar coordinates in the plane,

let $I_2 = \{(r, \theta) \mid 0 \leq r \leq 1\}$. For $0 \leq s \leq 1$, define

$$T(s, 0) = \left\{ (r, \theta) \;\middle|\; \begin{array}{l} [\, r = 1 \text{ or } r = 1 - s) \text{ and } s \leq \theta \leq 2\pi - s] \\ \text{or} \\ [\, 1 - s \leq r \leq 1 \text{ and } (\theta = s \text{ or } \theta = 2\pi - s)] \end{array} \right\}.$$

For $0 \leq s \leq 1$ and $0 = \theta = 2\pi$, define $T(s, \theta)$ to be the set $T(s, 0)$ rotated through the angle θ. In the proof of the above theorem, 2 auxiliary functions S and W are defined on I_n into itself, where S(P) is T(P), together with its interior and W(P) is the closure of $I_n - S(P)$. It is presumed that W(P) was meant to be T(P) together with the intersection of the exterior of T(P) with I_n. The difficulty lies in the statement that S and W are continuous, which is false. A "STANDARD" SAMPLE-HOLDER FOR X-RAY DIFFRACTION EXPOSURES AND ITS ABSORPTION CORRECTIONS, by H. L. Ritter. Sept. 1955 [12]p. incl. dtagrs. tables. (Rept. no. 1) ([AF]OSR-TN-55-297) (AF 18(600)485) AD 100173 Unclassified

The choice of a standard sample holder for liquids for x ray diffraction exposures and its absorption corrections are described. The absorption corrections, for a sample contained inside a cylindrical tube of annular cross section, are: (1) $A_{a,ac}$, the correction for diffraction in the annular tube and partially absorbed in the annulus and in the core; (2) $A_{c,ac}$, the correction for diffraction in the core and partially absorbed in the annulus and in the core; and (3) $A_{c,c}$, the correction for diffraction in the core and absorption in the core only (naked sample). The correction depends upon: (1) the diffraction angle (θ); (2) the radius of the tube; (3) the wall thickness of the tube; (4) the absorption coefficient of the sample; and (5) the absorption coefficient of the sample-holder material. Efforts to eliminate the necessity of applying a correction for the container by the use of a crystalline holder were not successful. The metric equivalent of the analytical procedure appeared to be more efficient than either the graphical or analytical method for computing the corrections. In an attempt to reduce the number of parameters involved in computing correction tables, standard experimental conditions were chosen, such as the use of only Mo-Kα radiation and a Pyrex-glass sample holder. The absorption coefficient was fixed and the number of parameters was reduced to 4. An attempt was then made to standardize the geometry of the sample tube itself. By fixing these parameters, the absorption becomes a variable function only of θ and the absorption coefficient of the sample. A procedure is given for the computation of absorption corrections for encased diffracters. Numerical values of these corrections were computed for the standard holder.

INTERACTION OF A SIDE JET WITH A SUPERSONIC MAIN STREAM, by M. V. Morkovin, C. A. Pierce, Jr., and C. E. Craven. Sept. 1952, 34p. incl. illus. diagrs. tables, refs. (Engineering Research bull. no. 35) [AF 33(038)19747] Unclassified

An experimental investigation was conducted in the University of Michigan supersonic wind tunnel (Ann Arbor) to explore the main characteristics of the flow and pressure field generated by a supersonic jet directed at 90° to the body into the 1.90-Mach-number tunnel stream. In particular, a study was made of the spreading characteristics of the jet and its gross effect on the normal force, drag, and moment of the cone-cylinder body, from which the jet issued. The phenomenon was investigated as a function of pressure ratio, P_0/P_s (jet stagnation pressure to tunnel static pressure), angle of attack of the body, and jet-nozzle geometry. Within a relatively short distance from the exit, the normal jet was turned in the direction parallel to the free stream even at pressure ratios of over 50. Simultaneously, it spread in all directions, mixing violently with the free stream. Optical evidence suggests that fringes of the jet are in contact with the cylinder. This may have practical implications for the use of hot side-control jets on bodies. The interaction resulted in regions of both high and low pressure over the body. The normal force on the body was decreased below the nominal jet side-thrust value, and the drag was increased above the no-jet value. A moment which depends on the geometry, particularly the length of the body, was generated about the nominal center of gravity of the body. (Contractor's abstract)

WING-BODY INTERFERENCE. PART II. EXPERIMENTAL INVESTIGATIONS OF CYLINDRICAL MODEL, by H. E. Bailey and R. E. Phinney. Final rept. Feb. 1954, 62p. incl. illus. refs. (Rept. no. 1937-2-F) [AFOSR-TN-54-77] (AF 33(038)19747) AD 28069
Unclassifted

Expertmental results obtained from a model consisting of a cylindrtcal body and 2 half wings were compared with the theoretical results of J. N. Neilson (Supersonic Wing Body Interference, Ph. D. thests, Calif. Inst. Tech., 1951) and with the results obtained in AD 25324. The Reynolds number for the tests based on a 2-in.-diam body was 7×10^5, which corresponds to an actual 2-ft-diam mtssile flying at M = 1.9 at an altttude of 90,000 ft or to a 2-in.-diam mtssile flying at M = 1.9 at 37,000 ft. Expertmental results agreed with the values predicted by lineartzed theory as long as only those portions of the body upstream of the Mach helix from the juncture of the body and the wing trailing edge were considered. Beyond the trailing edge, the theory is no longer valid, and only the experimental results are applicable. The agreement betwsen theory and expertment was improved by shifting the axial position at which the shock jumps were predtcted by linearized theory to the position which was indicated by simple shock-wave theory. Experimental results tndicated that a decrease in thickness of the turbulent boundary layer on the body caused a slight decrease in the viscous effects near the wing leading edge and consequently better agreement between expertment and theory. The character of the body boundary layer, that is, whether it is laminar or turbulent, may exert a strong influence on the shape of the body pressure profiles. The effect of a gap between wing and body appeared to be small on such integrated quantities as total lift and total drag on the body, although the pressure profiles on the body tn the vtctnity of the gap were radtcally altered because of the presence of wing-tip vortices at the inboard edge of the wing. (For Part I see item no. MIC. 01:004)

WING-BODY INTERFERENCE. PART III. EXPERIMENTAL INVESTIGATION OF BODY SIMULATOR PLATE, by H. E. Bailey and R. E. Phinney. Final rept. Feb. 1954, 47p. incl. illus. (Rept. no. 1937-3-F) [AFOSR-TN-54-78] (AF 33(038)19747) AD 28070
Unclassifted

Results of tssts at M = 1.9 are presented of a model which consists of a body simulator plate and a wing which could be placed next to the body simulator plate. The body plate may be moved parallel to itself so as to produce a gap between the wing and body plate. The wing angle of attack may be varied continuously over a range of ± 12°. The dthedral angle between the wing and the body plate may be varied. The experimental pressures measured on the wtng and on the body simulator plate agreed wtth the pressures prsdtcted by simple shock-wave and Prandtl-Meyer flow theory. The flow appeared to be conical for values of x (the distance aft of the leading edge of the wing) greater than 1. For values of x less than 1 the flow was not conical, and the full theorettcally predtcted pressure jump did not occur. There was some upstream propagation of the pressure dtsturbance which ortginated at the leading edge of the wing, with the amount of upstream propagation tncreasing for increasing x. For posttive angles of attack of the wing, the Prandtl-Meyer flow at the leading edge was preceded by a weak compression shock wave whtch appeared to be a continuation of the shock wave generated on the under side of the wing. The expertmental results obtained with a -8° angle of attack of the wing and a dihedral angle of 135° agreed with the linear theory of Lagerstrom and Van Dyke (Douglas Report 5M 3432, June 1949). The agreement between theory and expertment was good when the angle of attack of the wing was +8° and the dihedral angle 45°. For the cases (1) angle of attack of the wing +8° and dihedral angle 135° and (2) angle of attack of the wing -8° and dihedral angle 45°, the agreement between linearized theory and experiment was poor.

WING-BODY INTERFERENCE. PART I. THEORETICAL INVESTIGATION, by H. E. Bailey and R. E. Phinney. Final rept. Jan. 1954, 18p. incl. diagrs (Rept. no. 1937-1-F) (AF 33(038)19747) AD 25324
Unclassifted

The effect of viscostty on wing-body tnterference at supersonic speeds ts considered. A theoretical analysis is made tn whtch an inviscid flow ts assumed, and the differenttal equations of motion are lineartzed. The problem ts reduced to a combination of simpler wtng-body problems tn which: (1) the body-alone potential is obtained; (2) a ftctitious wing potential ts obtained which cancels the velocities induced tn the wing plane by the body-alone potential; and (3) an interference potential ts obtained whtch cancels the velocttties tnduced on the cylindrical body by the wing potential, but which does not tnduce any velocities in the wing plane. The solution obtained ts to be used tn combinatton with the solutions of J. N. Nielsen and W. C. Pitts (NACA Technical note no. 2677, Apr. 1952) and J. N. Nielsen, (California Inst. Tech., Ph. D. thesis, 1951) to obtain the pressure distribution on a cylindrical body as a result of the presence of a flat surface wing for any combination of body and wing angles of attack. The solution is valid only forward of the trailing edge of the wing.

ZERO DIVISORS AND COMMUTATIVITY OF RINGS, by J. E. McLaughlin and [I.] A. Rosenberg. July 1952, 17p. refs. (Technical rept. no. 1) (AF 18(600)-130) Unclassified

Published in Proc. Amer. Math. Soc., v. 4: 203-212, June 1953.

A study is made of the effect of the structure of the set of zero divisors on the associativity and commutativity of an alternative ring. A ring satisfies the alternative law if the $(x, y, z) = (xy)z - x(yz)$ is an alternating function of its arguments. In the case of a finite associative ring this problem has been studied by Herstein (A Proof of a Conjecture of Vandiver, Proc. Amer. Math. Soc., v. 1: 370-371, 1950). The theory of the radical of an alternative ring has been presented by Smiley (The Radical of an Alternative Ring, Ann. Math., v. 49: 702-709, 1948), and his definition will be used throughout this study. By the center of an alternative ring A, it is meant the set C of all elements c such that $(c, A, A) = (c, A) = 0$. Here $(x, y) = xy - yx$ is the commutator of x and y. If an alternative ring properly contains its center and all its zero divisors lie in the center, it will be shown that the set of zero divisors forms an ideal. Accordingly, the alternative Zorn rings (Kaplansky, I., Semisimple Alternative rings, Portugal. Math., v. 10: 37-50, 1951) are first studied where the set of left zero divisors forms a proper left ideal. Such a ring is a division ring modulo its radical, and, conversely, in a Zorn ring which is a division ring modulo its radical the set of left divisors forms a left ideal. In Section 3, it is assumed that all the zero divisors of an alternative ring lie in the center and then give sufficient conditions for the ring to be commutative and associative. In particular, this turns out to be the case for an algebraic algebra over an algebraically closed or finite field. In the next section, it is assumed only that the nilpotent elements lie in the center but here deal only with algebraic algebras. Under suitable hypotheses on the base field, it is again time that the algebra is associative and commutative. In the last section, the results are extended to real Banach algebras, replacing the concept of zero divisor by that of topological zero divisor. In particular, it is shown that a real Banach algebra with all its topological zero divisors in the center is the quaternions or commutative. (Contractor's abstract)

[INVESTIGATION IN THE THEORY OF SIMPLE RINGS], by I. A. Rosenberg. Final rept. Oct. 1952, 2p. (AF 18(600)130) Unclassified

The first main line of investigation dealt with the following rings: Let M be a vector space of dimension λ, $\chi \geq \chi_0$, over a division ring D which contains at most χ elements. If L is the ring of all linear transformations on M, it is known that all 2-sided ideals of L are of the form $F_\chi = \{a / \dim Ma < \chi'\}$. Thus, F_χ is a maximal 2-sided ideal, and so the ring $A = L - F_\chi$ is a simple ring. A has a unit, but no minimal ideal. By the general Jacobson structure theory, it is known that A is primitive and so admits faithful irreducible modules. It was the aim of the study to classify these. First attention was focussed on the commutings ring of endomorphisms E, however, it proved impossible to decide any question about it. The following questions were considered: (1) is E algebraic over D? (2) are all E's isomorphic? and (3) what is the transcendence degree of E over D? The next step was to consider under what conditions 2 irreducible right modules of A were isomorphic. As is well known, any irreducible right module can be thought of as A/J, where J is a maximal right ideal. It is then possible to prove that A/J is isomorphic to A/1 if and only if there is an a in A such that $aJ \subset I$, a not in 1. Thus, there certainly cannot be more irreducible modules isomorphic to a given one than there are elements in the ring A. But it can be seen that the ring A has $\leq \exp \chi$ elements. ($\exp \chi$ is written for 2^χ.) So, given one irreducible module, there cannot be more than $\exp \chi$ ones isomorphic to it. Next the maximal right ideals in A were counted. This was accomplished by returning to the ring L and picking a basis B of M. The Boolean algebra P(B) of subsets of B is known to possess $\exp \exp \chi$ distinct maximal ideals containing the ideal of all subsets of power $\leq \chi$. It can be shown that these lead to $\exp \exp \chi$ distinct maximal right ideals of L containing F_χ, and so to $\exp \exp \chi$ distinct maximal right ideals of A. Thus, there are exactly $\exp \exp \chi$ distinct irreducible modules for A.

ELECTRON DIFFRACTION INVESTIGATION OF PHOTOCONDUCTIVE CRYSTALLINE LEAD SULFIDE SURFACES, by L. O. Brockway and M. S. Wasserman Wasserman. Quarterly rept. no. , Dec. 5, 1952 - Mar. 5, 1953. July 1953, 17p. incl. diagrs. table, refs. [AFOSR-TN-55-19] (AF 18(600)175) AD 18174 Unclassified

The examination by electron diffraction and microscopy of chemically precipitated films of high and low photosensitivity has shown that both films have resolved lead sulfide crystallites of the order of 0.1-μ diameter along with some irregular agglomerates of 2 to 3μ. The agglomerates form a nearly continuous framework in the high-sensitivity films, but appear in a much lower concentration on the surface of the low-sensitivity films. This is the first indication of a structural difference between films of different sensitivities. The characterization of the oxidized phase in these films requires the preparation of films especially mounted for transmission diffraction photographs. Condensed films of lead sulfide about 0.15μ thick can

now be controlled in particle size between 0.01 and 0.1μ by altering the temperature of the substrate between 200° and 350°C. Preferred orientations in the lead sulfide occur to a small degree on glass under heat treatment, and are far more pronounced on selected single-crystal substrates. No extra phase has been identified in films condensed and heated at 10^{-4} mm pressure, although extra diffraction rings appear under conditions not favoring the larger particle sizes. That they disappear on heating for 3 minutes at 350°C, or longer at 300°C, makes the formation of an oxysulfate on the surface of the lead sulfide an unlikely explanation of the extra rings. AN EXPERIMENTAL INVESTIGATION OF THE STABILITY OF AXIALLY SYMMETRIC POISEUILLE FLOW, by R. J. Leite. Final rept. Nov. 1955, 82p. incl. illus. diagrs. refs. (Rept. no. 2072-2-F) ([AF]OSR-TR-56-2) (AF 18(600)350) AD 87670 Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Also published in Jour. Fluid Mech., v. 5: 81-96, Jan. 1959.

Results of an experimental investigation of the stability of Poiseuille flow are compared with the predictions of a recent unpublished mathematical analysis of the problem by G. M. Corcos and J. R. Sellars. A review of this theory is presented. The experiments were conducted in a lucite pipe 1.25 in. in diameter and 73 ft long. The air was supplied from a high-pressure tank, passed through a settling chamber, and discharged through the pipe to the atmosphere. A theodolite was used to align and level the pipe. All measurements were made with a hot-wire anemometer. The attainment of undisturbed laminar flow for all flow rates up to about R = 20,000, the maximum capacity of the system, was achieved with no difficulty, but the procurement of axially symmetric, fully developed velocity profiles was difficult. Results of the hot-wire measurements indicate that axially symmetric, fully laminar flow in a pipe is stable to small disturbances, whether they are axially symmetric or not, up to R = 13,000. Experimental values of rate of decay and of speed of propagation of the disturbances are in satisfactory agreement with theoretical predictions. Some dependence of the propagation speed of the disturbance on radial position was noted, although the theory does not postulate such a relationship. Instability and transition to turbulent flow are excited when the disturbance exceeds a given amplitude.

A SEQUENCE EXPERIMENT FOR THE STUDY OF THE RECIPROCITY LAW FAILURE AT LOW INTENSITIES (Abstract), by J. H. Enns, R. L. Martin, and E. Katz. Feb. 10, 1955, 1p. [AFOSR-TN-55-39] [AF 18(600)750] Unclassified

Presented at meeting of the Amer. Phys. Soc., Baltimore, Md., Mar. 17-19, 1955.

Published in Bull. Amer. Phys. Soc., v. 30: 33, Mar. 17, 1955.

The concept that the reciprocity law failure at low intensities results from disintegration of the latent image in its initial stages of formation has been supported experimentally by Webb and Evans in their publication of the sequence exposure curves, and theoretically by Katz. In principle the sequence experiment consists of exposing a photographic emulsion in part to high- and in part to low-intensity radiation, wherein the ratio of the two exposures and their sequence may be varied. An instrument will be described, which has recently been built in this laboratory and designed especially to record automatically sequence exposure data. An exposure is made on a 4 x 10" plate, each plate receiving 384 - 4 x 5mm squares uniformly exposed for densitometry measurements. Provision is also made to record plate calibration data. A few preliminary curves will be shown. (Contractor's abstract)

RESULTS OF INVESTIGATION OF LOW-INTENSITY RECIPROCITY LAW FAILURE, by R. L. Martin. Aug. 1956, 141p. incl. illus. diagrs. tables, refs. (Rept. no. 2158-5-T) [AFOSR-TR-56-39] (AF 18-(600)750) AD 96787 Unclassified

The physical properties of the photographic emulsion, the nature of the photographic latent image, the Mott and Gurney (Proc. Royal Soc. (London), v. A164: 151, 1938) theory of latent-image formation, and a simple model used by Webb (Jour. Opt. Soc. Amer., v. 40: 3, 1950) to calculate an effective electron trap depth are described. The single-trap depth model predicts a simple, isodense, low-intensity rlf (reciprocity law failure) curve whose slope rapidly approaches -1 with decreasing intensity exposure. A quantitative theory of the mechanism of latent-image formation proposed by Katz (Jour. Chem. Phys., v. 17: 1132, 1949) predicts noninteger low-intensity rlf slopes when an exponential distribution of trap depths is assumed. Pure AgBr emulsions were used for experiments of rlf vs grain size to avoid difficulties arising from the correlation between iodide content and grain size. The rlf slopes from 5 pure AgBr emulsions, whose average grain size ranged from about 0.2 to 5.0 sq μ, demonstrated a definite increase in slope with average grain size of emulsion used when developed with internal developer and a similar, but less marked, tendency with surface development. The effect was stronger when higher temperatures of storage and exposure

MIC. 05:003 - MIC. 06:002

were used. A simple model assuming 2 discrete trap depths provided low-intensity rlf curves of considerable structure which were qualitatively similar to experimental curves.

AN INVESTIGATION IN THE ZONE THEORY OF THE ENERGY OF ELECTRONS IN METALS, by G. B. Spence. Aug. 1956, 112p. incl. illus. diagrs. tables, refs. (Rept. no. 2158-7-T) [AFOSR-TR-56-40] (AF 18(600)750) AD 96788 Unclassified

The zone theory of electron energy bands was used in determining the phase boundaries of those alloys agreeing with the Hume-Rothery electron concentration rules. Studies showed that an energy gap cannot exist for some zones because of shape degeneracy. Shape degeneracies exist in the zones which cannot be constructed from an integral number of mappings of the unit cell of the reciprocal lattice of the alloy structure. They also exist in the zones of the γ-brass and β-Mn structures. The electron energy surfaces in some large zones are not qualitatively similar to the simple surfaces in the first zone of the conduction electrons of the noble metals. Two- and 3-dimensional problems are constructed from two 1-dimensional Schrödinger equations with potentials of 1 and 2 cosine terms, respectively. The 2-dimensional energy contours illustrate some of the complexities of the electron energies which occur in the large zones. For typical phase boundary problems, the density of states N, of the first phase is greater than the density of states N_2 of the second phase until some point beyond the peak in N_1. For such problems the total electron energy U_1 of the first phase, instead of increasing relative to U_2 as the zone is filled beyond the peak in N_1, continues to decrease relative to U_2 until that energy is reached at which the total number of electrons are equal in the 2 phases. The positions of the phase boundaries cannot be accurately predicted theoretically from the electron concentration corresponding to the peak in the density of states. (ASTIA abstract)

LUMINOSITY GENERATED BY SHOCK WAVES, by R. N. Hollyer, Jr., A. C. Hunting and others. Sept. 22, 1953 [3]p. [AF 18(600)983] Unclassified

Published in Nature, v. 171: 395-397, Feb 28, 1953.

Experimental investigations are reported of luminosity in nitrogen and in argon gases in the expansion chamber of a shock tube on release of hydrogen under several atmospheres of pressure; the luminosity is observed when the shock wave, produced by rupture of a diaphragm covering the compression chamber, is reflected from a plate at the end of the expansion chamber. Wave-speed photography of the region near the reflecting plate shows the luminosity to be confined initially to the region between the reflecting plate and the reflected shock until the shock meets the cold front originally dividing the gases on either side of the burst diaphragm. The luminous region thereafter is limited by the end plate and by the expansion wave generated at the meeting of the reflected shock and the interface. The photographs show a roughly triangular region with a duration in time of 1500-3000 μsec depending on shock strength and nature of the gas. Spectroscopic examination in preliminary tests with N and A showed merely the D lines of Na and the g line of Ca. Use of Kr and Xe in the expansion chamber to obtain stronger shocks and correspondingly higher temperatures permitted comparison of intensity of the g line of neutral Ca and the H and K lines of Ca II with increase in temperature. The g line alone is present in weaker shocks while for stronger shocks the H and K lines increase with the g line even decreasing, showing the luminosity of the gases behind the shocks to be purely a temperature phenomenon. Observations of spectral lines of metals and of the carrier gas with changes in temperature are described and discussed.

RADIATION FROM A STRONG SHOCK FRONT IN KRYPTON, by E. B. Turner. July 1955, 8p. incl. illus. diagr. (Rept. no. 2189-1-T) ([AF]OSR-TN-55-184) (AF 18(600)983) AD 68420 Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Also published in Phys. Rev., v. 99: 633, July 15, 1955.

Petschek (Phys. Rev., v. 84: 614A, 1951) observed that a very strong shock front in argon is usually seen as a bright luminous line. It is shown from wave-speed photographs in krypton, obtained with a revolving drum camera at an angle to the shock tube, that the luminosity is homogeneous across the front and not a wall effect. Another series of wave-speed photographs was made with a wedge interference filter placed in front of a horizontal slit on the shock tube. These showed mainly line radiation, but the lines were not those of krypton. A spectrum was obtained by rotating the film drum at such a speed that the image of the shock front was stationary on the film. The Swan bands of carbon, which arise from organic vapors, as well as the lines of calcium and sodium were observed. The sharp luminous front is apparently the result of inelastic collisions between these vapors and krypton atoms in the zone where translational equilibrium is not yet established. THE PRODUCTION OF VERY HIGH TEMPERATURES IN THE SHOCK TUBE WITH AN APPLICATION TO THE STUDY OF SPECTRAL LINE BROADENING, by E. B. Turner. May 1956, 170p. incl. illus. diagrs. tables, refs. (Rept. no. 2189-2-T) (AFOSR-TN-56-150) (AF 18(600)983) AD 86309 Unclassified

A small rectangular shock tube has been constructed expressly for the production of very strong shock waves in the rare gases. The tube is vacuum tight and driver gas pressures of up to 100 atm can be used. Wave-speed photographs of shock waves in the tube were made with a revolving drum camera for a large range of initial pressure ratios and the primary shock velocities were found to be considerably less than the theoretical values. The interaction of the reflected shock with the interface was studied both experimentally and theoretically. The delay time for ionization was studied in Xe, and an explanation was found for the shock front appearing as a thin luminous line. Spectra were taken of the shock-tube luminosity and such features as lines of metallic impurities, recombination continuum, and Stark broadening of the rare-gas lines were observed. It was found that intense Balmer lines of H can be produced behind the reflected shock at the end of the tube of adding about 1% H to Ne. Time-resolved spectra were made of H_β and the conditions of temperature, ion density etc., were calculated from the measured shock velocity. Comparison with the Holtsmark theory for first-order Stark broadening showed the experimental profiles to be about 20% wider. (Contractor's abstract)

SPECTRAL LINE PROFILES IN THE LUMINOUS SHOCK TUBE (Abstract), by E. B. Turner. [1956] [1]p. [AF 18(600)983] Unclassified

Presented at meeting of the Amer. Phys. Soc., Pasadena, Calif., Mar. 19-21, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 361, Nov. 23, 1956.

Although several investigators have observed the spectra of luminosity behind very strong shock waves, none have previously obtained quantitative data on spectral line shapes. Spectral observations were made at the end of the shock tube where the temperatures are somewhat higher than behind the primary shock wave. This has made necessary a theoretical and experimental explanation of the hydrodynamic processes at the end of the tube, namely, the interaction of the reflected shock with the interface. A revolving drum camera was used with a spectrograph to obtain time-resolved spectra of the luminosity. A new film calibration method was devised to eliminate the difficulties with reciprocity law failure, and the intensity profiles derived therefrom are fairly accurate. Shock waves were produced in neon, to which about 1% hydrogen was added. Profiles of the H_β line of hydrogen were obtained and found to be slightly wider than predicted by the Holtsmark theory, but in better agreement with the recent Kolb theory. The conditions behind the first reflected shock, as calculated from the primary shock velocity which was measured with a wave-speed camera, were approximately: T = 12000°K, ion density = 1.5×10^{16} ions/cc. COMBUSTION WITH OZONE-MODIFICATION OF FLAME SPEEDS C_2 HYDROCARBON-AIR MIXTURES, by M. E. Gluckstein, R. B. Morrison, and T. B. Khammash. Aug. 1, 1955, 10p. incl. illus. diagrs. table. (Rept. no. 2279-1-T) ([AF]OSR-TN-55-227) (AF 18(600)1186) AD 69771 Unclassified

The effect of ozonized air on the combustion of ethane, ethylene, and acetylene in a Bunsen burner is studied. Research was conducted to determine: (1) whether ozone introduced into a combustor would produce significant alterations in the combustion processes; and (2) the magnitude and direction of any changes. Data were obtained with ozone (O_3) concentrations of about 1% by weight. To determine if the partial ozonization of the combustion air would have any effect on combustion, the flame speeds for the mixture burning with and without ozone were determined experimentally. Flame speed is defined as the velocity of the unburned gas normal to the flame front. Ozone analysis was made by iodometric titration for O_3. When ozone was added or eliminated, the flames changed from button-shape to cone shape or vice versa. The behavior of ethane was the reverse of ethylene and acetylene, indicating that the flame speeds of ethylene and acetylene decreased when ozone was present, while that of ethane increased. The addition or removal of ozone from a stable flame often induced oscillations, blowoff, or flashback. Rich flames were more susceptible to instabilities than lean flames. (Contractor's abstract)

CONSIDERATIONS FOR THE ATTAINMENT OF A STANDING DETONATION WAVE, by J. Rutkowski and J. A. Nicholls. Sept. 1955, 24p. incl. illus. diagrs. (Rept. no. 2284-5-T) ([AF]OSR-TN-55-216) (AF 18-(600)1199) AD 73703 Unclassified

Presented at the Gas Dynamics Symposium on Aerothermochemistry, Northwestern U., Evanston, Ill., Aug. 22-24, 1955.

MIC. 09:001 MIC. 11:001

Also published in Proc. Gas Dynamics Symposium on Aerothermochemistry, Evanston, Ill., Northwestern U. (Aug. 22-24, 1955), 1956, p. 243-253.

Experimenial studies of detonation waves have hitherto been confined to unsteady 1-dimensional flow and normal wave conditions. The significant information deduced is rather limited owing to the singularity of the wave formation. The extension of the experimental work to the inclusion of standing detonation waves, stabilized in a channel, would immeasurably add to a better understanding of this complex phenomenon, in terms of the wave structure and wave stability. Experimental considerations of stabilizing and maintaining a detonation wave in a duct are described. These include particularly the supersonic flow of a combustible gaseous mixture over a wedge. The experimental requirement of generating the relatively high Mach numbers (M = 4.5 and higher) and the proper pressures and temperatures for the gaseous mixture at the test section are rather severe and demanding in apparatus. The practical requirements and limitations for a blow-down wind tunnel system are discussed. The theoretical considerations include a discussion of the steady 2-dimensional supersonic flow over a wedge wherein a stabilized nondiabatic wave is generated, with energy addition at the wave front. The idealized conservation equations for nonadiabatic waves lead to the polar diagram, which describes the various regimes of steady supersonic flow with oblique waves. The possible solutions and the flow conditions behind the stabilized wave are considered and are discussed in terms of initial flow conditions, energy release, and wedge angle. A graphical solution for the nonadiabatic wave polar is presented which permits a simple construction of the diagram. (Contractor's summary)

COMBUSTION STUDIES WITH A 12000-CURIE COLD SOURCE, by S. W. Churchill, A. Weir, Jr. and others. Dec. 1955, 53p. incl. illus. diagrs. tables, refs. (Rept. no. 2288-6-T) (AFOSR-TN-56-17) (AF 18(600)-1218) AD 90142 Unclassified

The effect of nuclear radiation from Au-198 and Au-199 on propane-air flames at low pressures was investigated experimentally. The source had an initial strength of 15,270 curies. Both the preflame mixture and the flame zone were irradiated. The number of ion pairs produced by β radiation greatly exceeded that produced by γ radiation. The rate of propagation of Bunsen flames was increased up to 50% by irradiation. The emission due to CH, C_2, and OH was measured at a series of elevations through a flat flame, and CH rotational temperatures were computed. The emission at 4315 Å owing to CH was increased up to 33%, and the emission at 5165 Å owing to C_2 was increased up to 150% with the source at a level of 1500 curies. The emission owing to OH was not affected significantly. Increases in CH rotational temperature up to 100% were calculated for a source level of 1500 curies. The maxima in the emission owing to C_2 and OH were observed to occur at an earlier stage than the maximum in emission owing to CH in the irradiated flames. (Contractor's abstract)

HEAT AND MOMENTUM TRANSFER FROM THE WALL OF A POROUS TUBE, by S. W. Churchill and H. E. Stubbs. Final rept. Mar. 1957, 71p. incl. diagrs. table, refs. (Rept. no. 2323-9-F) (AFOSR-TR-56-58) (AF 18(600)1335) AD 115001 Unclassified

Heat and momentum transfer from the wall of a porous tube to a fluid stream flowing in the tube were investigated analytically and experimentally. The investigation was limited to conditions where the main stream in the tube was turbulent and where a secondary flow, small relative to the primary, passed inwards or outwards through the porous wall. This small flow through the wall modified the usual velocity field in the tube and consequently the heat and momentum flux from the wall. In the analytical part of the investigation, the equations of motion of the fluid are simplified by approximations and suppositions about the distribution of turbulence to give an equation amenable to computation. From the latter equation temperature and velocity profiles for the tube are obtained as a function of the flow through the wall, and from these, values are derived for the friction coefficient of the flow and for the Nusselt modulus. The experimental work was designed primarily to determine the limitations of the analysis and was confined to circumstances in which the flow through the wall of the tube was inward. A re-interpretation of the experimental data of other investigators covering the case of flow outward through the wall is, however, given. The experiments indicate that the analysis is substantially correct when flow inward from the wall has a velocity less than .001 of the bulk velocity of the main stream and for a somewhat greater range of velocity when the flow is outward. For inward flow with a velocity of .001 of the main stream velocity, the heat and momentum transfer rates are reduced by about 13% from their values when there is no flow through the wall. For greater inward flow, little additional change takes place. (Contractor's abstract)

REVERSIBLE PROPERTIES OF FERROMAGNETS, [Parts I and III], by D. M. Grimes. Dec 1956, 56p. incl. diagrs., refs. (Technical rept. no. 1) (AFOSR-TN 56-464) (AF 18(603)8) AD 97082 Unclassified

Part III presented at the Conference on Magnetism, Boston, Mass., Oct. 18, 1956.

Part I also published in Jour. Phys. Chem. Solids, v. 3: 141-152, 1957.

Part I. Using a statistical model, equations are developed for the variation of the reversible susceptibility both parallel with and normal to the biasing magnetization as a function of the magnetization assuming that the susceptibility arises by domain rotation. The results are contrasted with previous results based upon domain-wall motion. It is concluded that the theory points out a new technique for the separation of the origins of the susceptibility. Equations are also given for the expected variation of the differential magnetostriction with magnetization both parallel with and normal to the field and for both domain wall motion and domain rotation. Quantitative results depend upon the fraction of the moments oriented in each direction. A function describing this distribution is discussed. An expression is given for the susceptibility matrix arising from domain rotation as a function of magnetization. Part II to be published as TN-57-209. Part III. Theory which was developed in Part I is compared with experimental data of Part II in relation to the separation of magnetization mechanisms by a new technique, the measurement and comparison of the parallel and transverse reversible susceptibilities. Theoretical curves are shown for the variation with magnetization of the wall-motional and domain-rotational susceptibilities and differential magnetostrictions. Applicability of theory is shown by susceptibility data charted for 3 ferrite samples considered to be of compositions $Ni_{.1682}Co_{.2992}Zn_{.5326}Fe_2O_4$, $Mg_{.97}Fe_{.03}Fe_2O_4$, and $Ni_{.3800}Fe_{.1282}Co_{.0330}Zn_{.4588}Fe_2O_4$. Theory and published data for Permalloy 45 are compared for magnetostriction.

THE LOGIC OF AUTOMATA, by A. W. Burks and H. Wang. Dec. 1956, 60p. incl. diagrs. refs. (Rept. no. 2512-2-F) (AFOSR-TN-56-539) (AF 18(603)72) AD 110358 Unclassified

Also published in Jour. Assoc. Computing Machinery, v. 4: 193-297, Apr. 1957.

Classes of automata are distinguished as fixed and growing, deterministic and probabilistic. Methods are presented for analyzing and synthesizing fixed, deterministic automata by 4 kinds of state tables. By use of these tables a decision procedure is obtained for determining whether or not 2 automaton junctions behave the same. Matrix theory is applied to some of the state tables, and theorems are proved about the resulting matrices and a corresponding normal form automaton. Finally, fixed, deterministic automaton nets are analyzed in terms of cycles. (Contractor's abstract)

HOLLOW BEAMS IN ELECTROSTATIC FIELDS, by L. A. Harris. May 1955 [25]p. incl. diagrs. (Technical note no. HB-2N) ([AF]OSR-TN-55-157) (AF 18(600)1169) AD 64523 Unclassified

Trajectories are calculated for the inner and outer edges of tubular electron beams in radial electrostatic fields. The beams are assumed to be of zero thickness initially and to have uniform axial velocity. Special cases considered include that of a beam inside a single drift tube and a beam between coaxial drift tubes. Both diverging and converging beams are treated in strong and weak radial fields. It is shown that strong radial fields effectively reduce the space-charge spread, at the same time deflecting the beam. Calculated results for a particular beam are presented as an example for each of these cases. (Contractor's abstract)

SOME CONDITIONAL PROBABILITY DISTRIBUTION FUNCTIONS, by G. E. Baxter. Oct. 1, 1956, 16p. (Technical rept. no. 1) (AFOSR-TN-56-483) (AF 18-(603)30) AD 97367 Unclassified

Two identities are derived which give the generating functions of the probabilities $P\{S_n < a, S_1 > 0, \ldots, S_n > 0\}$ and $P\{S_n \cdot a, S_1 \geq 0, \ldots, S_n \geq 0\}$ in terms of the distribution function of S_k, $k = 1, 2, \ldots$. The case where k becomes a continuous parameter t is considered, also, with the set of partial sums replaced by a separable stochastic process $\{x(t), 0 \cdot t < \infty\}$ with stationary, independent increments and $x(0) = 0$. The results are two theorems and proofs with examples of limiting and non-limiting cases in Section 5.

SAMPLE LENGTH EFFECT ON PERMEABILITY MEASUREMENT (Abstract), by S. P. Yu, D. Cheu and others. [1956] [1]p. [AFOSR TN 56 433] (AF 18(603)113) AD 96516 Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 23-24, 1956.

Also published in Bull. Amer. Phys. Soc., Series II, v. 1: 322, Nov. 23, 1956.

A sample-length effect has been observed in the initial permeability measurement of finely powdered Fe_2O_3 and paraffin mixtures. The peaking of the loss angles at sample lengths equal to multiples of quarter wavelength can not be accounted for by higher order modes or dimensional resonance. Calculation reveals that the loss angle is sensitive to non-ideal termination of the transmission line and the error in the location of voltage minimum at these lengths. For optimum accuracy a one-eighth wave-length sample should be used even though the "exact" method is employed. (Contractor's abstract)

ON REAL UNICURSAL CURVES, by T. Riabokin. Oct. 1952, 124p. incl. diagrs. refs. Final tech. rept. (Research rept. no. 86) (AF 18(600)329) Unclassified

Algebraic curves of degree n were investigated by topological methods for real curves with n(n-2) real points of inflection, as well as for the existence of real unicursal curves and the general methods of obtaining equations for such curves. It was proved that for any positive integer n there exists a curve of degree n which has n(n-2) real inflection points. A method was found of constructing such curves and a method of writing the equations of such curves. It was proved that for any positive integer n there exists a curve of degree n which has $\frac{(n-1)}{2}(n-2)$ real singular points. General methods were found for obtaining equations of real unicursal curves and for construction of such curves. A brief discussion of the relationship between these unicursal curves and Lissajous figures concludes the report. (Contractor's abstract, modified)

FLAME STABILIZATION ON BLUFF BODIES AT VARIABLE PRESSURES, by C.-C. Chang, C.-T. Hsu, and D. G. DeCoursin. [1956] [15]p. diagrs. refs. (AF 18(600)1456) Unclassified

Published in Proc. Fifth Biennial Technical Conference, Minnesota U., Minneapolis (Research rept. no. 137) Oct. 1956, p. 31-41.

The achievement of stable combustion in ramjets and turbojet afterburners is essential to the further development of air breathing jet propulsion. In solving this problem, extensive research is particularly required on the physical and chemical processes involved in stabilizing flames on bluff bodies. Recent investigations have greatly improved the understanding of the general mechanism of flame stabilization, however, most of this work has been carried out at atmospheric pressure. For ramjets flying at different

altitudes the static pressure in the combustion chamber may vary over a wide range. At present, little reliable information is available on flame stabilization at very low pressures. In order to simulate combustion at different altitudes and to carry out related basic research on this problem, the Combustion Research Lab. was recently established at the University of Minnesota under the sponsorship of the Air Force Office of Scientific Research. Work was begun in Sept. 1955, and construction of the major components of the facility has been completed. Work is now in progress on the calibration of the tunnels and construction of instrumentation so that research programs can be carried out in the near future. The present report consists of two parts: (A) a general review of recent literature on flame stabilization at atmospheric pressure; and (B) the combustion research facilities in the new lab. THE GENERAL LINEAR PARABOLIC EQUATION IN TWO VARIABLES, by R. H. Cameron. Jan. 31, 1956 [3]p. (Technical note no. 2) (AFOSR-TN-56-67) (AF 18(600)1144) AD 81059 Unclassified

It is the objective of this mathematical study to point out that the differential system:
(1a) $\frac{\partial H}{\partial t} = A(t,u)\frac{\partial^2 H}{\partial u2} + B(t,u)\frac{\partial H}{\partial u} + E(t,u)H$;
(1b) $H(O,u) = \alpha(u)$ can, under reasonable conditions, be transformed into the system; (2a) $\frac{\partial G}{\partial t} = \frac{\partial^2 G}{\partial \xi^2} +$ $\upsilon(t,\xi)G$; and (2b) $G(O,\xi) = \sigma(\xi)$ which has been studied by Cameron, Tingley and others (The Generalized Heat Flow Equation and a Corresponding Poisson Formula, Ann. Math., v. 59: 434-462, 1954). Thus, the existence, uniqueness, and minimality theorems obtained by Cameron and others for 2a and 2b can be made applicable to 1a and 1b.

DIFFUSION EFFECTS IN A BINARY ISOTHERMAL BOUNDARY LAYER, by E. R. G. Eckert and P. J. Schneider. Nov. 1955, 15p. incl. diagrs. table. (Technical rept. no. 5) ([AF]OSR-TN-55-258) (AF 18(600)1226) AD 100059 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 23: 384-387, Apr. 1956.

Improvements are made in the calculations by Smith (Jour. Aeronaut. Sciences, v. 21: 154-162, 1954) of the effects of molecular diffusion in a laminar boundary layer for cases of zero and finite heat transfer to porous flat plates. The results are presented for the isothermal case only, although the improvements are applicable to the heat-transfer case. Similarity solutions are obtained for plane longitudinal flow over a flat porous plate with normal injection of a fluid whose variable properties are widely different from those of the main stream. Variation of properties with mixture temperature and concentration are evaluated from results of molecular theory. Boundary-layer calculations are performed by the method of successive approximation for hydrogen injection into an air boundary layer under isothermal conditions. Calculated skin-friction coefficients are compared with corresponding values for the case of constant-property diffusion.

FLOW EQUATIONS FOR MULTICOMPONENT FLUID SYSTEMS. PART I. GENERAL EQUATIONS.

MIN. 07:003 - MIN. 07:005

PART II. BINARY BOUNDARY LAYER EQUATIONS, by N. A. Hall. Aug. 22, 1955, 33p. (Technical rept. no. 2) [AFOSR-TN-55-333] (AF 18(600)1226) AD 70114 Unclassified

Part I. The general flow equations for a multicomponent compressible Newtonian fluid are developed. In the development of these equations, it is assumed that: (1) the fluid medium is isotropic; (2) the medium is single phase and locally homogeneous, i.e., no relaxation phenomena occur; (3) no external force acts upon any component; (4) transport phenomena are linearly dependent on property gradients; (5) differences between the kinetic energy of motion of the several components are negligible, i.e., diffusion velocities are small in absolute magnitude. Mass continuity and diffusion motion, entropy, the stress tensor, and heat and diffusion flow are considered and the set of equations obtained are simplified for application to binary systems. In Part II these general flow equations are applied to 2-dimensional steady laminar flow over a flat plate, with or without pressure gradient along the surface, and the boundary-layer equations are developed critically.

MASS TRANSFER COOLING IN A LAMINAR BOUNDARY LAYER WITH CONSTANT FLUID PROPERTIES, by J. P. Hartnett and E. R. G. Eckert. Oct. 1955 [50]p. incl. diagrs. refs. (Technical rept. no. 4) [AFOSR-TN-55-375] (AF 18(600)1226) AD 77048 Unclassified

A study was made of the prediction of the heat transfer skin friction, and required coolant flows for transpiration-cooled high-speed aircraft surface or turbine blades. A preliminary examination is made of the laminar boundary-layer equations of momentum, diffusion, and energy for the case when the properties of the gas diffusing through the wall are identical with the properties of the free stream fluid. Simultaneous mass and heat-transfer solutions from the literature were supplemented by new calculations, where required, and are presented for the case of the flat plate and the plane stagnation flow. Solutions of the energy equations are also presented for the case of boundary-layer suction over a range of suction values for both the flat-plate and the plane stagnation flow. An evaluation of the recovery factor shows its sensitivity to both fluid injection and suction. With this information, the heat-transfer results can be applied to high velocities where viscous dissipation is important. (ASTIA abstract)

TRANSPORT PROPERTIES FOR BINARY GAS MIXTURES, by W. O. Carlson and P. J. Schneider. Jan. 1956 [46]p. incl. diagrs. tables, refs. (Technical rept. no. 7) ([AF]OSR-TN-56-45) (AF 18-(600)1226) AD 80557 Unclassified

The diffusion process associated with two-component flow over flat plates has been found from recent studies to have a marked effect on the boundary-layer development. This effect is particularly pronounced when the properties of the diffusing foreign gas are widely different from the properties of the free stream. Since the thermal and dynamical properties affect the flow, there is a definite need for accurate information on the variation of these transport properties with both temperature and diffusing gas concentration. A review has been made of the various methods available for calculating these properties, and methods have been developed and suggested which lend themselves to rapid calculation without an excessive loss in accuracy. Expressions for the following binary mixture properties are included: density, constant-pressure specific heat, thermal conductivity, binary diffusion coefficient, and thermal diffusion factor. MEASUREMENT OF RECOVERY FACTORS AND HEAT TRANSFER COEFFICIENTS WITH TRANSPIRATION COOLING IN A TURBULENT BOUNDARY LAYER AT M = 3.0 USING AIR AND HELIUM AS COOLANTS, by B. M. Leadon and C. J. Scott. Feb. 1956 [32]p. incl. illus. diagrs. (Research rept. no. 126) (AFOSR-TN-56-94) (AF 18(600)1226) AD 82502 Unclassified

Presented at meeting of the Amer. Phys. Soc., Pasadena, Calif., Mar. 19-21, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 365, Nov. 23, 1956.

Turbulent-recovery-factor and heat-transfer measurements have been made on a porous wall section at a nominal Mach number of 3.0 and a Reynolds number of approximately 10^6, using both air and He as the transpired gas. Measured heat-transfer coefficients correlate well with the compressible theory of Rubesin (An Analytical Estimation of the Effect of Transpiration Cooling on the Heat Transfer and Skin Friction Characteristics of a Compressible, Turbulent Boundary Layer Skin Friction and Heat Transfer, Jour. Aeronaut. Sciences, v. 21: 6, 1954) for air, and qualitatively with simple film theory for either coolant, indicating that the heat transfer from a turbulent-boundary layer can be reduced by transpiration cooling to well below that of the uncooled boundary layer at the same Reynolds number. The simple film theory (Heat, Mass, and Momentum Transfer for Flow over a Flat Plate with Blowing or Suction, by H. S. Mickley and others. NACA Technical rept. no. TN 3208, July 1954) is extended to apply to binary boundary layers with any concentration of foreign gas at the wall. (Contractor's abstract)

MASS TRANSFER COOLING OF A LAMINAR AIR BOUNDARY LAYER BY INJECTION OF A LIGHT-WEIGHT GAS, by E. R. G. Eckert, P. J. Schneider, and F. Koehler. Apr. 1956 [25]p. incl. diagrs. (Technical rept. no. 8) ([AF]OSR-TN-56-136) (AF 18(600)1226) AD 86014 Unclassified

Calculations are presented for mass transfer cooling of a laminar air boundary layer by injection of H. All properties in the binary boundary layer are considered to vary with both local mixture concentration and temperature. Results in the form of boundary-layer velocity, concentration, and temperature profiles are given for a particular free-stream air temperature of 392°F, a free stream Mach number of 12, a surface-to-free-stream temperature ratio of 6, and surface concentrations of 0, 0.2, 0.4, 0.6, 0.8, and 0.9. The injection rate and skin friction are presented as a function of the surface concentration. (Contractor's abstract)

TRANSPIRATION COOLING EXPERIMENTS AND TURBULENT BOUNDARY LAYER SEPARATION AT M = 3, by B. M. Leadon and C. J. Scott. [1956] [11]p. incl. illus. diagrs. (AF 18(600)1226) Unclassified

Published in Proc. Fifth Biennial Technical Conference, Minnesota U., Minneapolis (Research rept. no. 137) Oct. 1956, p. 15-20.

Published in Jour. Aeronaut. Sciences, v. 23: 798-799, Aug. 1956.

Turbulent recovery factors and heat-transfer measurements have been made on a porous flat plate imbedded in the floor of a supersonic channel operating at a nominal Mach number of 3.0 and an average Reynolds number of approximately 4×10^6 using both air and helium as the transpired gas. Total pressure and concentration (in the latter case) profiles were obtained and, assuming a reasonable temperature profile, velocity profiles were computed. Measured recovery factors show a definite reduction with transpiration of air and a strong reduction with helium. Separation occurs at lower blowing rates for helium transpiration.

THE MANGLER TRANSFORMATION AS APPLIED TO POROUS CONES AND HEMISPHERES, by C. J. Scott. Sept. 1956 [10]p. (Engineering memorandum no. 68) (AF 18(600)1226) Unclassified

The 2-dimensional laminar boundary-layer equations are given for a viscous, compressible, heat-conducting gas. It is pointed out that in axially symmetric flow about a body of revolution, the boundary-layer equations describing this flow differ from the 2-dimensional equations only in the equation of continuity. The boundary-layer equations for nonslender bodies in axial symmetric flow are presented, and the transformation relations desired are shown. The general expression of Mangler's transformation, which applies to any nonslender body of revolution, is developed. Mangler's transformation is then applied to conical flow and to flow about a hemisphere. The transformation relations at the stagnation point of a hemisphere and at the hemisphere-cylinder intersection ($\theta = \pi/2$) are shown.

THEORETICAL STUDY OF MASS TRANSFER COOLING BY INJECTION OF A LIGHT WEIGHT GAS, by E. R. G. Eckert and P. J. Schneider. [1956] [1]p. (AF 18(600)1226) Unclassified

Published in Proc. Fifth Biennial Technical Conference, Minnesota U., Minneapolis (Research rept. no. 137) Oct. 1956, p. 14.

The use of mass-transfer cooling is being investigated as a means of protecting the surfaces of high-speed vehicles against the high-temperature effects of intense aerodynamic heating. Boundary-layer similarity solutions have been obtained for high-speed laminar isothermal flow of air over a flat plate with normal injection of hydrogen varying inversely with the square root of the distance from the leading edge. In this case the momentum and diffusion equations are coupled through dependence of the transport properties on local concentration in the binary boundary layer, and accordingly solutions must be obtained by iteration. The decreased mass at the surface and the diffusion process accompanying injection of a light gas serve to reduce the surface velocity gradient and thus the local skin friction coefficient. At an injection rate corresponding to $f_w = -0.3$ the reduction in c_f is nearly 85% for hydrogen and 40% for helium. Similar calculations are being performed for the general heat-transfer case with hydrogen injection and a free-stream temperature of 392°F, a free-stream Mach number of 12, and a wall-to free-stream temperature ratio of 6. A detailed study of laminar "couette flow" with mass transfer has been undertaken in order to use it as a rough guide in predicting equilibrium surface temperatures and selecting the most effective coolants. Preliminary calculations indicated that the couette-flow model is a fair approximation to exact binary layer results providing the injection rate is reasonably low.

NUCLEAR SPIN RESONANCE OF AQUEOUS SODIUM ION, by J. E. Wertz and O. Jardetzky. [1956] [3]p. (AF 18(603)17) Unclassified

Published in Jour. Chem. Phys., v. 25: 357-358, Aug. 1956

Nuclear spin resonance absorption of ionic sodium in aqueous solutions of inorganic salts has been studied in a field of 7030 gauss. Although the absorption line is observable directly on an oscilloscope, it was found convenient to record its derivative. The shape of the derivative was found to correspond very closely to that of a Gaussian curve. The line width between points of maximum slope for the 3 M NaCl standard was found to be about 32 gauss. Although this width is much greater than that for proton lines, it is much less than the 0.2-gauss width for Cl^{35} as the chloride ion, although Na^{23} and Cl^{35} have quadrupole moments of similar magnitude. THE MOMENTUM INTEGRAL RELATION FOR COMPRESSIBLE, CONICAL FLOW AND TRANSFORMATION OF RESULTS TO PLATE FLOW, by W. S. Bradfield. July 9, 1951, 30p. incl. diagrs. tables, refs. (Engineering memo. no. 3) (AF 18(600)384) Unclassified

A completely general expression for the momentum theorem is written in vector notation. An equally general definition of divergence is made such that specification of coordinate systems is unnecessary. Using these two basic tools, the momentum integral relation for local skin friction coefficient and momentum thickness is obtained for two cases. The first is steady, compressible, conical viscous flow; the second is steady, compressible, viscous flow over a flat plate. The Hantzsche-Wendt laminar boundary layer transformation of displacement thickness from cone to plate is then applied to complete the calculation. (Contractor's abstract)

CHARACTERSITICS OF LAMINAR-AND TURBULENT-BOUNDARY LAYER AT SUPERSONIC VELOCITY, by W. S. Bradfield, D. G. DeCoursin, and C. B. Blumer. July 1952 [152]p. incl. illus. diagrs. refs. (Research rept. no. 83) (AF 18(600)384) U25573; ATI-172620 Unclassified

The design, development, and application are described for a balance system suitable for direct measurement of viscous shearing stress in conical supersonic flow. Skin friction coefficients were measured from about free stream M = 3.0 to 5 and Re = 1.4 to 11 million. Momentum loss in the laminar and turbulent boundary layer on an exact duplicate of the balance system model was measured at an intermediate free system M = 3.47 and Re = 0.45 to 22 million. These results were used as a check against balance-system results. Reasonable agreement was observed. The experimental results compared with flat plate theory. In the interest of effecting an experimental comparison of flat plate results with cone flow measurements, experiments were conducted in the laminar boundary layer on a flat plate. These measurements are compared with the present cone flow results and with the results of previous investigators. Transition was measured on conical models in blowdown and continuous wind tunnels by application of the pitot-tube traverse method.

THE STAGNATION STREAMLINE ASSOCIATED WITH

CERTAIN TWO-DIMENSIONAL BODIES IN SHEAR FLOW OF A PERFECT LIQUID NEAR A WALL, by B. M. Leadon. June 10, 1953, 20p. incl. illus. (Research rept. no 93) (AF 18(600)384) AD 20937 Unclassified

For several cases of closed bodies composed on sources and sinks and axially horizontal doublets in shear flow, the stagnation streamline is found to diverge away from the wall and toward higher velocities when no wall is present. In the case of that class of closed bodies generated by a distribution of sources and sinks on a line parallel to a straight wall, it is proved for 2-dimensional flows that the stagnation point occurs between the line of singularities and the wall. The cases of a circular cylinder near a wall and far from a wall in linear shear flow are compared to show that a stagnation point occurs on the body farther from the wall than its center but still inclined upward and toward higher shear flow velocities, respectively. If a vortex is required to describe the probe shape, it can cause a downward stagnation streamline inclination, and therefore a negative position error for the probe. Accompanying this would be a stagnation point on the wall. (ASTIA abstract)

THE EFFECT OF LEADING EDGE BLUNTNESS ON MOMENTUM LOSS MEASUREMENTS IN A LAMINAR SUPERSONIC BOUNDARY LAYER, by W. S. Bradfield, D. G. DeCoursin, and C. B. Blumer. Sept. 1953, 19p. illus. (Research rept. no. 96) (AF 18(600)384) AD 21496 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 21: 373-382, 398, June 1954.

An experimental investigation was made to ascertain the effect of leading-edge bluntness on momentum-loss measurements in the laminar boundary layer of a flat plate. Measurements were made in a wind tunnel with an asymmetric channel operating continuously at M = 3.05 (free stream). The test section was 1.75 in. wide by 2.0 in. high. The leading edge of the flat plate was hollow ground to provide additional sharpness and to avoid a strong attached shock wave on the lower side of the model. Leading edge thicknesses of 0.3, 5.9, and 11.7 mils were used. The data indicated that the effect of leading edge bluntness is an important consideration. The ratio of the leading edge thickness to theoretical values of boundary layer displacement thickness at the measuring station appeared to be a criterion of the magnitude of this effect. The blunting effect was demonstrated to be separate from the effects of heat transfer and pitot tube size. The effect on the total measured momentum loss appeared to be generally stronger than that on local measurements of viscous shear at the plate surface. The presence of a detached shockwave at the plate leading edge was considered responsible for the discrepancy between theoretically predicted and measured momentum losses. Comparable experiments on a 15° cone showed little effect of tip blunting on measurements in the laminar boundary layer.

A CHARACTERISTICS ANALYSIS OF THE FLOW ABOUT A BLUNT LEADING EDGE, by C. J. Scott. Nov. 1953, 24p. incl. diagrs. refs. (Engineering memo. no 26) [AF 18(600)384] AD 25533 Unclassified

An application of the method of characteristics to the flow about a blunt leading edge is presented. Qualitative results are obtained by considering the steady, two-dimensional, rotational inviscid flow behind a curved, detached, shock wave. The plate boundary layer was not considered. An explanation of the flow conditions downstream from the leading edge is presented on the basis of characteristics analysis. The results of the analysis show that large velocity and pressure gradients are present near the leading edge. These gradients are shown to be damped as the flow proceeds downstream. An envelope of compression wavelets coalesces to form a secondary shock wave downstream of the detached shock wave. The secondary shock results from the centrifugal forces which produce an over-expansion of the flow around the curved leading edge. The effect of the presence of the detached shock on the flow conditions far downstream from the leading edge is confined, for all practical purposes, to a region adjacent to the plate surface approximately six-leading-edge thicknesses high. Fluid elements in streamlines above this height undergo changes in total pressure which are less than 1%. (Contractor's abstract)

THE EFFECT OF CONE TIP BLUNTING ON THE SUPERSONIC CONICAL LAMINAR BOUNDARY LAYER, by C. B. Blumer, W. S. Bradfield, and C. J. Scott. Mar. 1954, 15p. illus. diagrs. refs. (Engineering memo no. 29) (AFOSR-TN 54-83) (AF 18(600)384) AD 34618 Unclassified

An experimental investigation was conducted to determine the effect of cone tip blunting on the supersonic, laminar, conical boundary layer as indicated by pitot tube surveys. Tests were conducted at a cone surface Mach number of 2.90 with two cone tip diameters. Boundary layer surveys were made over a range of Reynolds numbers from 500,000 to 1,800,000. The present investigation paralleled a previous study which was concerned with the effect of leading edge thickness on the boundary layer formed on a flat plate. The results indicate that the effect of tip blunting on the conical boundary layer is much less evident than the corresponding effect of the leading edge blunting on the plate boundary layer for equal values of t^*_{th}. A

MIN. 09:008 - MIN. 10:001

relationship is presented which predicts the deviation of experimental momentum thickness from the idealized boundary layer theory as a function of cone tip diameter. This relation is in reasonable agreement with the experimental results. Experimental local and average shear stress coefficients are presented as a function of Reynolds number and are compared with laminar boundary layer theory. (Contractor's summary)

FINAL MODIFICATION OF A CONICAL SKIN FRICTION BALANCE SYSTEM AND MEASUREMENTS AT $M_1 = 2.6$, by C. B. Blumer and W. S. Bradfield. Feb. 1955, 1v. incl. illus. diagrs. refs. (Research rept. no. 111) [AFOSR-TN-55-80] (AF 18(600)384) AD 65520 Unclassified

Final development of an instrument capable of the accurate measurement of local skin friction coefficients in the axially symmetric, conical, turbulent boundary layer is reported. This single component balance system is housed within a 15° cone. Measurements of skin friction coefficients were made at a cone surface Mach number of $M_1 = 2.6$ over a Reynolds number range from 1×10^6 to 8×10^6. The data of primary interest are the measurements in the fully turbulent boundary layer, although transitional data are also presented. The turbulent data are compared with the results of other investigations. The agreement between these data and other experiments in the conical boundary layer is acceptable, but the present turbulent data do not agree with experiments in the 2-dimensional turbulent boundary layer which have been transformed to cone flow for comparison. AN EXPERIMENTAL STUDY OF THE EFFECT OF SMALL ANGLES OF ATTACK ON THE LAMINAR BOUNDARY LAYER OF A CONE, by D. G. DeCoursin. Aug. 1955 [62]p. incl. illus. diagrs. table, refs. (Research rept. no. 121) ([AF]OSR TN-55-405) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)384 and Ordnance Corps under DA 01-021 ORD-4589) AD 78480 Unclassified

An experimental investigation was conducted concerning the effect of angle of attack on the laminar boundary layer on a cone. The experimental technique involved the measurement of total pressure distribution through the boundary layer on the windward and leeward sides of the model. Velocity profiles, skin friction, and other pertinent data were calculated from these measurements. The tests were made with a 15° cone at $M_\infty = 2.73$ and over an angle of attack range of 0° to 4°. The local skin friction coefficient in the laminar boundary layer on the windward side increases with angle of attack, and the measured increases were in good agreement with the plane of symmetry theory developed by Moore. No laminar data were obtained on the leeward side of the model because of the change in boundary-layer character with angle of attack, which caused a boundary layer with a more nearly turbulent character to occur on the leeward side. Laminar skin friction measured at zero angle of attack was 10% below the theory of Chapman and Rubesin (applied to cone flow). (Contractor's abstract)

DIRECTIONAL EFFECT OF MOVING CHARGES, by T.-S. Liu and E. G. Voltin. June 1956, 33p. incl. illus. diagrs. tables. (Research rept. no. 129) (AFOSR-TR-56-29) (AF 18(600)599) Declassified

Experiments were conducted in a supersonic wind tunnel with a free jet test section at Mach numbers 1.5, 2.0, 2.5, and 3.0 to investigate the directional effect of moving charges. One-ounce bare spherical charges were used in the tests. A strengthening of the blast effect of 98% at Mach number 1.5, 6% at Mach number 2.0, 44% at Mach number 2.5, and 53% at Mach number 3.0 was noted from pressure pulse measurements. The strengthening was qualitatively confirmed by spark photography of the blast wave shape. No conclusive correlation of the strengthening effect to the angle or to the velocity of the moving charge was established in this series of experiments. However, this technique of determining the directional effect of moving did prove to be feasible, and the pressure recordings and optical observations obtained were satisfactory.

THE RUNNING TIME FOR SUPERSONIC BLOWDOWN WIND TUNNELS, by T.-S. Liu. [1953] 20p. incl. illus. table, refs. [AF 18(600)851] Unclassified

Published in Proc. Third Midwestern Conference on Fluid Mechanics, Minnesota U. Inst. of Tech., Minneapolis (Mar. 23-25, 1953), Minneapolis, Univ. Press, June 1953, p. 547-566.

Factors affecting the duration of run for supersonic blowdown wind tunnels (intermittent type) are discussed. Simple equations for the calculations of running time are derived for different tunnel configurations; atmospheric intake; high pressure intake; heated stagnation condition; unheated stagnation condition; discharging to the atmosphere; and discharging to a vacuum reservoir. Three possible conditions to cease the wind tunnel operation are treated separately. A unified "Running Time Parameter" is developed which permits the plotting of generalized curves of this parameter as a function of Mach numbers with one or two variables. Calculated values of running time from equations developed are compared with the reported experimental values of existing wind tunnels. The results from this study not only facilitate the determination of wind tunnel running time of known arrangement, but also serve the designers to adjust the requirements of some components of a blowdown wind tunnel with others prescribed during the design stage of such wind tunnels. ANALYTICAL STUDY OF SIMILARITY PARAMETERS FOR AERODYNAMIC MODEL-TESTING AT HIGH TEMPERATURES. PHASE I (SIMILARITY LAWS FOR STRUCTURAL-AERODYNAMIC MODELS), by L. A. Scipio, II and L. C. Teng. Aug. 22, 1954 [44]p. incl. diagr. refs. (Research rept. no. 104) [AFOSR-TN-54-187] (AF 18(600)851) AD 44792 Unclassified

A study was made to determine similarity parameters for wind-tunnel testing of thermal stresses and strains produced in free flight resulting from aerodynamic heating. Two general types of structures were considered: (1) solid or thick skin, and (2) shell or thin skin. The results indicate that similarity between prototype and its model is possible in each of the above cases. For solid or thick skin structures, it was assumed that all dimensions could be scaled by the same scale factor:

$$N_L \left(N_L = \frac{(X_1)_{\text{model}}}{(X_1)_{\text{prototype}}} \right)$$

For shell structures, it was assumed that all linear dimensions of the prototype except the skin thickness are scaled by N_L. In both cases, thermal stress similarity can be achieved by using the same materials for both model and prototype. The attendant rules for construction of a structural-aerodynamic model having the requisite similarity to each of the above types of structures establish conditions for an experimental study of the structural behavior and integrity of various types of aircraft and missiles. (Contractor's abstract)

Minnesota U. Rosemount Aeronautical Labs., Minneapolis.

TEMPERATURE SIMILARITY LAWS FOR THIN SHELLS WITH INTERNAL STRUCTURES AND FOR SANDWICH STRUCTURES, by L. A. Scipio, II, L. C. Teng, and I. K. Ebcioglu. Oct. 1954, 42p. incl. diagrs. tables. (Research rept. no. 106) ([AFOSR-TN-54 284) (AF 18(600)851) AD 62663 Unclassified

Can the results of small-scale supersonic wind-tunnel tests be used to study the structural behavior and integrity of aircraft and missiles in free flight in the presence of aerodynamic heating? The purpose of the investigation described is to answer this question for web and sandwich structures. Experimental tests can be made on small-scale models of these structural types to study the behavior of their prototypes under temperature load. This is possible only by the use of different materials for the models than those of the prototype. It can be concluded from these results that similarity in the stress field is impossible to achieve.

MIN. 11:004 - MIN. 12:004

This means that for practical application, the temperature distribution that a prototype will experience under a given set of conditions is obtainable from wind-tunnel tests, but the resulting stress distribution must be calculated. The fact that the model is constructed of a different material than the prototype to assure similarity in the temperature fields, rules out the possibility of assuring stress similarity. It is clear that these materials, while possessing characteristics required for temperature similarity, will not at the same time have required elastic properties. (Contractor's abstract)

THE DESIGN OF A REGENERATIVE-TYPE HEATER FOR AN INTERMITTENT SUPERSONIC WIND TUNNEL, by T.-S. Liu, E. J. C. Sun, and R. K. Knutson. Mar. 1955, 29p. illus. diagrs. tables, refs. (Engineering memorandum no. 48) (AF 18(600)851) Unclassified

A regenerator-type heater was designed and fabricated in the circuit of the 12 in. x 12 in. supersonic blowdown wind tunnel at the Rosemount Aeronautical Lab. The highest temperature expected is 900°F, which corresponds to the stagnation temperature at Mach number 3.5 in the stratosphere. This heater would cover test conditions for Mach numbers from 2.0 to 3.5, altitude of 20,000 to 60,000 ft, and a wide range of Reynolds numbers. All these conditions dictate a possible maximum air mass flow rate of more than 300 lb/sec. The heater system consists of a heat regenerator, a furnace, blowers, and circulating ducts. The heat storage units in the regenerator are aluminum oxide spheres. General Electric Calrod heating elements are used in the furnace. Design considerations, parameters, procedures, and calculated performances are presented in this paper.

ELECTRON SPIN RESONANCE OF SEMIQUINONES, by J. E. Wertz and J. L. Vivo. Dec. 1955 [2]p. incl. diagrs. (AFOSR-TN-55-277) (AF 18(600)479) AD 14149 Unclassified

Also published in Jour. Chem. Phys., v. 23: 2441-2442, Dec. 1955.

Semiquinone free radical intermediates in the reduction of quinones or the oxidation of hydroquinones were demonstrated first by magnetic susceptibility and by potentiometric measurements. The electron spin resonance absorption of semiquinone ions in the oxidation of hydroquinone and methyl-substituted hydroquinones was shown to be a more sensitive means of detecting them.

A TWO-STAGE INTEGRATOR FOR MAGNETIC RESONANCE LINES, by J. E. Wertz. [Aug. 25, 1955] [14]p. incl. diagrs. table, refs. (AFOSR-TN-55-278) (AF 18(600)479) Unclassified

A two-stage integrator is designed to give the integral of a nuclear or electron spin resonance signal. This permits the recording of weak absorption lines when a phase detector is used, its output being nearly the first derivative. A second integrator gives on a register a figure proportional to the area under the absorption curve. (Contractor's abstract)

ELECTRON SPIN RESONANCE OF 1, 4-NAPHTHOSEMIQUINONE ION, by J. E. Wertz and J. L. Vivo. Nov. 14, 1955 [1]p. incl. diagr. [AFOSR-TN-55-428] (AF 18(600)479) AD 141513 Unclassified

Also published in Jour. Chem. Phys., v. 24: 479, Feb. 1956.

Since the naphthosemiquinones coplanarity of the quinoid ring and the adjacent ring is assumed, an extra electron spin resonance multiplicity above that observed in the benzoquinones is to be expected. This holds true for 1, 4-naphthosemiquinone dissolved in basic alcohol solution, 3 groups of lines being observed. The 2, 3 dimethylseminaphthoquinone ion yielded 7 groups of lines, with 21 individual lines in the 5 inner groups. The 2-methyl-1, 4-naphthosemiquinone ion yielded 5 groups of lines having 24 discernable components.

MULTIPLE THIO-RADICALS IN SULFURIC ACID SOLUTION, by J. E. Wertz and J. L. Vivo. Sept. 13, 1955 [1]p. incl. diagrs. [AFOSR-TN-55-430] (AF-18(600)479) AD 141511 Unclassified

Also published in Jour. Chem. Phys., v. 23: 2193-2194, Nov. 1955.

The electron spin resonance absorption of thiophenol in sulfuric acid consists of lines A and B. It is observed that the A line disappeared slowly, while the B line was still present after 30+ days. Line B appeared to be the same as the one obtained from thianthrene. Diphenyl disulfide, 1-thionaphthol, and 2-thionaphthol gave 2 lines similar to those of thiophenol. Line B for thiophenol, diphenyl disulfide, and thiathrene had 5 hyperfine components suggesting that the unpaired electron is associated with a 4-proton system, much as found in the semiquinone radical of hydroquinone. It was suggested tentatively that a radical of the type $(C_6H_6S)H^+$ causes the A line.

ELECTRON SPIN RESONANCE OF DEFECT CENTERS IN MAGNESIUM OXIDE (Abstract), by J. E. Wertz and J. L. Vivo. Nov. 16, 1955 [1]p. [AFOSR-TN-55-432] [AF 18(600)479] Unclassified

Presented at meeting of the Amer. Phys. Soc., Southern Calif. U., Los Angeles, Dec. 28-30, 1955.

Published in Phys. Rev., v. 100: 1792, Dec. 15, 1955.

Attempts to find electron spin resonance (ESR) absorption by imperfection centers in MgO were complicated by the multiplet spectra of impurities. After a detailed study, we found one line which disappears on heating in vacuum. The splitting factor g is 2.003 along a principal axis, and the corresponding line width is 4.2 gauss, twelve-fold narrower than for KCl. This line and an absorption band at 2600 A which disappears on heating in vacuum, are presumably the result of excess oxygen. Heating in air at 600°C increases the intensity of the ESR line. Tentatively it is assumed that the ESR centers are O^- ions, although experiments on oxygen uptake at higher temperatures would indicate that at 600° the process would be very slow. Exposure to x-rays after annealing gives an ESR line of similar g-value and width, which decays slowly.

Nuclei of non-zero spin take up discrete orientations in a magnetic field, and transitions between the spin energy levels occur as a resonant process with radiation in the radiofrequency region. The frequency of resonant absorption to a first approximation depends solely upon the nuclear species. More accurately, it may be modified by a number of effects. Besides resonant frequency, the absorption line amplitude and width may yield important information about the interactions of a nucleus with its atomic environment. Local magnetic fields due to other nuclei in a rigid solid may broaden or split a line. Paramagnetic ions may cause both a broadening and a shift. Shielding of the nucleus by outer electrons displaces a line and may give rise to a multiple-line spectrum if identical but chemically non-equivalent nuclei exist in the same molecule. The transmission of nuclear polarization effects through an electron-pair bond may lead to observable multiplicity. Rapid chemical exchange of non-equivalent nuclei leads to a single line intermediate between the positions of the separated lines. Solvent interactions—especially hydrogen bonding—may cause major shifts. Hydration of an ion may alter its resonance absorption line characteristics to a marked degree. When a nucleus possesses a quadrupole moment, the absorption line amplitude and width are very sensitive to electric field gradients arising from anisotropic interactions such as ion-pair or complex formation. Even a sodium ion shows a marked sensitivity to its environment. Examples of such interactions are given for both inorganic and organic systems. (Contractor's abstract)

ESTIMATION OF PROBABILITIES MONOTONE IN SEVERAL PARAMETERS, by H. D. Brunk, G. M. Ewing, and W. R. Utz. July 1954 [18]p. incl. diagrs. (Technical note no. 1) ([AF]OSR-TN-54-159) (AF 18(600)1108) AD 36970 Unclassified

The problem is considered of the estimation of probabilities which depend upon several parameters and which are monotone in each separately. The problem is formulated by considering a set I of a finite number N of points $\mathbf{x} = (x_1, x_2, \ldots, x_n)$ in n-space each of which is associated with a probability $p(\mathbf{x}) = p(x_1, x_2, \ldots, x_n)$ that is known to be monotone in each variable separately. The probability p is assumed to be non-increasing in each variable. Corresponding to each $\mathbf{x}$, a finite number of trials are made of an event with probability $p(\mathbf{x})$; $a(\mathbf{x})$ of them are successes, and $b(\mathbf{x})$ are failures. The a priori probability that a specified $a(\mathbf{x})$ of the trials will result in success and that a specified $b(\mathbf{x})$ of them will result in failure is given by $\prod(p) = \prod_{\mathbf{x} \in I} p(\mathbf{x})^{a(\mathbf{x})} [1-p(\mathbf{x})]^{b(\mathbf{x})}$. The class of functions $p(\mathbf{x})$ defined on I, which are monotone nonincreasing in each variable separately, and bounded by 0 and 1 is denoted by P. The general problem is that of determining a function $\bar{p}(\mathbf{x}) \in P$ which affords a maximum value to the product $\prod = \prod(p)$ defined above, so that $\prod(\bar{p}) = \max_{p \in P} \prod(p)$. A HELLY THEOREM FOR MONOTONE FUNCTIONS, by H. D. Brunk, G. M. Ewing, and W. R. Utz. July 1954, 13p. (Technical note no. 2) ([AF]OSR-TN-54-167) (AF 18(600)1108) AD 37022 Unclassified

The principle result is the proof of a Helly theorem for sequences of monotone functions of n-variables. The theorem is stated as follows: let $\{F_q(x_1, x_2, \ldots, x_n)\}$ be a sequence of monotone functions all of the same type on the set S, $a_i \leq x_i \leq b_i$, and let A be a positive number such that $|F_q(x_1, x_2, \ldots, x_n)| < A$ for $q = 0, 1, 2, \ldots$. Then there exists a sequence of integers $q_0 < q_1 < q_2 \cdots$ and a monotone function $F(x_1, x_2, \ldots, x_n)$ bounded by A such that $\lim_{i \to \infty} F_{q_i}(x_1, x_2, \ldots, x_n) = F(x_1, x_2, \ldots, x_n)$ on S. The proof of the theorem utilizes the selection principle of D. V. Widder

(The Laplace Transform, p. 26, Princeton U. Press Princeton, N. J., 1941) and the following result: if $F(x_1, x_2, \ldots, x_n)$ is a real-valued monotone function on the set S, $a_i \leq x_i \leq b_i$, $i = 1, 2, \ldots, n$, then there is a set R consisting of the points of a countable collection of (n-1)-spaces, $x_i = a_i^j$, $i = 1, 2, \ldots, n$, $j = 1, 2, \ldots$, such that F is continuous at all points of S-R.

THE EXTENSIONS OF HOMEOMORPHISMS AND THE LIMITS OF ORBITS, by H. D. Brunk, G. M. Ewing, and W. R. Utz. Aug. 1954, 18p. (Technical note no. 3) ([AF]OSR TN-54-200) (AF 18(600)1108)
AD 48173 Unclassified

A paper by Schweigert (Bull. Amer. Math. Soc., v. 46: 963-969, 1940) is extended which concerned the nature of the limit set of a convergent sequence of point or component orbits under a pointwise periodic homeomorphism of compact metric space onto itself. Similar results are obtained for pointwise periodic, recurrent, and almost periodic transformations when compactness of the space is replaced by equicontinuity of the transformation. Schweigert's results do not hold if the word compact is weakened to complete. Schweigert's treatment of the extension of homeomorphisms from sets dense in a given space to the entire space is continued.

A THIRD ORDER DIFFERENTIAL EQUATION, by W. R. Utz. July 1955, 6p. (Technical note no. 5) (AF OSR TN 55-215) (AF 18(600)1108) AD 95834
Unclassified

Also published in Monatsh. Math., v. 60: 329-332, 1956.

A proof is presented of the following theorem. Assume that $f(x)$ is a real differentiable function such that $\lim_{x \to \infty} f(x) = c$, $0 < c < \infty$, and such that $f'(x)$ is bounded as $x \to \infty$. Assume that $p(x)$ is a real polynomial such that for a real number $a > 0$, $p(a) = 0$ and $p'(a) = 0$. If $y = y(x)$ is a solution of $f(x)y''' - yy'' + p(y') = 0$ which is valid for all large values of x and for which $\lim_{x \to \infty} y'(x) = a$, then $y = ax + b$, where b is a constant. This theorem generalizes a theorem of Hardy (Proc. Cambridge Phil. Soc., v. 35: 652-653, 1939) in which $f(x) = 1$, $p(y') = 2(y'^2 - 1)$, and $a = 1$. (Contractor's abstract)

MAXIMUM LIKELIHOOD ESTIMATION OF RESTRICTED PARAMETERS, by H. D. Brunk. Sept. 1956, 26p. refs. (Technical rept. no. 7) (AFOSR-TN 56 391) (AF 18(600)1108) AD 96049
Unclassified

Also published in Ann. Math. Stat., v. 28: 607-616, Dec. 1955.

The maximum likelihood estimation for independent random sampling from a finite number of populations belonging to exponential families is discussed when the parameter point is known to lie in a proper subset of its "natural" range. "Exponential family" is defined for the distribution functions $F(x; \ )$. A minimum problem with side conditions is formulated for solution. With an a priori upper or lower bound which is assignable to each estimator of a single parameter, computing the maximum likelihood estimator

MIS. 01:008 MIS 01:009

is reviewed as a problem in non-linear programming. A geometric approach technique and a means of obtaining the solution when the parameter point is restricted to a "convex" subset of its "natural" range are discussed. With populations of the same exponential family and order restrictions on the parameters, the maximum likelihood estimates are independent of the exponential family containing the populations. The property of the maximum likelihood estimate, related to sufficiency, is discussed.

MIS. 01:008

Missouri U. Dept. of Mathematics, Columbia.

A NOTE ON AUTONOMOUS SECOND ORDER NON-LINEAR DIFFERENTIAL EQUATIONS, by W. R. Utz. Sept. 1956, 12p. (Technical rept. no. 8) (AFOSR-TN-56-420) (AF 18(600)1108) AD 96230
Unclassified

Also published in Proc. Amer. Math. Soc., v. 7: 1047-1048, 1956.

Theorems on the boundedness of solutions of second order nonlinear differential equations are used as a departure for a more detailed examination of the behavior of solutions of such equations for large values of the independent variable. Theorems are cited which give sufficient conditions for the existence of constants A, B > 0, such that if $x = x(t)$ is a solution of the given equation valid for all large t, then $|x(t)| < B$ for all $t > A$, where A and B may depend upon the particular solutions $x = x(t)$. The coefficients in the equation are assumed to be differentiable throughout the analysis, and the function $x(t) \equiv 0$ is a solution of each equation considered. Use is made of the fact that, because of the uniqueness of solutions, no solution not identically zero is tangent to the t-axis. (Contractor's abstract, modified)

SOME HELLY THEOREMS FOR MONOTONE FUNCTIONS, by H. D. Brunk, G. M. Ewing, and W. R. Utz. [1956] [8]p. [AF 18(600)1108] Unclassified

Published in Proc. Amer. Math. Soc., v. 7: 776-783, Oct. 1956.

Let S denote a closed n-dimensional interval of the Euclidean n-space. A function $F(x_1, x_2, \ldots, x_n)$ defined on S is called "monotone" by the authors if it is monotone nondecreasing in each x_i $(i = 1, 2, \ldots, n)$ and if the first and second differences of F are non-negative. The following theorem (of a type which was first treated by E. Helly, Akad. Wiss. Wien. S.-B. IIa, v. 121: 265-297, 1912) is proved by the authors: Let $\{F_q(x_1, x_2, \ldots, x_n)\}$ be a sequence of monotone functions on S with

$$|F_q(x_1, x_2, \ldots, x_n)| \leq A \quad (q = 0, 1, 2, \ldots).$$

There exists a sequence of integers $q_0 < q_1 < q_2 < \ldots$ and a monotone function $F(x_1, x_2, \ldots, x_n)$ bounded by $\pm A$ such that

$$\lim_{i \to \infty} F_{q_i}(x_1, x_2, \ldots, x_n) = F(x_1, x_2, \ldots, x_n)$$ on S. For the proof of this result the following theorem is used: If $F(x_1, x_2, \ldots, x_n)$ is a monotone function on S, then there exists a set R of points of countably many $(n-1)$-spaces $x_i = a_i^j (i = 1, 2, \ldots, n; j = 1, 2, \ldots)$ such that F is continuous at all points of S-R. As consequences of both these results, also theorems on extended real valued functions F(i. e. $-\infty \leq F(x_1, x_2, \ldots, x_n) \leq +\infty$) are stated. Finally, by means of a simple example in two variables; it is shown that the first mentioned theorem does not hold if the functions F_q are only monotone in each of their variables. (Math. Rev. abstract)

EXPERIMENTAL EVIDENCE FOR THE EXISTENCE OF ABNORMAL OH ROTATIONAL "TEMPERATURES" IN LOW-PRESSURE FLAMES, by H. P. Broida and H. J. Kostkowski. [1955] [1]p. [AFOSR-TN-55-59] [CSO-18-600-25] Unclassified

Published in Jour. Chem. Phys., v. 23: 754, Apr. 1955.

Preliminary spectroscopic measurements are reported on OH absorption in low pressure (1.5 to 6 mm Hg) acetylene-oxygen flames, having relative intensities of the $^2\Sigma \longrightarrow {}^2\pi$ transition of OH characterized by rotational "temperatures" many times larger than the calculated adiabatic temperatures. An OH line rather than a continuum source was used to avoid influence of the resolving power of the monochromator on the measured absorption; the line, narrower than those in the flame, was obtained by discharge through water vapor at a pressure of 0.5 mm Hg with an ac electronic amplifier modulated by a metal chopper placed between the discharge and flame to amplify only the discharge radiation. The OH line absorption, thus measured essentially at the peak of the lines, was found to be very small. At 1.9 mm Hg in an acetylene-oxygen (in the ratio of 2 to 5) flame which was 7.5 cm thick, the greatest absorption of the strong $Q_f 5$ (0 – 0) line was only 15%. The absorption of the first line of the R_2 and second line of the P_f branches was less than 3% and 5%, respectively. The observed small absorption was confirmed by a two-path method. At the same position of the same flame on which the direct absorption measurements were made, the emission "temperatures" (as determined from the P_f and R_2 branches) were 6600°K for the single path and 6900°K for the double path. This difference is well within the experimental error. The ration of the double- to the single-path intensities also showed negligible absorption. This consistent set of experimental results shows that measured nonthermal rotational distributions of OH emission intensities in low-pressure acetylene flames are not caused by self-absorption.

THE FLUORESCENCE AND AVERAGE LIFETIME OF EXCITED OH ($^2\Sigma$, $^2\pi$) IN FLAMES, by H. P. Broida and T. Carrington. Aug. 19, 1955 1 p. incl. diagr. (AFOSR-TN-55-276) (CSO-630-55-25) AD 85606 Unclassified

Also published in Jour. Chem. Phys., v. 23: 2202, Nov. 1955.

This study is concerned with the fluorescence of OH (measured as approximately 1 part in 10^7 of the light incident on the flame) in an acetylene-oxygen flame burning at atmospheric pressure. It is found that radiationless transitions are important in taking away excess electronic energy from the OH molecules in the flame. Measurements indicate that each collision removes some electronic energy, leading to quenching. As a result, the average lifetime of excited OH radicals in the flame is of the order of 6×10^{-10} sec.

SPECTRAL ABSORPTION METHOD FOR DETERMINING POPULATION "TEMPERATURES" IN HOT GASES, by H. J. Kostkowski and H. P. Broida. Sept. 26, 1955 [9]p. incl. illus. diagrs. tables, refs. [AFOSR-TN-55-458] [CSO-630-55-25] AD 106164 Unclassified

Also published in Jour. Opt. Soc. Amer., v. 46: 246-254, Apr. 1956.

A spectroscopic method, useful for strongly absorbed lines, has been investigated for measuring temperatures of hot gases. The minimum transmission of discrete spectral lines in gases at equilibrium has a simple dependence upon the absolute temperature, and this relation is used to measure temperature from a straight line plot. An experimental study has been made of the absorption due to the rotational lines of OH ($^2\Sigma \longleftarrow {}^2\pi$) between 3067 and 3090 Å in an oxygen-acetylene flame. It is shown that temperatures measured by this method are less affected than the conventional one by lack of sufficient resolving power, flame thickness, and various light sources (either continuous or line). TEMPERATURE OF FLAMES, by H. P. Broida and A. M. Bass. Technical rept. Dec. 1954-Dec. 1955. Jan. 16, 1956, iv, incl. illus. diagrs. tables, refs. (NBS rept. no. 4418) (AFOSR-TR-56-5) (CSO-630-55-25) AD 80550 Unclassified

The High Temperature Spectroscopy Laboratory of the National Bureau of Standards dates its research from 1949. The emission and absorption of radiant energy by a hot gas system are studied for information on the characteristics of the fundamental physical and chemical quantities involved. The work of the past year is given. In the ultraviolet region of the spectrum, the radiation emitted from flames at low pressure is surveyed. The result is the development of a new and convenient method for determining flame temperatures and the discovery of a previously unobserved region of burning in hydrocarbon flames. In the infrared, work is done on the measurement of the widths of resolved lines in the spectrum of CO. The distortion effects and a correction method for the spectrometer slit on recorded spectrum lines are considered. The details of the investigations are given in the report.

A NOTE ON THE PREPARATION OF SOLID OZONE AND ATOMIC OXYGEN (Abstract), by H. P. Broida and J. R. Pellam. [Nov. 3, 1954] [1]p. [CSO-680-56-21] Unclassified

Published in Jour. Chem. Phys., v. 23: 409, Feb. 1955.

Solid O_3 containing atomic O was prepared by passing O at a pressure of 0.1 to 3 mm Hg through a discharge region maintained by a microwave (2450 mc/sec) voltage. A violet coloration was observed on the cold walls within 15 to 30 sec after starting the flow of O through the discharge. The material became thick and began to peel and crack from the surface. The violet solid had the pungent odor of O_3 and decomposed rubber. When a small amount of H_2O was added prior to starting the O flow, a colorless amorphous solid was obtained which was attributed to O_3.

INTERPRETATION OF SPECTRA OF ATOMS AND MOLECULES IN SOLID NITROGEN CONDENSED AT 4.2°K, by C. M. Herzfeld and H. P. Broida. Oct. 13, 1955 [6]p. incl. illus. diagrs. table, refs. ([AF]OSR-TN-55-371) (Sponsored jointly by Air Force Office of Scientific Research and Office of Naval Research under CSO-680-56-21) AD 71618 Unclassified

Also published in Phys. Rev., v. 101: 606-611, Jan. 15, 1956, (Title varies).

The emission spectra observed from solids condensed at 4.2°K from an electric discharge through nitrogen are explained by assuming that large numbers of nitrogen atoms are deposited in the process. Approximate calculations of the interactions of the atoms with the surrounding solid show that the observed shifts, splittings, and changes of half-life of some atomic lines have the proper direction and magnitude. Analysis of new band system provides evidence for the formation of nitrogen molecules from atoms in the solid and provides information about a new electronic state of N_2 which may be the $^5\Sigma_g^+$ state. On this basis, a lower limit to the heat of dissociation of nitrogen of 9.632 ev can be given.

THEORY OF SPECTRA OF ATOMS AND MOLECULES IN SOLID NITROGEN CONDENSED AT 4.2°K (Abstract), by C. M. Herzfeld. Nov. 7, 1955, 1p. (AFOSR-TN-55-412) (CSO-680-56-21) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 58, Jan. 30, 1956.

The observed emission spectra[1] of solids condensed at 4.2°K from electric discharges through nitrogen are explained by assuming that large numbers of atoms in various excited states are deposited in the process. Approximate calculations show that one set of emission lines corresponds to the forbidden $^2D \longrightarrow {}^4S$ transition in N atoms, which is perturbed by crystal field effects. Band emission spectra are obtained which arise when atoms combine to form molecules in highly excited states. The most intense band band system is analyzed, and arises from the $^5\Sigma \longrightarrow A^3\Sigma$ transition. The analysis provides values of D_0 (= 1060 cm^{-1}), and r_0 (approximately 1.5A), for $^5\Sigma$, and a lower limit of 9.632 ev for the heat of dissociation of the ground state of N_2. Several effects of the crystal field on the molecular levels are observed. (Contractor's abstract)

THEORY OF SPECTRA OF ELECTRIC DISCHARGE PRODUCTS COLLECTED AT LOW TEMPERATURES, by C. M. Herzfeld. [1955] 7p. (CSO-680-56-21) Unclassified

The effects of perturbations of atoms and molecules in solids and the effect of the solid on the spectra of atoms is discussed in relation to the crystal field theory. Electric fields set up by neighboring molecules and ions are explicitly written out with special attention given to field symmetry. The average effects of these fields on a particular ion are then calculated with quantum mechanical perturbation theory. Relative splittings of ionic energy levels are thus deducible and relative transition probabilities estimated; agreement between theoretical calculations and experimental findings is usually good. Interactions between a specific ion and its neighbors must be considered if absolute magnitudes of splittings and transition probabilities are to be calculated; no reliable general technique is available to do this difficult operation in most cases.

THE (0, 1) AND (1, 2) BANDS OF THE $^2\Delta - {}^2\Pi$ SYSTEM OF CH, by N. H. Kiess. Mar. 18, 1955 71p. incl. illus. diagrs. tables, refs. (NBS rept. no. 3975) (In cooperation with Maryland U., College Park) [AFOSR-TN-55-181] [CSO-680-56-30] AD 67081 Unclassified

A description is presented of the experimental procedures for photographing the (0, 1) and 1, 2) bands of the $^2\Delta - {}^2\Pi$ system of the band spectra of the CH molecule, and the analysis of the structure of these bands. The theory of the spectra of diatomic molecules is given

NBS. 07:002 - NBS. 07:005

briefly in order to introduce those results and methods which are necessary for the analysis of the band structure. The previous work on the CH spectra is summarized. Although the (0, 1) band of the $^2\Delta - ^2\pi$ system was first noticed in 1916, its faintness prevented any high-resolution work; hence, the identity of its emitter could not be conclusively established. It is found, however, that a lean acetylene-oxygen flame burning on a slot burner emits this band with sufficient intensity for high-resolution work. The analysis shows that this band is the (0, 1) band of the $^2\Delta - ^2\pi$ system, and revelas the (1, 2) band of this system. It also leads to the determination of molecular constants for rotation, vibration, Λ-doubling, and spin-splitting. Although many of these constants have been determined from the analysis of other CH bands, the data from the (0, 1) and (1, 2) bands serve both to check the accuracy of the values given for these constants and to determine some new constant.

EXPERIMENTAL PROOF FOR THE EXISTENCE OF NONTHERMAL ROTATIONAL DISTRIBUTIONS OF OH ($^2\Sigma^+$) IN FLAMES, by H. P. Broida and H. J. Kostkowski. Nov. 15, 1955 [5]p. incl. diagrs. tables, refs. [AFOSR-TN-55-459] [CSO 680-56-30] AD 122249 Unclassified

Also published in Jour. Chem. Phys., v. 25: 676-680, Oct. 1956.

Experiments have been carried out to determine whether nonthermal rotational distributions in the $^2\Sigma^+$ electronic state of OH observed in certain flames are caused by self-absorption. A study of emission (single and double path) and absorption of OH between 3064 Å and 3350 Å in atmospheric and low-pressure flames has shown that self-absorption is negligible in at least 2 cases in which nonthermal distributions are found. This leads to the conclusion that anomalous "temperatures" of OH measured previously in hydrocarbon flames at low pressure and in highly diluted flames at atmospheric pressure are real. SPECTRA EMITTED FROM SOLID NITROGEN CONDENSED AT 4.2° K FROM A GAS DISCHARGE, by A. M. Bass and H. P. Broida. Dec. 7, 1955 [8]p. incl. illus. diagrs. tables, refs. [AFOSR-TN-55-460, CSO-680-56-30. AD 106165 Unclassified

Also published in Phys. Rev., v. 101: 1740-1747, Mar. 15, 1956.

Products of an electrical discharge in flowing nitrogen are frozen at liquid helium temperatures. The solid material emits a glow. Emission spectra have been obtained in the region of 2200 Å to 7000 Å. The most intense features of these spectra, 5 sharp lines near 5230 Å and 3 diffuse lines between 5530 Å and 5670 Å, are attributed to radiation from nitrogen atoms as affected by the solid lattice. There is a less intense series of bands, degraded to the red, extending from 3500 Å to 6400 Å. This system most probably arises from a transition of the N_2 molecule, probably to the $A^3\Sigma_u^+$ state. In the same region, there is a group of very weak diffuse bands which may be emission from NO_2. In addition, several weak bands are attributed to the β- and γ-systems of NO and to NH. When the flow of nitrogen and the electrical discharge are removed, an afterglow from the solid is observed. The spectrum of the afterglow shows only the group near 5230 Å and a weak line at 5944 Å. The half-life of this afterglow radiation is about 15 sec. Intensities of all other features decay to zero in less than 1 sec. (Contractor's abstract)

SLIT FUNCTION EFFECTS IN THE DIRECT MEASUREMENT OF ABSORPTION LINE HALF-WIDTHS AND INTENSITIES, by H. J. Kostkowski and A. M. Bass. Feb. 15, 1956 [5]p. incl. diagrs. table. [AFOSR-TN-56-25] (CSO-680-56-30) AD 122982 Unclassified

Also published in Jour. Opl. Soc. Amer., v. 46: 1060-1064, Dec. 1956.

The distortion of spectral lines by the finite band pass of spectrometers is an effect which must be considered in measuring line shape parameters. The differences between actual line half-widths and line intensities and those which would be obtained directly from measurements by spectrometers with Gauss and Cauchy shaped slit functions have been calculated for Lorentz and Doppler lines of varying widths and intensities. A method of utilizing these results to correct actual measurements is developed. (Contractor's abstract)

SPECTROSCOPIC SURVEY OF ENERGY DISTRIBUTIONS OF OH, C_2, AND CH RADICALS IN LOW-PRESSURE ACETYLENE-OXYGEN FLAMES, by H. P. Broida and D. F. Heath. [Mar. 2, 1956] [7]p. incl. illus. diagrs. tables, refs. AFOSR-TN-56-46. (CSO-680-56-30) AD 80558 Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 4, 1956.

Also published in Jour. Chem. Phys., v.26: 223-229, Feb. 1957.

Rotational and vibrational "temperatures" from electronic transttions of OH, C_2, and CH radicals have been measured in detail as functions of position in low-pressure acetylene-oxygen flames. Pressures were varied from 0.8 to 6.0 mm Hg. Trends of "iemperaiure" are presented ai functions of mixture, pressure, posttion, mass-flow rate, and burner size. Abnormalities in "temperaiure" are dtscussed. Evtdence is presenied for the extstence of a newly dtscovered region ai the base of the flame. This regton is aboui 0.1 the visible flame ihickness and is characterized by strong emtssion of C_2 and CH relative to OH and by relatively high "temperatures" of C_2 and CH. Just above this region, the OH rotational "temperaiure" is very high, about 9000° K, and is independent of pressure. (Contractor's abstract)

ON THE RELAXATION OF VIBRATIONAL NONEQUILIBRIUM DISTRIBUTIONS. III. THE EFFECT OF RADIATIVE TRANSITIONS ON THE RELAXATION BEHAVIOR, by R. J. Rubin and K. E. Shuler. Mar. 6, 1956, 18p. (AFOSR-TN-56-106) (CSO-680-56-30) AD 82020 Unclassified

Also published in Jour. Chem. Phys., v. 26:137-142, Jan. 1957.

In previous papers of this series (Parts I and II), a theoretical study was made of the collistonal relaxation of a system of harmonic oscillators (with $h\nu/kT \ll 1$) from tnitial vibraiional nonequilibrium distributions, and of ihe influence of the collisional transition probabilities on the relaxation behavior. This paper is concerned with ihe extension of this study to include the effects of concurrent radiative transitions on ihe relaxation behavior. Concurrent radiative transitions do not change the relaxation behavior of the system of harmonic oscillators from that found previously for purely collistonal transitions. The only change is in the time-scale of the relaxation, in that the expressions obtained in Part I must be multiplied by a factor of the form $\exp[-t/\tau]$, where τ is the lifetime of the oscillators in their excited vibrational and electronic energy levels. STABILIZATION OF FREE RADICALS AT LOW TEMPERATURES, by H. P. Broida. June 15, 1956, 18p. illus. diagrs. refs. (AFOSR-TN-56-139) (CSO-680-56-30) AD 86016 Unclassified

Also published in Ann. N. Y. Acad. Sciences, v. 67: 530-545, May 24, 1957.

Several methods are discussed for the production of free radicals for low-temperature stabilization. These methods are grouped tnto two categories: (1) methods in which the radicals are frozen into a solid after preparation at htgh temperaiure, and (2) methods in which the radtcals are produced directly in the solid at low temperature. In the ftrsi group, radtcals are formed tn a gas by eleciric discharges, high iemperature, or chemtcal reactions, and ihen solidified on a cold wall before they can react. In the second group, radicals are formed in the cold solid by irradiation of the proper material with γ-rays, x-rays, or ultraviolet light, or by bombardment with accelerated particles such as electrons, neutrons, or protons. The tncreased use of paramagnetic resonance absorptton measurements, the adaption of nuclear resonance, the study of thermal and electrical properties, and the use of x-ray diffraction techniques are all approaches which should give valuable information about free radicals. The ability to place free radicals in a solid permits the characteristics of the solid to be studied by means of the sensitivity of detecting free radicals whose properties are affected by the f rce fields of the solid.

SPECTROSCOPIC OBSERVATIONS ON PENTABORANE-AIR FLAMES AND EXPLOSIONS, by W. G. Berl, E. L. Gayhart and others [July 19, 1956] 1p. incl. illus. ([AF]OSR-TN-56-183) (Sponsored jotntly by Bureau of Ordnance under Nord-7386 and Air Force Offtce of Scientific Research under CSO-380-56-30) AD 87056 Unclassifted

Also published in Jour. Chem. Phys., v. 25: 797, Oct. 1956.

Spectroscopic studies were made by adding 0 to the N-diluted B_5H_9 in a flow system to prepare B_5H_9-O mixtures which were ignited by an electric spark producing a rapidly expanding flame kernel. The duration of such explosions is of the order of a msec. The main spectral features observed (B_5H_9-N ratio = 1:69.5) were the α bands of BO between 3370 Å and 6200 Å owing to the transitton from the $A^2\Pi_1$ staie to the $X^2\Sigma^+$ ground state. A weak system of diffuse bands observed in the same region was identical with the so-called "boric acid fluctuation band." No emission was observed at wavelengths shorter than 3350 or longer than 6400 Å. Neither BH, BN, nor OH bands were observed in either the diffusion flame or in the explosions. The BO-α and B_2O_3 bands observed in the low-temperature (~500°K) diffusion flame apparently indicated a chemiluminescent origin of the radiation in the flame.

STEREOSCOPIC STUDIES OF SOLIDS CONDENSED AT 4.2°K FROM ELECTRIC DISCHARGE THROUGH NITROGEN, OXYGEN, HYDROGEN, WATER, AND AMMONIA, by H. P. Broida. [Aug. 15, 1956] [6]p. incl. illus. diagr. [AFOSR-TN-56-362] (CSO-680-56-30) AD 95448 Unclassified

Also published in Proc. Conference on Chemical Aeronomy, Harvard U., June 1956, from The Threshold of Space, 1957, p. 194-199.

Absorption spectra between 2200 and 35,000 Å have been obtained of solids condensed at 4.2°K after passing N, O, H, H_2O, and NH_3 separately through an electrodeless discharge (Bass and Broida). Comparison spectra of the same solidified gases which were not subjected to the discharge have been obtained. A number of bands occur in the discharge products which do not occur in materials which have not passed through the discharge. These bands are diffuse and fairly broad (generally greater than 100 cm^{-1}). They disappear at higher temperatures and do not reappear when the solids are cooled again.

ABSORPTION SPECTRA OF SOLIDS CONDENSED FROM AN ELECTRICAL DISCHARGE THROUGH OXYGEN (Abstract), by A. M. Bass and H. P. Broida. [1956] [1]p. (CSO-680-56-30) Unclassified

Presented at Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 11-15, 1956.

Published in Symposium on Molecular Structure and Spectroscopy. Abstracts, 1956, p. 23.

The products of a high frequency electrical discharge in flowing oxygen are frozen out on a fused silica plate maintained near the temperature of liquid helium. The absorption spectra of the collected material are studied as a function of layer thickness and of temperature. Spectra are obtained over the range 2200 to 8500 A with prism spectrographs, and from 1 to 3.5 microns with a grating spectrometer, using a cooled lead sulfide detector. The absorption spectrum of the condensate from the discharge through oxygen shows some 25 diffuse bands in the range 3500 to 7000 A. A few of these bands correspond to bands observed in solid molecular oxygen. In the ultraviolet there is a strong continuous

absorption starting at about 3500 A and increasing very rapidly toward shorter wavelengths. In the infrared two bands, about 20 cm^{-1} wide, are observed peaking at 3030 and 3499 cm^{-1}. The band at 3030 cm^{-1} may be due to ozone, which in the gas phase has an absorption band at 3050 cm^{-1}. In addition there are observed six narrow lines (about 2 cm^{-1} wide) coming from the fused silica collecting plate. The two strongest lines, at 3364 and 3470 cm^{-1}, show marked broadening and shift by about 10 cm^{-1} to shorter wavelengths upon warming the plate from liquid helium temperature to room temperature. LINE-WIDTHS AND SHAPES IN CO AT PRESSURES ABOVE ONE ATMOSPHERE (Abstract), by H. J. Kostkowski and A. M. Bass. [1956] [1]p. (CSO-680-56-30) Unclassified

Presented at Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 11-15, 1956.

Published in Symposium on Molecular Structure and Spectroscopy. Abstracts, 1956, p. 50.

The widths of self-broadened lines in the first overtone band of CO at pressures from 2½ to 20 atm were measured directly with a small grating menochromator whose spectral slit-width was approximately 0.25 cm^{-1}. Line intensities were also determined but at pressures below one atmosphere. Both the line widths and intensities are believed to be in error by less than 5%. These independently determined parameters were then used with assumed line shapes to calculate the absorption, as a function of pressure, at various troughs throughout the band. Comparisons were made with actual measurements to try to obtain some information about the line shape and widths for pressures up to 60 atm. The method for determining the width and intensity of the lines as well as the results obtained on widths and shapes are presented. (Contractor's abstract)

DIRECT MEASUREMENT OF LINE WIDTHS AND INTENSITIES IN CARBON MONOXIDE AT 2.35 MICRONS (Abstract), by A. M. Bass and H. J. Kostkowski. [1956] [1]p. [CSO-680-56-30] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 14, Jan. 30, 1956.

The widths and intensities of absorption lines have been measured in the first overtone vibration-rotation band of CO at 2.35 microns. Sufficiently high CO pressures were used so that direct measurements could be made with a grating spectrometer having a spectral slit width of about 0.3 cm^{-1}. Data were obtained at room temperature for a range of pressures from 1/4 to 67 atm and for path lengths from 5 to 750 mm. The direct measurements at 5 and 10 atm were corrected by about 10% for the distortion effects of the finite spectrometer slit width. The results obtained are discussed in terms of the line shape and the pressure dependence of line widths in CO and are compared with results obtained from the curve-of-growth method in this work and by others. SPECTROSCOPIC STUDY OF "TEMPERATURES" DETERMINED FROM OH, C_2, AND CH RADICALS IN LOW-PRESSURE ACETYLENE-OXYGEN FLAMES (Abstract), by D. F. Heath and H. P. Broida. [1956] [1]p. [CSO-680-56-30] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 13, Jan. 30, 1956.

Rotational and vibrational "temperatures" from electronic transitions of OH, C_2, and CH radicals have been measured in detail as functions of position in low-pressure acetylene-oxygen flames. Pressures were varied from 1.6 to 6.0 mm Hg. Trends of temperature are presented as functions of mixture, pressure, position, mass flow rate, and burner size. Abnormalities in temperature are discussed. Evidence is presented for the existence of a new "burning" region at the base of the flame. This region is about 1/10 the visible flame thickness and is characterized by strong emission of C_2 and CH relative to OH and by relatively high temperatures of C_2 and CH. Just above this region the OH rotational temperature is very high, about 9000°K. (Contractor's abstract)

NBS. 08:002 - NBS. 08:005

A prism spectrometer has been changed to a long wavelength grating spectrometry by removing the prism and by replacing the Littrow mirror with a grating. Gratings of 320 and 180 lines/in. were used for the region 50 to 125 microns. A thermocouple with a crystal quartz window served as the detector. Stray radiation was greatly reduced by the use of reflection filters. Three types of reflection filters were found to be efficient. They were gratings with 2000 lines/in., roughened silver mirrors, and reststrahlen plates of NaCl, KBr, and CsBr. The absorption lines of water vapor were used to calibrate the spectrometer. The spectra of several substituted ethylenes and ethanes have been measured, and absorption bands have been found between 50 and 100 microns.

MICROWAVE SPECTRUM AND STRUCTURE OF SULFURYL FLUORIDE, by D. R. Lide, Jr., D. E. Mann, and R. M. Fristrom. Apr. 1956 [25] p. incl. diagrs. tables, refs. (NBS rept. no. 4650) (AFOSR-TN-56-269) (CSO-680-56-31) AD 88989 Unclassified

Also published in Jour. Chem. Phys., v. 26: 734-739, Apr. 1957.

The microwave spectrum of sulfuryl fluoride (SO_2F_2) has been investigated. The spectra of the S^{32} and S^{34} species in natural abundance have been analyzed, and the structure has been determined with the aid of the S^{34} isotope shift. The correction for zero-point vibration was shown to be small. The structural parameters are: r_{SO} = 1.405 ± 0.003A, r_{SF} = 1.530 ± 0.003A, ∠OSO = 123°58' ± 12', and ∠FSF = 96°7' ± 10'. The molecular dipole moment is 1.110 ± 0.015 Debye units. A number of satellite lines were observed and assigned to excited vibrational states. Some anomalies in the measured rotational constants for the excited states have been interpreted in terms of a Cortolts-type interaction between the fundamentals $\nu_4(A_1)$ and $\nu_5(A_2)$. From an analysis of this interaction the frequency of the hitherto unobserved $\nu_4(A_1)$ fundamental was found to be 388 ± 15 cm^{-1}. (Contractor's abstract)

NORMAL COORDINATE ANALYSIS OF HALOGENATED ETHYLENES. I. GENERAL METHODS, by D. E. Mann, T. Shimanouchi and others. Apr. 1956, 28p. incl. diagr. refs. (NBS rept. no. 4654) (AFOSR-TN-56-272) (CSO-680-56-31) AD 89482 Unclassified

Also published in Jour. Chem. Phys., v. 27: 43-51, July 1957.

Methods and detailed algebraic expressions are given for the normal-coordinate analysis of ethylenic molecules. They are applied to the calculation of potential constants, normal modes, and vibrational frequencies for a series of perhalogenated ethylenes. A force field of the Urey-Bradley type is used for the planar vibrations, and a simple valence-type potential function is applied to the nonplanar motions. The force constants established for the molecules with V_h symmetry are to be used, with only linear interpolation and no further adjustment, to calculate the fundamental frequencies and modes of all the remaining, less symmetrical ethylenes. For the V_h molecules, the vibrational secular equations are set up in the customary GF matrix fashion. The other ethylenes require a somewhat different form which is more readily adapted to calculation by an electronic digital computer. In order that the force constants determined for the V_h molecules be as good as possible, a method is given for their adjustment by a least-squaring process. (Contractor's abstract)

NORMAL COORDINATE ANALYSIS OF HALOGENATED ETHYLENES. II. PERHALOGENATED ETHYLENES, by D. E. Mann, L. Fano and others. Apr. 1956, iv. incl. diagrs. tables, refs. (NBS rept. no. 4655) (AFOSR-TN-56-273) (CSO-680-56-31) AD 89483 Unclassified

Also published in Jour. Chem. Phys., v. 27: 51-59, July 1957.

The methods described in item no. NBS. 08:004 have been applied to the normal coordinate analysis of the fundamental vibrations of 27 perhalogenated ethylenes which contain F, Cl, or Br. Force constants for the planar modes of the key molecules (C_2F_4, C_2Cl_4, and C_2Br_4) have been obtained by an adjustment procedure

based on the method of least squares. The agreement between the calculated and observed fundamentals is quite good. The constants established for the key molecules were then used, either directly or with a simple interpolation scheme, to calculate the fundamentals of the remaining 24 ethylenes. Comparisons with experimental results have been made where possible and indicate good agreement for the out-of-plane, as well as in-plane vibrations. The planar normal modes of C_2F_4, C_2Cl_4, and the 5 fluorochloroethylenes are depicted. (Contractor's abstract)

VIBRATIONAL SPECTRUM AND FORCE CONSTANTS OF DIBORON TETRACHLORIDE, by D. E. Mann and L. Fano. Aug. 1956, 25p. incl. diagrs, tables, refs. (NBS rept. no. 4811) (AFOSR-TN-56-450) (CSO-680-56-31) AD 96795 Unclassified

Also published in Jour. Chem. Phys., v. 26: 1665-1670, June 1957.

The infrared spectrum of gaseous diboron tetrachloride (B_2Cl_4) and the Raman spectrum of the liquid are analyzed. The molecular symmetry is shown to be V_d, in accord with the electron diffraction result for the vapor. A complete vibrational assignment is given. The fundamentals are (in cm^{-1}): 1131, 401, 225 in a_1; 730, 291 in b_2; 917, 617, 180 in e. A normal coordinate analysis, based on a Urey-Bradley potential function and a least-squares method of force constant adjustment, is used to establish the assignment. With the aid of the third-law entropy, the barrier restricting internal rotation about the B-B single bond is fixed at 1700 ± 600 cal/mole. (Contractor's abstract)

AN EXTENSION OF GAUSS' TRANSFORMATION FOR IMPROVING THE CONDITION OF SYSTEMS OF LINEAR EQUATIONS, by G. E. Forsythe and T. S. Motzkin. [1952] 9 p. incl. refs. [CSO-670-54-12] Unclassified

Published in Math. Tables and Other Aids to Computation, v. 6: 9-17, Jan. 1952.

Gauss (Werke, Bd. 9, Tuebner, Leipzig, 1903, pp. 250-253, 278-281; for an annotated translation by G. E. Forsythe, see same journal, v. 5: 255-258, 1952; see also R. Dedekind, Gesammelte mathematische Werke, Bd. 2, Vieweg, Braunschweig, 1931, pp. 293-306) suggested the following transformation to improve the convergence of the relaxation method for the solution of a system of linear equations (1) $\sum a_{ij}x_j = b_i$ (i = 1, 2, ..., n) of which the matrix (a_{ij}) is symmetric and positive definite. Replace x_i by $y_1 - y_{n+1}$ (i = 1, 2, ..., n) and adjoin to the system an (n + 1)th equation by adding the first n. The new system is redundant but this does not matter since the x_i's are determined by the differences of the y_i's. Interest in this transformation was roused by its description by Zurmühl (Matrizen ..., Springer, Berlin-Göttingen-Heidelberg, 1950, p. 280; Math. Rev., v. 12: 73). The authors study a generalization of the above transformation; they consider $x_i = y_i + s_i y_{n+1}$ where the s_i's are parameters. They also consider the case when (a_{ij}) is singular. Let λ_i be the characteristic root of (a_{ij}). Let $\lambda = \max|\lambda_i|$ and let $\mu = \min|\lambda_i|$ where we disregard vanishing λ_i. It is suggested that the size of the ratio λ/μ, called the P-condition number, is decisive in the speed of convergence of iterative solutions of (1). (cf. von Neumann and Goldstine, Bull. Amer. Math. Soc., v. 53: 1021-1099, 1947; Turing, Quart. Jour. Mech. Appl. Math., v. 1: 287-308, 1948; J. Todd, Quart. Jour. Mech. Appl. Math., v. 2: 469-472, 1949; Proc. Cambridge Philos. Soc., v. 46: 116-118, 1950). It is shown that the characteristic roots of the transformed matrix separate those of the original and that although values of the s_i can be chosen to reduce the P-condition number it is not true that the original Gauss transformation will always effect this. The case of a well-known 4 x 4 ill-conditioned matrix is discussed in numerical detail. (Math. Rev. abstract)

BOOLEAN GEOMETRY. 1., by L. M. Blumenthal. Feb. 11, 1952, 28p. (NBS rept. no. 1482) [CSO-670-54-12] U72062 Unclassified

Also published in Rend. Circ. Matem. Palermo, Series II, v. 1: 1-18, 1952.

This paper studies the geometry of the distance space obtained by associating with each two elements a, b of a Boolean algebra the element $d(a, b) = ab' + a'b$ of the algebra as distance. Since $d(a, b) = 0$ if and only if $a = b$, $d(a, b) = d(b, a)$, and $d(a, b) + d(b, c) = d(a, c)$ for each three elements a, b, c of the algebra, the distance function has the formal properties of a metric. This permits, as well as motivates, the introduction of geometric notions into Boolean algebra, and suggests that the application of metric methods might yield new results as well as novel interpretations of old ones. Theorems of order (linearity) are established, and properties of segments are obtained. (Extracted from rept.)

ON PÓLYA FREQUENCY OF FUNCTIONS. III. THE POSITIVITY OF TRANSLATION DETERMINANTS WITH AN APPLICATION TO THE INTERPOLATION PROBLEM BY SPLINE CURVES, by I. J. Schoenberg

NBS. 09. 004 - NBS. 09:007

and A. Whitney. Feb. 18, 1952, 24p. (NBS rep. no. 1[illegible]) [CSO-670-54-12] U72067 Unclassified

Also published in Trans. Amer. Math. Soc., v. 74: 246-259, Oct. 1953.

A non-negative function $\Lambda(x)$ in $L(-\infty, \infty)$ is called a Pólya frequency function if for any two sets of increasing numbers

$$x_1 < x_2 < \ldots < x_n,\ y_1 < y_2 < \ldots < y_n,\ n = 1, 2, \ldots,$$

we have the inequality $D \equiv \det \|\Lambda(x_i - y_j)\|_{1,n} \geq 0$. It was shown in Part I that the bilateral Laplace transform of $\Lambda(x)$ is the reciprocal of an entire function $\psi(s)$ of the form

$$\psi(s) = Ce^{-\gamma s^2 + \delta s} \prod_{\nu=1}^{\infty} (1 + \delta_\nu s)e^{-\delta_\nu s},$$

where $C > 0$, $\gamma \geq 0$, δ_ν are real, $0 < \gamma + \sum \delta_\nu^2 < \infty$. Case 1 is that in which $\psi(s) = \prod (1 + \delta_\nu s)$, $\sum |\delta_\nu| < \infty$, case 2 that in which $\gamma > 0$ or $\gamma = 0$ and $\sum |\delta_\nu| = \infty$. It is shown in the present paper that D is always positive in case 2. In case 1 let k be the number of $\delta_\nu > 0$, h the number of $\delta_\nu < 0$. Then

$D > 0$ if and only if $x_{\nu-k} < y_\nu < x_{\nu+h}$ for $\nu = 1, \ldots, n$ with the convention that $x_r = -\infty$ if $-\infty \leq r < 1$ and $x_r = +\infty$ if $n < r \leq +\infty$. The proof involves the consideration of a large number of subcases. If $x_+ = \max(0, x)$, $\Lambda(x) = e^{-x}(x_+)^k$ is a Pólya frequency function belonging to case 1 and the main theorem shows that $\det \|[x_i - y_j)^k]\| > 0$ if and only if $x_{\nu-k-1} < y_\nu < x_\nu$, $\nu = 1, \ldots, n$. A spline function of degree k is an expression of the form $F(x) = P_k(x) + \sum_{\nu=1}^{n} A_\nu [(x - \xi_\nu)_+]^k$ where $P_k(x)$ is an arbitrary polynomial of degree $\leq k$ and the ξ_ν are the n given knots. The interpolation problem consists in deciding if a spline curve can be laid through $n + k + 1$ given points (x_ν, Y_ν), the degree k and the knots ξ_ν being given. Necessary and sufficient conditions are given with the aid of the spectal result mentioned above. (Math. Rev. abstract)

ON LINEAL ENTIRE FUNCTIONS OF n COMPLEX VARIABLES, by T. S. Motzkin and I. J. Schoenberg. [1951] [10]p. [CSO-670-54-12] Unclassified

Published in Proc. Amer. Math. Soc., v. 3: 517-526, Aug. 1952.

A polynomial $P(z) = P(z_1, \ldots, z_n)$ with complex coefficients is called lineal if it is a product of linear functions. An entire function f(z) is called lineal if it is the limit of a sequence of lineal polynomials uniformly convergent on every compact set. The author proves that f(z) is lineal if and only if it vanishes on planes only. If f(z) is lineal, it can be written as a Weierstrass product

$$l(z) = \exp G(z) \prod_{1}^{n} (z, c_j) \prod_{1}^{\infty} P_k(z, d_k)$$

where G(z) is an entire function, c_j and d_k complex vectors, and

$$P_k(u) = (1-u)\exp\left(u + \tfrac{1}{2}u^2 + \ldots + \frac{1}{k-1}u^{k-1}\right).$$

The function f(z) is called really linear if the approximating polynomials split into products of linear functions with real coefficients. This happens if and only if

$$f(z) = \exp\left(\sum_1^m c_{rs}z_r z_s + (z,d)\right)\prod_1^n (z,c_j)\prod_1^\infty (1+(z,d_k))e^{-(z,d_k)},$$

where c_j, d and d_k are real vectors, $\sum \|d_k\|^2$ convergent and $\sum_1^m c_{rs}z_r z_s \geq 0$ for every real z. Finally f(z) is called positively linear if the approximating polynomials split into linear factors with positive coefficients. In this case the vectors c_j, d, and d_k have positive coordinates, $\sum \|d_k\|$ converges and the quadratic form vanishes. Detailed proofs of these statements are given. (Math. Rev. abstract)

THE RELAXATION METHOD FOR LINEAR INEQUALITIES, by T. S. Motzkin and I. J. Schoenberg. Aug. 13, 1952, 21p. (NBS rept. no. 1881) [CSO-670-54-12] Unclassified

Presented at meeting of the Amer. Math. Soc., Sept. 1952.

Also published in Canad. Jour. Math., v. 6: 393-404, 1954.

This paper presents an elegant proof of the fundamental theorem established in the article reviewed above and obtains new results for the case $\lambda = 2$ (the reflection method). Denoting by A the solution set of a consistent system of m linear inequalities in n indeterminates, it is shown that the reflection method always terminates when dim A = n, while if dim A = r < n then either the sequence $\{p_\nu\}$ terminates, or else there is a number ν_0 such that for $\nu \geq \nu_0$ the points p_ν are on a spherical surface S_{n-r-1} having the r-dimensional subspace containing A as axis (i.e., L_r is the locus of points equidistant from the points of S_{n-r-1}). The concluding section of the paper is concerned with establishing analogous theorems for the reflection process when the (infinite) set of half-spaces considered all contain a given bounded, closed, and convex subset A (which it is desired to enter) and their boundaries are supporting hyperplanes of A. ON REPRESENTATIONS OF FINITE GROUPS, by T. S. Motzkin and O. Taussky. Sept. 27, 1952 [2]p. [CSO-670-54-12] Unclassified

Published in Neterl. Akad. Wetensch. Proc. Ser. A. Indag. Math., v. 55: 511-512, 1952.

If every pair of matrices A, B of a faithful representation (by matrices over the complex field) of a finite group Γ has the property (L) that their roots α_t and β_t can be ordered so that the roots of $\lambda A + \mu B$ are $\lambda\alpha_t + \mu\beta_t$ for all complex λ and μ, then Γ is abelian; also, if the roots of $\prod C_k$, each C_k = A or B, are the corresponding products of the α_t and β_t, Γ is abelian. If the matrix elements may be in a field of finite characteristic, examples show that p(A, B) may have roots $p(\alpha_t, \beta_t)$ for every polynomial and yet Γ be non-abelian. (Math. Rev. abstract)

EIGENVECTORS OF MATRIC POLYNOMIALS, by M. Marcus. Nov. 24, 1952, 13p. (NBS rept. no. 2077) [CSO-670-54-12] Unclassified

Also published in Jour. Res. Nat'l. Bur. Standards, v. 51: 33-36, July 1953.

The object of this paper is to compare the eigenvectors of an arbitrary n x n matrix A over the complex field with those of the matrix polynomial f(A). While it is well known that each eigenvector of A is an eigenvector of f(A), it is not, in general, true that A and f(A) have identical eigenvectors. In this regard a necessary and sufficient condition that A and f(A) have identical eigenvectors is given. The condition is that both (1) and (2) hold: (1) $f'(\lambda) \neq 0$ for all eigenvalues λ of the matrix A corresponding to nonlinear elementary divisors; (2) the values of $f(\lambda)$ are distinct for all eigenvalues of λ of the matrix A corresponding to linear elementary divisors. When either (1) or (2) fails to hold, then f(A) has eigenvectors that are not eigenvectors of A. This situation is also discussed. (Contractor's abstract)

A THEOREM ON CONVEX CONES WITH APPLICATIONS

NBS. 09:013 - NBS. 09:016

TO LINEAR INEQUALITIES, by J. W. Gaddum. [Dec. 1952] [4]p. (NBS. rept. no. 1473) [CSO-670-54-12] U72061 Unclassified

Published in Proc. Amer. Math. Soc., v. 3: 957-960, Dec. 1952.

This note is concerned with the convex cone associated with the two systems of linear inequalities,

(1) $\sum_{j=1}^{n} a_{ij}x_j \geq 0$, $i = 1, 2, \ldots, m$, and

(2) $\sum_{j=1}^{n} a_{ij}x_j \geq 0$, $i = 1, 2, \ldots, m$, where the symbol $\geq$

demands that the inequality ($>$) hold for at least one value of i. For brevity these systems are written (1) $Ax \geq 0$ and (2) $Ax \geq 0$. Interpreting $(a_{i1}, \ldots, a_{in})$ as a vector a_i in E_n, with initial point at the origin, we denote by A convex cone generated by these m vectors and by A^* the polar cone, the vectors of which give the solutions of (1). The purpose of this paper is to show that in general $A \cdot A^* \neq 0$ and to characterize the cases in which A and A^* do intersect in the null vector. Some applications are then made to obtain theorems on the existence of, and methods of obtaining, solutions of (1) and (2).

TWO EXISTENCE THEOREMS FOR SYSTEMS OF LINEAR INEQUALITIES, by L. M. Blumenthal. Dec. 12, 1951 [10]p. (NBS rept. no. 1356) [CSO-670-54-12] Unclassified

Also published in Pacific Jour. Math., v. 2: 523-530, Dec. 1952.

The author develops the theory of linear inequalities by means of metric methods which was initiated in a previous paper [Duke Math. Jour. v. 15, 955-966 (1948) Preliminaries – E_n: n-dimensional Euclidean vector space. $p_1, p_2, \ldots p_n, p_{n+1}$: vectors of E_n such that $p_1, p_2, \ldots, p_{n-1}$ are linearly independent. L: linear manifold spanned by $p_1, \ldots, p_{n-1}$. x_{il} ($l = 1, \ldots, n$): components of p_l ($l = 1, \ldots, n+1$) with respect to a normal orthogonal basis. p_n and p_{n+1} lie on the same or on opposite sides of L according as the product of the signed volumes

$V(p_1, \ldots, p_{n-1}, p_n) \cdot V(p_1, \ldots, p_{n-1}, p_{n+1}) = |x_{kl}| \cdot |x_{hl}|$ (k, l = 1, 2, ..., n, h = 1, 2, ..., n - 1, n + 1) $|\text{sum } x_{kl}\, x_{hl}| = |(p_k, p_h)|$ is positive or negative. If the p_l's are unit vectors, $(p_k, p_h) = \cos p_k p_h$. Theorems – System ($g_*$) of linear inequalities in n indeterminates with rank $r + 1$: $(p_l, x) \geq 0$, $l = 1, \ldots, m$, one at least of the left members having to be positive. A p_l, A^T transpose of A, B AA^T. The system (g_*) has a solution if and only if and only if a shifting of rows and corresponding columns exists such that (i) the upper left principal minor M of B of order $r + 1$ does not vanish, (ii) each minor of B formed from M by replacing its last row with that part of the jth row of B contained in the first r + 1 columns (j = r + 2, r + 3, ..., m) is positive or zero. The second theorem is concerned with the existence of a nontrivial solution of the same system of inequalities, the positivity requirement being dropped. (Math. Rev. abstract)

MINIMAX THEOREMS, by K. Fan. Jan. 1953 [6]p. [CSO-670-54-12] Unclassified

Published in Proc. Nat'l. Acad. Sciences, v. 39: 42-47, Jan. 1953.

This note contains three generalizations of von Neumann's minimax theorem. These theorems, however, involve no structures of linear space. The first theorem can be used to provide simple proofs for

minimax theorems for infinite games. The second theorem generalizes Kneser's minimax theorem by eliminating the structure of linear spaces. The third theorem is free of topological structures. This is made possible by generalizing von Neumann's almost periodic functions on a group.

ON THE APPROXIMATION OF LINEAR ELLIPTIC DIFFERENTIAL EQUATIONS BY DIFFERENCE EQUATIONS WITH POSITIVE COEFFICIENTS, by T. S. Motzkin and W. Wasow. [Jan. 1953] [7]p. [CSO-670-54-12] Unclassified

Published in Jour. Math. and Physics, v. 31: 253-259, Jan. 1953.

The problem considered is that of approximating a given linear elliptic second-order partial differential equation $L[u] = 0$ in n-space by a linear difference equation $L_h[u] = 0$ (referring to a square mesh of width h) in such a way that (i) the operator $L_h[u]$ should be a formal analogue of $L[u]$, (ii) the equation $L_h[u] = 0$ should express the value of n at a lattice point P as a weighted average, with positive weights, of the values of n at certain lattice points $Q_1, \ldots, Q_s$. If the system of neighboring points $S = \{Q_1, \ldots, Q_s\}$ is given and contains at least all lattice points whose distance from P does not exceed $(nh)^{1/4}$, condition (i) can always be satisfied. The authors prove that for no S can condition (ii) be satisfied for all elliptic equations, but that for any given equation condition (ii) can be satisfied by choosing S appropriately. Condition (ii) is of importance for proving the solvability of Dirichlet's problem for the difference equation and the convergence of the solution of this problem to the appropriate solution of the differential equation, and also in view of the connection between linear elliptic equations and random walks. Condition (ii) also implies a maximum principle for solution of $L_h[u] = 0$, which the authors establish in the last section of this paper. (Math. Rev. abstract)

ON THE DERIVATIVE OF A POLYNOMIAL AND CHEBYSHEV APPROXIMATION, by T. S. Motzkin and J. L. Walsh. Aug. 25, 1951, 20p. (NBS repl. no. 1444) [CSO-670-54-12] Unclassified

Also published in Proc. Amer. Math. Soc., v. 4: 76-87, Feb. 1953.

Let E be a closed and bounded point set in the complex z-plane, $\mu(z)$ a positive function continuous on E. Let f(z) be continuous on E. The Chebyshev polynomial of best approximation $t_m(z)$ is the polynomial of degree not exceeding m such that $\max\{\mu(z)|f(z) - t_m(z)|\}$, for $z \in E$, is least. In particular, if $f(z) = z^{m+1}$, then $T_{m+1}(z) = z^{m+1} - t_m(z)$ is called the Chebyshev polynomial of degree m + 1 for E with the weight function $\mu(z)$. This paper discusses the properties of these polynomials (explicit expressions, location of zeros) for the case that E is a finite set and contains just one point too many to preclude the case of interpolation when all deviations can be made to vanish. The following theorem is established: Let E be the finite set of distinct points $z_1, \ldots, z_n$ $(n > 1)$, $\omega(z) = (z - z_1)\ldots(z - z_n)$. Let also the positive numbers $\lambda_1, \ldots, \lambda_n$ be given such that $\sum \lambda_i = 1$. Then the Chebyshev polynomial $T_{n-1}(z)$ for E with the weight function $\mu(z_i) = (\lambda_i|\omega'(z_i)|)^{-1}$, is the polynomial

$$T_{n-1}(z) = \omega(z) \sum_1^n \frac{\lambda_i}{z - z_i}.$$

Since $T_{n-1}(z_i) = \lambda_i \omega'(z_i)$, it is observed that the arguments of the quantities $T_{n-1}(z_i)$ are independent of the choice of the λ_i and that the origin belongs to the convex hull of the $T_{n-1}(z_i)$. These results are applied to a discussion of the Chebyshev polynomial of best approximation $t_{n-2}(z)$ to an arbitrary function f(z) and weight function $\omega(z)$ in the case that the set E has exactly n distinct points. A GENERALIZATION OF THE KRONECKER CAPELLI THEOREM ON A SYSTEM OF LINEAR EQUATIONS, by S. N. Tchernikow. C. D. Bensier, Jr. and T. S. Motzkin, ed. Feb. 5, 1953, 19p. (NBS repl. no. 2346) (Trans. from Matematicheskii Sbornik, v. 15 (57): 437-447, 1944) (In cooperation with California U., Los Angeles) (Sponsored jointly by National Bureau of Standards, Washington, D. C. and [Air Force] Office of Scientific Research under [CSO-670-54-12] Unclassified

The value of the present paper rests on two main features: it treats, apparently for the first time, linear inequalities with complex coefficients, and it gives, in its real specialization (which the author leaves unmentioned) an explicit criterion for solvability that enables one, in principle, to decide on solvability (compatibility, consistency) from the coefficients by an algebraic-combinatorial method. The type of system treated is the one most important in the theories of errors and observations and of the approximate solution of linear equations.

ON SMOOTHING OPERATIONS AND THEIR GENERATING FUNCTIONS, by I. J. Schoenberg. [1953] [32]p. [CSO-670-54-12] Unclassified

Published in Bull. Amer. Math. Soc., v. 59: 199-230, 1953.

This is an exposition of various problems most of which were solved by the author and his collaborators, grouped under the general title of smoothing operations. The problems deal mainly with the characterization and properties of certain transformations belonging to one of the following types. (*) The finite linear transformation $y_l = \sum_1^n a_{lk} x_k$, $l = 1, \ldots, m$. (**) The sequence convolution $y_n = \sum_{-\infty}^{+\infty} a_{n-\nu} x_\nu$. (***) The integral convolution $g(x) = \int_{-\infty}^{+\infty} A(x-t) f(t) dt$. A problem considered for the three types is the characterization of variation-diminishing transformations. For (*) this was solved (partially) by the author (Math. Z., v. 32: 321-328, 1930) and by Motzkin (Basel dissertation, 1933, Jerusalem, 1936). A different solution was also given by Schoenberg and Whitney (Compositio Math., v. 9: 141-160, 1951), who also considered cyclic v.d.t. For (**) the problem was solved by the author (Courant Anniversary Volume, Interscience, New York, 1948, pp. 351-370); the (necessary and sufficient) condition being that $\{a_n\}$ is a totally positive normalized sequence. For (***) the problem was solved by the author (Acta Sci. Math. Szeged, v. 12, Pars B, 97-106, 1950). A necessary and sufficient condition in this case is that except for a sign $A(x)$ be a Pólya frequency function. Various other problems are discussed: notably, when can a transformation (**) be referred to as a smoothing operation (Schoenberg, Quart. Appl. Math., v. 4: 45-99; 112-141, 1946; and Courant Anniversary Volume, same ref. as above); convex curves in higher dimensional spaces, and the problem of characterizing totally positive sequences by means of the associated generating function $\sum_{-\infty}^{\infty} a_n z^n$ which was successfully solved by the author (Courant Anniversary Volume, same ref.), Aissen, Schoenberg and Whitney (Jour. Analyse Math., v. 2: 93-103, 1952); and Edrei (Ibid. v. 2: 104-109, 1952; Canad. Jour. Math., v. 5: 86-94, 1953). (Math. Rev. abstract)

A CHARACTERIZATION OF NORMAL MATRICES, by A. J. Hoffmann and O. Taussky. July 7, 1953, 10p. (NBS rept. no. 2662) [CSO-670-54-12] Unclassified

Also published in Jour. Res. Nat'l. Bur. Standards, v. 52: 17-19, Jan. 1954.

A matrix A is called normal if $AA^* = A^*A$, where A^*

is the transposed and conjugate matrix of A. It is known that for a pair of commuting matrtces, A, B, there exists an ordering of the characteristic roots $\alpha_1, \ldots, \alpha_n$ of A and $\beta_1, \ldots, \beta_n$ of B, such that every polynomial p(A, B) has characteristic roots the numbers $p(\alpha_1, \beta_1)$. This property ts, in general, weaker than commutativity, but does imply it if $B = A^*$. It is shown that this property already tmplies commutativity of A and A^* if it ts assumed to holy for only one polynomial, provided the latter is suttably chosen. Polynomials of first and second degree are examined for their suitability. (Contractor's abstract)

LEAST p-th POWER POLYNOMIALS ON A REAL FINITE POINT SET, by T. S. Motzkin and J. L. Walsh. July 7, 1953, 29p. (NBS rept. no. 2661) (Sponsored jointly by Office of Naval Research and [Air Force] Offtce of Scientific Research under [CSO-670-54-12]) AD 28411 Unclasstfied

Also published in Trans. Amer. Math. Soc., v. 78: 67-81, 1955.

The authors consider polynomials

$$T_{n+1}(z) = z^{n+1} + \sum_{1}^{n+1} b_r z^{n+1-r}$$

which minimize a devtation from zero of the form

$$\delta(|T_{n+1}(z_1), \ldots, T_{n+1}(z_m)|)$$

and the z_k form a ftnite real point set E; tn most of the cases the T_{n+1} are not unique. For a general class of δ, between two zeros of a T_{n+1} lies a potnt of E; numerous other properties are proved. In the case $\delta = \sum u_k |T_{n+1}(z_k)|$, $u_k > 0$, the totality of T_{n+1} form a convex set generated by basic polynomials having their zeros at points of E; the set of T_{m-1} can be found explicttly, even tf E is not real. If $\delta = \sum u_k |T_{n+1}(z_k)|^p$, $p > 1$, a separation property holds for the zeros of T_n, T_{n-1}. Other results connect best aproximations with tnterpolation, covering also cases of approximation by famtlies of functions more general than polynomtals. (Math. Rev. abstract)

THE DOUBLE DESCRIPTION METHOD ON THE SEAC, by S. Pollack. Dec. 9, 1953, 6p. Incl. tables. (NBS rept. no. 2961) [CSO-670-54-t2] Unclassifted

The method of double descrtption for ftnding all vertices of a convex set descrtbed by a system of linear tnequalitties has been coded by SEAC tn the (frequently occurrtng) special case that all vartables are non-negative. A general description of the code ts given. The code makes judicious use of 3 magnetic tape units in order to handle the accumulated quantities of information. The object of the code is to find all the vertices of the convex set satisfying

(1) $x \geq 0 \qquad x = (x_1, \ldots, x_n)$
(2) $Ax \geq b$

The computation takes place not in n-dimensional affine space, but in the convex region of n-dtmensional projective space consisting of all potnts $(y_o, y_1, \ldots, y_n)$ where $y_1 \geq 0$, $i = 0, 1, \ldots, n$;

(3) $x_i = \frac{y_i}{y_o}$ $(i = 1, \ldots, n)$.

A number of computational experimerts with the method are presented.

ON THE SOLUTION OF THE CATERER PROBLEM, by J. W. Gaddum, A. J. Hoffman, and D. Sokolowsky. Dec. 16, 1953, 12p. incl. diagr. tables. (NBS rept. no. 2971) [CSO-670-54-12] Unclassified

Published in Naval Research Logistics Quart., v. 1: 223-229, Sept. 1954.

Walter Jacobs has shown how a problem arising in connection with the overhaul of engines by the Air Force could be treated by linear programming. This paper presents an explicit algorithm for computing the solutions of the problem. The problem is introduced as follows: Let $t_1, \ldots, t_m$ be gtven constants, $r_1, \ldots, r_n$ given non-negative constants, let X be a variable, $z = (z_1, \ldots, z_n)$ be a variable vector lying in the rectangular parallelopiped (1) $0 \leq z_i \leq r_i$, $(i = 1, \ldots, n)$. Let $A_1, \ldots, A_m$ be gtven vectors in n-space, the coordinates of each consisting of 1's and 0's such that: (2) The 1's in each A_i are consecutive; and (3) if the coordtnates tn A_i which are 1 are a, a + 1, ..., b, and the coordinates tn A_j which are 1 are c, c + 1, ..., d, and if $a < c$, then $b \leq d$. We assume tacitly that each A_i contains at least one t. The problem ts: for any number $\lambda \geq 0$, to find values for X and z, subject to (1) and (4) $(A_i, z) \geq t_i - X$ $(i = 1, \ldots, m)$ which minimtze the ltnear form $\lambda X + \sum_{i+1}^{n} z_i$. The solutions to the problem are:

	X	z_1	z_2	z_3
$\lambda \geq 2$	-t	3	5	5
$2 \geq \lambda \geq t$	1	1	5	3
$t \geq \lambda \geq 0$	10	0	0	0

THE RELAXATION METHOD FOR LINEAR INEQUALITIES, by S. Agmon. [1954] [11]p. [CSO-670-54-12] Unclassified

Published in Canad. Jour. Math., v. 6: 382-392, 1954.

If $\sum_{j=1}^{n} a_{ij}x_j + b_i \geq 0$ (i = 1, 2, ..., m) is a consistent system of linear inequalities, the non-empty solution set A is the product of the m closed half-spaces H_i (i = 1, 2, ..., m) defined in the n-space E_n of the indeterminates x_j by the individual inequalities of the system. Denote by π_i the hyperplane bounding H_i (i = 1, 2, ..., m) and let p be an arbitrary point of E_n. If p non-ϵ A, consider the point $p_1 = p + \lambda(q - p)$, where q is the orthogonal projection of p on a farthest π_i, and λ is a positive constant at most 2. If p_1 non-ϵ A, a similar process yields p_2, and a continuation of the procedure (with λ fixed) either terminates in a point of A or an infinite sequence of points $p_1, \ldots, p_n, \ldots$ is obtained, all outside A. The process is known as the relaxation method for linear inequalities. The principal result of this paper is the fundamental one of justifying the method by proving that if $0 < \lambda < 2$, an infinite sequence yielded by the process converges to a point of A. (Math. PROCEEDINGS OF THE SECOND SYMPOSIUM IN LINEAR PROGRAMMING, WASHINGTON, D. C. (Jan. 27-29, 1955), 2 vols., by H. A. Antosiewicz, ed. [1955] 685p. incl. diagrs. refs. [CSO-670-54-12] Unclassified

A linear Programming Symposium, sponsored by the Air Force Office of Scientific Research, was held jointly by the National Bureau of Standards and the Directorate of Management Analysis, DCS/Comptroller, USAF, in Washington, D. C., 27-29 January 1955. The thirty-three papers presented appear in these two volumes of the Proceedings (six by abstract), under the general headings of Applications and Economic Theory (in Volume I), and Computation, the Theory of Linear Inequalities, and Developments in Linear Programming (in Volume II). The papers range from the basic theory concerning the solution of linear inequalities to a representative number of different applications.

AN EXTREMUM PROPERTY OF SUMS OF EIGENVALUES, by H. [W.] Wielandt. [1955] [5]p. [CSO-670-54-12] Unclassified

Published in Proc. Amer. Math. Soc., v. 6: 106-110, Feb. 1955.

Let A be a Hermitian operator in n-dimensional unitary space R_n, having eigenvalues $\alpha_1 \geq \alpha_2 \geq \ldots \geq \alpha_n$. Let S be a subset of the set $\{1, 2, \ldots, n\}$, and Let $R = (R_\sigma)_{\sigma \epsilon S}$ be a family of subspaces of R_n such that $\dim R_\sigma = \sigma$, $R_\sigma \subset R_\tau$ $(\sigma \leq \tau)$. Let $A_R = \min \{\sum_{\sigma \epsilon S}(Ax_\sigma, x_\sigma): x_\sigma \epsilon R_\sigma, (x_\sigma, x_\tau) = \delta_{\sigma\tau}\}$. Then the author shows that $\sum_{\sigma \epsilon S} \alpha_\sigma = \max_R A_R$. A dual result is also given. The author then deduces the following theorem. Let A, B and C be Hermitian operators such that A + B = C. Let (α_ν), (β_ν), (γ_ν) be their respective sequences of eigenvalues, each arranged in decreasing order. Let S be a subset of $\{1, 2, \ldots, n\}$ containing k elements. Then

$$\sum_{\sigma \epsilon S} \gamma_\sigma \leq \sum_{\sigma \epsilon S} \alpha_\sigma + \sum_{k=1}^{k} \beta_k.$$

This is shown to be equivalent to a statement by V. Lidskiĭ (Dokl. Akad. Nauk SSSR (N.S.), v. 75: 769-772, 1950): if α, β, γ are the points (α_ν), (β_ν), (γ_ν) and the above assumptions hold, then γ lies in the

SOME METRIC INEQUALITIES IN THE SPACE OF MATRICES, by K. Fan and A. J. Hoffman. [CSO-670-54-12] Unclassified

Published in Proc. Amer. Math. Soc., v. 6: 111-116, Feb. 1955.

Let $||A||$ be any unitarily invariant norm in the vector space of n x n matrices over the complex field, i.e., such that $||A|| = ||UA|| = ||AU||$ for every unitary matrix U. The authors prove the following inequalities. If $A = UH$, where U is unitary and H is non-negative definite, and W is also unitary, then $||A-U|| \leq ||A-W|| \leq ||A + U||$. This is analogous to the statement that if $z (\neq 0)$ is a complex number, the nearest and farthest points of the unit circle are $\operatorname{sgn} z = z/|z|$ and $-\operatorname{sgn} z$. If H is Hermitian, then $||A - \frac{1}{2}(A + A^*)|| \leq ||A - H||$. (The point of the real axis nearest to z is $\Re z$. If H and K are Hermitian, and U and V are their respective Cayley transforms, i.e., $U = (H - iI)(H + iI)^{-1}$, $V = (K - iI)(K + iI)^{-1}$, then $||U - V|| \leq 2||H - K||$. Furthermore if (α_ν) and (β_ν) are the singular values of $\frac{1}{2}(U - V)$ and $H - K$ respectively, each sequence being arranged in decreasing order, then $\alpha_\nu \leq \beta_\nu (1 \leq \nu \leq n)$. PAIRS OF MATRICES WITH PROPERTY L, [PART] II, by T. S. Motzkin and O. Taussky. [1955] [5]p. [CSO-670-54-12] Unclassified

Published in Trans. Amer. Math. Soc., v. 80: 387-401, Nov. 1955.

This paper, equally interesting as to results and method, continues the study of pairs of matrices, A, B (over an algebraically closed field F of characteristic $p \geq 0$) with the property L (that is, if α_i, β_i are the roots of A, B taken in a certain order, then $\lambda\alpha_i + \mu\beta_i$ (i = 1, ..., n) are those of $\lambda A + \mu B$ for all $\lambda, \mu \in F$), which the authors began in Part I (same Trans., v. 73: 108-114, 1952). The roots of $\lambda A + \mu B$ are the roots in ν of the polynomial

$$f(\lambda, \mu, \nu) = |\nu I - \lambda A - \mu B| = \prod_{i=1}^{n} f_i \nu^i$$

whose ν-discriminant Δ (like the coefficient f_i) is a form in λ, μ; its roots in the ratio λ/μ are the so-called discriminant roots of the pencil $\lambda A + \mu B$. In the case of property L one has $f(\lambda, \mu, \nu) = \prod_{i=1}^{n}(\nu - \lambda\alpha_i - \mu\beta_i)$ and therefore $\Delta = \prod_{i<k}(\lambda\alpha_i + \mu\beta_i - \lambda\alpha_k - \mu\beta_k)^2$. Thus all discriminant roots are of even order (except when $\Delta \equiv 0$) and their number is $\leq \frac{1}{2}n(n-1)$ in the case L. Conversely, a pair A, B is said to have the property D if all its discriminant roots are of even order or if $\Delta \equiv 0$. Thus from L follows D. The first part of the paper establishes a sufficient condition for D to imply L. In the case of characteristic $p \neq 2$ that is so if no $\lambda A + \mu B$ has a root of multiplicity ≥ 3 or two different double roots. The proof is based on a discussion of the so-called characteristic curve C of the pencil $\lambda A + \mu B$ which, in the projective λ, μ, ν-plane over F, is represented by the equation $f(\lambda, \mu, \nu) = 0$. In the case L it splits into straight lines. By counter-examples it is shown that the conditions are necessary if $p \neq 2$ and $p \neq 2, 3, 5$, respectively. If $p = 2$ all pairs have property D, but not necessarily L. If $p \neq 2$ and $n = 2$, then D (with $\Delta \not\equiv 0$) implies L and thus, apart from scalar multiples, there is only one matrix with double characteristic root in an L-pencil. In the subsequent part of the paper the method of the characteristic curve C is further employed to prove the following results. If in the pencil $\lambda A + \mu B$ all matrices are diagonable and $n \leq p$ (if $p \neq 0$), then A, B have the property L and they can be diagonalized simultaneously and therefore commute. (If $n > p$ the property L must be assumed for this result to hold.) If a single matrix in the pencil is not diagonable, then the theorem fails to be true. The paper concludes with three theorems in a way inverting the preceding result. Assuming the complex pair A, B commutative, it is shown that it is the limit of a sequence of simultaneously diagonable commuting matrix pairs (thus extending the known fact that every complex matrix is the limit of a sequence of diagonable matrices). Commutative A, B over F are in general diagonable; "in general" means that within the manifold of commutative pairs there is a lower-dimensional submanifold of non-diagonable pairs. (Math. Rev. abstract)

COMPLETE SEQUENCES AND APPROXIMATIONS IN NORMED LINEAR SPACES, by P. Davis and K. Fan. [1956] 64p. refs. (NBS rept. no. 4637) (AFOSR-TN-56-110) (In cooperation with American U., Washington, D. C. and Notre Dame U., South Bend, Ind.) (Sponsored jointly by Air Force Office of Scientific Research under CSO-670-54-12, Office of Naval Research and National Science Foundation) AD 82506 Unclassified

Also published in Duke Math. Jour., v. 24: 183-192, Mar. 1957.

An analysis is made of 4 types of completeness of $\{f_n\}$, a sequence of elements in a normed linear space X: (1) $|\Phi(f_n)| \leq a_n$, $n = 1, 2, 3, \ldots$ implies $\Phi = 0$; (2) $\lim_{n\to\infty} \Phi(f_n) = 0$ implies $\Phi = 0$; (3) $|\Phi_n(f_n)| \geq a_n$,

n = I, 2, 3, ... implies

$\|\Phi\| < b$; and (4) $\sum_{n=1}^{\infty} |\Phi(f_n)|^p < \infty$ implies $\Phi = 0$. The symbol Φ denotes any continuous linear functional on X. Completeness of the first type is called $\{a_n\}$- completeness and theorems are given for constructing $\{a_n\}$ - complete sequences from a given complete sequence. Several examples in concrete function spaces are given to show that the concept of $\{a_n\}$- completeness is a natural one in analysis. Completeness theorems of the Paley-Wiener type (Amer. Math. Soc. Colloq. Pub., v. t9: t00-108, 1934) are proved for the first 3 types of completeness. (ASTIA abstract)

UNIQUENESS THEORY FOR ASYMPTOTIC EXPANSIONS IN GENERAL REGIONS, by P. Davis. [t955] 16p. (NBS rept. no. 4638) (AFOSR-TN-56-t11) (CSO-670-54-12) AD 82507 Unclassified

Also published in Pacific Jour. Math., v. 7: 849-859, 1957.

Necessary and sufficient conditions on the sequence of constants $\{m_n\}$ are given in order that the relation

$$\|f_n\|^2 = \int_C |f_n(z)|^2 ds$$

$$\int_C \left| \frac{f(z) - a_0 - a_1(z-t) - \ldots - a_{n-1}(z-1)^{n-1}}{(z-1)^n} \right|^2 ds <$$

$Mk^n n!_n{}^2$ will determine f(z) uniquely from the asymptotic coefficients a_n. The uniqueness theorem states that given an arbitrary sequence of positive constants $\{m_n\}$, the class $A(m_n)$ is a uniqueness class for asymptotic expansions at z = t only if for all t > 0, the

$$\lim_{n \to \infty} \sup \int_C \log \left(\sum_{k=0}^{n} \frac{t^k}{m_k^2} |(z-1)^{n-k}|^2 \right) \frac{\partial}{\partial n} \log |m(z)| ds = \infty.$$

The uniqueness theory under consideration is that of distinguishing nontrivial subclasses of A within which the asymptotic expansion at z = t, $f(z) \sim \sum_{n=0}^{\infty} a_n (z-t)^n$ in the sense of Poincaré is unique. The problem relates to a simply connected region D with an analytic boundary C for which z = 0 is an interior point and z = 1 lies on the boundary. The tangent to C at z = t is assumed not to parallel the real axis. (ASTIA abstract)

CONTRACTIBILITY AND CONVEXITY, by H. W. Kuhn. [1954] [3]p. (Sponsored jointly by Air Force Office of Scientific Research under [CSO-680-56-50], Logistics Project, Office of Naval Research and Princeton U., N. J.) Unclassified

Published in Proc. Amer. Math. Soc., v. 5: 777-779, Oct. 1954.

The purpose of this mathematical study is to present a purely geometrical result that appeared as a by-product of research in the theory of games. Though a proof of the theorem has already been published by I. Liberman (On Certain Characteristic Properties of Convex Bodies, Matem. Sbornik, v. t3: 239-262, 1943), the present proof retains its interest, both for its conciseness and the fact that it reveals a connection between the geometry of convex sets and fixed-point theory. The following result is proved: In order that a locally contractible compact set X in n-dimensional Euclidean space be convex, it is necessary and sufficient that the set X be contractible and that every support contact of X be contractile. Liberman's theorem is stronger than the result just proved in that it does not presuppose local contractibility. This condition entered the proof by way of the fixed-point theorems and it does not seem possible to eliminate it directly without a stronger theorem than exists in the literature.

DAMPING OF ELASTICALLY SUPPORTED ELEMENT IN A VACUUM TUBE, by S. Levy, E. V. Hobbs and others. June t952, 7p. illus. diagrs. (NBS rept. no. t707) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-t8-600-22] and Atomic Energy Commission) ATI 207894 Unclassified

This report describes a phase of the development work on the Ramberg vacuum tube accelerometer. It is shown that it is possible to damp the motion of an element in a vacuum by making the tube part of a two-degree-of-freedom system. The equations of motion of this system are presented. The optimum values of the parameters are determined on SEAC, the Bureau of Standards electronic automatic computer, for a particular set of design requirements. In carrying out this computation, SEAC is used not only to compute the responses of the system for given values of the parameters, but also to choose that set of parameters for which the performance is optimum. A description is given of a lube mount built in accordance with the computations and of the degree of damping achieved. (Contractor's abstract)

Dressler, and E. C. Lloyd. [1955] [38]p. incl. diagrs. tables, refs. (ASME Paper no. 55-A-181) ([AF]OSR-TN-55-409) [CSO-18-600-22] AD 119564 Unclassified

Presented at Diamond Jubilee annual meeting of the Amer. Soc. Mech. Engineers, Chicago, Ill., Nov. 13-18, 1955.

The pressure-deflection characteristics of corrugated diaphragms are correlated by methods of dimensional analysis. Experimental results for various sizes, materials, thicknesses, and shapes of diaphragms indicate that the performance for diaphragms of any given shape may be computed from a dimensionless formula derived from experimental data on other diaphragms of that shape. Linear shell equations are derived for combined bending and stretching effects with lateral loading terms for rotationally symmetrical shells in appropriate independent and dependent variations suitable for complicated meridial shapes, and with boundary conditions associated with practical diaphragm applications. The method used for solving this system of equations on an electronic digital computer is described,and numerical solutions are presented for a specific diaphragm subject to uniform pressure loading. Suggestions are presented for future research, both theoretical and experimental, on diaphragm properties and performance. (A supplement Behavior of all local stresses is attached.) THE VIBRATION OF TRIANGULAR WINGS (Abstract), by R. F. Dressler. [Sept. 1956] [1]p. [CSO-18-600-22] Unclassified

Presented at Ninth International Congress of Applied Mech., Brussels (Belgium), Sept. 5-13, 1956.

The vibration of a delta wing is considered as an eigenvalue problem for the elastic plate equation $\Delta^4 W - \lambda W = 0$ for right triangles of constant thickness having various aspect ratios. One side is clamped, and the other side and hypotenuse are free. The problems are transformed to one isosceles triangular domain with two essential parameters, the aspect ratio and Poisson's ratio, the latter appearing explicitly in the boundary conditions for the free edges. The associated finite difference matrix is solved numerically for its lowest eigenvalue and eigenvector by electronic digital computer. To permit local elimination of mesh points exterior to the hypotenuse boundary, it is necessary to use asymmetric finite-difference operators in the boundary conditions for the free edges and the sharp corner. These then lead to asymmetric matrices. To determine dependence of modal shapes and frequencies upon Poisson's ratio, various problems have been computed using matrices of order 78. The computational method incorporates a technique with orthogonal hypergeometric polynomials of degree 19 to separate eigenvalues for faster convergence. Results for one value of Poisson's ratio are compared with known experimental values due to Gustafson, and indicate the magnitude of overall damping and loading in the experimental cases. ABSOLUTE MEASUREMENT OF VIBRATION AMPLITUDES, by W. Koidan. Sept. 1953, 11p. incl. diagrs. (NBS rept. no. 2799) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-610-55-22], and Atomic Energy Commission) AD 18512 Unclassified

By means of a modification of the pistonphone, a technique was developed to obtain the response of a capacitance type vibration pickup probe; the reciprocity calibration of a condenser microphone was used as a reference. The raised center portion of a circular piston, driven by a Ba titanate cylinder, projects into one end of a 19.9-cc cavity, the shelf of the piston being located outside of the enclosure. A calibrated condenser microphone is coupled to the other end of the cavity and responds to the sound pressure developed by the piston. The output of an annular capacitance type vibration pickup, which detects the motion of the piston shelf, is compared with the generated microphone voltage. With the microphone removed from the cavity, the output of the probe, located adjacent to the top surface of the piston is compared with that of the annular pickup. The probe response is computed from these measurements and the microphone response. Mechanical coupling

between the driver and the main supporting structure is minimized by the use of vibration mounts and the maintenance of a small, acoustically sealed clearance between the piston and the cavity enclosure. Calibrations of the probe have been obtained from 100 to 10,000 c with an estimated probable error not exceeding 0.5 db. Peak vibration amplitudes as small as 10^{-9} cm can be measured with a comparable degree of accuracy by a similar probe built for high sensitivity. (Contractor's abstract)

ELASTIC WAVES IN ANISOTROPIC MEDIA, by J. L. Synge. Apr. 2, 1956 [25]p. incl. diagr. (NBS rept. no. 4601) (AFOSR-TN-56-143) [CSO-610-55-22] AD 86301 Unclassified

Also published in Jour. Math. and Phys., v. 35: 323-334, Jan. 1957.

Against the background of 21-constant elastic theory, isotropy presents a highly degenerate case, and the study of waves in isotropic media throws little light on the algebraic structure of the theory of waves in anisotropic media. Some known results are given in tensor notation, for the sake of convenience and compactness, and new general results are developed for waves in a layer of anisotropic material. In the limit in which the layer becomes a half-space, we have a generalization of Rayleigh waves, and it is found that, in general (for a given frequency), the surface waves either do not exist at all, or are propagated in certain discrete directions with certain speeds. Calculations for a medium possessing transverse isotropy are given; it is shown that the slowness surface (or, equivalently, the wave surface) possesses a spheroidal sheet. (Contractor's abstract)

APPARATUS FOR THE DIRECT DETERMINATION OF THE DYNAMIC BULK MODULUS, by J. E. McKinney, S. Edelman, and R. S. Marvin. [Jan. 30, 1956] [6]p. incl. illus. diagrs. tables, refs. (Sponsored jointly by Office of Navat Research, Atr Force Office of Scientific Research under CSO-680-56-20, Atomic Energy Commission, and National Bureau of Standards) Unclassified

Presented at annual meeting of the Soc. of Rheology, New York, Nov. 2-4, 1955.

Published in Jour. Appl. Phys., v. 27:425-430, May 1956.

An apparatus has been developed for the direct measurement of the reat and imaginary parts of the dynamic bulk modulus of sotid and liquid materials over the frequency range of 50 to 10,000 cps. Ptezoetectric crystals serving as driver and detector, together with the sample and a confining liquid, are contained in a cavity small compared with the wavelength of sound at these frequencies. Static pressure is superposed to eliminate the effect of small air bubbles. The comptex compltances of the sample, confining ttquid, and the cavity, are additive in this region, where the compliance is pure dilatation. The dynamic compliances of several natural rubber-sultur mixtures were obtained tn a preltmtnary evaluation ot the behavtor ot the apparatus. (Contractor's abstract)

STATIONARY PRINCIPLES FOR FORCED VIBRATIONS IN ELASTICITY AND ELECTROMAGNETISM, by J. L. Synge. Mar. 26, 1956, t9p. tnct. dtagr. (NBS rept. no. 4582) (AFOSR-TN-56-122) (tn cooperation with Amertcan U., Washtngton, D. C.) [CSO-680-56-38] AD 825t8 Unclassttted

Also published in Proc. 8th Symposium on Appl. Math. ot the Amer. Math. Soc., Apr. t956.

The concepi of a function-space with a suitable scalar product is used to exhibit several siationary prtnctples tn a simple geometrtcal form. The basic technique is to split the problem so that a point of a function-space, which corresponds to the solution of a physical problem, is the point of intersection of 2 orthogonal linear sub-

spaces. If the metric is positive-definite, Schwarz's inequality yields 2 minimum principles. If the metric is indefinite, one orthogonality condition exists which yields 2 stationary principles. The stationary principles are either known or closely related to known results. Illustrations are given for the vibrating membrane, vibrations of an elastic body, and electromagnetic vibrations. A procedure for improving approximations is considered.

ELASTIC SCATTERING OF PHOTONS FROM 5 TO 30 MEV (Abstract), by E. G. Fulter. 1955, 1p. (CSO-640-55-33) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 1955.

A brief discussion is given of previous measurements that have been made of the elastic scattering of photons having energies in the region of the "giant resonance." This is followed by a brief description of the experimental techniques that are being used at NBS to study the elastic scattering cross-section for various nuclei. It was this work that led to the first determination of the elastic scattering cross-section as a function of photon energy. The results that have been obtained to date are discussed. These results are presented in the form of a systematics of the photonuclear interaction as derived from the elastic scattering measurements.

THE ELASTIC SCATTERING OF PHOTONS, by E. G. Fuller and E. Hayward. Feb. 10, 1954 [7]p. incl. illus. table. (NBS rept. no. 3129) ([AF]OSR-TN-54-13) (CSO-670-53-22) AD 28184 Unclassified

Also published in Phys. Rev., v. 94: 732-733, May 1, 1954.

Measurements were made on the elastic scattering cross section as a function of photon energy. X-rays observed were produced by a 50-mev betatron and were scattered by Au, Pb, and U. An NaI(Tl) crystal 5 in. in diameter and 4 in. long, a DuMont 5-in.-diameter photomultiplier tube, a linear amplifier, and a series of discriminators with associated scaling units were used to detect the rays. With the crystal in the direct beam from the betatron at the zero degree position, the number of counts were observed which were produced for a charge collected on the ionization chamber. The resonance scattering for the 3 elements was near 15 mev. (ASTIA abstract)

AN EVALUATION STUDY OF A FAST-NEUTRON SPECTROMETER BASED ON THE TOTAL ABSORPTION PRINCIPLE, by M. R. Ctetand. Oct. 27, 1952 [40]p. incl. diagrs. refs. (NBS rept. no. 2036) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-680-57-2], and Atomic Energy Commission) AD 1815 Unclassified

The Monte Carlo sampling procedure has been used to evaluate a proposed spectrometer for neutrons with energies above 1.0 mev. The instrument employs a cylindrical phosphor 5 centimeters in diameter and 5 centimeters long composed of a half-and-half mixture of phenylcyclohexane and methyl borate activated with 3-5 grams of p-terphenyl and 10-15 milligrams of diphenylhexatriene per kilogram of phosphor. The total light output pulse which results from recoil charged particles indicates the neutron energy and is observed with a photomultiplier tube. It was arranged to record only those events in which the neutron is first thermalized by elastic collisions and then captured by boron. The capture criterion with the small volume scintillator strongly favors neutrons that lose most of their energy at the first collision and leads to good energy resolution. The efficiency for the borated scintillator is shown to be 0.15% and the energy resolution about 10% for 14.0 mev neutrons. The mean time interval between the recoil proton pulse and the boron capture pulse is shown to be 2.0 microseconds with 18.8% B^{10} in the methyl borate. A brief summary of other neutron spectrometers and calculations for an infinite volume scintillator are also presented. (Contractor's abstract)

RESISTANCE STRAIN GAGES, by D. Namkoong, D. W. Hinze, and W. R. Campbell. June 1953, 5p. illus. diagrs. (NBS rept. no. 2537) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-680-57-2], and Atomic Energy Commission) AD 17289 Unclassified

Twenty SR-4 type PA-3 resistance strain gages and twenty G-H type A820S resistance strain gages were calibrated for post yield tensile strains up to 0.14. For strains up to 0.04 the strains indicated by ten single gages of each type did not differ from the applied strain by more than 1500 x 10^{-6}. For strains above 0.04 and up to 0.065 nine of the ten G-H gages indicated strains within 3.7% of the applied strain. All ten G-H gages failed at applied strains between 0.07 and 0.12. For strains above 0.04 and up to 0.12 nine of the ten SR-4 gages indicated strains within 4.7% of the applied strain. No gage failed at strains less than 0.12, and seven of the gages sustained strains up to 0.135, the maximum strain applied. Higher strains could not be applied because of limitations in the strain-measuring equipment. (Contractor's summary)

CHARACTERISTICS OF TWO TYPES OF TEMPERATURE-COMPENSATED RESISTANCE STRAIN GAGES, by D. W. Hinze, D. Namkoong, and W. R. Campbell. June 1953 [15]p. incl. illus. diagrs. table, refs. (NBS rept. no. 2552) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research CSO-680-57-2], and Atomic Energy Commission) AD 17288 Unclassified

Tensile calibrations and measurements of gage output vs. temperature were made on SR-4 gages of types EBD-1S and EBD-1D. Six gages of each type were calibrated for strains up to 0.0025 at temperatures ranging from 70° to 250°F. With the exception of two gages of type EBD-1S, calibration factors were within the tolerance set by the manufacturer. No significant variation of calibration factor with temperature was observed. The performance of the gages with respect to linearity, zero shift, and stability was generally improved by preloading. Eight EBD-1D gages and nine EBD-1S gages attached to unstressed bars were subjected to varying temperatures in the range 0° to 300°F. Gage output, measured as apparent strain, for the EBD-1D gages on 24S-T aluminum alloy did not vary more than ± 50 x 10^{-6} for temperatures between 50° and 280°F. Temperature sensitivity in this range from the EBD-1S gages on hot rolled spring steel produced maximum variations in apparent strain of ± 100 x 10^{-6}. (Contractor's summary)

DIRECT MEASUREMENT OF THE NUCLEAR ABSORPTION OF X-RAYS (Abstract), by H. W. Koch and R. S. Foote. Apr. 30, 1953 [1]p. [CSO-680-57-2] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 30-May 2, 1953.

Published in Phys. Rev., v. 91: 455, July 15, 1953.

The nuclear absorption of x-rays from a betatron operating at 30 mev has been measured directly for carbon and copper. The technique employed good geometry, the maximum tolerable number of absorber mean free paths (4 to 8.5), and an x-ray spectrometer with high detection efficiency and good energy resolution. Carbon absorbers 5 cm in diameter, up to 306 cm long and an absorber 25 cm in diameter and 30 cm long were used. The x-ray cone was 0.06 degrees. The source to spectrometer distance was 935 cm. The detector was a calibrated NaI total absorption spectrometer. The pulse-height spectrum produced by x-rays transmitted by a particular absorber was analyzed and showed marked depressions in intensity due to nuclear absorption. The percentage intensity change is proportional to the absorber length and to the ratio of nuclear to electronic absorption. The maximum length is limited by the geometry. The copper results give one nuclear absorption peak at approximately 18 mev as expected. The carbon data show pronounced nuclear absorption peaks below 20 mev. (Contractor's abstract)

TOTAL-ABSORPTION X-RAY SPECTROMETRY: APPLICATION TO BETATRON EXPERIMENTS, by H. W. Koch and R. S. Foote [1954] [3]p. incl. illus. diagrs. [CSO-680-57-2] Unclassified

Published in Nucleonics, v. 12: 51-53, Mar. 1954.

Physical and operating charactertstics as well as general applicattons are given of a NaI sctntillation spectrometer which can measure the energy of individual x-ray photons tn the range from ½ to 50 mev with an energy resolution better than 11% and a detection efficiency larger than 80%. The spectrometer ts called a total absorption spectrometer because tndtvidual x-ray photons that enter the device are almost totally absorbed tn a sctntillator. The absorption results tn a light pulse. The magnitude of a majority of the light pulses ts proportional to the x-ray photon energy. Research involving use of the spectrometer is briefly summartzed with regard to: (1) determination of the shape of the x-ray photon spectrum from a betatron; (2) the study of the "giant resonance" nuclear absorption; and (3) observation of x-ray absorption by tndtvidual nuclear levels. DIRECT OBSERVATION OF THE NUCLEAR ABSORPTION AND ELASTIC SCATTERING OF X-RAYS, by H. W. Koch. [1955] [5]p. [CSO-680-57-2] Unclassified

Published in Proc. Conference on Nuclear and Meson Physics, Glasgow (Scotland) (July 1954), 1955, p. 155-159.

The application of large crystal scintillation spectrometers to the measurement of x-ray energies makes possible 2 companion experiments. In the first, the white light or continuum of x-rays from a 50-mev betatron ts transmitted by long absorbers. At constant energy, the x-ray photons are detected individually and their energies recorded. Dark absorption bands are found in the spectra resulting from giant resonance absorption. In the 2nd experiment, elastic scattering cross section is measured for x-rays scattered at an angle of 120°. In most cases the cross-section curves show 2 peaks.

RESPONSE OF A SODIUM IODIDE SPECTROMETER TO HIGH ENERGY ELECTRONS (Abstract), by H. W. Koch, J. M. Wyckoff, and B. Petree. 1955, 1p. [CSO-680-57-2] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28, 1955.

Published in Phys. Rev., v. 99: 663, July 15, 1955.

Mono-energetic electrons from a 50 mev betatron operated between 1 and 20 mev were used to study the performance of a 5" by 4" and a 5" by 9" NaI(Tl) total absorption spectrometer. The pulse height distributions produced by bombardment of the central axis of the large crystals show very peaked distributions with small tails. The energy resolution reached tts optimum valus at 10 mev where the total width at half maximum ts 4%, whereas the comparable resolution for 10 mev x-rays would be 9%. This added width to the x-ray pulse height distribution results largely from the escape of the annihilation photon from the crystal. Synthesis of the x-ray distributions from the electron distributions and the linearity of spectrometer response to electron energy will be discussed. (Contractor's abstract)

THE ANGULAR DISTRIBUTION OF 15-MEV GAMMA RAYS SCATTERED FROM C^{12} (Abstract), by J. E. Leiss and J. M. Wyckoff. [1956] [1]p. [CSO-680-57-2] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 197, Apr. 26, 1956.

NBS. 18:011 - NBS. 18:013

Fuller, Hayward, and Svantesson have observed a 15-mev gamma ray tn their elastic scattering experiments and have associated this line with resonant scattertng by the 15.09-mev level tn C^{12}. Ustng the NBS synchrotron operating at 82 mev and a NaI detector in a technique similar to that of Fuller and Hayward but wtth better resolution, the angular dtstribution has been measured of these 15-mev gamma rays scattered tn a 2.32 gm/cm^2 graphite target. This distribution is conststent with the $1 + \cos^2\theta$ dtstribution expected for dipole absorption but is inconsistent with $1 - 3\cos^2\theta + 4\cos^4\theta$ expected for quadrupole absorption. This result establishes this level in C^{12} as a J = 1 level. The absorption length for the gamma rays in graphite after correction for Compton degraded photons in the target ts 2.2 gm/cm^2 in reasonable agreement wtth Fuller et al. (Contractor's abstract)

CRYSTAL SPECTROMETER CALIBRATION OF A HIGH ENERGY X-RAY INTENSITY MONITOR (Abstract), by H. W. Koch, J. E. Leiss, and J. S. Pruitt. 1956, 1p. [CSO-680-57-2] Unclassifted

Presented at meettng of the Amer. Phys. Soc., Washington, D. C., Apr. 26, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 199, Apr. 26, 1956.

Preltminary tests have been made of a new technique for the absolute energy calibration of high energy x-ray monitors. With this method the total number of x-ray photons transmttted through a carbon absorber is determined with a 5-in. diameter, 9-in. long sodium iodide crystal in a good geometry arrangement. Such a spectrometer counts about 96% of the incident photons. If the primary photon spectrum and the carbon absorption coefficients are assumed known, the spectrometer counts can be related to the total energy in the primary x-ray beam. Measurements were made with carbon absorber lengths of 306, 401, and 497 gm/cm^2 for synchrotron energies of 56, 80, and 110 mev. The data were used to determine a value of 4480 erg/esu/cm for a flat ionization chamber monitor at 80 mev. The estimated uncertainty is ± 4%, mostly due to an inadequate knowledge of the carbon absorption coefficients, to which the calculations are very sensitive. Improved techniques should allow a reduction of this uncertainty. This method allows accurate monitor calibrations with smaller beam intensities than can be used with a calorimeter. DIFFERENTIAL CROSS SECTION MEASUREMENTS FOR THIN-TARGET BREMSSTRAHLUNG PRODUCED BY 2.7 TO 9.7 MEV ELECTRONS, by N. Starfelt and H. W. Koch. Jan. 25, 1956 [39]p. tncl. diagrs. tables, refs. (NBS rept. no. 4507) [CSO-680-57-2] Unclassified

Also published in Phys. Rev., v. 102: 1598-1612, June 15, 1956.

The electron beam removed from a 50-mev betatron and a total absorption scintillation spectrometer containing a sodium iodide crystal 5 in. in diameter and 9 in. long were used for the measurement of bremsstrahlung cross sections that are differential in photon energy and angle. Thin targets of beryllium, aluminum, and gold were bombarded by electrons with kinetic energies of 2.72, 4.54, and 9.66 mev. The bremsstrahlung spectra from thick tungsten targets were also studied. The results were compared with the differential cross-section predictions of Sauter, Schiff, and Gluckstern and Hull. The spectral shapes obtained with the beryllium and aluminum targets agreed with those expected from theory for the electron energies of 2.72 and 4.54 mev. The 9.66-mev experiment gave 20% more low-energy than intermediate-energy photons when compared with theory. For gold the experimental cross sections for the high photon energies are larger than theory with the differences increasing with decreasing electron primary energy. Evidence for electron-electron bremsstrahlung is obtained from the absolute magnitude of the differential cross section, which are $(Z + 1)/Z$ times larger than theory within the

experimental errors. The thick-target tungsten spectra produced by 9.66-mev electrons decreased more rapidly with increasing photon energy than did the thin-target cross sections derived by Schiff. (Contractor's abstract)

MEASUREMENT OF THE RESPONSE OF HIGH-ENERGY X-RAY DETECTORS (Abstract), by J. E. Leiss, J. M. Wyckoff, and H. W. Koch. 1956, 1p. [CSO-680-57-2] Unclassified

Presented at meeting of the Amer. Phys. Soc., New Haven, Conn., June 21-23, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 284, June 21, 1956.

Quantitative interpretations of most data from high-energy x-ray detectors, particularly spectrometers require accurate pulse height distributions produced by mono-energetic x-rays. These response distributions have been difficult to obtain above 20 mev. A preliminary study will be described which has been used to measure the response of a 5" by 9" sodium iodide spectrometer to 33 mev x-rays. The method consists in the unfolding of an experimental curve of counts, $a(E_o, k_o)dk$, recorded in a fixed differential pulse height bin, dk, at k_o and produced by a synchrotron spectrum, whose peak energy, E_o, was varied from 30 to 60 mev. The spectrum was distorted by a 180-cm carbon absorber so that the total count of transmitted photons could provide a sufficiently accurate normalization of the counts in the activation curve. The desired response S(K, E)dk for a photon of energy E, can be evaluated from the activation integral $a(E_o, k_o)dk = \int_0^{E_o} P(E_o, E)e^{-\tau x} s(k_o, E)dEdk$ with tables of the inverse of the bremsstrahlung number spectrum matrix, $P(E_o, E)$. The method can provide response functions of detectors for any given experimental arrangement. (Contractor's abstract)

PARAMETERS OF THE 15 MEV LEVEL IN C^{12} (Abstract), by E. Hayward and E. G. Fuller. [1956] [1]p. [CSO-680-57-2] Unclassified

Published in Physica, v. 22: 1138, Nov. 1956.

Bremsstrahlung x-rays have been used to excite a level in C^{12}, presumably the first T = 1 state which decays by magnetic dipole radiation to the ground state. The scattered photons have been detected by a NaI(Tl) spectrometer and the pulse height distribution studied. Measurements have been made of (1) the absolute number of 15 mev photons scattered, which is a measure of the integral scattering cross-section, and (2) the attenuation produced when a carbon absorber is placed between the betatron and the scattering target. The latter is a measure of the peak absorption cross-section in the level. Both quantities have been measured using either graphite or polystyrene targets and absorbers approximately 2 g/cm^2 in thickness. For example, the self-absorption (and therefore the peak absorption cross-section) is so great that only half of the photons are transmitted through such an absorber whereas electronic processes would only reduce the intensity by 3%. If the nuclear absorption cross-section associated with this level is expressed as a Doppler-broadened Breit-Wigner formula, the observed transmission yields a value of 24.6 ± 2.5 barns for the peak absorption cross-section in the resonance. Since the maximum cross-section that a magnetic dipole transition proceeding from a J = 1 level can have is $4\pi\lambda^2/\pi$ or 32 barns at 15 mev, the measured peak cross-section gives $\Gamma_\gamma/\Gamma = 0.77 \pm 0.0$[illegible] for the branching ratio. The level width, obtained by combining the peak absorption cross-section with the integral scattering cross-section of 2.1 ± 0.2 mb/mev, is then 74 ± 11 ev. (Contractor's abstract)

A NaI(Tl) scintillation spectromeier biased io deteci only photons tn the upper energy tip of a betairon-produced bremsstrahlung spectrum ts used to measure the differential nuclear elastic scattering cross section at 120° as a function of photon energy from 4 io 40 mev. The targets ranged in Z from Na io U. Total cross sections are calculaied by assuming a dipole angular distribution. The scaiiering cross sections tend io exhibii two maxima, one below the particle threshold thai corresponds to the scattering by separaie levets, and one thai follows the giant resonance for photon absorption. Both the maximum cross section and the energy of the giani resonance vary smoothly with A from Na to U and are roughly proportional to $(NZ/A)^2$ and $A^{-1/3}$, respectively. The dipole dispersion relation ts used to compare the scattering data with the neutron yield data tn the giani resonance region. (Coniractor's abstract)

OXYGEN-16(γ, pγ')N^{t5} AND O^{16}(γ,pγ')O^{15} (Abstract), by N. Svantesson. [1956] [1]p. (CSO-630-55-35) Unclassified

Presented ai meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. t: 27, Jan. 30, 1956.

The pulse height distribution produced by the photons emitted by a waier targei trradtated by bremsstrahlung spectra was studied as a function of the peak energy of the bremssirahlung specira from 16-30 mev. A 20 channel analyzer was used io cover the range of pulse stzes from 2-12 mev. A peak appears tn the pulse heighi dtsirtbution for bremsstrahlung energies greaier than 21 mev. A compartson with the pulse height disiribution produced by the 4.43 mev phoion from a RaD-Be source gives 6.3 mev as the energy of the phoion emiiied by the oxygen target. Both the energy and the threshold of this line are consisteni with tts resulting from the decay of the second excited staies of N^{15} and O^{15} following (γ, p) and (γ, n) processes in O^{16}. Ii is estimated that no other lines tn N^{15} and O^{15} are preseni in the pulse height disiributions with intensities as greai as 20% of thai of the 6.3 mev line. The activation curve of this line indicates thai the cross section for tis production peaks at aboui 24 mev with a cross section of a few miliibarns. (Contracior's abstract)

X-RAY EXCITATION OF 15-MEV LEVEL IN C^{12} (Abstract), by E. G. Fuller, E. Hayward, and N. Svaniesson. 1956, 1p. (CSO-630-55-35) Unclassified

Presenied ai meeting of the Amer. Phys. Soc., New York, Jan. 30- Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 10, Jan. 30, 1956.

A pronounced maximum in the spectrum of photons scaiiered by a carbon targei trradiaied by bremsstrahlung specira having 15 mev < E_{max} < 40 mev was observed. The threshold for the production of this line based on the Cu^{63}, Cu^{65}, B^{10}, and Be^9 (γ, n) thresholds is 13.0 ± 0.2 mev. The line presumably results from the elastic scatiering by the 15.09 mev, T = 1 level tn C^{12}. The excitation function of this line as a function of E_{max} is consisteni with a 15.09 mev isochromat calculated from Schiff bremsstrahlung spectra. When 2.1 g/cm^2 of graphiie was placed between the scattering targei and the betatron, the scattered counts were attenuated by a factor of 0.49 ± 0.04. When 7.8 g/cm^2 of grapiie was placed between the scatiering target and the detector, the scattering intensity was reduced by 0.8t ± 0.07. For this latter case the expected electronic transmission is 0.87. The level width is then less than the energy given the recoiling C nucleus (~10^4 ev). The mean scattering cross sections from 14.4 to 15.8 mev is C.7 ± 0.2 mb. (Contractor's abstract)

A MINIATURE BARIUM TITANATE ACCELEROMETER, by L. Fleming. Nov. 26, t95t, 22p. incl. diagrs. tables. (NBS rept. no. 1004) (Sponsored jointly by

Office of Naval Research, [Air Force Office of Scientific Research under CSO-640-55-9], and Atomic Energy Commission) ATI-140036 Unclassified

A miniature barium titanate accelerometer is described. Several models of the NBS barium titanate accelerometer have been constructed differing only in dimensions. The small 3/8 in. -diam Model 3 is found most generally useful at NBS where it is used for monitoring vibration sources and for measuring vibrations in comparatively small structures. Experimental results to date show that the sensitivity transverse to the axis is less than one-fifth the sensitivity along the axis. Temperature effects upon sensitivity of "piezoelectric" barium titanate are reported as less than 5% from -60°C to + 70°C. The lower limit is not yet known, but the safe upper limit is about 90°C. Data from controlled experiments on aging effects are at present lacking. General principles of vibration pickups are discussed. The barium titanate accelerometer in the form described has proved highly practical in a variety of vibration-measurement applications.

ELECTRICAL NOISE FROM INSTRUMENT CABLES SUBJECTED TO SHOCK AND VIBRATION, by T. A. Peris. Jan. 1952, 17p. diagrs. tables. (NBS rept. no. 1388) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-640-55-9], and Atomic Energy Commission) ATI-144492 Unclassified

Also published in Jour. Appl. Phys., v. 23: 674, June 1952.

Existing information on the reduction of spurious signals from instrument cables is reviewed. A tentative theory is formulated to account for the known data. Subsequent experiments confirm this theory and allow the formulation of a detailed mechanism of noise generation in cables. The noise may be eliminated for practical purposes (reduced by a factor of 500 or more in some cases) by having continuous electrical conduction between both surfaces of the insulating dielectric and the adjacent conductors. A simple procedure is outlined to make short lengths of this cable for laboratory use and an industrially applicable method is suggested. There appears to be no limit on how small the diameter of such cables could be made. (Contractor's abstract)

METHODS OF RESPIRATORY GAS ANALYSIS, by H. J. Morowitz. June 1952, 13p. incl. table, refs. (NBS rept. no. 2167) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-640-55-9], and Atomic Energy Commission) AD 3989 Unclassified

This report is a survey designed to examine the existing methods of respiratory gas analysis and to look into additional physical instruments and techniques which may be applicable to the problem. The following methods seem to contain the most promise or to merit further basic study to ascertain their potentialities. (1) Mass spectrometry, because of its versatility in handling a wide range of materials should prove a valuable tool in future respiratory analysis work. Its disadvantages lie in the expense of the equipment and the professional skill required to operate and maintain an instrument. (2) The potentialities of critical flow methods used in conjunction with chemical reactions should be investigated. If sufficiently short response times can be obtained, this technique offers a wide range of possibilities. (3) Absorption spectroscopy is very satisfactory when absorption occurs in a workable range of spectrum. The study of new sources and detectors may enhance the range of applicability of these techniques. (4) For the rapid determination of oxygen, an extension of paramagnetic methods should in theory provide a workable method. The measurement of ionization currents should also be investigated in regard to oxygen measurement. Both possibilities are in need of further experimental work. (5) Emission spectrometry offers rapid response along with the potentiality of measuring several gases. However, basic work must be done on discharge phenomena before this can be developed into a routine analytical tool. Obtaining a utilizable emission from oxygen has thus far proven a very difficult problem.

THERMALLY OPERATED GLASS VALVE TO PROVIDE VERY SMALL CONTROLLED GAS FLOW RATES, by R. Forman. June 27, 1952 [12]p. incl. illus. diagrs. (NBS rept. no. 1762) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-640-55-9) ATI-168762 Unclassified

NBS. 21:006 - NBS. 21:010

Information is presented on the development of a glass metal valve which can provide small controlled vacuum leaks. It combines the advantages of a glass instrument with that of reproducibility over a definite range of leak rates. A number of possible variations in the design of the valve suggest themselves. Replacement of the nickel sleeve, for instance, with a metal having a much higher creep strength at elevated temperatures would have obvious advantages. Another interesting design change is the use of piezoelectric or magnetostrictive properties of materials rather than that of thermal expansion for opening and closing the valve.

A BROADBAND, LOW-LEVEL, ERROR-VOLTAGE DETECTOR, by M. L. Kuder. June 15, 1953, 9p. incl. diagrs. (NBS rept. no. 2603) [CSO-640-55-9] AD 17283 Unclassified

An error-voltage detector is described which used ordinary germanium diodes in a circuit of unusual zero-drift stability, and which is self-compensating for the temperature coefficients of the crystals. The crystals are operated at a high carrier potential as compared to their contact potentials. An RF chopper principle was used in place of the conventional (limited bandwidth) mechanical choppers. Tests showed that a control signal of 1 mv would produce a Δit of approximately 12 ohm in about 3000 ohm of resistance of each germanium diode. This condition results from an excitation at 30 mc and an experimentally determined optimum amplitude of about 200 mv. A 0.4% unbalance of the bridge is obtained which produces an output of about 0.0008 v. Transformed to the 50-ohm output, this provides about 0.0001 v to the amplifier. A very useful output control-signal with an over-all bandwidth of about 1 mc was obtained from the amplifier. Production of a useful output requires a gain of about 95 db. The zero drift did not exceed 1 mv/day. Possible applications of the detector are discussed.

A SIMPLE, OBJECTIVE TEST FOR CABLE NOISE DUE TO SHOCK, VIBRATION OR TRANSIENT PRESSURES, by T. A. Perls. May 1955 [17]p. incl. illus. tables. (NBS rept. no. 4094) (Sponsored jointly by Office of Naval Research under NAonr 21-48, [Air Force] Office of Scientific Research under CSO-640-55-9, and Atomic Energy Commission) AD 67143 Unclassified

A survey was made of methods used or proposed for objecttve, reproducible, notse-tndex tests of the electrtcal rotse generated tn cables subjected to shock, vtbration, and transtent pressures. A reproducible test ts described by J. Hannon (BuShips Memorandum, Ser 8f7A3-M-1561A) tn which a suitable weight ts clamped at the center of a 5-ft length of test cable suspended belween supports 4 ft apart. The cable nolse ts recorded when the cable and weight are released from a position 90° from the verttcal. The test cable ts shunted to a tolal capacttance of 1000 ptcofarads, the tnput tnipedance of the first preamplifier is made equal to 10 megohms, and the over-all frequency response of the amplifying and recordfng system ts chosen flat wtthin ± 15% from 5 to 40 c. The notse tndex was taken as the number of ptcocoulombs (or millivolts) peak-to-peak recorded tn a series of swtngs of the cable. The noise ftgure for any particular sample ts repeatable wtthin ± 30%, but thts ftgure may vary by a factor of 3 or more for dtfferent samples of the same cable. Tests of 21 cables, conststing of JAN types, commercial cables with and wtthout clatmed low-notse properties, commerctal pre-production samples of low-notse cables, and the NBS low-noise cable described hy Perls (Jour. Appl. Phys., v. 23: 674-680, 1952), ytelded notse tndices ranging from 0. f to 1600. After simulated severe use, the range of noise tndices was from 0. 2 to f900, wtth the notse tn one of the cables tncreased by a factor of 50. A posstbly significant decrease was noted for several other cables. (ASTIA abstract)

SURVEY OF STRESS-STRAIN RECORDERS FOR TESTfNG MATERIALS, by R. R. Bouche and D. R. Tate. May 1955, 20p. illus. tables, refs. (NBS rept. no. 4109) (Sponsored jointly by Office of Naval Research under NAonr 21-48, [Air Force] Office of Sctenttftc Research under CSO-640-55-9, and Atomtc Energy Commission) AD 67f44 Unclassified

A discussion is presented on the principles of operation (mechanical, electrical, and optical) and the performance characteristics of stress-strain recorders. The recorders include only those whtch plot simultaneously stress vs strain. In an accuracy study of stress-strain recorders, 3 widely used recorders and associated extensometers were subjected to performance tests. The results of the performance tests could not be considered an evaluation of the performance of all recorders of the type tested. The recorders tested conformed reasonably well with ASTM Spec E83-52T established for the evaluation of strain measuring devices. The errors in strain indication were essentially within the given tolerances. The recorders described were considered suitable for obtaining an automatic plot of the stress-strain diagram of specimens under certain testing conditions. The use of stress-strain recorders is ltmited under extreme conditions of high temperature, creep testing, measuring large plastic strains, and testing specimens of unusual shape or of some nonmetallic malertals.

A RECORDING MICROWAVE HYGROMETER, by J. Sargent. June 1955 [53]p. incl. illus. diagrs. tables, refs. (NBS repl. no. 4257) (Sponsored jointly by Office of Naval Research under NAonr 21-48, [Air Force] Office of Scientific Research under CSO-640-55-9, and Atomic Energy Commission) AD 71410 Unclassified

A description is given of a microwave refractometer designed to measure and record the water-vapor pressure in air particularly at very low vapor pressures. At low water-vapor pressures the instrument has a sensitivity of 0.005 mb, with a four decade range extending to 95 mb. By means of microwave techniques the difference in refractive index between dry and humid air is determined and then converted to vapor pressure by an empirical formula. The instrument can be readily calibrated by the use of pure gases whose dielectric constants are precisely known. Because of the automatic null-balancing technique used, the calibration has exceptional stability. Test results involving the measurement of known vapor pressures in the ranges of 0 to 0.2 mb and 0 to 20 mb are described. Possible applications of this instrument for the measurement of refractive index variation, and its use for quality control, are briefly discussed.

A STUDY OF BASIC LIMITATIONS TO THE CONCEPT AND MEASUREMENT OF TEMPERATURE; INCOMPLETE EQUILIBRIUM, by C. M. Herzfeld. Jan. 1956, 14p. refs. (NBS rept. no. 4420) (Sponsored jointly by Office of Naval Research under NAonr 21-48, Air Force Office of Scientific Research under CSO-640-55-9, and Atomic Energy Commission) AD 85386 Unclassified

A survey was made of problems associated with temperature measurement during the approach to equilibrium. Methods are described for measuring temperature from (1) the population of atomic levels; (2) the spectral time reversal; (3) the Doppler line width; (4) the vibrational spectra; (5) the rotational spectra; (6) optical pyrometers; (7) thermocouples; and (8) the velocity of sound. Additional methods include the pneumatic, the pyrometric-cone, and the absolute radiation-intensity methods. The survey revealed that temperature, in the equilibrium sense can be measured with an accuracy which depends only on the intrinsic limits of the apparatus. In most practical situations, T (temperature) is not well defined, but one or several T* (quantities which resemble T) can often be found which can be measured and defined with sufficient accuracy. In situations which are too complex to allow definition of a T*, a purely empirical temperature-like parameter T** may exist which can be measured and can be related empirically to other features of the system.

CORRECTIONS IN HIGH ACCURACY FRESNEL REGION MICROWAVE INTERFEROMETRY, by E. S. Dayhoff. Feb. 1956 [101]p. incl. illus. tables, refs. (NBS rept. no. 4514) (Sponsored jointly by Office of Naval Research under NAonr 21-48, Air Force Office of Scientific Research under CSO-640-55-9, and Atomic Energy Commission) AD 87803 Unclassified

In optical interferometry the wavelength is ordinarily so small compared with the transverse dimensions of the apparatus that no account need be taken of possible corrections to the apparent phase velocity due to diffraction effects. In the analogous microwave interferometer, where propagation is only quasi-optical, this happy situation does not exist since the wavelength is not so small that diffraction effects of low order are negligible. The attainment of high absolute accuracy in phase velocity measurements by microwave interferometry then requires a thorough study of the low order corrections to measured phase velocity. This report is concerned with such corrections in the case where (1) the wavelength is small but not negligible compared with the dimensions of the apparatus and (2) the radiating aperture subtends at least one Fresnel zone from the mid point of the travelling mirror. An expression is obtained giving the correction to be applied to the observed wavelength in terms of the antenna pattern of the radiator, an experimentally observable quantity. A discussion is also given of the sources and effects of multiple paths of propagation as they would influence

phase velocity measurements. Methods for their reduction and correction are suggested. (Contractor's abstract)

ELECTRONIC ANALOG-TO-DIGITAL CONVERSION, by M. L. Kuder and L. A. Marzetta. Mar. 31, 1956, 27p. incl. illus. (NBS rept. no. 4647; supersedes NBS rept. no. 1117) [CSO-640-55-9] AD 111631
Unclassified

As a prelude to the development work reported herein, the general field of analog-to-digital conversion was reviewed. It was apparent that in all these systems, it is the analog elements which permit errors to accrue in the parameter conversions. Therefore, the two elements in all of these converter systems which seemed worthy of the most attention were the comparison-voltage generator, and the balance detector. The latter element is sometimes referred to as the end-point resolver. This report covers some unique details of these two critical digitizing elements, as well as several schemes for their utilization in high speed converter systems. Methods for digital read-out and multichannel sampling are discussed. The high sampling rates can result in upwards of 500 complete 3-digit conversions per second.

ELECTRONIC ANALOGUE OF SUPERSONIC FLOW, by L. S. G. Kovasznay and N. Newman. Dec. 1956 [43]p. incl. illus. diagrs. refs. (NBS rept. no. 4893) (Sponsored jointly by Air Force Office of Scientific Research under CSO-640-55-9, Office of Naval Research under NAonr 21-48, and Atomic Energy Commission)
AD 139062 Unclassified

Supersonic flow of a perfect fluid obeys a second order nonlinear partial differential equation termed a "quasi-linear hyperbolic equation." The principal tool for solving such equations is the method of characteristics. An electronic analogue device has been constructed that simulates the method of characteristics not only in the case when the characteristics are fixed (linearized equation) but also when the location of the characteristics depends on the solution itself (nonlinear equations). In the latter case, however, the simplest type of nonlinearity was chosen purely for electronic convenience. The electronic equipment is built around a cathode ray tube flying spot scanner and is so arranged that the scan lines form the characteristics of the differential equation. The boundary conditions are fed into the machine as an opaque mask and the solution (flow pattern) is obtained as an image on a second cathode ray tube (monitor). The experiment has served only to demonstrate feasibility of the approach and has not been carried beyond that stage. (Contractor's summary)

SOME ASPECTS OF THE TWO-FLUID MODEL OF SUPERCONDUCTIVITY (Absiract), by E. Maxwell and P. M. Marcus. Jan. 22, 1953 [2]p. [CSO-670-53-8] Unclassified

Presented at meeting of the Amer. Phys. Soc., Cambridge, Mass., Jan. 22-24, 1953.

Published in Phys. Rev., v. 90: 346-347, Apr. 15, 1953.

The two-fluid model of a superconductor has derived added support from the recent observation that the threshold curves for a family of superconducting isotopes are geometrically similar curves, a fact consistent with the model. This is true for any two-fluid model in which the normal fluid alone contributes entropy. The detailed shape of the threshold field curve is determined by the particular form chosen for the entropy (or for the free energy) of the superconducting state. One specific form (α-model) was proposed by Gorter and Casimir (Physik. Z., v. 35: 963, 1934) on heuristic grounds, another by Koppe (Ann. Physik, v. 1: 405, 1947). Precise measurements on Sn, Hg, Tl, and in support the critical field equations calculated from the α-model:

$$\left(\frac{H}{H_0}\right)^2 = 1 - \frac{1}{\alpha}\left(\frac{T}{T_c}\right)^2 + \frac{1-\alpha}{\alpha}\left(\frac{T}{T_c}\right)^{2/(1-\alpha)},$$

where α is a parameter characteristic of each superconductor. (Contractor's abstract)

Some refined measurements of the critical field curves for tin, thallium, indium, and mercury have been completed and the results compared with the specific predictions of the Gorter-Casimir and the Koppe versions of the two-fluid model of superconductivity. Neither version is completely adequate, although each has points in its favor. The Koppe prediction of a universal critical field curve for all superconductors is not verified. The Gorter-Casimir α-model has greater flexibility than the Koppe model and, although it is capable of giving a fair description of the critical field data, it is in some respects also inconsistent with the data. The isotope effect in thallium has been observed and is consistent with the half-power law. (Contractor's abstract)

Evaluation was made of factors affecting the precision and accuracy of an absolute thermometer which uses thermally generated noise in conductors as a measure of temperature. An accuracy of at least 0.1% is required for measurements to be useful as a primary standard from 1000°K and up. Consideration was given to a thermometer designed by Garrison and Lawson (Rev. Scient. Instruments, v. 20: 785-794, 1949) which had synchronous rectifier and an electronic integrator added to the original circuit. The precision of measurement depended upon the sensitivity of the circuit to small differences in the average amplitude of the noise fluctuations. Study indicated that, even with a perfectly disturbance-free synchronous switch system, an observation time of 8 min was required for each adjustment of the standard resistor toward noise balance near the balance point of 0.1% temperature measurement precision. Noise balance stability sufficient for 0.05% precision could not be achieved.

SUPERCONDUCTING TRANSITIONS IN TIN WHISKERS, by O. S. Lutes and E. Maxwell. Mar. 15, 1955 [3]p. incl. diagrs. [AFOSR-TN-55-151] [CSO-670-53-8]
Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 97: 1718-1720, Mar. 15, 1955.

The superconducting resistance transitions of several tin whiskers have been observed in the liquid-helium temperature range. The results are compared with those for larger wires and significant differences are found. In particular the transitions in a transverse magnetic field are discontinuous at temperatures substantially lower than the zero-field transition temperature. This result differs from that for larger wires, which show intermediate resistance at these temperatures. (Contractor's abstract)

HYSTERESIS IN SUPERCONDUCTING TIN WHISKERS (Abstract), by O. S. Lutes and E. Maxwell. [Oct. 1955] [1]p. ([AF]OSR-TN-55-395) [CSO-670-53-8]
Unclassified

Presented at N. S. F. Conference on Low Temperature Physics and Chemistry, Baton Rouge, La., Dec. 29, 1955.

The superconducting transitions of tin whiskers oriented parallel to a magnetic field show size effects with respect to both critical field and hysteresis behavior. In addition the hysteresis is observed to have a strong temperature dependence. The whisker diameters ranged from 0.7 to 2.7 microns. For the smallest whisker the critical field was greater that that of bulk tin by a factor of 2.9 at 3.5°K. For the largest whisker this ratio was reduced to 1.2. Even for the latter the critical fields near T_c were considerably greater than predicted by the London theory. The hysteresis exhibited by all the whiskers was negligibly small above 3.5°K. In the case of the largest whisker $\frac{\Delta H_c}{H_c}$ increased to 20 per cent at 2.2°K, but for the smallest whisker it was only 2 per cent at the same temperature. The shape of the resistance transition appears to depend on the amount of hysteresis observed, being nearly

discontinuous when the hysterests ts sizable but somewhat soread out when the hysterests ts small, t.e., near T_c. (Cortractor's abstract)

SUPERCONDUCTIVITY OF MICROSCOPIC TIN FILAMENTS, by O. S. Lutes. Nov. 9, 1956 [38]p. tncl. tllus. dtagrs. refs. (NBS rept. no. 4931) (AFOSR-TN-56-525) (CSO-670-53-8) AD 110348 Unclassified

Also published in Phys. Rev., v. 105: 1451-1458, Mar. 1, 1957.

An expertmental determination has been made of the magnetic fteld necessary to tnduce the superconductng transition tn mtcroscoptc tin ftlaments called "whtskers." For temperatures near the zero-fteld transition temperature, T_c, the results are unambtguous, and tn this regton the crttical fteld are stgnificantly higher than those of a bulk superconductor. At lower temperatures, the crttical fteld curve splits tnto two parts, the upper curve gtvtng the field for destruction of superconductivtty and the lower curve the fteld for restoration. The temperature dependence of the crttical field is compared wtth the predtctions of the London and Ginsburg-Landau theortes of superconductivtty. It ts found that the London theory ts tnadequate to describe the data over the whole useful range, whereas the Ginsburg-Landau theory provtdes a satisfactory fit. The disappearance of hysterests occurs at a temperature for which $2.0 \leq h_c/H_c \leq 2.4$, where h_c/H_c ts the ratio of whisker to bulk critical fields. This is tn reasonable agreement with the Ginsburg-Landau-Stlin condttion for the onset of second order transitions. An effective value of λ_0, the penetratton depth at 0°K, is dertved from the data for each whisker. λ_0 shows a strong dependence on the normal electrtcal conductivity, as estimated from the change tn reststance at the transition. At long mean free path, the results are in agreement with those obtained from bulk spectmen measurements, but at short mean free path the present λ_0 values are higher (Contractor's abstract)

DETERMINATION OF SINUSOIDAL ACCELERATION AT PEAK LEVELS NEAR THAT OF GRAVITY BY THE "CHATTER" METHOD, by C. W. Kissinger. Sept. t954 [29]p. incl. illus. diagrs. tabte. (NBS rept. no. 3339) (Sponsored jotnly by Air Force Office of Scientiftc Research under CSO-670-53-10, Office of Naval Research under NAonr 21-48, Atomic Energy Commission, and Bureau of Aeronautics) AD 46276 Unclassified

An accelerometer is descrtbed, in which a loose mass bounces, or "chatter," when the peak acceleration of a vertical sinusoidal motion exceeds the acceleration due to gravity. The device is useful, for example, tn settng the acceleration level of vtbration generators used tn the calibration of vtbration ptckups. A theoretical relation ts dertved between the amount by which peak acceleration exceeds ± 1 g, and the point tn the cycle at which the loose mass, after havtng separated, again contacts that part of the accelerometer on which tt was resting. Ustng this relation tn conjunction wtth the accelerometer descrtbed, acceleration levels from about 1.01 g to 1.04 g may be set with an accuracy of approximately ± 0.5% at frequenctes up to 60 cps, and wtth somewhat decreased accuracy to about 150 cps. In the accelerometer descrtbed, a clamping screw ts provided, by means of which the chatter of the loose mass may be prevented when desired. This allows the accelerometer to be used as a self-caltbrating secondary standard for levels of acceleration other than + 1g, and at frequenctes up to about 1200 cps. (Contractor's abstract)

DESIGN FEATURES OF A MAGNETIC DRUM MEMORY FOR THE NATIONAL BUREAU OF STANDARDS WESTERN AUTOMATIC COMPUTER (SWAC), by R. Thorensen. Apr. 30, 1952, 7p. (NBS rept. no. 1635) [CSO-670-54-7] Unclassified

Presented at Electronic Computers Symposium, Calif. U., Los Angeles, Apr. 30-May 2, 1952.

A magnetic drum memory has been designed for the SWAC having a capacity of over 6000 binary digit word. Primary consideration has been given to simplicity of design together with maximal efficiency in transfer of information between the new magnetic drum memory and the existing electrostatic memory. A system is used in which the waiting time for access to the memory is almost completely eliminated. This system is being constructed of less than a dozen different types of basic single-tube plug-in units. These units have been developed to a high degree of stability under a variety of conditions of loading and aging. It is estimated that the entire magnetic drum, involving amplifiers, selection matrices, and control equipment necessary for the tie-in with the SWAC will contain only 250 vacuum tubes.

A MAGNETOSTRICTION MAGNETOMETER, by T. A. Perls. May 1952, 17p. incl. diagrs. tables, refs. (NBS rept. no. 1632) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-670-54-7], and Atomic Energy Commission) ATI 154524 Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1952.

Abstract published in Phys. Rev., v. 87: 230, July 1, 1952.

Several interesting magnetic effects have been observed, including large changes in the magnetostrictively excited vibration amplitude of long rods with changes in the externally applied steady magnetic field. It was found that these changes in amplitude could not be accounted for by independently observed changes in the resonant frequency and damping of the rod, but rather were related to changes in slope of the curve of magnetostriction vs. intensity of magnetization. Proposed investigations are described, including a specimen-stabilized oscillator, a determination of the most favorable annealing procedure, and the possible use of fine wires rather than long rods. STRESS-INDUCED NOISE IN CABLES (Abstract), by T. A. Peris. [1952] [1]p. (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-670-54-7], and Atomic Energy Commission) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 31, Feb. 1-2, 1952.

Published in Phys. Rev., v. 86: 613, May 15, 1952.

Stress-induced cable noise interferes with the transmission of signals in many different types of measurement, control, detection, and communication. The present investigation was undertaken in connection with the design and evaluation of very small barium titanate transducers for acceleration and pressure measurements. A quantitative theory of the mechanism of noise generation predicts a triboelectric separation of charge as a result of intermittent contact between the insulating dielectric and either of a pair of conductors. The necessary redistribution of charge produces a current pulse through the terminating network. Quantitative predictions of this theory are verified by a series of simple experiments. Stress-induced noise is practically eliminated in cables having conductive coatings both inside and outside of the insulating dielectric. Comparison of such an experimental, light, flexible, coaxial cable, 0.07 in. od, with a standard microphone cable of similar dimensions, shows a reduction in signals caused by twisting and squeezing by a factor of at least 200. There appears to be no limitation on arrangement and number of conductors, or on size and flexibility of cables made by this method. An industrially applicable method of construction will be suggested. (Contractor's abstract)

TRANSIENT RESPONSE OF LINEAR SYSTEMS (Abstract), by J. F. Koenig. [1952] [1]p. (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-670-54-7], and

Atomic Energy Commission) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1952.

Published in Phys. Rev., v. 87: 231, July 1, 1952.

In the design of an nth order linear system it is desired that the transient response, for given initial conditions, be of a specified form. Criteria are presented for obtaining specified transient responses, for various initial conditions, in linear systems described by nth order characteristic equations. The author's results are presented in the form of theorems which relate the roots and coefficients of the characteristic equation to the transient response, for various initial conditions. One of the theorems gives the conditions on the roots of the nth order characteristic equation such that there will be no overshoot for a step function input to the linear system. Closely related work recently reported by Z. S. Bloch is summarized. (Contractor's abstract)

ON THE ZEROS OF POLYNOMIALS AND THE DEGREE OF STABILITY OF LINEAR SYSTEMS, by J. F. Koenig. Jan. 13, 1953 [7]p. incl. illus. tables, refs. (In cooperation with Illinois U. Electrical Engineering Research Lab.) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-670-54-7], and Atomic Energy Commission) Unclassified

Published in Jour. Appl. Phys., v. 24: 476-482, Apr. 1953.

A method is presented for finding zeros of the nth degree real or complex polynomial as its coefficients (or their parameters) are varied. Several new theorems are presented. The method is based on new theorems, some concerning determinants, and on known theorems. It is applied to characteristic equations of linear physical systems with or without feedback. Root trajectories in the complex plane can be visualized without plotting them from "root trajectory diagrams" which show curve families for real or complex roots of a polynomial equation in a plane having two coefficients of the polynomial equation as coordinates. The diagrams can be used in the converse manner to determine the coefficient values corresponding to a desired dominant complex pair or real root. (Contractor's abstract)

CATHODE-RAY-OSCILLOGRAPH BEAM INTENSIFICATION, by J. H. Park and H. N. Cones. Feb. 1953 [19]p. incl. illus. diagrs. (NBS rept. no. 2281) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-670-54-7], and Atomic Energy Commission) AD 3986 Unclassified

A method has been developed for momentarily intensifying the electron beam obtained from a cold-cathode discharge tube. This momentary intensification is about fifty times its steady state value. The utilization of this method of beam intensification for obtaining very high writing speeds with a CRO has been described in R. P. No. 2231. This intensification phenomena is not dependent to any very great extent on the gas used in the discharge tube. The material surrounding the discharge at and near the cathode must be a dielectric such as glass and not a conductor if intensification by superposed small pulses is to be obtained. When full voltage is suddenly applied to the discharge tube an intensified beam is obtained at times, but results are usually not repeatable. A satisfactory theoretical explanation for this beam intensification phenomena was not obtained. Such an explanation will probably not be attained until the steady state mechanism of the discharge in a high-voltage cold-cathode tube is completely understood. Although such discharge tubes have

NBS. 25:009 - NBS. 25:012

been tn use for over thirty years there is still no expertmentally vertfied theory for exptaining their behavtor. Continued studies of exactly what happens when full voltage ts suddenly applted to the electrodes might eventually yield a satisfactory theory. The most tmportant objective of this work which was to learn enough about the tntenstfication phenomena so that tt could be used to obtain very high writing speeds with the CRO has been achieved. The CRO, wtth tntenstfication, has already been used tn an tnvestigation of tnsulator puncture using surges with rates of voltage rtse up to 11,000 kv per mtcrosecond. It ts now betng used to study front of wave measurements on rapidly rising voltage surges. (Contractor's summary)

MULTICHANNEL PULSE-HEIGHT ANALYZER USING A STORAGE TUBE (Abstract), by J. A. Cunningham. Apr. 30, 1953 [1]p. [CSO-670-54-7] Unclassifted

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 30-May 2, 1953.

Published in Phys. Rev., v. 91: 437, July 15, 1953.

A stmple and reltable electronic pulse-hetght analyzer permtttng the use of many channels has been developed for pulsed accelerator applttcations. The voltage pulses to be analyzed are tntroduced to the verttcal plates of a selected 3 JPI CRO tube, on whose outer face a wtre screen ts mounted. Durtng the accelerator off-time, a sawtooth sweep voltage is applied to the same deflection plates. The output pulses of the storage tubes are then analyzed during the sweep. The time differences between the sweep start and the output pulses determine the heights of the original input pulses. A simple time gate-scaler device enables the use of a large number of channels. Tests on spectrum analyses have proven the followtng dtstinct advantages: (t) voltage pulses whose peak values were maintained for a period as short as 0.05 microsecond have been analyzed. The minimum time response of the storage tube has not yet been checked. (2) Ttme dtfferences and thus pulse-height measurements are tndependent wtthin 0. I% of analyzer supply voltage changes of t5%. (3) Wtth the available storage tubes tt is eastly practical to obtain 100 channels. A large ratio of the resolving power to the number of channels being used permits a small error due to boundary effects. (Contractor's abstract)

HIGH-RANGE ACCELEROMETER CALIBRATIONS, by T. A. Perls and C. W. Kissinger. June 1954 [26]p. incl. illus. diagrs. table. (NBS rept. no. 3299) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research under CSO-670-54-7], and Atomic Energy Commission) AD 36647 Unclassified

The need for calibrations at high levels of acceleration is discussed. The theory is presented for a method of obtaining such calibrations by impact methods, using an electrical integrator. The method does not require a knowledge of either the pulse shape or the pulse width, although the latter is limited from both above and below by practical considerations related to the integrator and to the accelerometer under test. Three actual test schemes are described, including the use of a simple ballistic pendulum, an air gun, and an inclined trough. Preliminary data are also presented on a method for obtaining linearity data from steady-state resonant vibrations at levels, so far, up to 1090 g. The steady-state tests established the linearity of one of the NBS 33-14 accelerometers within ± 2% up to 1090 g, and were used for calibration of a commercially available piezoelectric accelerometer within ± 4% up to 665 g. The results of the transient high-g tests on one of the NBS 33-14 accelerometers showed that it becomes strongly nonlinear at -48,000 g, while it has good linearity to at least +40,000 g and -30,000 g.

STABILITY OF NONLINEAR FEEDBACK CONTROL SYSTEMS, by J. F. Koenig. Aug. 1954, 18p. incl. diagrs. refs. (NBS rept. no. 3619) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research under [CSO-670-54-7], and Atomic Energy Commission) AD 47005 Unclassified

A general method based on a continued-fraction expansion of the coefficients of a complex differential equation is presented for the determination of the stability of nonlinear feedback control systems. Each nonlinear system is expressed mathematically as a characteristic equation having complex coefficients. The method determines whether all roots have negative real parts as required for stability. The method is applied to 2 relay servomechanisms with hysteresis. The deviation of a general method to obtain stability boundary curves is illustrated by its application to a relay servomechanism with hysteresis. A parametric stability diagram shows the distance any stable nonlinear system is from instability in terms of any 3 parameters of the system. The continued-fraction theorems of Frank (Bull. Amer. Math. Soc., v. 52: 144-157, 1946) are applied to the determination of the stability of induction motors with series capacitors.

A BASIC METHOD OF DETERMINING THE DYNAMIC CHARACTERISTICS OF ACCELEROMETERS IN ROTATION, by W. A. Wildhack and R. O. Smith. Rev. Mar. 1955, 4p. incl. illus. (Paper no. 54-40-3) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research under [CSO-670-54-7], and Atomic Energy Commission) AD 118806 Unclassified

The earth's gravitational field furnishes a convenient sinusoidal forcing function for a vibrating system (e.g., an accelerometer) rotating in a vertical plane. The centrifugal field decreases the restoring force on the vibrating mass. Resonance occurs at lower frequencies and with greater amplitudes than in the case of excitation by linear vibration. The response ratio (vibration amplitude/static displacement caused by gravity) is greater than unity for all damping ratios up to unity. The resonant frequency for zero damping occurs at 0.707 times the natural undamped frequency. From measurements of the maximum response ratio, and of the frequency at which this ratio decreases to unity, one may determine both the damping ratio and the undamped natural frequency of any system whose damping ratio is less than unity. The response equation for the rotational excitation is given, and the solutions are presented in graphic form. Experimental test results obtained by this method are included. (Contractor's abstract)

A METHOD FOR STEADY-STATE ACCELEROMETER CALIBRATIONS UP TO ± 4000 g AND TEST RESULTS ON TWO ACCELEROMETERS, MODEL A314-T MANUFACTURED BY THE GULTON MANUFACTURING CORP., METUCHEN, N. J., by T. A. Perls, C. W. Kissinger, and D. R. Paquette. Mar. 1955, 17p. incl. illus. tables. (NBS rept. no. 3924) (Sponsored jointly by Ordnance Corps., Office of Naval Research, [Air Force Office of Scientific Research under CSO-670-54-7], and Atomic Energy Commission) AD 77944 Unclassified

Two Gulton accelerometers, Model A-314, Serial Nos. 280 and 281 have been calibrated by a new steady-state method at peak accelerations up to ± 2200 g. Within the accuracy of the method (the average scatter of the sensitivity data was ± 1.5%), the two accelerometers were linear up to the highest acceleration tested. Another Gulton accelerometer of a similar, possibly somewhat less rugged, type (Model A-314), was found to be linear within ± 2% up to ± 4000 g. The average sensitivity at room temperature of the accelerometers, Serial 280 and 281, as received, was 1.16 ± .01 mv/g and 1.19 ± .01 mv/g, respectively, in excellent agreement with the values given by the manufacturer. Incidental data were also presented on temperature dependence of capacitance and voltage sensitivity, over a small range of temperatures, on cable-loading and mounting-strain effects, and on transverse response of the two Model A-314T accelerometers. Resonant-frequency data were included for the accelerometer Model A-314.

A BARIUM-TITANATE ACCELEROMETER WITH WIDE FREQUENCY AND ACCELERATION RANGES. DATA OBTAINED SINCE APRIL 1953, by T. A. Perls and C. W. Kissinger. June 1955 [35]p. incl. illus. tables. (NBS rept. no. 2330a) [Sponsored jointly by Office of Naval Research under NAonr 21-28, Air Force Office of Scientific Research under CSO-670-54-7, and Atomic Energy Commission] AD 68070 Unclassified

The additional investigations performed with the NBS 33-14 accelerometer are described together with the modifications which are incorporated in the models NBS 33-17, 18, and 19 accelerometers. A special test jig was designed and built in which single crystals could be investigated under different orientations and under asymmetrical loading with a controlled orientation with respect to both the crystal and the base of the test jig. The cable connection to the body of the accelerometer was modified to eliminate the set screw and cable shim. The new connector consists of a compression nut and lead washer which fit into a tapped hole in the side of the accelerometer body. Attempts were made to verify experimentally the predicted lowering of the resonant frequency by shock exciting the test accelerometer while mounted in an 80-g small steel block. The observed mounted resonant frequencies varied only slightly with the mass which loaded the crystals and were all between 40 and 50 kc. A steady-state frequency-response test was performed with the NBS 33-17 accelerometer by comparison with the output of a sensitive displacement measuring system. The accelerometer was mounted on a steel plate which was attached to the end of a piezoelectric vibration generator. Four additional accelerometers were also mounted on the steel plate at 90° intervals in the plane transverse to the direction of vibration as a means of measuring the transverse motion.

A LARGE BARIUM-TITANATE ACCELEROMETER FOR SHOCK-VELOCITY MEASUREMENTS, by T. A. Perls and C. W. Kissinger. June 1955, 9p. illus. (NBS rept. no. 4121) (Sponsored jointly by Office of Naval Research under NAonr 21-48, [Air Force] Office of Scientific Research under CSO-670-54-7, and Atomic Energy Commission) AD 68484 Unclassified

The instrument has sufficient charge sensitivity to permit integration with a passive network and still retain output voltage so that an impulsive change of velocity of 5 fps can be recorded with good amplitude on any high-impedance 10-mv recorder. To achieve the highest possible resonant frequency, the accelerometer base, the $BaTiO_3$ disks, and the loading mass must be in contact over their entire mating surfaces so that the assembly will act as a compression spring. When the accelerometer is mounted on a heavy object the theoretical resonant frequency should be about 0.7 times the unmounted resonant frequency; this assumes perfect coupling between the base of the accelerometer and the surface to which it is mounted. With a reasonably flat mounting surface and 3 mounting bolts tightened with a 40- to 70-lb-ft torque, the resonant frequency of the accelerometer with commercially flat crystals is 4900 c when it is mounted on a 22-lb mass and 4600 c on a 62-lb mass. These frequencies are about 10% lower than those theoretically expected from the unmounted resonant frequency together with the loading mass and total weight of the accelerometer. By extrapolation, the resonant frequency of the accelerometer when mounted on an infinite mass should be about 4400 c. The advantages and disadvantages of the present integrating accelerometer over the seismic-type velocity meter are discussed.

THE FIELD EMISSION X-RAY MICROSCOPE, by R. A. Schrack. July 13, 1956, 1v. tncl. tllus. diagrs. refs. (NBS rept. no. 4775) (AFOSR-[T]R-56-27) [CSO-680-56-19] AD 90012 Unclassifted

The ftrst utilizalion of fteld emtssion electron source in an electron optical system was accomplished in this x-ray shadow mtcroscope. The mtcroscope was constructed prtnctpally of glass and brass. The separate parts are fttted together wtth rubber O-ring seals and stopcock grease. Ustng a 20 l/sec glass otl diffuston pump and a liquid N cold trap, an operating vacuum of better than 5×10^{-6} mm Hg was obtained in 2 hr. A strong field created at the surface of a very small point by applying a potential of about 10,000 v to 125 μ W wire, allows the emission of electrons. The electrons are focused by an electrostatic electron lens into a small area on a thin target of Au. X-rays are produced by the electron impact (Bremmstrahlung) in a very small volume in the target. The generated x-rays are transmitted through the target and used to produce a shadow image on photographic film. The HV pulse supplies the electron lens through a phase-compensated voltage divider which allows adjustment of the focal length of the electron lens to produce focusing conditions at all times during the electron emission pulse. The W field emitter is raised to 2000°K to remove C contamination, and is operated at about 1400°K to preclude contamination. Design requirements for the lens system indicated a 3-element unlvoltage electrostatic lens. Results showed the best photographs taken with the x-ray mlcroscope indicated at resolution on the order of 5μ.

A FIELD EMISSION X-RAY PROJECTION MICROSCOPE (Abstract), by R. A. Schrack, R. C. Placious, and L. Marton. [1956] [1]p. [CSO-680-56-19] Unclasstfted

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 167, Apr. 26, 1956.

Electrons from a fteld emission source are focused by an electron optical system to a small spot to produce a small bremsstrahlung source for x-ray projection mtcroscopy. A ftne tungsten potnt ts operated as a fteld emtsston source at elevated temperature, termed T-F emisston by Dyke and hts coltaborators. The elevated temperature maintains a clean tungsten surface tn a dynamtc vacuum system operattng at a pressure of 2×10^{-7} mm Hg. The voltage supply is pulsed 60 cps wtth a ten percent duty cycle. The pulse current

is about 100 microamps for 10-kv pulse voltage. About 3×10^{-3} of the total current is focused to a spot to produce x-rays. Exposure time for a density of 1 is about 10 min for the above current and voltage and fast no-screen x-ray film without cover. Details on target and resolution are presented. EXCITATION AND SEPARATION OF PURE HIGH-ORDER MODES IN LARGE HIGH-Q CAVITIES, by C. T. Zhan and W. G. Schweitzer, Jr. Apr. 5, 1956 [9]p. incl. diagrs. (Bound in its NBS rept. no. 5673; AFOSR-TR-56-94; AD 136740) (CSO-680-57-9) AD 136740(a) Unclassified

Also published in Jour. Appl. Physics, v. 27: 929-937, Aug. 1956.

In order to extend the range of cavity resonance techniques, a successful method has been developed for the suppression of undesired modes of a densely populated cavity spectrum. It is based on the nodal properties of the usual simple solutions of the wave equation. The analytic continuation of any such solution may be regarded as a master mode pattern which defines an infinite variety of elementary cavities or cells all having one frequency in common. These properties provide the basis for a novel principle in the design of cavity-coupling systems. By suitable choice of a "complex" of these elementary cells, devices can be obtained with remarkable transducing, filtering, or suppressing properties. An experimental test of the foregoing ideas has been made in which it was possible to excite a well-separated very high order TE_{0mv} mode in a large cylindrical cavity, at a frequency of 20,000 mc. The observed Q for this preferred mode was of the order of one million. As an additional test quantitative experiments have been performed on a special type of complex cavity in which the number of elementary cells could be varied. (Contractor's abstract)

PHOTOEMISSION FROM SILVER INTO SODIUM CHLORIDE, THALLIUM CHLORIDE, AND THALLIUM BROMIDE, by W. T. Turner. [Dec. 2, 1955] [8]p. incl. diagrs. refs. (AFOSR-TN-55-444) (CSO-670-53-19) AD 140140 Unclassified

Published in Phys. Rev., v. 101: 1653-1660, Mar. 15, 1956.

The photoelectric work function for the transfer of electrons from a metal directly into an insulating crystal has been investigated for Ag on samples of NaCl, TlCl, and TlBr. The results obtained do not confirm the existence of this process in the samples studied although the apparatus had a current sensitivity of 1×10^{-17} amp. Mott and Gurney have suggested that the work function of the metal-insulator contact would be less than the vacuum work function of the metal by an amount equal to the electron affinity of the insulator. Previous experimental evidence supporting this picture of the contact appears less conclusive in the light of the results of this investigation. During the investigation of the Tl halides, photosignals were observed far beyond the intrinsic edge (0.38μ for TlCl and 0.46μ for TlBr at -150°C). Intrinsic irradiation at low temperature appreciably enhanced the long-wavelength photoresponse. The enhanced response could be bleached by heating the sample to room temperature. It was established that the photoresponse was a property of the crystal rather than photoemission from Ag into the crystal. (Contractor's abstract)

SYMPOSIUM ON EMBRYONIC NUTRITION, Brown Univ. (July 23-24, 1956), ed. by D. Rudnick. Univ. of Chicago Press, 1958, 113p. incl. diagrs. tables, refs. (The Developmental Biology Conference Series, 1956; sponsored in part by Air Force Office of Scientific Research under MIPR-680-56-52) Unclassified

The eventual goal of chemical embryologists is to discover how the growing embryo converts food energy into the differential morphology of its species. The present state of knowledge, however, as summarized in this conference, permits descriptions of measurements rather than of the mechanisms involved. The 6 papers presented are considered to contain important contributions to the store of information on nutritional requirements and metabolism of the embryo, enzyme formation and activity, protein synthesis and the use of antigens as tracers. Their specific titles are: embryonic energy exchange; metabolic patterns in the sea-urchin embryo; yolk utilization in fishes; antigens as tracers of embryonic synthesis; nutrient necessities in chick development; and enzymes — formation and growth.

Proliferating tissues may be part of the over-all growth of an organism or of local growth; they may provide replacement of worn-out parts, as in molting or shedding, or may constantly renew adult tissues, such as skin and blood. A tissue must reproduce itself as well as carry out its specific function; in both cases its dynamics are affected by its physical and chemical environment. In this conference the variables involved in proliferation and differentiation, requirements and upsetting factors, rates and ratios, and the different methods for studying tissue growth and function were discussed. The following specific topics were discussed: renewal systems; methods for estimating the rate of proliferation; methods for estimating production and delivery of white blood cells; methods for estimating cell loss; examples of renewal systems; factors influencing the rate of cell production and cell loss in renewal systems; blood cell-producing organs; and factors influencing blood cell production.

STRUCTURE AND PROPERTIES OF SOLID SURFACES. A CONFERENCE ARRANGED BY THE NATIONAL RESEARCH COUNCIL, LAKE GENEVA, WISCONSIN, SEPTEMBER 1952, ed. by R. Gomer and C. S. Smith. Chicago, Univ. of Chicago Press, 1953, 491p. incl. illus. diagrs. tables, refs. (AF 18(600)354) Unclassified

An attempt is made to find some common denominators for some of the diverse problems existing in the field of surface studies. Fourteen papers are presented which cover the following main categories: (1) thermodynamics and theories of surface forces; (2) the structure of a surface and means of determining it; (3) growth processes of and on surfaces; and (4) processes on surfaces which leave them relatively unaltered. The book opens with a concise and critical review of the thermodynamics of surfaces and the potentialities of the thermodynamic approach. Each paper is followed by a discussion which interrelates the common aspects of the 4 categories mentioned. A combined author and subject index is included.

AN INFRARED RAPID SCANNING SPECTROMETER AND ITS USE IN THE MEASUREMENT OF THE SPECTRA OF SHORT-LIVED MOLECULES (Abstract), by K. N. Tanner and R. L. King. [1956] [1]p. [MIPR-670-55-40] Unclassified

Presented at Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 11-15, 1956.

Published in Symposium on Molecular Structure and Spectroscopy. Abstracts, 1956. p. 57.

A rapid scanning infrared spectrometer has been designed and constructed to search for certain fundamental bands of the free radicals NH_2, CH_3, and CH_2. The monochromator uses the same off-axis parabola design as the Perkin-Elmer Mod. 12, but the Littrow mirror has been replaced by a Littrow-Wadsworth combination in which the Littrow mirror rotates continuously. The detector is a cooled lead telluride photoconductive cell. The spectrum is presented on a double beam oscilloscope. An "optical vernier" system synchronizes the oscilloscope sweep and also generates a set of linear fiductary marks, each corresponding to about 4 minutes of Littrow mirror rotation, which are presented on the second trace of the oscilloscope. The radicals are generated by flash photolysis in one meter quartz absorption cell. This spectrometer is capable of scanning the 3μ band of ammonia in about 4 msec with essentially no loss in resolution from conventional slow speed, narrow band scanning, in about 2 msec with slight loss, and in less than one msec with somewhat greater resolution loss. The results of using this instrument to search for the 3μ bands of NH_2, CH_3, and CH_2 are presented.

ON CONDITIONS FOR THE STABILITY OF SOLUTIONS OF PENDULUM-TYPE EQUATIONS, by J. C. Lillo and G. Seifert. Nov. 8, 1954, 6p. (Rept. no. 1) ([AF]OSR-TN-54-312) (AF 18(600)1112) AD 53191 Unclassified

<u>Also published in</u> Jour. Appl. Math. and Phys. (ZAMP), v. 6: 239-243, 1955.

The equation $\ddot{\theta} + \alpha f(\theta)\dot{\theta} = g(\theta)$, where $f(\theta)$ and $g(\theta)$ are twice differentiable functions of period 2π in θ, $f(\theta) > 0$, $\int_0^{2\pi} g(\theta)d\theta > 0$, and $g(\theta)$ has simple zeros, has for sufficiently small α a solution $\theta(t)$ such that $\theta = \gamma(\theta)$ is a non-negative function of period 2π in θ. It is also known that if no such solution exists, each solution of this equation tends to some fixed value θ_j, a zero of $g(\theta)$, as $t \to +\infty$. In this note, bounds on a critical value α_c are obtained, this critical value being such that $\alpha \leq \alpha_c$ implies the existence of a periodic $\gamma(\theta)$, while $\alpha > \alpha_c$ implies nonexistence of such a $\gamma(\theta)$. ON STABILITY QUESTIONS FOR PENDULUM-TYPE EQUATIONS, by G. Seifert. Mar. 31, 1955, 14p. incl. diagr. (Rept. no. 2) ([AF]OSR-TN-55-92) (AF 18-(600)1112) AD 70032 Unclassified

<u>Also published in</u> Jour. Appl. Math. and Phys. (ZAMP), v. 7: 238-247, 1956.

The differential equation $\ddot{\theta} + f(\theta, \alpha)\dot{\theta} = g(\theta)$, where f and g are functions having continuous derivatives everywhere, $\alpha > 0$, $f(\theta + 2\pi, \alpha) = f(\theta, \alpha)$, $g(\theta + 2\pi) = g(\theta)$, and $g(\theta) = 0$ has simple roots, is considered. Conditions are given under which each solution coincides

with or asymptotically approaches a periodic solution; here periods 0 and $+\infty$ are allowed if a solution of period zero is interpreted as a constant and solution of period $+\infty$ are solutions $\theta(t)$ for which $\theta(t) \to \theta_0$, a finite constant, for $t \to +\infty$ and $t \to -\infty$. Conditions are also given under which solutions exist which are not asymptotically stable in the sense given above. A special example is given to illustrate the possibility of satisfying all conditions given above such that $f(\theta, \alpha)$ has negative values for each $\alpha > 0$. (Contractor's abstract)

STABILITY OF SOLUTIONS OF PENDULUM-TYPE EQUATIONS, by G. Seifert and J. C. Lillo. May 31, 1955, 6p. (Rept. no. 3) ([AF]OSR-TN-55-158) (AF 18-(600)1112) AD 65891 Unclassified

The behavior as $t \to t + \omega$ of solutions $\theta(t)$ of a differential equation of the type $\ddot{\theta} + f(\theta, \alpha)\dot{\theta} = g(\theta)$, where f and g have continuous derivatives with respect to θ everywhere, f is continuous in α, $g(\theta)$ has zeros, all of which are simple, and $f(\theta + 2\pi, \alpha) = f(\theta, \alpha)$, $g(\theta + 2\pi) = g(\theta)$ hold for all θ, is studied. Conditions, involving primarily the dependence of f on the parameter α, under which all solutions exhibit types of stability as $t \to +\infty$ are derived. The existence and behavior of certain types of periodic solutions of this equation which affect stability questions are also studied with respect to explicit conditions on f and g. (Contractor's abstract)

ON PENDULUM-TYPE EQUATIONS AND ROTATED VECTOR FIELDS, by G. Seifert. Aug. 20, 1955, 8p. (Rept. no. 4) ([AF]OSR-[TN]-55-217) (AF 18(600)-1112) AD 75906 Unclassified

The behavior as $t \to +\infty$ of solutions $v(t)$ of $\ddot{v} + f(v, \alpha)\dot{v} = g(v)$, where f and g have continuous derivatives with respect to v everywhere, f is continuous in α, $g(v)$ has zeros, all of which are simple, and $f(v + 2\pi, \alpha) = f(v, \alpha)$, $g(v + 2\pi) = g(v)$ hold for all v, is first studied. Conditions, involving primarily the dependence of f on the parameter α, under which all solutions exhibit types of stability as $t \to +\infty$ are derived. The existence and behavior of certain types of periodic solutions of this equation which affect stability questions are also studied with respect to explicit conditions on f and g. In the second part of this project, systems were considered ($\dot{x} = P(x, y, \alpha)$, $\dot{y} = Q(x, y, \alpha)$) where P and Q satisfy Lipschitz conditions in x and y, have continuous derivatives P_α and Q_α, and $\begin{vmatrix} P & Q \\ P_\alpha & Q_\alpha \end{vmatrix} \geq 0$ for (x, y) in a domain D and α in an interval I, the equality holding for at most an isolated set of points in D; the critical points of the system are isolated and independent of α. It was found that cycles of the system, which were asymptotically stable, vary monotonically and continuously at values of α for which such cycles exist. A result concerning the existence of other cycles for a system having an unstable critical point and a cycle surrounding it is obtained and application of this is made to the existence of cycles for systems arising from second order equations of the form $\ddot{x} + f(x, \dot{x})\dot{x} + g(x) = 0$. RECURSIVE REAL NUMBERS, by H. G. Rice. [1953] [12]p. (Technical rept. no. 1) (AF 18(600)480) AD 25697 Unclassified

Also published in Proc. Amer. Math. Soc., v. 5: 784-791, Oct. 1954.

Four equivalent definitions are given for the concept of recursive real numbers. A proof is presented that if $a_0, a_1, a_2, \ldots$ is a recursively enumerable, recursively convergent sequence of rational numbers with the limit a, and b is any rational number where $b \neq a$, then there exists an effective method for deciding whether $b > a$ or $b < a$. However, there exists no effective general method for deciding, given 2 recursive real numbers a and b, whether or not $a = b$. The recursive real numbers are demonstrated to form a field, $\mathcal{C}$, and the set $\mathcal{C}(i)$ is stated to be algebraically closed. However, the analog of the Bolzano-Weierstrass theorem, that every bounded recursively enumerable set of numbers of $\mathcal{C}$ has a limit point in $\mathcal{C}$, does not hold. (ASTIA abstract)

RECURSIVELY ENUMERABLE SEQUENCES, by H. G. Rice. [1953] [28]p. (Technical rept. no. 2) (AF 18-(600)480) AD 17839 Unclassified

NHU. 01:003 - NYU. 02:002

Recursively enumerable (RE) convergent sequences of sets of nonnegative integers are studied. The sets are drawn from the class of recursive sets, and from other classes generated from the recursive sets by adjoining limits of sequences. The main theorem connects the structure obtained with the Borel class structure generated over the recursive sets by RE sums and products. Concepts which appear as generalizations of recursive characteristic function and recursive enumerating function are introduced to prove this theorem. Similar concepts are applied to sequences of functions to obtain a structure with analogies to the Baire classification. Properties of certain Boolean algebras are discussed. An application to real numbers is developed. (ASTIA abstract)

INVESTIGATIONS IN RECURSION THEORY, by H. G. Rice. Final repl. Jan. 28, 1954, 8p. ([AF]OSR-TR-54-4) (AF 18(600)480) AD 52943 Unclassified

The work reported may be grouped under 3 headings. I. Recursive Real Numbers. The definitions of Specker are used, with general in place of primitive recursive functions. The recursive real numbers form a field closed under recursively convergent sequences. The recursive complex field is algebraically closed. Decision procedures for "=" and "<" are discussed. II. The Structure Over the Recursive Sets. A theorem is given connecting recursively enumerable (RE) sequences of sets with RE unions and intersections. Some properties of the resulting structure are discussed, and some applications made to reduction of decision problems. A Baire-like classification of functions is displayed. III. Recursive Distinguishability. The concept, due to McNaughton, is mentioned and a conjecture is stated. (Contractor's abstract)

PURE QUADRUPOLE SPECTRUM OF METHYL IODIDE VAPOR, by F. Sterzer and Y. Beers. Jan. 15, 1954, 1p. [Report no. 289.1] ([AF]OSR-TN-54-9) (AF 18(600)968) Unclassified

Presented at meeting of the Amer. Phys. Soc., Detroit, Mich., Mar. 18-20, 1954.

Published in Jour. Chem. Phys., v. 22: 2094, Dec. 1954.

In a symmetric top molecule, transitions can take place between quadrupole hyperfine levels of the same J and K provided that K = 0. Because of its large quadrupole coupling constant, CH_3I^{127} has several lines of this type with computed intensities sufficient for observation in the uhf region. Using the spectrometer reported previously, we have observed the following lines: J = K = 3, F = 11/2 $\longrightarrow$ 9/2, 444.76 ± 0.10 mc/sec; J = K = 4, F = 13/2 $\longrightarrow$ 11/2, 481.05 ± 0.10 mc/sec; J = K = 5, F = 15/2 $\longrightarrow$ 13/2, 503.05 ± 0.15 mc/sec. The identities of the first two lines were confirmed from Stark splittings. These measured frequencies are perfectly consisted with the quadrupole coupling constant obtained from microwave rotational spectra if second order theory is employed.

THE LINE WIDTH PARAMETER OF HDO AT LOW FREQUENCIES, by Y. Beers, G. Herrmann, and F. Sterzer. Aug. 12, 1954, 4p. (Rept. no. 289.2) ([AF]OSR-TN-54-204) (AF 18(600)968) AD 40179 Unclassified

The relative line width parameters of the $6_1 \longrightarrow 6_2$ and $3_2 \longrightarrow 3_3$ lines at respectively 2394.56 mc/sec and 826.64 mc/sec was determined as 1.0 ± 0.1, and the absolute value of the parameter of these lines was measured as 0.41 cm^{-1} at one atmosphere. The latter value is in good agreement with work by Strandberg (Jour. Chem. Phys., v. 17: 901, 1949) in the conventional microwave region. Therefore no basis was found to support any hypothesis that the discrepancy between calculated and measured values of the absorption

of radiation in the atmosphere by water is due to a variation in the line width parameter. (Contractor's abstract)

THE DISCREPANCY IN THE ROTATIONAL CONSTANTS OF BROMOFORM, by G. Herrmann. Aug. 25, 1954, 4p. (Rept. no. 289.3) ([AF]OSR-TN-54-218) (Sponsored jointly by Office of Naval Research under Nonr-62100 and [Air Force] Office of Scientific Research under AF 18-(600)968) AD 43894 Unclassified

Also published in Jour. Chem. Phys., v. 22: 2093, Dec. 1954.

In the determination of the rotational constants of bromoform a large unexplained discrepancy was found between the results of Williams and Gordy (Jour. Chem. Phys., v. 20: 1524, 1952) working in the K-band and of Kojima et al. (Jour. Chem. Phys., v. 20: 804, 1952) in the S-band. In the present experiment an attempt was made to repeat the S-band measurements of Kojima with a spectrometer having a greater sensitivity. This sensitivity has been verified by measurements on other molecules. No bromoform lines could be observed, and it must be concluded that they are too weak to be detected. Therefore the results of Kojima must be rejected as being due to some spurious effect. (Contractor's abstract)

PURE QUADRUPOLE SPECTRA OF CH_3I AND CF_3I VAPORS, by F. Sterzer and Y. Beers. Apr. 28, 1955 [30]p. incl. diagrs. tables, refs. (Rept. no. 289.5) ([AF]OSR-TN-55-109) (AF 18(600)968) AD 63422 Unclassified

Also published in Phys. Rev., v. 100: 1174-1180, Nov. 15, 1955.

The theory of $\Delta J = 0$, $\Delta F = \pm 1$ transitions of symmetric top molecules having a nucleus with a large quadrupole moment on the axis is presented first. Then, the manner in which the gaseous state spectrum converge on the pure quadrupole solid state spectrum as J becomes infinite is discussed in detail. An experiment is described in which 6 quadrupole lines of CH_3I and 1 of CF_3I were observed in the region between 290 and 520 mc/sec. The experiment yielded values of the quadrupole coupling constants of - 1933.99 ± 0.25 mc/sec and - 2142.5 ± 1.8 mc/sec, respectively, for CH_3I and CF_3I. These values are in agreement with previous values obtained elsewhere from rotational transitions. (Contractor's abstract)

LOW-FREQUENCY ROTATIONAL SPECTRUM OF HDO, by S. Weisbaum, Y. Beers, and G. Herrman. Sept. 1955 [5]p. incl. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18-(600)968) and Office of Naval Research) Unclassified

Published in Jour. Chem. Phys., v. 23: 1601-1605, Sept. 1955.

In the region between 475 and 3500 mc/sec one P-branch and five Q-branch lines in the spectrum of HDO were completely measured and identified. These data contributed materially to an evaluation of the structural constants of the molecule. From the data obtained by this and other microwave spectroscopy projects, the principal moments of inertia were computed, respectively, as having the values of 1.1982, 3.0862, and 4.3887 in units of gm cm^2 x 10^{-40}. In addition, the shape of the 3_2 ⟶ 3_3 line at 824.64 mc/sec was extensively studied. At low pressure the wings of the line were shown to be wider than is consistent with the Lorentz line shape probably due to the presence of satellite lines arising from the hyperfine splitting of the energy levels by the quadrupole moment of the deuteron. The observed effects are consistent with a quadrupole coupling constant of 272 ± 90 kc/sec with respect to an axis along the O – D bond. (Contractor's abstract)

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Also published in Bull. Amer. Phys. Soc., Series II, v. 1: 13, Jan. 30, 1956.

The inversion spectrum of the ground vibrational state of ND_3 has been investigated in the frequency region from 1520 to 1600 mc. From the 17 rotational fine structures observed, 8 were identified from their hyperfine structure. The revised, semi-empirical formula predicting the lines yielded the values a = 5.12 mc and b = 2.62 mc for the fine structure constants, and ν_0 = 1591.44 mc for the unperturbed ground inversion frequency. Splitting of K = 3 lines was observed for J = 3, J = 4, and J = 5, and found in good agreement with theoretical predictions based on infrared data. Nitrogen satellites were observed in the, 1, 1; 2, 2; 3, 3; 4, 3; and 5, 3 lines. Separations were within 10 kc of calculated values. A best fit was obtained by assigning the N quadrupole moment the value $(eQq)_N$ = 4080 ± 3 kc which is slightly smaller than its value in NH_3, and the magnetic coupling constant a, the value 2 ± 2 kc. The hyperfine structure of K = 1 lines was observed for J = 1, J = 2, and J = 3. This hyperfine structure is a result of the lifting of the K degeneracy by interactions arising from the deuterons. Line shapes were brought into agreement with theory by the method of contour fitting. The structure was found to depend primarily on the deuteron quadrupole coupling constant which was assigned the value $(eQq)_D$ = 200 ± 20 kc and on the magnetic parameter ϵ, (representing coupling of deuteron magnetic moments with molecular rotation) which was assigned the value ϵ = -1.9 ± 0.5 kc. In deriving the quadrupole moments, the usual assumption of cylindrical symmetry about bonds was made. The value of $(eQq)_D$ is in agreement with values obtained in other molecules. The value of ϵ is smaller by a factor of 2 than the value derived theoretically from known values of the magnetic constants in NH_3. (Contractor's abstract)

HYPERFINE STRUCTURE IN THE ℓ-TYPE DOUBLING SPECTRUM OF HCN, by L. Yarmus. July 1, 1956. 6p. incl. diagr. tables, refs. (Rept. no. 289.7) (AFOSR-TN-56-506) (AF 18(600)968) AD 110321 Unclassified

Also published in Phys. Rev., v. 104: 365-367, Oct. 15, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 13, Jan. 30, 1956.

Direct ℓ-type transitions for HCN have been observed for J = 1, 2, 3, 4, and 5. Values obtained of the asymmetry parameter η = -0.082 ± 0.005 and the magnetic coupling constant c_l = 13 ± 5 kc/sec are in good agreement with previous work. For N^{14} the value eq_mQ = -4.81 ± 0.02 mc/sec is 5% higher than that obtained in the ground vibrational state. This change in eq_mQ can be explained by a decrease in the hybridization of the σ bond. (Contractor's abstract)

A PRACTICAL APPROACH TO THE PROBLEM OF STALL FLUTTER, by C.-T. Wang, R. J. Vaccaro, and D. F. De Santo. June 1955 [12]p. incl. diagrs. tables. (Rept. no. 354-1) ([AF]OSR-TN-55-98) (AF 18(600)1372) AD 86237 Unclassified

A method is presented by which the real part of the dynamic moment coefficient may be obtained from a flutter test on a single blade oscillating in torsion alone in the stall region. The data may be used to predict the critical flutter velocity and frequency of a blade with the same geometrical properties oscillating with 2 degrees of freedom and having arbitrary elastic and inertial properties. The method could possibly be applied to cantilever blades by using either a representative section or a Rayleigh-type analysis. Flutter experiments were carried out in the 7- by 10-ft wind tunnel by using the NACA 0012 airfoil section and an airfoil section with a circular-arc mean chamber line of 25° included angle and NACA 0007 thickness distribution. The Reynolds number range for the tests was about 1 to 3 x 10^5.

FLUTTER VELOCITY AND AMPLITUDE PREDICTIONS ON ISOLATED BLADES IN STALLED FLOW BY SINGLE-DEGREE-OF-FREEDOM ANALYSIS, by R. J. Vaccaro. Jan. 1957 [106]p. incl. illus. diagrs. tables.

(Rept. no. 354-2) (AFOSR-TN-56-592) (AF 18(600)-1372) AD 115019 Unclasstfied

The stall flutter problem for isolated compressor blades is investigated by experimental means without an attempt at application of information from the classical theory. Consequently, significant aerodynamic data are sought in the stall region. A method is proposed whereby airforces may be computed, using the equations of motion, from a single degree of flutter test. These airforces take the form of a real and an imaginary part of the moment coefficient versus k for given values of initial angle of attack, elastic axis location, and airfoil shape. Prediction of flutter speeds and frequencies and estimates of torsional amplitudes of cantilever blades installed flow can then be made.

NEGATIVE ION EFFECT IN HALOGEN QUENCHED GEIGER COUNTERS, by H. Sherman. Aug. 8, 1956, 1v. incl. diagrs. tables, refs. (AFOSR-TR-56-32) (AF 18-(600)1460) AD 95807 Unclassified

Using pulsed x-rays as a source of ionization, measurements of time lags have been made in Geiger counters filled with the following gases: Ne and Cl_2; Ne, A, and Cl_2; A and I_2; Ne and I_2; and Kr and I_2. The values of time lags observed range from 13 to 0.3μ sec depending upon the concentration of halogen gas in the counter and the overvoltage. It is shown that the delays cannot be due to negative ions, but are probably caused by the relatively long time that it takes for the halogen molecules to de-excite the noble gas metastables formed in the avalanche. Assuming that negative ions are formed in the counters, Shinohara and Akuisu (Jour. Sci. Res. Inst. (Tokyo), v. 47: 80, 1953) have given a quantitative description of the variation in counter efficiency as a function of the radial distance of the ionizing event from the central wire. Using a collimated beam of x-rays to excite the counter, the above theory has been tested, and good agreement of theory and experiment has been found. In particular, it has been shown that the formation of negative ions may sharply reduce the efficiency of a counter near the cathode. An extension of the above theory indicates that another effect of negative ions is to increase the plateau slopes of these counters. Detailed observations of plateau slopes support this conclusion. PHOTO-THERMOELASTICITY: AN EXPLORATORY STUDY, by G. Gerard and A. C. Gilbert. May 1956 [37]p. incl. illus. diagrs. tables. (Technical rept. no. SM 56-11) ([AF]OSR-TN-56-237) (AF 18(600)-1471) AD 88357 Unclassified

The optical and physical properties of the photoelastic plastic, Paraplex P-43 were determined from 70° to -40°F. This castable polystryrene resin is free from the time-edge effect and can be cemented with relative ease. The techniques and equipment described were developed to obtain the modulus of elasticity, the material fringe value, and the thermal expansion coefficient as a function of temperature. Procedures are recommended for the embedding of thermocouples in P-43 that do not cause disturbances in the observed fringe pattern. Satisfactory correlation was obtained between the observed and the theoretically determined fringe distributions in disk and long beam models which were representative of the interference and the thermal gradient type of thermal stress fields, respectively. For short beams, severe end effects were observed which extended for a distance about equal to the beam depth. During the initial stages of sudden temperature application, the thermal stress field at the upper edge and free end regions were independent of the beam dimensions.

NOTE ON PHOTOTHERMOELASTICITY, by G. Gerard and A. C. Gilbert. [1956] [1]p. incl. illus. [AF 18(600)1471] Unclassified

Published in Jour. Aeronaut. Sciences, v. 23: 702-703, July 1956.

Investigation has been made into the use of photoelastic techniques to determine thermal stresses arising from transient temperature gradients. Since photoelastic materials generally creep when exposed to elevated temperatures, the temperature gradient was established by refrigeration. The temperature gradient was applied to the upper surface of a beam, and fringe photographs were taken of the model in a polariscope at successive time intervals. Thermocouples were used to monitor the temperature distribution. The first picture was taken at time of maximum fringe order. The succeeding pictures taken showed that the fringe order decreased as the temperature gradients became less severe.

The existence of even or odd solutions of Mathieu's

NYU.06:002 - NYU.06:005

equation with period π or 2π depends on the vanishing of certain infinite determinants. These determinants were expressed in terms of the values of the even or odd solutions at $x = \pi/2$, where x is the independent variable. The method applied uses theorems about the order of growth of the solutions with respect to both x and the parameters. A representation of the solutions as a finite Fourier integral was also derived by the method. An indication is given as to how far the results can be extended to the case of more general equations of Hill's type. The periodic solutions of the inhomogeneous Mathieu equations were constructed by using an inversion formula for certain infinite matrices. The connection between Hill's equation and the construction of transparent layers is reviewed.

THE SCOPE OF THE IMAGE METHOD, by J. B. Keller. Apr. 1953, 10p. incl. illus. (Research rept. no. BR-2) (AF 18(600)367) AD 11888 Unclassified

Also published in Communications on Pure and Appl. Math., v. 6: 505-512, Nov. 1953.

The image method is defined for regions in Euclidean n-space bounded by planes, and all the regions to which it applies are determined for every boundary-condition choice. The boundary conditions considered include $G = 0$, $\partial G/\partial n = 0$, and $\partial G/\partial n + hG = 0$, where G represents Green's function and h is a constant. The method is also applicable to differential equations on the surface of a sphere and to regions bounded by great circles. All the regions on the sphere to which the method applied are obtained. The main difficulty in extending the method to Riemann surfaces is the construction of the Green's function for full space. An extension is also possible to regions bounded by an even number of pair-wise parallel planes with the boundary condition of periodicity. For certain regions only a finite number of images occur, and the sums used in defining the Green's function are finite. Convergence of the sums must be examined for other cases.

ALGEBRAIC ASPECTS IN THE THEORY OF SYSTEMS OF LINEAR DIFFERENTIAL EQUATIONS, by W. Magnus. June 1953, 35p. refs. (Research rept. no. BR-3) (AF 18(600)367) AD 14714 Unclassified

Also published in Communications on Pure and Appl. Math., v. 7: 649-673, Nov. 1954.

A discussion is presented of the connection between the Baker-Hausdorff formula and systems of linear differential equations. A proof is given of an algebraic theorem which characterizes Lie-elements in a free non-commutative ring, and analytic criteria are derived for the existence of solutions of systems of linear differential equations in terms of a finite number of quadratures. The range of validity is discussed for the representation of solutions in the form of an exponential function of a matrix. The case corresponding to a second-order differential equation is studied in detail. (ASTIA abstract)

EIGENFUNCTION EXPANSIONS ASSOCIATED WITH A NON-SELF-ADJOINT DIFFERENTIAL EQUATION, by B. Friedman and L. I. Mishoe. Jan. 1954, 29p. (Research rept. no. BR-4) ([AF]OSR-TN-54-24) (AF 18(600)367) AD 18195 Unclassified

Also published in Pacific Jour. Math., v. 6: 249-270, 1956.

Consideration is given to the problem of expanding a function of bounded variation in terms of the eigenfunctions of a non-self-adjoint differential system, $u'' + q(x)u + \lambda[p(x)u - u'] = 0$, where $u(0) = u(1) = 0$. Restrictions which were previously imposed were eliminated. A proof is given of the theorem: Let $F(x)$ be a function of bounded variation for $0 \leq x \leq 1$ and let $u_n(x)$ be the eigenfunctions of the system $(A + \lambda B)u = 0$, $u(0) = u(1) = 0$, where A is the operator $\frac{d^2}{dx^2} + q(x)$ and where B is the operator $-\frac{d}{dx} + p(x)$. Further, let $v_n(x)$ be the eigenfunctions of the system adjoint to $(A + \lambda B)u = 0$, $u(0) = u(1) = 0$; and let $C(\lambda)e^{\lambda x}$ be the Wronskian of the equation $(A + \lambda B)u = 0$. If

$$F(0+) + \exp\left[-\int_0^1 p\,dt\right] F(1-) = 0(I),$$

then the series

$$\sum_{-\infty}^{\infty} u_n(x) \int_0^x F(\xi)\left[\frac{p(\xi)v_n(\xi) + v_n'(\xi)}{C'(\lambda_n)}\right] d\xi \quad (II)$$

converges to $F(x)$ at every point where $F(x)$ is continuous in $0 < x < 1$. At all other points, the series converges to $\frac{1}{2}F(x + 0) + \frac{1}{2}F(x - 0)$. If $F(x)$ does not satisfy the boundary conditions I, then the series II converges to

$$\tfrac{1}{2}F(x + 0) + \tfrac{1}{2}F(x - 0) - \tfrac{1}{2}\exp\left[\int_0^x p\,dt\right]\left[F(0+) + \exp\left[-\int_0^x p\,dt\right] F(1-)\right].$$

ON THE EXPONENTIAL SOLUTION OF DIFFERENTIAL EQUATIONS FOR A LINEAR OPERATOR, by W. Magnus. [1954] [25]p. [AF 18(600)367] Unclassified

Also published in Communications on Pure and Appl. Math., v. 7: 649-673, Nov. 1954.

The first pari of the paper gives a proof and applications oi a characierization oi the Lie elemenis in a iree associative algebra R with n free generators $x_1, \ldots, x_n$ over a field f_0 with zero characieristic applied by Friedrichs in his quantum-mechanical investigaiions (same Communications, v. 6: 1-72, 1953). An element of R can be uniquely wriiien as a linear combination $F(x_1, \ldots, x_n)$ of power producis $x_{\nu_1}^{\alpha_1} \ldots x_{\nu_m}^{\alpha_\nu}(\nu_1 \neq \nu_2 \neq \ldots \neq \nu_m; m = 0, 1, \ldots)$ with coefficienis from f_0 or, in an exiended sense, as a formal power series. A Lie element of R is an elemeni which can be generaied from $x_1, \ldots, x_n$ by the Lie multiplication $[uv] = uv - vu$ and linear combinations. Let R' be an isomorphic replica of R, and $\bar{R}$ the direci produci of R and R'. $\bar{R}$ is generated, say in case of iwo generaiors $x_1 = x$, $x_2 = y$ of R, from four generaiors x, y, x', y' satisiying the conditions $xx' = x'x$, $xy' = y'x$, $yx' = x'y$, $yy' = y'y$. Friedrichs' iheorem says: $F(x, y)$ is a Lie elemeni if and only if $F(x + x', y + y') = F(x, y) + F(x', y')$. The author gives a proof of the theorem and applies it io a derivation of ihe Baker-Hausdorff iormula which shows thai ihe unique soluiion z of the equation $e^x e^y = e^z$ is a Lie elemeni oi ihe iree algebra generaied by x and y. The author further investigaies a coniinuous analogue oi the Baker-Hausdorii iormula: iei A(i) be a known function in R oi a real parameier i. Assuming thai a differeniiation with respeci io i may be defined obeying ihe ordinary laws of differeniiaiion, the differeniial equation $dU/di = AU$ with the initial condition $U(0) = 1$ may be considered. The problem is io show ihai the soluiion U(i) can be wriiien in the iorm $U(i) = \exp\Omega(i)$ with an $\Omega(i)$ obiainable from A(i) by the operations of Lie multiplicaiion and iniegration processes. A iormula is obtained satisfying these requirements (see also corresponding considerations in Feynman, Phys. Rev., v. 84: 108-128, 1951). The convergence questions connected with the formula are then discussed in the second part of the paper, in particular for the iinite mairix algebra over the complex field and various sufiicient conditions ior convergence are obtained. AN ABSTRACT FORMULATION OF THE METHOD OF SEPARATION OF VARIABLES, by B. Friedman. July 1955, 25p. incl. diagrs. (Research repi. no. BR-12) ([AF]OSR-TN-55-219) (AF 18(600)367) AD 68272 Unclassified

Also published in Proc. Conierence on Differential Equations, Maryland U., College Park, Mar. 17-19, 1955, p. 209-226.

The concept oi the direct product oi Hilberi spaces is used to show that the idea oi the separation of variables leads to a method ior solving operator equations in which the operaior is a sum oi the direct products oi operators in the iactor spaces. A discussion oi the manner in which boundary conditions aiiect the use oi

separation of variables shows that certain boundary-value problems for hyperbolic equations have a well-defined solution. A contour integral representation for the solution of some partial differential equations is obtained which, by suitable deformation of the contour, gives alternative representations for the solution. This representation shows that the Green's function for a partial differential equation may be written as the convolution of the Green's function for the separated ordinary differential equations. A study of the form of the solution given by the contour representation indicates the manner in which the Sommerfield radiation condition ensures the uniqueness of the solution of boundary-value problems for infinite domains.

ASYMPTOTIC SOLUTIONS OF MAXWELL'S EQUATIONS INVOLVING FRACTIONAL POWERS OF THE FREQUENCY, by M. Kline. Oct. 1955 [20]p. incl. diagrs. refs. (Research rept. no. BR-14) ([AF]OSR-TN-55-396) (AF 18(600)367) AD 82977 Unclassified

Also published in Communications on Pure and Appl. Math., v. 8: 595-614, Nov. 1955.

A pulse solution of Maxwell's equations is the electromagnetic field resulting from a source having a Heaviside unit function time behavior. The corresponding steady-state solution is the field originating from the same source but having a harmonic time behavior. This mathematical study relates the singularities of the pulse solution (discontinuities of E, H, or their time derivatives) with respect to the time variable to the steady-state field. It shows that the steady-state field can be expressed as a sum of fields each determined by a singularity of the pulse solution. In particular, the asymptotic expansion of the steady-state field in powers of $1/\omega$, where ω is the harmonic frequency, is determined completely by the behavior of the pulse solution in the neighborhood of its singularities. The singularities permitted in this study include infinities of any one of the successive time derivatives of the pulse field vectors E and H and give rise to asymptotic series in fractional powers of $1/\omega$. The principal theorem generalizes an earlier result in which only the zeroth and positive integral powers of $1/\omega$ occurred in the asymptotic series. (Contractor's abstract)

OPERATORS WITH A CLOSED RANGE, by B. Friedman. Dec. 1955 [12]p. (Research rept. no. BR-16) ([AF]OSR-TN-55-398) (AF 18(600)367) AD 82978

Also published in Communications on Pure and Appl. Math., v. 8: 539-550, Nov. 1955.

Linear operators with closed ranges are studied in Hilbert space. It is proved that if a (possibly-bounded) operator L and its adjoint L^* have closed ranges, then so does the operator $L + D$, where D is any dyad operator, i.e., D is defined as $D = \sum_{i=1}^{k} a_i(b_i, x)$, where a_i and b_i, $i = 1, \ldots, k$, are elements of the Hilbert space. This result is used to give a simple proof of the "alternative" theorem for (1) systems of n simultaneous equations, and (2) equations of the form $x + Cx = a$, where C is any linear completely continuous operator. ON THE FUNCTIONS OF THE PARABOLIC CYLINDER, by D. I. Epstein. June 1956, 24p. (Research rept. no. BR-19) (AFOSR-TN-56-270) (AF 18(600)367) AD 88990 Unclassified

An addition theorem is obtained for the separated solutions of the reduced wave equation in parabolic cylinder coordinates; it is based on the property that the reduced wave equation is invariant under translations and rotations of the coordinate system. An interesting feature of the theorem is that the basic set of the separated solutions that are regular and one-valued everywhere is split into two disjoint subsets such that the addition theorem for the functions of one set involves functions of that set only. A brief discussion is devoted to the problem of expanding any separated one-valued regular solution in terms of the solutions belonging to the basic set. Certain integrals which arise in diffraction problems and involve functions of the parabolic cylinder are evaluated asymptotically for large values of a parameter. The parameter in question is the reciprocal wavelength of the incident electromagnetic field. (Contractor's abstract)

ON A FREDHOLM EQUATION IN DIFFRACTION THEORY, by I. J. Epstein. Oct. 1956, 31p. (Research rept. no. BR-20) (AFOSR-TN-56-489) (AF 18(600)367) AD 110302 Unclassifted

The problem of diffraction of a plane wave by a circular aperture in a place screen has been treated by Levine and Schwinger, who reduced it to a system of infinitely many linear equations. This system has been modified by Bouwkamp, and Magnus has proved that Bouwkamp's system is equivalent to a Fredholm integral equation of the second kind. If $\alpha = ka$, where k is the wave number of the incident wave and a denotes the radius of the circular aperture, then the coefficients of Bouwkamp's system depend on α. Their asymptotic behavior for $\alpha \longrightarrow \infty$ is investigated and explicit expressions for the first few terms are stated in this report. The integral equation equivalent to Bouwkamp's system degenerates into an integral equation of the first kind as $\alpha \longrightarrow \infty$. The solution of the degenerate integral equation can be given explicitly, and a perturbation method yields some formulas for the solution of the original equation if α is large.

PERSISTENT INTERNAL POLARIZATION, by H. P. Kallmann. Annual rept. Oct. 15, 1954-Oct. 14, 1955. Jan. 1956, 78p. incl. diagrs. tables, (Progress rept. no. 5) (AFOSR-TN-56-49) (AF 18(600)1004) AD 81041 Unclassifted

The behavior of persistent internal polarization (PIP) in various powder samples is investigated. Two methods are developed for producing samples having reproducible values of polarization under all conditions, the PIP of which can be predicted. The laws of light release and of spontaneous decay are considered, and the dependence of PIP on the thickness of the sample is determined. As a result of this study, a means of increasing considerably the polarization unit area has been found. A charge of over 10^{-7} coulombs/sq cm has been observed with a decay of only 25% in 24 hr. (Contractor's abstract, modified)

HOLE MOTION IN ANTHRACENE CRYSTALS, by H. P. Kallmann and M. Silver [1956] 3p. incl. tables. [AF 18(600)1004] Unclassifted

Published in Proc. of meeting on "Fluorescence and Photoconductivity," Garnisch-Partenkirchen (Germany), Aug. 1956.

The rectifying effect observed previously in inorganic photoconductive crystals and powders when these substances are excited in a thin layer adjacent to one of the electrodes has been explained on the assumption that the electron is the primary carrier of charge

since the current was larger when the excited layer was next to the negative electrode. Sentner observed the reverse effect in organic crystals. The conclusion being that holes are the primary carrier of charge here. These experiments have a limitation that the electrodes may have an unknown effect on the entire process. This paper describes experiments in which the effects of the electrodes are eliminated by measuring the rate of production and light release of the internal polarization. Since only the internal polarization is observed, there is no effect of electrodes on the process. These measurements confirm the conclusion that the positive holes are the more mobile charge carriers. (Contractor's abstract)

ON THE BOUNDARY LAYER WITH VARIABLE PRANDTL NUMBER, by E. R. van Driest. Sept. 1, 1954, 17p. diagrs. tables, refs. [AFOSR-TN-54-259] [AF 18(600)786] Unclassified

In supersonic flight, the heating of air vehicles due to friction in the boundary layer is becoming more and more acute, primarily for structural reasons. However, the relation between aerodynamic heating and fluid friction is a strong function of the Prandtl number, which is a measure of the relative capacities of the fluid to transport locally momentum and energy. The Prandtl number ordinarily varies across the boundary layer, and will be considered in this paper to be due to turbulent as well as laminar motion. Whether the boundary layer be laminar or turbulent, the variable Prandtl number appears in the recovery and Reynolds-analogy factors which arise in the mathematical analysis of the rate of heat transfer to or from the boundary layer. It is the object of this paper, therefore, to derive first the general expressions for the recovery and Reynolds-analogy factors valid for both laminar and turbulent flow and, then to calculate numerical results for experimental and design purposes. THE LAMINAR BOUNDARY LAYER WITH VARIABLE FLUID PROPERTIES, by E. R. van Driest. Jan. 19, 1954, 46p. incl. diagrs. (Rept. no. AL-1866) (AF 18-(600)786) AD 40547 Unclassified

The laminar boundary layer analysis of Crocco is extended to include variable Prandtl number. Accurate calculations on skin-friction and heat transfer coefficients and on recovery and Reynolds-analog factors are presented for flat plates subjected to a large range of Mach number in the isothermal atmosphere and in heated wind tunnels at supply temperatures from 0° to 2000°F. The NBS-NACA gas tables were used. Experimental data on recovery factor are compared with the theory. Boundary-layer stability is calculated. (Contractor's abstract)

THE TURBULENT BOUNDARY LAYER WITH VARIABLE PRANDTL NUMBER, by E. R. van Drtest. Apr. 2, 1954, 34p. incl. illus. refs. (Rept. no. AL-1914) [AF 18(600)786] AD 49814 Unclassified

The general theory for the solution of the energy equation for laminar boundary layers with variable Prandtl number is applied directly to the turbulent case in order to extend the von Kármán analogy between heat transfer and fluid friction to include a turbulence Prandtl number other than unity and a realistic sheer distribution other than constant across the turbulent portion of the boundary layer. The calculation of heat-transfer coefficients for high and low speeds is discussed, including application to liquid metals. The general heat-transfer theory is compared with data for the supersonic flow of air over a flat plate in a wind tunnel. (Contractor's abstract)

PRINCIPLES OF PRECISION COLORIMETRY. A GENERAL APPROACH TO PHOTOELECTRIC SPECTROPHOTOMETRY, by C. N. Retitey and C. M. Crawford. Nov. 1954 [38]p. tncl. diagrs. tabtes. (Repl. no. Chem. no. 1-CNR) ([AF]OSR-TN-54-364) (AF 18(600)1160) AD 59506 Unclassified

Also published in Anal. Chem., v. 27: 716-725, May 1955.

An inquiry has been made into the effect of slit width, sensitivity, and dark current knob settings on spectrophotometric precision with a view toward the development of improved high-precision methods. An expression for the relative error is derived, and the conditions for its mtnimization are discussed under assumptions sufficiently general to include and extend previous

techniques. Four methods are distinguished, of which 2 are new. One of the new methods gives the best precision attainable, using 2 reference solutions and other conditions selected to make this statement true. The selection procedure is described. The other new method is applicable to trace analysis, and represents a compromise when solutions sufficiently concentrated to permit optimum conditions are not available. Both methods promise, in their respective applications, substantial improvement in precision over former methods at small extra cost in time and effort. (Contractor's abstract, modified)

CHRONOPOTENTIOMETRIC TITRATIONS, by C. N. Reilley and W. G. Scribner. Feb. 1955 [23]p. incl. diagrs. (Rept. no. Chem. no. 2-CNR) ([AF]OSR-TN-55-63) (AF 18(600)1160) AD 58135 Unclassified

Also published in Anal. Chem., v. 27: 1210-1215, Aug. 1955.

A new method of end point detection based upon chronopotentiometry is described. The relationship between chronopotentiometric and potentiometric titrimetry is discussed, as well as the possible types of titration curves and the factors which govern the sensitivity of the method. Although chronopotentiograms of a permanent sort are more easily obtained with a recorder, variable transition times for titrations can be measured simply and conveniently with only a "B" battery, variable resistor, pH meter, and a stop watch. The method is illustrated by the titration of ferric ion with ceric ion, copper ion with versene, arsenic ion with iodine, and the successive titration of a mixture of stannous and ferrous ions with ceric ion. The method has the advantages of the amperometric method, but seems especially applicable to the titration of small volumes or concentrations, and in situations where stirring is undesirable. AMPEROMETRIC TITRATION OF TWO- AND THREE-COMPONENT MIXTURES OF METAL IONS WITH EDTA, by C. N. Reilley, W. G. Scribner, and C. Temple. Aug. 1955 [21]p. incl. diagrs. tables. (Rept. no. Chem. no. 3-CNR) ([AF]OSR-TN-55-342) (AF 18(600)1160) AD 75459 Unclassified

Also published in Anal. Chem., v. 28: 450-454, Apr. 1956.

The combined use of cathodic diffusion current of metal ions and anodic diffusion current of EDTA (ethylenediaminetetraacetate) under controlled pH conditions made possible the successful amperometric titration of multicomponent mixtures. In this way the successive titration of a bismuth-lead-calcium, iron-manganese, or copper-calcium mixture was effected. The results of an experimental survey of the stability of the 15 common metal ions with EDTA at pH 2, 4, and 9.1 indicate the feasible titration of each under certain conditions. Cobalt (II) ethylenediaminetetraacetate was found to give an anodic wave with a half-wave potential of +0.140V vs SCE independent of pH from 4.5 to 10.5. The stability constant of cobalt(III) ethylenediaminetetraacetate was then computed to be $10^{40.7}$ (μ = 0.1). Two new polarographic methods for determining stability constants are described and their limitations are discussed. (Contractor's abstract)

COULOMETRIC TITRATIONS WITH ELECTRICALLY GENERATED EDTA, by C. N. Reilley and W. W. Porterfield. Oct. 1955 [18]p. incl. diagrs, table. (Rept. no. Chem. no. 5-CNR) ([AF]OSR-TN-55-343) (AF 18(600)1160) AD 75458 Unclassified

Also published in Anal. Chem., v. 28: 443-447, Apr. 1956.

An investigation was undertaken to test the feasibility of extending the application of coulometric titrations into complexometry. If a general method for the coulometric generation of ethylenediaminetetraacetic acid (EDTA or H_4Y) could be found, it would be highly probable that the coulometric method could be used for the successful titration of the alkaline earths, rare earths, and metal ions such as Mn^{2+}, Fe^{2+}, Co^{2+}, Ni^{2+}, Cu^{2+}, Ca^{2+}, Zn^{2+}, Cd^{2+}, Hg^{2+}, Pb^{2+}, Al^{3+}, In^{3+}, Th^{4+}, Pd^{2+}, Bi^{3+}. The solution of the problem required the discovery of a mode of generating EDTA with 100% current efficiency, and the development of a compatible and

NCU. 01:006 - NCU. 01:008

sensitive endpoint detection device. Successful coulometric titration of Ca, Cd, Zn, and Pb ions was accomplished by the indirect electrical generation of EDTA released upon reduction of mercuric EDTA chelate at an Hg pool. The pertinent equilibrium conditions are summarized in a potential-vs-pH diagram which, in conjunction with polarograms for kinetic effect, gives information concerning the solution conditions desired. Extension of the method to the titration of other metal ions appears feasible.

A RAPID ELECTROCHEMICAL METHOD FOR THE DETERMINATION OF METAL CHELATE STABILITY CONSTANTS, by R. W. Schmid and C. N. Reilley. [1956] [19]p. incl. diagrs. table, refs. (Rept. no. Chem. no. 6-CNR) (AFOSR-TN-56-213) (AF 18(600)-1160) AD 87529 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 5513-5518, Nov. 5, 1956.

An outline is presented of a proposed potentiometric method for the rapid and simple determination of stability constants of 1:1 metal chelates (1 mol of chelating agent reacting with 1 mol of metal ion) under equilibrium conditions. Determinations were made of the stability constants of various metal ions with the chelating agent, ethylenediaminetetraacetic acid (EDTA), for comparison with constants obtained by the original and modified Bjerrum methods (Bjerrum, Metal Ammine Formation in Aqueous Solution, P. Haase and Son, Copenhagen, 1941; and Helv. Chim. Acta, v. 34: 1492, 1951) and the polarographic method (Chem. Revs., v. 29: 1, 1941). For a solution of EDTA and a mercuric-EDTA complex, a stability constant of $10^{22.1}$ was calculated between pH 4 and 8. One EDTA ion reacted with 2 different metal ions when at least one of the metal ions was Hg^{++}; the bimetal complex formed more easily at lower pH's. The method fails with metal chelate complexes whose cations hydrolyze easily, and with metal chelates which have relatively negative oxidation potentials.

A NEW INDICATOR FOR THE COMPLEXOMETRIC TITRATION OF CALCIUM AND MAGNESIUM, by G. P. Hildebrand and C. N. Reilley. [1956] [18]p. incl. diagrs. tables, refs. (Rept. no. Chem. no. 7-CNR) (AFOSR-TN-56-408) (AF 18(600)1160) AD 96217 Unclassified

Also published in Anal. Chem., v. 29: 258-264, Feb. 1957.

An improved method is described for titrating Ca with ethylenediaminetetraacetic acid (EDTA) after Mg is precipitated as MgOH by the addition of KOH (pH ≈12 to 13). Calcon (Helv. Chim. Acta, v. 31: 678, 1948) was considered to be applicable for titration of Ca in the presence of Mg at high pH (12.5). The color change with calcon (Color Index 202) is sharp from pink through purple to pure blue. The continuous variation method was used to determine the ratio of dye to metal ion in Ca complex with calcon. At pH 12.25, the stability of the dye in the complex was poor. As the time increased, the solutions which contained appreciable amounts of the complex decreased in absorbance to give an over-all effect of increasing the value of n, where n is the number of dye molecules/Ca^{++}. After standing for 30 min, the n value increased from 1.07 to 1.09, and after 90 min to 1.19. Data indicated a 1:1 ratio between the Ca^{++} and the dye for the complex at pH 12.25. The values for the ionization constants of the dye were calculated from the absorbance-vs-pH curve, and the stability constants of the metal-dye complexes were determined. Methods for determining Ca and Mg are described.

A NEW COMPLEXON FOR THE TITRATION OF CALCIUM IN THE PRESENCE OF MAGNESIUM, by R. W. Schmid and C. N. Reilley. [1956] [15]p. incl. diagrs. tables, refs. (Rept. no. Chem. no. 8-CNR) (AFOSR-TN-56-409) (AF 18(600)1160) AD 96218 Unclassified

Also published in Anal. Chem., v. 29: 264-268, Feb. 1957.

The complexometric determination of Ca and Mg has found wide application in the analysis of H_2O, limestones, soils, and physiological studies. A procedure is proposed which avoids a chemical separation of the 2 elements by employing a titrant which will selectively complex Ca. The titrations of various samples were designed in a block to detect statistically any possible influence of Mg on the results of the Ca titration with ethyleneglycol-bis-(β-aminoethylether)-N, N' tetraacetic acid (I). Titrations were carried out at 5 concentration levels of Ca (1.5, 2.5, 4.0, 6.0, and 10.0 mg). For each level, the titrations were carried out in different concentrations of Mg present (1:0, 1:1, 1:2, 1:5, and 1:10). The amount of Mg is designated as the molar ratio of Mg to Ca. The presence of Mg in the range investigated does not have any significant influence on the results obtained for titration of Ca with I, but a variation of slightly more than 5% between the levels of amount of Ca was found. This is probably caused by the difference in accuracy obtained when various amounts of titrant volume are used. The error for a single Ca titration was ±0.83% with 95% confidence limits, the average error being ±0.30%. The values found for Mg were obtained by difference. The average error of ±0.7% is about twice as large as the average error in the Ca titration.

ON A CLASS OF LINEAR DIFFERENTIAL SYSTESM, by W. M. Whyburn. June 1955, 19p. (Rept. no. 1) ([AF]OSR-TN-55-136) (AF 18(600)1139) AD 65674 Unclassified

Also published in Rev. de Ciencias (Lima, Peru), v. 60: 43-59, 1958.

A study is made of linear differential systems of type: $Y' + P(x)Y - YQ(x) = R(x)$, $A_1Y(a)A_2 + B_1Y(b)B_2 = C$, where capital letters represent n x n matrices. Systems of this form arise in studies of adjoint relationships, and in applied problems. While these might be replaced by systems of more conventional form, where the matrices involved are of order n^2, definite advantages are gained by direct treatment. This study indicates some of these advantages and displays resolvent roles played by systems of types: $U' + P(x)U = 0$, $A_1U(a) + B_1U(b) = 0$; $V' - VQ(x) = 0$, $V(a)A_2 - V(b)B_2 = 0$. DIFFERENTIAL SYSTEMS WITH BOUNDARY CONDITIONS AT MORE THAN TWO POINTS, by W. M. Whyburn. [1955] 21p. refs. [AF 18(600)1139] Unclassified

Published in Proc. Conference on Differential Equations, Maryland U., College Park (Mar. 17-19, 1955), 1956, p. 1-21.

Differential systems are discussed which consist of a set of n first order ordinary differential equations in $y_i(x)$, $(i = 1, \ldots, n)$, together with boundary conditions that may involve the values of these functions at more than two points of a fixed interval X: $a \leq x \leq b$. For systems involving "initial" values at more than one point there is given a brief survey of known results; in the case of a system of the form

(*) $y_n' = f_n(x, y)$, $y_i' = f_i(x, y) + g_i(x, y)y_{i+1}$ $(i = 1, \cdots, n-1)$, in $y = (y_1, \cdots, y_n)$ the author employs a theorem of R. Conti (Ann. Mat. Pura Appl., v. 35: 155-182, 1953) to establish various results concerning the dependence of solutions on the initial points and initial values. There is established also an existence theorem for a system involving a set of differential equations somewhat more general than (*) and initial values at more than one point. A survey is presented of the literature on systems consisting of a set of linear differential equations and boundary conditions involving the values of the $y_i(x)$ at the endpoints of X and also at the points of a given subset of $a < x < b$ of suitable character, with special attention to the case of discontinuous solutions restricted by interface conditions. A NON-LINEAR BOUNDARY VALUE PROBLEM FOR SECOND ORDER DIFFERENTIAL SYSTEMS, by W. M. Whyburn. [1955] [14]p. (AF 18(600)1139) Unclassified

Published in Pacific Jour. Math., v. 5: 147-160, Mar. 1955.

The author proves the existence of sets of characteristic numbers for nonlinear systems of the form $dy/dx = K(x, y, z; \lambda)z$, $dz/dx = g(x, y, z; \lambda)y$ with the boundary conditions $\psi(a, \lambda) = o$, $\phi(a, \lambda) = \phi(b, \lambda)$, where $\psi(x, \lambda) = \gamma(x, \lambda)z(x, \lambda) - \delta(x, \lambda)y(x, \lambda)$, $\phi(x, \lambda) = d(x, \lambda)z(x, \lambda) - \beta(x, \lambda)y(x, \lambda)$, $\beta(x, \lambda)$ does not change sign, $\delta(a, \lambda) \pm o$ and $\Delta(\lambda) = d(a, \lambda)\delta(z, \lambda) - \beta(a, \lambda)\gamma(a, \lambda) \pm o$ and gives oscillation theorems for the associated solutions. The method used and the results obtained generalize and extend those given in an earlier paper of the author (Trans. Amer. Math. Soc., v. 30: 848-854, 1928). (Math. Rev. abstract)

IMPROVED APPROXIMATIONS TO DIFFERENTIAL EQUATIONS BY DIFFERENCE EQUATIONS, by W. R. Mann, C. L. Bradshaw, and J. G. Cox. Jan. 1956, 11p. incl. tables. (Rept. no. 2) (AFOSR-TN-56-57) (AF 18(600)1139) AD 81049 Unclassified

Also published in Jour. Math. and Phys., v. 35: 408-415, Jan. 1957.

The purpose of this mathematical study is to illustrate a method for approximating differential equations with difference equations more closely than is done with the usual finite difference approaches, but without introducing higher order differences. The method involves using a "star" having no greater thickness, in the direction of any one independent variable, than the order of the differential equation being approximated. Using such a star, further reduction in truncation error is achieved by properly adjusting the "weights" with which the various points enter. The study is taken up largely with an illustration of the usefulness of the method in the solution of a 2-region, 2-dimensional, 1-group reactor problem which is simple enough to be solved analytically. Numerical data, obtained on the ORACLE of the Oak Ridge National Laboratory, enable a comparison to be made of the analytical solution for the buckling with values obtained by the ordinary difference methods and those obtained by the refined process presented. The results show that the refined process gives significantly greater accuracy than the ordinary difference methods, and the cost in increased labor is comparatively small.

ON THE THEOREMS OF LEDERMANN AND OSTROWSKI ON POSITIVE MATRICES, by A. Brauer. Feb. 1957 [14]p. (Technical rept. no. 3) (AFOSR-TN-56-338) (AF 18(603)38) AD 95214 Unclassified

Also published in Duke Math. Jour., v. 24: 265-274, June 1957.

Let A be a positive matrix, R the greatest and r the smallest sum of the elements of a row. It was proved by Frobenius that the greatest positive characteristic root ω of A satisfies the inequalities $r \leq \omega \leq R$. This result was improved by Ledermann and by Ostrowski who obtained bounds for ω as function of R, r, and the smallest element m of A. In this paper, the best possible bounds for ω as function of R, r, and m are obtained. These results are further improved by replacing m by the elements of the main diagonal and the minima of the off-diagonal elements of certain columns. Moreover, the result of Frobenius that ω is greater than or equal to the greatest element of the main diagonal is improved. (Contractor's abstract)

A NEW PROOF OF THEOREMS OF PERRON AND FROBENIUS ON NON-NEGATIVE MATRICES. I. POSITIVE MATRICES, by A. Brauer. May 1957, 17p. refs. (Technical rept. no. 4) (AFOSR-TN-56-576) (AF 18-(603)38) AD 110398 Unclassified

Also published in Duke Math. Jour., v. 24: 367-378, Sept. 1957.

The theorem of Perron and Frobenius is considered which states that a positive matrix A has a positive characteristic root ω which is simple and greater than the moduli of all the other characteristic roots of A. The coordinates of a characteristic vector belonging to ω are chosen as positive numbers. The proof gives a simple method to compute ω and the coordinated of a characteristic vector belonging to ω without determining the characteristic equation. The roots ($|z \leq \omega$ greatest positive root) are shown to lie in the interior or on the boundary of the oval of Cassini $|z - a_{ii}||z - a_{jj}| \leq (\omega - a_{ii})(\omega - a_{jj})$ with a_{ii} and a_{jj} the two smallest elements of the main diagonal of A.

PARTIALLY BALANCED INCOMPLETE BLOCK DESIGNS WITH TWO ASSOCIATE CLASSES AND THREE REPLICATIONS, by W. H. Clatworthy. June 1952, 136p. incl. tables, refs. (Mimeograph series no. 54) (AF 18(600)83) Unclassified

The object of this investigation is to completely enumerate the arithmetically possible connected partially balanced incomplete block designs with two associate classes and three replications, and either to give constructions for the new designs having $3 \leq k \leq 10$ or else prove them impossible. This objective has been achieved. It was hoped that this investigation would result in several new designs, thus making available to the experimenter a large number of designs from which he could choose the most appropriate one for his particular experiment. As it turned out, there are only three new designs with r = 3 and all other designs were shown to be impossible. Several closely related to those under investigation were either solved or proved impossible.

ASYMPTOTIC SOLUTIONS OF COMPOUND DECISION PROBLEMS, by J. F. Hannan. Apr. 23, 1953, 77p. incl. refs. (Mimeograph series no. 68) (AF 18(600)83) Unclassified

Robbins introduced the idea of a compound decision problem and showed that in the case where the component decisions were between N(-1, 1) and N(1, 1) there exists a decision function $\underline{t}$ whose risk approaches the risk of the best "simple" decision function based on a knowledge of the proportion of component problems in which the true distribution is N(1, 1). In Chapter I this result was generalized to two (arbitrary) fully specified populations and strengthen the conclusion by the replacement of "simple" by "invariant." In Chapter II a theorem was proved which made this strengthening possible, obtaining its proof by a Density Central Limit Theorem (DCLT) for n-concave densities which was applied to the generalized binomial (GB). In Chapter III the exact distribution was found of the statistic D_n^+ and was used to obtain an elementary derivation of the asymptotic distribution (originally obtained by Kolmogoroff).

ON A HEURISTIC METHOD OF TEST CONSTRUCTION AND ITS USE IN MULTIVARIATE ANALYSIS, by S. N. Roy. [June 1953] [19]p. refs. (Reprint series no. 38) [AF 18(600)83] Unclassified

Published in Ann. Math. Stat., v. 24: 220-238, June 1953.

In this paper two closely related heuristic principles of test construction called Type I and Type II methods, of which Type II is identified with the usual likelihood ratio method, are noticed as underlying most of the classical tests of hypothesis, simple or composite, on means of univariate normal populations and on total or partial correlations or regressions in the case of

multinormal vartates. In these sttuations the two methods are found to lead to identical tests hzvtng properties which happen to be very good tn certatn cases and moderately good tn others. For certain types of compostte hypotheses an extenc'on ts then made of the Type I method which ts applted to construct tests of three dtfferent classes of hypotheses on multinormal populattons (so as to cover, between them, a very large area of multivariate analysis), yielding in each case a test in general different from the correspond.ng and current likelihood ratio test. In each case, however, the two tests happen to come out identical for some degenerate "degrees of freedom." In contrast to the likelthood ratio rest tt ts found that in these cases, for general "degrees of freedom," the correspondtng Type I test is much easter to use on small samples, because of the relatively greater simplicity of the corresponding small sample distribution problem under the null hypothesis. In each case a lower bound of the power function of the Type I test is also given (against all relevant alternatives), anything ltke which, so far as the author ts aware, would be far more dtfftcult to obtatn for the Type II tests tn these sttuattons. In thts paper the general approach to the two methods ts enttrely of a heurtstic nature except that, under fairly wtde condtttons, a lower bound to the power functions for each of the two types of tests ts tndtcated to be readtly available, which, however, ts much too crude or wide a bound tn general. TWO-STAGE PROCEDURES FOR ESTIMATING THE DIFFERENCE BETWEEN MEANS, by S. G. Ghurye and H. Robbtns. Aug. 1953, 15p. tables. (Mtmeograph sertes no. 80) (AF t8(600)83) AD 17840 Unclasstfted

Also published in Btometrika, v. 41: 146-152, June 1954.

Two populations P_t (t = 1, 2) wtth unknown means θ_i and vartances σ_t^2 are gtven, and the difference $\theta_1 - \theta_2$ ts to be estimated. If the mean $(X_{t,1} + X_{1,2} + \ldots + X_{t,n})/n$ of a sample from P_t ts denoted by $t_i(n)$, then $t_1(n_1) - t_2(n_2)$ ts an unbtased estimate of $\theta_1 - \theta_2$ with vartance $\sum_1(\sigma_t^2/n_t)$. Assumtng the cost of sampltng to be a known tinear function of the number of observations, the cost of taking n_1 observations from P_1 and n_2 from P_2 ts $a_1n_1 + a_2n_2 + a_3$. If there ts a prescrtbed upper bound A_0 to the cost of sampltng, n_1 and n_2 are subject to the restrtction $a_tn_1 + a_2n_2 \leq A = A_0 - a_3$. When the ratio σ_2/σ_1 on which the expresston for the optimum values depend ts not known, a 2-stage procedure for estimattng $\theta_1 - \theta_2$ can be used, taking a sample of $m_t + m_2$ observations, m_t from P_t, then ustng estimales of σ_t obtained from this preltmtnary sample to dtstribute the remaining observattons between P_t. The performance of thts esiimation procedure was investigated. The P_t was assumed to be normal, and the variance of the 2-stage estimate was evaluated. It was shown that as m_1, m_2, and A approach ∞ in a certain way, the ratio of this variance to the minimum variance $V^0(A)$ tends to unity. The asymptotic result for more generat populattons was also proved. (ASTIA abstract)

SEQUENTIAL PROCEDURES IN PROBIT ANALYSIS, by T. V. Narayana. Special rept. Oct. 1953, 108p. incl. diagrs. tables, refs. (Mimeograph series no. 82) (AF 18(600)83) AD 25735 Unclassified

Studies were made on the problem of estimating the dose corresponding to the median effective dose (ED50) from a series of tests for quantal responses; the case when observations are taken on individuals rather than on groups of individuals is considered essentially. A résumé is given of the results of Mood and Dixon (Jour. Amer. Stat. Assoc., v. 43: 109-126, 1948). A stochastic approximation process of Robbins and Monro is considered with reference to the problem. Consideration is given to the application of the Mood and Dixon method to rankits where tolerance is supposed to be rectangularly distributed rather than normally. Studies were made of 2 alternative techniques of procedure (the 1-rule and the 3-rule) which aim at concentrating testing near the mean. The 1-rule takes into account at the n^{th} observation all of the previous observations on the level on which the n^{th} trial was made. The total number of successes and failures on this level is used, together with the result of the n^{th} observation, to decide where the next trail is made. The 3-rule is similar to the 1-rule, but takes into account the results of all previous observations on any particular level as well as of the observations on the 2 neighboring levels in deciding where the next trial is made. The performances of the Mood and Dixon method, 1-rule, and 3-rule are compared in small samples. The asymptotic properties of the Mood and Dixon method and the 1- and 3-rules are investigated. The actual asymptotic probability distribution was obtained for (1) rankit analysis and (2) a truncated normal population. Methods of analyzing data obtained by the 1- and 3-rules in samples of moderate sizes are considered.

SIMULTANEOUS CONFIDENCE INTERVAL ESTIMATION, by S. N. Roy and R. C. Bose. [Dec. 1953] [24] p. (Reprint series no. 43) (AF 18(600)83) Unclassified

Published in Ann. Math. Stat., v. 24: 513-536, Dec. 1953.

This paper discusses (in section 1) a set of sufficient conditions under which simultaneous confidence interval estimation is possible. In section 2 some univariate examples are considered. Sections 3 to 6 are concerned with multivariate applications. Section 3 gives the notation and preliminaries for multivariate applications. Section 4 gives confidence bounds on linear functions of means for multivariate normal populations. Sections 5 and 6 give respectively confidence bounds on certain functions of the elements of population covariance matrices and population canonical regressions, from which a chain of simpler consequences would follow by the application of a set of matrix theorems. This has been partly indicated in this paper.

ON A CLASS OF DECISION PROCEDURES FOR RANKING MEANS, by K. C. Seal. Special rept. June 1954, 109p. incl. tables, refs. (Mimeograph series no. 109; CIT rept. no. 13) ([AF]OSR-TN-54-234) (AF 18(600)-83) AD 51378 Unclassified

Also published in Ann. Math. Stat., v. 26: 387-398, Sept. 1955.

An infinite class of multiple procedures is suggested for ranking means of $(n + 1)$ normal populations with a common but unknown variance. The object is to select a group of populations from $(n + 1)$ populations on the basis of samples of equal size, one from each population,

such that the least upper bound of the probability of an incorrect choice is a preassigned number irrespective of the unknown population means. Consideration is given to an infinite class of decision rules that satisfy this fundamental requirement, and that also possess the properties of unbiasedness and of gradation. The problem of choosing one member from this infinite class that has further desirable properties is also investigated. (ASTIA abstract)

SEQUENTIAL PROCEDURES IN CERTAIN COMPONENT OF VARIANCE PROBLEMS, by N. L. Johnson. [1954] [10]p. incl. tables. (Mimeograph series no. 65) (AF 18(600)83) Unclassified

Published in Ann. Math. Stat., v. 25: 357-366, June 1954.

The primary purpose of this paper is to discuss certain sequential procedures for discriminating between two values for the ratio of variance components in a simple one-way classification. In order to clarify the presentation of the three procedures discussed, they will first be applied (in section 2) to the problem of discrimination between two values for the ratio of variances in two distinct normal populations. The arguments in section 3 closely parallel those in section 2, and the form of the two sections has been made as similar as possible, to emphasize this parallelism. Section 4 contains some formulae used in calculating approximate average sampling numbers presented in the earlier sections. (Contractor's abstract)

A USEFUL THEOREM IN MATRIX THEORY, by S. N. Roy. [1954] [4]p. (Reprint series no. 53) [AF 18-(600)83] Unclassified

Published in Proc. Amer. Math. Soc., v. 5: 635-638, Aug. 1954.

If A and B are any two matrices, the theorem of this article states that the square of the absolute value of any characteristic root λ of AB is greater [less] than or equal to the product of the minimum [maximum] characteristic root of AA^* by the minimum [maximum] characteristic root of BB^*. A short proof is the following. First, if F is hermitian, and x is a variable unit vector, $xx^* = 1$, the minimum of xFx^* is equal to the minimum characteristic root ρ_1 of F.

$$(F = U \cdot \mathrm{diag}(\rho_1, \ldots, \rho_n) \cdot U^*,$$
$$UU^* = I \longrightarrow xFx^* = y_1\rho_1\bar{y}_1 + \cdots + y_n\rho_n\bar{y}_n$$

with $y = xU$, $yy^* = 1$. Second, the minimum characteristic root of $(AB)(AB)^*$ is less than or equal to the square of the absolute value of any characteristic root λ of AB. ($zz^* = 1$, $z(AB) = \lambda z \longrightarrow z(AB)(AB)^*z^* = \lambda\bar{\lambda}$; apply first statement with $F = (AB)(AB)^*$.). Third, the characteristic roots of $(AB)(AB)^*$ and A^*ABB^* are the same. Fourth, the minimum characteristic root of the product of two hermitian matrices, as A^*A, BB^*, is greater than or equal to the product of the respective minimum characteristic roots of the factors. UNBIASED ESTIMATION OF FUNCTIONS OF THE BINOMIAL PROPORTION, by S. K. Mitra. Feb. 1, 1955, 17p. (Mimeograph series no. 122; CIT rept. no. 18) ([AF]OSR-TN-55-51) (AF 18(600)83) AD 56935 Unclassified

Explicit characterizations are given for the class of estimable functions (EPF) of the parameter p in the binomial population and the subclass G of EPF's possessing uniformly minimum variance unbiased estimators (UMVUE). The EPF's not possessing UMVUE, the explicit expression for the unbiased estimator with minimum variance at some $p' \epsilon \Omega$(the parameter space) is given. The subclass G* of G of EPF's possessing unreasonable UMVUE has been considered when $\Omega = [0, 1]$. Such estimators are necessarily inadmissible in the Waldian sense, with any loss function which increases with the absolute error. No attempt is made, however, either to prove or disprove the admissibility of reasonable UMVUE (in general) in such a case except for f(p) = p with loss function proportional to squared error, when it is shown that the reasonable UMVUE for p is admissible also. ON INVERTING A CLASS OF PATTERNED MATRICES. PART 1, by S. N. Roy and A. E. Sarhan. Feb. 23, 1955, 23p. (Mimeograph series no. 123; CIT rept. no. 16) ([AF]OSR-TN-55-78) (AF 18(600)83) AD 56936 Unclassified

Also published in Biometrika, v. 43: 227-231, Pts. 1 and 2, June 1956.

Consideration is given to the inversion of a class of patterned matrices that come up in different fields of statistics, including least squares solutions relating to problems like estimation of population parameters by ordered or unordered observations, analysis of variances and covariance, response surfaces, etc. In order to make it available even to those who have little background of matrix theory and other parts of mathematics but who still need to invert such matrices, the treatment is made as simple and elementary as possible, with appropriate illustrative examples from the different fields of application. The actual matrices discussed do not by any means exhaust the list of all patterned matrices that might be useful in the various sectors. They are merely illustrative and other matrices will be discussed in a sequel to this note, to be called Part II, which will be based on the same technique, as is indicated and used here. In this technique, use is made of the facts that: (i) a nonsingular square matrix has a unique inverse and (ii) for the class of patterned matrices considered here it is possible to guess a form for the inverse with a few unknown (and thus flexible) parameters which could then be determined by equating to the identity matrix the product of the original matrix and the inverse that is guessed. At the moment, the guess is just intuitive but it is believed that is a deeper general calculus behind the whole thing, which may come to light in the near future, thus making the inversion of such matrices an entirely trivial problem.

A GENERALIZATION OF ANALYSIS OF VARIANCE AND MULTIVARIATE ANALYSIS TO DATA BASED ON FREQUENCIES IN QUALITATIVE CATEGORIES OR CLASS INTERVALS, by S. N. Roy and M. A. Kastenbaum. June 1, 1955, 27p. (Mimeograph series no. 131; CIT rept. no. 19) ([AF]OSR-TN-55-167) (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)83 and U. S. Public Health Service under HTS 5065(c)) AD 70214 Unclassified

In the situation indicated by the title a p-variate body of data arranged in a q-way classification will formally look like a body of data arranged in a (p + q)-way table, but the fundamental distinction between a so-called "variate" and a so-called "way of classification" is that along the direction of a "variate," the marginal frequencies are stochastic variates, while along a "way of classification," the marginal frequencies are fixed or prescribed. The hypotheses of "no total correlation," "no multiple correlation," "no partial correlation," "no canonical correlation," "no main effect," "no interaction," etc., are translated into hypotheses on the structure of the probabilities over the different cells or categories, and, with large sample assumptions, these hypotheses are tested by χ^2 with appropriate degrees of freedom. No exact test in terms of the original multinomial distribution is attempted in this paper. (Contractor's summary)

THE RATIO OF VARIANCES IN A VARIANCE COMPONENTS MODEL, by W. A. Thompson. July 1953, 15p. (Mimeograph series no. 74) (AF 18(600)83) Unclassified

Also published in Ann. Math. Stat., v. 26: 325-329, June 1955.

In section 1 a lemma is proved which may sometimes be used to find the class of all statistics whose distributions are independent of the nuisance parameters. In section 2 this lemma is then applied to the general incomplete block variance components model to find the class of statistics whose distributions depend only on λ, the ratio of the two variances involved. Section 3 then finds a test of the hypothesis $\lambda < \lambda_0$ versus $\lambda > \lambda_1$. (Contractor's summary)

SOME CLASSES OF PARTIALLY BALANCED DESIGNS, by R. C. Bose and W. H. Clathworthy. [1955] [21]p. incl. tables. (AF 18(600)83) Unclassified

Published in Ann. Math. Stat., v. 26: 212-232, June 1955.

The paper deals with PBIB (partially balanced incomplete

NCU. 04:026 - NCU. 04:029

block) designs with two associate classes and $k > r \geq 2$, with $\lambda_1 = 1$ and $\lambda_2 = 0$. It is shown how the parameters for all such designs depend on the three integral parameters k, r, and t, which satisfy the restrictions that (i) $1 \leq t \leq r$, (ii) $rk(r-1)(k-1)/t(k+r-t-1)$ is a positive integer. For the particular case r = 3 it is shown that all designs with t = 2 or 3 necessarily exist, but if t = 1, then the only possible value of $k > r$ is k = 5. The designs with t = 2 are well known lattice designs and those with t = 3 are duals of certain balanced incomplete block designs. The design for k = 5 is constructed, the only construction in the paper. Other results are a less demanding definition of PBIB designs with two associate classes, and a lemma and five corollaries concerning the block structure of PBIB design with two associate classes having $\lambda_1 = 1$ and $\lambda_2 = 0$, with $p_{11}^1 = k - 2$ (but with no special assumption about the relationship between r and k). CONTRIBUTIONS TO THE STATISTICAL ANALYSIS OF CATEGORICAL DATA, by S. K. Mitra. Dec. 1955, 146p. (Mimeograph series no. 142; CIT rept. no. 22) (AFOSR-TN-56-43) (AF 18(600)83) AD 80555 Unclassified

The problems considered in this mathematical study are of 2 types: (1) multivariate analysis in which samples from 1 population are categorized according to several characteristics; and (2) analysis of variance in which samples from several populations are categorized according to 1 and the same characteristic. Hypotheses applicable to each of these situations are posed and tested. Chapter I gives a heuristic justification for the various frequency χ^2-tests. Chapter II discusses 2 theorems in minimum χ^2 and their applications. Chapter III investigates the property of asymptotic independence of test criteria in several cases of simultaneous testing in multivariate analysis. Chapter IV considers factorial multinomial experiments, their analysis, and a multidecision problem involving, in a restricted situation, the choice of the "best" (in some sense) among several populations. The final chapter presents some applications of the asymptotic power functions (in the Pitman sense) for the various types of χ^2-tests treated. (Contractor's abstract, modified)

AN INTRODUCTION TO SOME NONPARAMETRIC GENERALIZATIONS OF ANALYSIS OF VARIANCE AND MULTIVARIATE ANALYSIS, by S. N. Roy and S. K. Mitra. Nov. 1955, 35p. refs. (Mimeograph series no. 139, CIT rept. no. 21) (AFOSR-TN-56-44) (AF 18-(600)83) AD 80556 Unclassified

Also published in Biometrika, v. 43: 361-376, Dec. 1956.

The concepts of a previous study (item no. NCU. 04:022) are extended to a systematic exposition which: (1) is based on a clear distinction between a variate and a way of classification which results from differing experimental situations and sampling schemes; (2) sets up different probability models for the different situations: and (3) poses different types of hypotheses dependent on the existence of the situation as a multivariate analysis, analysis of variance, or a mixed type. The discussion is illustrated by the case of 2 analogous null hypotheses under 2 different probability models. These eventually have the same χ^2 with the same distribution under the respective null hypotheses, but their asymptotic powers differ. Examples from multivariate analysis are presented to show χ^2 additivity in a probabilistic and asymptotic sense. The concept of interaction in the analysis of variance is discussed in terms of randomized block experiments in which ranking procedures may change from block to block.

ON A DECISION RULE FOR A PROBLEM IN RANKING MEANS, by S. S. Gupta. May 1956, 104p. incl. tables, refs. (Mimeograph series no. 150) ([AF]OSR-TN-56-300) (AF 18(600)83) Unclassified

The author proposes and studies a statistical decision rule for the following situation. An experimenter is to select one or more populations which possess some characteristic, i.e., a large mean, guaranteeing that the probability of including the population with largest mean in the selected group is at least (1 - a), where a is a small pre-assigned number. The decision procedure proposed is one of a class first formulated by K. C. Seal. This paper explains a precise procedure, examines its properties and the statistic on which it is based, and illustrates its application.

MOMENTS OF ORDER STATISTICS FROM A NORMAL POPULATION, by R. C. Bose and S. S. Gupta. July 1956, 13p. incl. tables, refs. (Mimeograph series no. 154) (AFOSR-TN-56-501) (AF 18(600)83) AD 110316 Unclassified

The problem of obtaining the moments of $(X)_k$, the k^{th} order statistic for a sample of size n from a normal population N(0, 1), is considered. The t^{th} moment of $X_{(k)}$, $\mu_t'(n, k)$, can be expressed in terms of lower moments of order $t - 2t$, [$t = 1, 2, \ldots, t/2$ or $(t-1)/2$], and the integral $\int_{-\infty}^{+\infty} P_{t+1}(x)e^{-(t+1)x^2/2}dx$ where $P_{t+1}(x)$ for $t > 0$ is defined by $P_{t+1}(x)$ $= k\binom{n}{k} \frac{d^t}{d\Phi^t}\left[\Phi^{k-1}(1-\Phi)^{n-k}\right]$; Φ is replaced by $\Phi(x)$ after differentiation. $P_t(x)$ is a polynomial of degree $(n - t)$ in $\Phi(x)$ if $n \leq t$, and is zero if $n > t$. Exact values of all odd order moments can be derived when $n \leq 5$, and all even order moments when $n \leq 6$. Tables of exact moments $\mu_t'(n, k)$ for $t = 3$ and 4 are worked out. In general the integral is numerically evaluated by the Gauss-Jacobi method of mechanical quadrature (Szego, Gabor, Orthogonal Polynomials, New York City, American Mathematical Society Colloquium Publications, v. 23, 1939) based on the zeros and the weight factors of the Hermite polynomials.

MULTIPLE RANGE TESTS FOR CORRELATED AND HETEROSCEDASTIC MEANS, by D. B. Duncan. Dec. 1956, 17p. incl. diagr. refs. (Mimeograph series no. 161) (AFOSR-TN-56-597) (In cooperation with Florida U.) (Sponsored jointly by Florida Agricultural Experiment Station, U. S. Public Health Service, and Air Force Office of Scientific Research under AF 18(600)83) AD 115024 Unclassified

A complete method for the extension of the multiple range tests is presented. The closeness is indicated between the properties of these complete tests of heteroscedastic and correlated means and the properties of the corresponding tests of homoscedastic and uncorrelated means. A short-cut skipping principle is also presented which is useful in applying multiple range tests to a large number of treatment means or totals. The basic rule for complete tests is stated as follows: (1) any subset of p means is homogeneous if the largest adjusted difference in the sub-set fails to exceed the critical value R_p'; (2) any 2 means not both contained in the same homogeneous subset are significantly different; and (3) any 2 means both contained in the same homogeneous subset are not significantly different. Numerical examples are given for the test of unequally replicated means and for the test of treatment of the properties is made in discussing the 2-mean significance levels and the higher-order significance levels and power.

BOUNDS FOR THE DISTRIBUTION FUNCTION OF SUM OF INDEPENDENT, IDENTICALLY DISTRIBUTED RANDOM VARIABLES, by W. Hoeffding and S. S. Shrikhande. Oct. 1953, 31p. (Mimeograph series no. 84) (AF 18(600)458) AD 25736 Unclassified

Also published in Ann. Math. Stat., v. 26: 439-449, Sept. 1955.

The problem under study was that of obtaining bounds for the cumulative distribution function of the sum of n independent, identically distributed random variables with k prescribed moments and given range. For $n = 2$ the best bounds are attained or arbitrarily closely approached with discrete random variables which take on at most $2k + 2$ values. Explicit bounds are obtained for the case of nonnegative random variables with a given

NCU. 05:002 - NCU. 05:005

mean for n = 2; for arbitrary values of n, bounds are obtained which are asymptotically best in the tail of the distribution. Some of the results are considered to contribute to the more general problem of obtaining bounds for the expected value of a given function of independent, identically distributed random variables when the expected values of certain functions of the individual variables are given.

ON THE RELATION BETWEEN ESTIMATING EFFICIENCY AND THE POWER OF TESTS, by R. M. Sundrum. Jan. 1954, 6p. (Mimeograph series no. 90; CIT repl. no. 4) [AFOSR-TN-54-28] (AF 18(600)458) AD 35248 Unclassified

Also published in Biometrika, v. 41, Pts. 3 and 4: 542-544, Dec. 1954.

A condition is derived for the case of normal distributions for the validity of the assumption that a statistic which has a high efficiency in estimating an unknown parameter also gives a powerful test of hypotheses about that parameter. An example from genetics by Fisher (Statistical Methods for Research Workers, 11th ed., Oliver and Boyd, Edinburgh, 1950) is given of a failure of this assumption. A presumption in favor of using the more efficient estimator is established by showing that the derived condition fails only in situations where the power of the resulting test is less than one half.

A FURTHER APPROXIMATION TO THE DISTRIBUTION OF WILCOXON'S STATISTIC IN THE GENERAL CASE, by R. M. Sundrum. Jan. 1954, 13p. incl. table. (Mimeograph series no. 89; CIT repl. no. 3) [AFOSR-TN-54-29] (AF 18(600)458) AD 35147 Unclassified

Also published in Jour. Roy. Stat. Soc., Series B, v. 16: 255-260, 1954.

General expressions are derived for the third and fourth moments of Wilcoxon's (Biometrics, v. 1: 80, 1945) 2-sample test statistic. This is a distribution-free test of the hypothesis that 2 samples $(X_1, X_2, \ldots, X_m)$ and $(Y_1, Y_2, \ldots, Y_n)$ are independent random samples from the same population. The test is based on the statistic

$$U = \sum_{i=1}^{m} \sum_{k=1}^{n} d_{ik} \text{ where } d_{ik} = 1 \text{ if } X_i < Y_k = 0 \text{ otherwise.}$$

The third and fourth moments depend on relatively few parameters. The general expressions contain the third and fourth moments for the null case as derived by Mann and Whitney (Ann. Math. Stat., v. 18: 50, 1947) and Haldane and Smith (Ann. Eugenics, v. 14: 117, 1948) as special cases. A short table is given of the values of these parameters under normal alternatives.

NCU. 05:005

ON SOME SIGN TESTS OF RANDOMNESS UNDER HYPOTHESES OF LINEAR TREND, by R. M. Sundrum. Mar. 1954, 13p. incl. table. (Mimeograph series no. 96; CIT repl. no. 5) ([AF]OSR-TN-54-70) (AF 18-(600)458) AD 35148 Unclassified

General expressions are obtained for the third and fourth moments of a sign test of randomness proposed by Moore and Wallis (Jour. Amer. Stat. Assoc., v. 38. 153-164, 1943). Two additional results are obtained: (1) the general expressions are applicable to the moments of a bivariate difference-sign test proposed by Stuart (Jour. Amer. Stat. Assoc., v. 47: 416-424, 1952) when his parameters are suitably redefined; and (2) the parameters which occur in these expressions are also involved in the formula for the variance of another test of randomness based on the number of turning points proposed by Moore and Wallis (A Significance Test for Time Series, National Bureau of Economic Research, 1941). This test is based on the statistic $T = \sum_{i=1}^{n-2} T_i$, where $T_i = 1$ if $(X_i - X_{i+1})(X_{i+1} - X_{i+2}) < 0 = 0$ otherwise. The results of Moore and Wallis for the null case, $E(T) = \frac{2(n-2)}{3}$ and $\sigma^2(T) = 16n - 29)/90$, were generalized to certain non-null cases by Levene (Ann. Math. Stat., v. 23: 34-56, 1952) in an asymptotic form. These results are obtained exactly. The values of the parameters occurring in these formulas are computed for some special cases. (ASTIA abstract)

FURTHER CONTRIBUTIONS TO THE THEORY OF PAIRED COMPARISONS, by M. G. Kendall. [June 1954] 30p. incl. diagrs. tables. (Mimeograph series no. 108; CIT rept. no. 7) ([AF]OSR-TN-54-146) (AF 18(600)458) AD 37805 Unclassified

Also published in Biometrics, v. 11: 43-62, Mar. 1955.

A theory of paried comparisions is discussed in which n objects are presented to each of m observers, two at a time, and the observer states which of the two he prefers. The problem is to select $k < n$ objects which are most preferred in some sense. Several solutions are considered which correspond to different interpretations of the phrase most preferred. The theory is illustrated by problems such as scoring a chess tournament in which the scores are regarded as a matrix. Various means of reallocating scores are presented which are equivalent to taking successive powers of the matrix. A proof is presented that the process of repeated powering converges to a limiting ranking.

DISTRIBUTION OF LINEAR CONTRASTS OF ORDER STATISTICS, by J. St. Pierre. [1954] [2]p. [CIT rept. no. 14] [AFOSR-TN-54-267] [AF 18(600)458] Unclassified

Presented at meeting of the Institute of Math. Statistics, Montreal (Canada), Sept. 10-13, 1954.

Abstract published in Ann. Math. Stat., v. 26: 806-807, Dec. 1954.

Consider $n + 1$ independent normal population with unknown means, $m_0, m_1, \ldots, m_n$, respectively, and with a common known variance $\sigma^2 = 1$. Suppose a sample of size N is available from each population; and let $x_{(0)} > x_{(1)} > \ldots > x_{(n)}$ be the ordered sample means. Consider the linear contrasts $z = x_{(0)} - c_1 x_{(1)} - \ldots - c_n x_{(n)}$, where $\sum_1^n {}_1 c_i = 1$, $c_i \geq 0$, $(i = 1, 2, \ldots, n)$. The probability density function of the contrasts z is derived under the null hypothesis $H_0: m_0 = m_1 = \ldots = m_n$. The density of the contrasts z is also obtained in the case of three populations, under the hypothesis $-\infty < m_2 \leq m_1 \leq m_0 < +\infty$. Particular hypotheses are considered and tables are given. Finally, the particular contrast $y = x_{(0)} - x_{(1)}$ is considered in the general case. (Contractor's abstract)

MOST ECONOMICAL MULTIPLE-DECISION RULES, by W. J. Hall. Aug. 1954, 160p. incl. diagrs. tables, refs. (Mimeograph series no. 115; CIT rept. no. 10) ([AF]OSR-TN-54-268) (AF 18(600)458) AD 44786 Unclassified

Also published in Ann. Math. Stat., v. 29: 1079-1094, Dec. 1958.

Multiple-decision theory is extended to the following cases: (1) decision rules for deciding among m alternatives which minimize the sample size subject to bounds on the m probabilities of choosing the preferred alternative or of choosing, in a sense, the correct alternative under the prevailing one of m possible situations; and (2) decision rules which minimize the sample size subject to bounds on each of the probabilities, less than $1 - m$ in number, of making incorrect decisions. Solutions to the first problem are likelihood-ratio decision rules, and solutions to the second problem are unlikelihood-ratio decision rules. Problems of both simple and composite discrimination are considered, and characterization and existence theorems are given. A number of examples are treated which are generalizations of some of the common statistical tests. The theory is applicable to multivariate as well as univariate problems. This generality enables some k-population problems, such as deciding which of several populations has the largest mean, to be covered by a consideration

NCU. 05:011 - NCU. 05:014

of a set of k observations (one from each univariate population) as one observation from a k-variate population. A generalization to a most economical theory of decision functions is considered in which the maximum expected cost is minimized, subject to bounds on the expected loss function. Some particular examples of 2- and 3-decision rules are treated in an appendix. A nomograph is given for explicitly obtaining such rules, and brief tables of most economical sample sizes are computed from it.

ON THE DISTRIBUTION OF THE NUMBER OF SUCCESSES IN INDEPENDENT TRIALS, by W. Hoeffding. Apr. 1955, 13p. (Mimeograph series no. 128; CIT rept. no. 13) ([AF]OSR-TN-55-96) (AF 18(600)458) AD 61149 Unclassified

Also published in Ann. Math. Stat., v. 27: 713-721, Sept. 1956.

Let S be the number of successes in n independent trials and let p_j denote the probability of success in the j-th trial, j = 1, 1, ..., n (Poisson trials). The problem of finding the maximum and the minimum of Eg(S), the expected value of a given real-valued function of S, is considered when ES = np is fixed. It is well known that the maximum of the variance of S is attained when $p_1 = p_2 = \ldots = p_n = p$. This can be interpreted as showing that the variability in the number of successes is highest when the successes are equally probable (Bernoulli trials). This interpretation is further supported by the following 2 theorems which are proved. If b and c are 2 integers, $0 \leq b \leq np \leq c \leq n$, the probability $P(b \leq S \leq c)$ attains its minimum if, and only if $p_1 = p_2 = \ldots = p_n = p$ unless b = 0 and c = n (Theorem 5). If g is a strictly convex function, Eg(S) attains its maximum if and only if $p_1 = p_2 = \ldots = p_n = p$ (Theorem 3). These results are obtained with the help of 2 theorems concerning the extrema of the expected value of an arbitrary function g(S) under the condition ES = np. Theorem 1 gives necessary conditions for the maximum and the minimum of Eg(S). Theorem 2 gives a partial characterization of the set of points at which an extremum is attained. Corollary 2.1 states that the maximum and the minimum are attained when $p_1, p_2, \ldots, p_n$ take on at most 3 different values, only 1 of which is distinct from 0 and 1. Applications of Theorems 3 and 5 to problems of estimation and testing are given. (Contractor's abstract)

ON A CERTAIN CLASS OF STOCHASTIC APPROXIMATION PROCESSES, by D. L. Burkholder. May 1955, 79p. incl. refs. (Mimeograph series no. 129; CIT rept. no. 14) ([AF]OSR TN-55-168) (AF 18(600)458) AD 70213 Unclassified

Also published in Ann. Math. Stat., v. 27: 1044-1059. Dec. 1956.

Methods are investigated which in certain cases will give information about: (1) the solutions of the equation $M(x) - \alpha = 0$, if any exist; and (2) the location of the maximum of M, if it exists. M is a function from the real numbers into the real numbers. The function is not assumed to be known, but for each real number x there is a probability distribution function H such that $\int_{-\infty}^{\infty} y\,dH(y/x) = M(x)$. The literature is surveyed for information relevant to the first problem for the case when the root exists uniquely. Results on convergence with probability 1 are given for the case where the assumption of a unique root is not satisfied. Blum's

result (Ann. Math. Stat., v. 25: 382-386, 1954) that the stochastic approximation process $\{x_n\}$ of type A_2 converges to θ with probability 1 is obtained with several of his conditions relaxed. Results on asymptotic normality are also given in connection with problem 2. Stochastic approximation processes of type A_3 are shown to give information about the location of points of inflection of M under certain conditions. Results on convergence with probability 1 and on asymptotic normality are given for the problem of locating the maximum of a probability density function.

THE ROLE OF ASSUMPTIONS IN STATISTICAL DECISIONS, by W. Hoeffding. July 1955, 17p. incl. refs. (Mimeograph series no. 136; CIT rept. no. 16) ([AF]OSR-TN-55-263) (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)-458 and [Office of Ordnance Research under DA-04-200-ORD-355]) AD 75910 Unclassified

Also published in Proc. Third Berkeley Symposium on Mathematical Statistics and Probability, California U., Dec. 1954, and June and July 1955, p. 105-114.

The first part of this paper is concerned with the problem of investigating how the performance of a decision rule is affected when the assumptions under which it was derived are violated, with emphasis on assumptions concerning the class of distributions. Consequences of assuming that the distribution is continuous or normal are discussed. The second part deals with distinguishable sets of distributions, a concept related to the problem of the existence of unbiased or consistent tests. Criteria for the distinguishability of 2 sets by means of a test based on finitely many observations and by a sequential test are considered, and their uses are illustrated. An example of 2 sets which are distinguishable only by a randomized test is given. (Contractor's abstract)

ON A CLASS OF NON-PARAMETRIC TESTS, by J. R. Rosenblatt. Aug. 1955, 106p. incl. tables, refs. (Mimeograph series no. 138; CIT rept. no. 15) ([AF]OSR-TN-55-319) (AF 18(600)458) AD 75602 Unclassified

A class of nonparametric statistical decision problems is characterized by partition of a set of possible probability distributions into sets defined by the value of a functional. Particular attention is given to a class of functionals of the form $E_\varphi(X;F)$, where X is a vector random variable with distribution $F(x)$, and especially to the subclass in which the function $\varphi(x)$ takes only the values zero and 1. Certain families of decision procedures are considered, which are based on functions of the observed values of X which depend on these values only through the function $\varphi(x)$. Two principal types of results have been obtained. (1) Methods are developed for determining the asymptotic relative efficiency of 2 families of decision procedures under assumptions such that the methods are applicable in the situation described above. These methods are applied in particular to comparison of a family of 2-sample tests based on the Wilcoxon-Mann-Whitney statistic with a family of tests based on a related statistic which has binomial distribution. (2) Certain 2-sample decision problems, for which $E\varphi(X)$ is the probability of an event, are investigated. Some properties of the related families of decision procedures are obtained for small and large finite sample sizes, under assumptions which imply that the (nonparametric) sets of alternatives are very large. (Contractor's abstract)

A NOTE ON TRUNCATION AND SUFFICIENT STATISTICS, by W. L. Smith. Nov. 1955, 10p. (Mimeograph series no. 140; CIT rept. no. 17) (AFOSR-TN-56-36) (AF 18(600)458) AD 80547 Unclassified

Also published in Ann. Math. Stat., v. 28: 247-252, Mar. 1957.

Generalizing earlier observations by Fisher and Hotelling, Tukey (Ann. Math. Stat., v. 20: 309-311, 1949) showed that if a family of distributions admits a set of sufficient statistics, then the family obtained by truncation to a fixed set, or by a fixed selection, also admits the same set of sufficient statistics (this wording is Tukey's; a precise mathematical statement is given later). Tukey's proof assumed the relevant family of probability measures to be dominated by a fixed measure function, and made use of the factorization theorem concerning sufficient statistics in this case. In the present short note, Tukey's result is first reproved without assuming domination (and, hence, without appealing to the factorization theorem). Then it is shown that, under general conditions, if a sufficient statistic has one or more of the properties of completeness, bounded completeness, or minimality, before truncation, it preserves such after truncation. The treatment is on the lines of the abstract discussion of sufficient statistics given by Halmos and Savage (Ann. Math. Stat., v. 20: 225-241, 1949). Familiarity with the results given in this latter paper is assumed. For definitions of completeness, bounded completeness, and minimality, and for a discussion of the significance of these concepts reference is made to Lehmann and Scheffé (Shankhya, v. 10: 305-340, 1950). ON SUFFICIENT STATISTICS WHEN THE RANGE

NCU. 05:019 - NOR. 01:001

DEPENDS UPON THE PARAMETER, by W. L. Smith. Nov. 1955, 21p. (Mimeograph series no 141; CIT repl. no. 18) (AFOSR-TN-56-37) (AF 18(600)458) AD 80548 Unclassified

This mathematical study strengthens a theorem concerning the factorability of the probability density function presented by R. C. Davies (Ann. Math. Stat., v. 22: 43-57, 1941). Let $\{\mu_\theta\}$ be a family of probability measures defined on a measurable space (X, F_x), where θ, the parameter, is a point in the abstract parameter space Ω. It is assumed that $\{\mu_\theta\}$ is dominated by some fixed σ-finite measure λ, and that $f_\theta = d\mu_\theta/d\lambda$ represents some fixed version of the probability densities. $(\mu_\theta^n, X^n, F_x^n)$ is written for the n-product probability measure space derived in the usual way; evidently $\prod_1^n f_\theta(x_i)$ is measurable F_x^n. Furthermore, it is clear that μ_θ^n is dominated by λ^n, and $f_\theta^n = d\mu_\theta^n/d\lambda^n$ is written for some version of the probability densities on X^n. If $\underset{\sim}{x}_n = (x_1, x_2, \ldots, x_n)$ is a point of X^n, then $\{\underset{\sim}{x}_n\}$ is written for the finite subset of X which consists of the n points $x_1, x_2, \ldots, x_n$. When $\underset{\sim}{x}_n$ and $\underset{\sim}{x}_{n+1}$ appear in the same context, it is understood that the first n coordinates of $\underset{\sim}{x}_{n+1}$ are the coordinates of $\underset{\sim}{x}_n$ (repeated sampling). Then $\underset{\sim}{x}_n \in X^n$ a θ-set $t_n(\underset{\sim}{x}_n) = \left\{\theta : \prod_1^n f_\theta(x_i) > 0\right\}$. This set-valued function may be considered to be a statistic defined on X^n, and this study is concerned with necessary and sufficient conditions for t_n to be a sufficient statistic for $\{\mu_\theta^n; \theta \in \Omega\}$.

ANALYSIS OF PAIRED COMPARISON DESIGN WITH INCOMPLETE REPETITIONS, by J. W. Wilkinson. Apr. 1956, 81p. incl. tables, refs. (Mimeograph series no. 147) (AFOSR-TN-56-189) (Sponsored jointly by Air Force Office of Scientific Research under AF 18-(600)458 and National Research Council of Canada) Unclassified

Published in Biometrika, v. 44: 98-113, Pts. 1 and 2, June 1957.

A method of paired comparison of treatments is frequently used when quantitative measurement of treatment effects is not possible or practicable. The problem of analysis of the paired comparison designs developed by Bose and Kendall was studied. Other designs were obtained by constructing the complementary designs corresponding to the designs given by Bose. The designs have a high degree of symmetry as they are balanced by numbers of comparisons, objects compared, and numbers of observers on given comparisons. Some test procedures for examining the relative rating of the number of objects to be compared, and some large-sample properties of the tests and examples to clarify the test procedures are given.

ON RENEWAL THEORY, COUNTER PROBLEMS AND QUASI-POISSON PROCESSES, by W. L. Smith. Jan. 1956, 31p. refs. (Mimeograph series no. 144) (AFOSR-TN-56-191) (AF 18(600)458) AD 87064 Unclassified

Also published in Proc. Cambridge Philos. Soc. (England), v. 53: 175-193, 1957.

The standard machinery of renewal theory, with certain minor additions, is used to derive without recourse to unnatural boundary conditions the asymptotic results given by Hammersley (Proc. Cambridge Philos. Soc. (England), v. 49: 623-637, 1953). Two methods of censoring a renewal process are given. The first process is designated the guarantee-censor process. Such a process occurs if the renewals carry a maker's guarantee to replace without charge the renewal if it needs replacement in less than a certain number of time units from its moment of installation. The second process is called the paralysis-censor process because it corresponds to the effect of an automatic self-paralysis mechanism in a counter of a type described by Hammersley. A formula for the variance of the number of recorded points given by Hammersley for the guarantee-censor case is shown to be erroneous. Correct formulas for the case of the paralysis-censor are derived.

SOME RATIONALITY QUESTIONS ON ALGEBRAIC GROUPS, by M. A. Rosenlicht. July 1956, 43p. refs. (AFOSR-TN-56-318) (AF 18(600)1571) AD 94854 Unclassified

Also published in Ann. Math. Pura Appl., v. 43: 25-50, 1957.

The connected linear algebraic group over the field of complex numbers G is defined over a field k and the perfect arbitrary field k(G) is k – isomorphic to a subfield of a transcendental extension of k. Rationality questions dealing with solvable algebraic groups are expressed as results. The propositions formulated therefrom evidence that much information on the structure of the group can be obtained by the study of the type of field extension obtained by adjoining the characteristic roots of a generic element of an algebraic group of matrices to the field of the generic element. Fields of definition of generalized Jacobian varieties of curves are considered and an example is given of a connected algebraic group whose maximal connected linear algebraic subgroup is not defined over the same field.

SOME BASIC THEOREMS ON ALGEBRAIC GROUPS, by M. [A.] Rosenlicht. [1956] [43]p. (AF 18(600)-1571) Unclassified

Published in Amer. Jour. Math., v. 78: 401-443, Apr. 1956.

The purpose of this paper is to give a systematic development of some basic results in the theory of algebraic groups. The main results proved are structure theorems dealing with the existence in an algebraic group G of a normal algebraic subgroup H such that H and G/H are of specified types. The most important of these results, announced by Chevalley in 1953 and first proved in print by Barsotti (Ann. Mat. Pura Appl., v. 38: 77-119, 1955; Atti Accad. Naz. Lincei. Rend. Cl. Sci. Fis. Mat. Nat., v. 18: 43-50, 1955), asserts that if G is connected then there exists a linear H such that G/H is an Abelian variety. The first two parts of the paper develop the necessary concept of factor group, in its natural setting of transformation spaces and orbit varieties. The general methods stem from Nakano (Mem. Coll. Sci. Univ. Kyoto. Ser. A. Math., v. 27: 55-66, 1952) and Weil (Amer. Jour. Math., v. 77: 355-391; 493-512, 1955), but here are generalized to permit reducible varieties. The third part deals with the homomorphism theorems. The natural group isomorphism $G/H \supseteq (G/N)/(H/N)$ is shown to be birational, buth the natural isomorphism $H/(H \cap N) \supseteq HN/N$ is not always so; it is, however, rational and purely inseparable. Reformulating Weil's notion of "isogeny" of Abelian varieties in a way appropriate to arbitrary algebraic groups, the author obtains a result somewhat more precise than the fact that $H/(H \cap N) \supseteq HN/N$ is a purely inseparable isogeny. This permits him similarly to recapture for algebraic groups the Jordan-Hölder-Schreier theorem via Zassenhaus' lemma. The fourth part treats connected algebraic groups which are solvable (in the strong sense that the factor groups of some normal chain are all birationally isomorphic to either the additive or multiplicative group of the universal field. The main result here is that if V is a transformation space for such a group G and if $\tau: V \to W$ denotes the canonical generically surjective rational mapping of V onto the orbit variety W, then there exists a "cross-section," i.e., a rational mapping $\sigma: W \to V$ such that $\tau\sigma = 1$. The final part of the paper develops the structure theorems as mentioned above. (Math. Rev. abstract)

Also published in Jour. Appl. Phys., v. 27: 651-655, June 1956.

In this study, measurements were made of the specific heat, temperature coefficient of expansion, Young's modulus, and yield point in Cu_3Au alloys. It has been established that this alloy undergoes a phase transition between 550° and 600°C, and possible another one near 850°C. The temperature of the 550°-600°C transition decreases sharply as the composition of the alloy deviates from Cu_3Au. (Contractor's abstract, modified)

ACOUSTIC RELAXATION EFFECT IN Mn_3O_4, by M. E. Fine and C. Chiou. Aug. 14, 1956 [9]p. incl. diagrs. (AFOSR-TN-56-312) (AF 18(600)1468) AD 94847 Unclassified

NOR. 03:003 - NOT. 01:003

Also published in Phys. Rev., v. 105: 121-122, Jan. 1, 1957.

Internal friction and Young's modulus for specimens of polycrystalline Mn_3O_4 rods were determined as functions of temperature by the resonant longitudinal vibration method using piezoelectric excitation and detection of vibrations. Specimen 1 was sintered in air at 1100° and 1200°C. Internal friction peaks occur near 75°C at 60 kc/sec, and near 105°C at 180 kc/sec. Specimen 2A was sintered in He at 1100°C. An internal friction peak occurs near -10°C at 50 kc/sec. Specimen B was sintered additionally in air at 1200°C and showed a second peak near 75°C at 75 kc/sec. Compared with internal friction peaks in Fe_3O_4 and Ni-Fe ferrites, those in Mn_3O_4 are quite broad. Young's modulus, plotted as a function of temperature for specimen 1, showed a rapid decrease on heating in the region of the internal friction peak. By analogy with magnetite and Ni-Fe ferrites, the internal friction peaks in Mn_3O_4 are attributed to a stress-induced change in the distribution of Mn^{++} and Mn^{++++}.

THE STRENGTH OF AN ALLOY CONTAINING ZONES, by A. Kelly and M. E. Fine. Dec. 27, 1956, 7p. refs. (AFOSR-TN-56-581) (AF 18(600)1468) AD 115005 Unclassified

Also published in Acta Metallurgica, v. 5: 365-367, July 1957.

Rough estimates are made of the stress necessary to force a dislocation through a Guinier-Preston zone in an Al alloy containing 2 atomic % Cu and in an Al alloy containing 13 atomic % Ag. The values found are significantly less than those calculated using a model for the strength of a precipitation hardened alloy proposed by Orowan. It is suggested that the process of shearing the zones determines the initial flow stress in these age-hardening alloys. (Contractor's abstract)

SOLUTIONS OF TRANSCENDENTAL EQUATIONS BY ITERATIONS, by R. De Vogelaere. Nov. 1954, 22p. incl. diagrs. tables, refs. (Technical repl. no. 1) (AF 18(600)776) Unclassified

The solution of a nonalgebraic equation $f(x) = 0$ is a very common problem in numerical analysis. If a first approximation of the solution is known, a very popular class of methods used is iteration methods. Although none of the principles given in this study are new, it was felt interesting to assemble and to compare the different method commonly used, and their criteria of convergence. In addition, a combination of those methods well suited for electronic digital computers is given which will solve, in general, any problem of this kind. The usefulness of the point of view here taken is made clear when a comparison of methods is made. First, definitions on iterations are attempted, and general convergence theorems are given.

ON THE STRUCTURE OF SYMMETRIC PERIODIC SOLUTIONS OF CONSERVATIVE SYSTEMS, WITH APPLICATIONS, by R. De Vogelaere. Dec. 1954, iv. incl. diagrs. tables, refs. (Technical repl. no. 2) (AF 18(600)776) Unclassified

In studying a given algebraic curve, it is necessary to investigate the properties of such a curve near an ordinary point; however, this does not furnish any information on the behavior of the curve in the large. The knowledge of the singular points will furnish one of the tools for such a study in the large and the classification of these points into double points, triple points, cusps, etc., will be of utmost importance. A similar situation arises in the study of differential equations. Consider those of the type

$$\frac{d^2x}{dt^2} = \frac{\partial}{\partial x}U(x,y),\quad \frac{d^2y}{dt^2} = \frac{\partial}{\partial y}U(x,y);$$

$$\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = 2U(x,y).$$

Here again the properties of existence and uniqueness of a solution, or of the behavior near a solution do not give any information on the manifold of solutions in the large. Moreover, the complete knowledge of one solution for an infinite time gives rise to a new difficulty except for periodic solutions. These may be taken as analogous to the singular point of an algebraic curve, and their knowledge and classification may furnish a good tool to advance in the study of such equations. Such classification is considered here, and is made dependent on a correspondence of solutions of the differential equation with points on a 2-dimensional manifold. Such a manifold can easily be constructed, in general, if there exists a surface which is crossed by all the trajectories. This surface is called surface of section by Poincaré, and to successive intersections of the surface of section by the trajectories correspond successive points A and B on the manifold. The correspondence of B to A defines a transformation T of the manifold into itself, and the problem of finding periodic solutions of the differential equations is equivalent to the determination of the fixed points of transformation T. It is not, unfortunately, generally easy to obtain a simple surface of section. Therefore, it makes sense to consider the similar transformation that can be deduced from the successive intersection of part of a surface satisfying less stringent conditions. This transformation furnishes those periodic solutions which cross this surface, and this gives at least a partial answer to the problem. In a certain number of applications, e.g., the billiard ball problem and the restricted 3 bodies problem, the transformation T is the product of 2 involutions M_1M_0. This paper will restrict itself to such a transformation.

AN AERO-THERMODYNAMIC PROPULSION METHOD, by S. Lal and I. Michelson. Sept. 1956, 81p. incl. diagrs. tables, refs. (Rept. no. 100-1) (AFOSR-TN-56-523) (AF 18(600)1501) AD 110341 Unclassified

A first-phase study is summarized in which the basic aerodynamic and propulsion properties are investigated for a propulsive system in which friction heating of the boundary layer is utilized for the vaporization and superheating of an internally circulated coolant-fuel. For supersonic flow within the earth's atmosphere, there is a double benefit from such an arrangement: reduction to within tolerable limits of peak skin temperatures, as well as improvement of propellant performance as compared with fuels at ordinary temperatures. The aerodynamic investigation consists of an examination of heat transfer properties of boundary layers on three-dimensional configurations at moderate and high Mach numbers, in relation to skin friction of the same layers. Computations are carried out for the specific impulse of sample coolant-fuels. In the absence of reliable data on heat transfer in high temperature hypersonic flows, as well as more complete analysis of coolant-fuels and flight plan optimizations, a full systems evaluation analysis is not attempted in the present report, but is planned for further study in the immediate future. OXIDATION REACTIONS AS RELATED TO HYDROCARBON STRUCTURE AND ENGINE KNOCK, by C. E. Boord, K. W. Greenlee, and J. M. Derfer. [Apr. 1951] 25p. incl. tables, refs. (AF 33(038)22959) Unclassified

Presented at Symposium on Combustion Chemistry at the 119th meeting of the Amer. Chem. Soc., Cleveland, Ohio, Apr. 1951.

The free-radical chain-reaction mechanism for the oxidation of hydrocarbons is outlined in detail. The point of attack is through the H atoms of the hydrocarbon. The initiation is assumed to involve all types of H (primary, secondary, and tertiary) in the order of their numbers and relative reactivities. The propagation phase involves a complex sequence of step-wise reactions. The termination phase functions in the same manner as in other chain reactions. The 3 factors which unite to determine the velocity of the combustion and hence the critical compression ratio are the initiation rate, the very high free-radical formation in the propagation phase, and the peroxidation of tertiary free-radicals. On the basis of the reaction mechanism described, the following points are explained: (1) high critical compression ratios for paraffin gases, (2) low critical compression ratios for the higher normal paraffins, (3) the high values for highly branched paraffins, (4) the fall of critical compression ratio with increase in intake manifold temperature, (5) the basis for dual-fuel ignition in the gas-diesel engine, (6) the basis for rich-mixture performance, (7) high critical compression ratios for aromatic hydrocarbons, and (8) the high blending octane numbers of mono-olefins.

ISOLATION OF ALKYL HYDROPEROXIDES FROM

COMBUSTION REACTIONS OF HYDROCARBONS (Abstract), by E. W. Malmberg, D. L. Fishel and others. [1953] [2]p. [AF 33(038)22959] Unclassified

Presented at meeting of the Amer. Chem. Soc., Los Angeles, Calif., Mar. 15-19, 1953.

Published in 123rd meeting of the Amer. Chem. Soc. Abstracts of Papers, 1953, p. 52-M-53-M.

Alkyl hydroperoxides play an important role in the generally accepted mechanism of noncatalytic oxidation of hydrocarbons; to date no proof of the presence of these intermediates has been reported. In the present investigation, chromatographic and other chemical studies have been made on known organic peroxy compounds which may occur in combustion products of hydrocarbons; these classes include alkyl hydroperoxides, carbonylhydrogen peroxide addition products, and percarboxylic acids. These methods were applied to the study of intermediates isolated from the reactions which occur in a hydrocarbon-air mixture when subjected to the compression stroke of a motored engine, in a turbulent flame, and in a heated tube. When iso-octane was used as a fuel in the engine experiments, four major chromatographic zones were obtained from the condensate; their chromatographic properties and other chemical data gave a preliminary identification as alkyl hydroperoxides. This conclusion was confirmed by comparing the polarographic properties of known peroxides and these zones. Carbonylperoxide addition compounds and percarboxylic acids were eliminated as possibilities; the peroxides from iso-octane all showed the half-wave reduction potential which is uniquely characteristic of alkyl hydroperoxides. Characteristic alkyl hydroperoxide zones were also obtained from other engine samples, the turbulent flame, and the heated tube reaction. (Contractor's abstract)

A CHROMATOGRAPHIC STUDY OF CARBONYL COMPOUNDS PRESENT IN A HYDROCARBON-AIR FLAME, by E. W. Malmberg. June 30, 1953 [4]p. incl. tables, refs. [Technical rept. no. 7] (AF 33(038)22959) Unclassified

Presented at meeting of the Organic Div. of the Amer. Chem. Soc., Atlantic City, N. J., Sept. 1952.

Published in Jour. Amer. Chem. Soc., v. 76: 980-983, Feb. 20, 1954.

A study has been made of the carbonyl compounds which are present in a hydrocarbon-air flame. The experimental methods included formation and chromatographic separation of the 2,4-dinitrophenylhydrazone derivatives. In addition to the carbonyl compounds which are to be expected in the light of presently accepted mechanisms, a number of synthesis products were obtained, compounds in which the length of the carbon chain was increased. These results are interpreted in terms of the free radicals which must have been present, including the formyl radical. Three products, glyoxal, methylglyoxal, and formaldehyde, were found to be common to 18 hydrocarbon fuels. Quantitative analysis for these products showed no correlation with the type of fuel. This fact seems to indicate that the differences in the burning characteristics of hydrocarbons lie in the earlier stages of the combusion. (Contractor's abstract)

KINETICS OF OXYGEN UPTAKE BY CYCLOHEXENE IN THE LIQUID PHASE, by A. T. Touma and F. H. Verhoek. [1954] 5p. incl. diagrs. tables. [AFOSR-TN-54-73] (AF 33(038)22959) Unclassified

Published in Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y., Reinhold, 1955, p. 741-745.

The oxidation rate of cyclohexene, both as a pure liquid and in benzene, in contact with oxygen-enriched air is studied. Since Pyrex surfaces affected the oxidation rate, the experiments were conducted in Teflon-lined containers over a temperature range of 15°-40°C. The data show that the oxidation of liquid cyclohexene is accounted for satisfactorily by the mechanism of Bolland and Gee (Trans. Faraday Soc., v. 42: 236, 1936), with second-order hydroperoxide decomposition as the initiating step.

INVESTIGATION OF CARBONYL INTERMEDIATES IN THE PREFLAME REACTIONS IN AN ENGINE (Abstract), by E. W. Malmberg, J. A. Bobbitt and others. [1953] [1]p. [AF 18(600)787; continuation of AF 33(038)22959] Unclassified

Presented at meeting of the Amer. Chem. Soc., Chicago, Ill., Sept. 6-11, 1953.

Published in 124th meeting of the Amer. Chem. Soc. Abstracts of Papers, 1953, p. 39-O.

The carbonyl compounds which form in the well-known preflame reactions, reactions which occur in a hydrocarbon-air mixture upon adiabatic compression in an engine cylinder, have been studied with n-heptane, n-pentane, propane, and propene. The compounds were isolated as dinitrophenylhydrazones and these products were studied qualitatively and quantitatively by application of chromatographic methods. Samples were collected from the exhaust and from the cylinder at various times during the compression by means of a Cox valve. Studies were made both with the engine driven by an electric motor and with spark ignition. Qualitatively, the carbonyl products which are formed are in accord with the reaction mechanism based upon formation and decomposition of alkyl hydroperoxides. Quantitative analyses were made for known components which accounted for 80 to 85% of the total yield of hydrazones. The quantitative results are valuable because they indicate the relative importance of several alternate paths of reaction, and because they have justified certain procedures in the use of the engine. One of these results is a very good indication that the results from a motored engine without autoignition are closely comparable to the results when spark ignition is used. (Contractor's abstract)

LIQUID PHASE OXIDATION OF ETHYLCYCLOHEXANE BY MOLECULAR OXYGEN (Abstract), by J. Hoffman and C. E. Boord. [1953] [1]p. [AF 18(600)787) Unclassified

Presented at meeting of the Amer. Chem. Soc., Chicago, Ill., Sept. 6-11, 1953.

Published in 124th meeting of the Amer. Chem. Soc. Abstracts of Papers, 1953, p. 34-O.

The oxidation of ethylcyclohexane by molecular oxygen at 120°C and atmospheric pressure has been studied. Runs were made for periods of 24, 48, and 100 hours by slowly bubbling oxygen into the hydrocarbon. A yield of 4 to 6% of hydroperoxides at 48 hours was obtained. This appeared to be a mixture of secondary and tertiary hydroperoxides as evidenced by decomposition products. At the end of 24 hours, ketones were already present in appreciable amount as well as small amounts of fatty acids. At the end of about 30 hours carbon dioxide and acetaldehyde were noted in the effluent gases. A hydroperoxide concentrate of better than 98% purity was obtained through distillation and sodium salt formation. This appeared to be mostly a mixture of secondary hydroperoxides. Upon distillation of a 24-hour sample evidence was found for the presence of cyclohexanone, methylcyclohexyl ketone, and ethylcyclohexanone(s). A 100-hour sample was heated at 120°C in the absence of oxygen until all the hydroperoxide had decomposed. A good yield (based on hydroperoxide) of methylcyclohexyl ketone and ethylcyclohexanone(s) was obtained. The hydroperoxides from a 24 hour sample were decomposed with 70% sulfuric acid. Cyclohexanone, methylcyclohexyl ketone, and ethylcyclohexanone(s) were found among the decomposition products. Water extraction of a 24-hour sample afforded a keto acid which appeared to be mostly α-ketocyclohexyl acetic acid. Further extraction with aqueous sodium carbonate gave a small amount of a mixture of several fatty acids of variable and unknown composition. (Contractor's abstract)

HOW DO MOTOR-FUELS BURN? by C. E. Boord. Oct. 27, 1953, 19p. incl. diagrs. refs. [AF 18(600)787)] Unclassified

Published in O. S. U. Engineering Experiment Station News, v. 25: 9-16, 1953.

The theories of hydrocarbon oxidation are reviewed, and supporting evidence is presented to show why various hydrocarbons behave differently when used as fuels in internal combustion engines. The oxidation, although initially involving peroxidation, actually proceeds by different steps in each case. The reactions proceed each at its own characteristic rate and produce different intermediate products. Combustion velocities are dependent upon the structure of the hydrocarbon and the engine conditions. Studies involving every phase of the problem from room temperature oxidation to the most severe engine conditions gave strong support to the peroxidation theory. Oxidation products were identified by chromatographic, polarographic, and infrared spectrometric techniques. The characteristic differences of typical hydrocarbon structures have not been determined.

COMPARISON OF INTERMEDIATE-COMBUSTION PRODUCTS FORMED IN ENGINE WITH AND WITHOUT IGNITION, by W. C. Davis, M. L. Smith and others. Jan. 14, 1954 [10]p. incl diagrs. [AFOSR-TN-54-20] [AF 18(600)787] Unclassified

Presented at annual meeting of the Soc. of Automotive Engineers, Detroit, Mich., Jan. 11-15, 1954.

Published in SAE Trans., v. 63: 387-395, 1955.

Engine combustion tests were conducted on a modified Coordinating Fuel Research (CFR) Engine, type F4, of the single-cylinder, variable compression ratio design. Precombustion reactions in the motored, nonfiring engine produced the same carbonyl compounds as the firing engine. The carbonyls from gas samples withdrawn at various crank angles were absorbed in 2,4-dinitrophenylhydrazine-HCL, and identified by chromatography. The yield of total carbonyl /° of crank angle was constant to -20°, then increased sharply across the top center to a maximum at +10°. With pentane fuel, the carbonyls sampled were formaldehyde and acetaldehyde, 60 - 70%; propionaldehyde, acrolein, and crotonaldehyde, 10 - 20%, the balance being unidentified. Heptane gave formaldehyde and acetaldehyde, each in yields of 20 - 30%, the balance being unidentified. Isooctane gave formaldehyde 30 - 40%, isobutryaldehyde 15%, actaldehyde and acetone, each in yields of 5 - 10%, the balance being unidentified. It was noted in the discussion that a motored engine should operate at higher rpm than a fired engine for comparable data, and that there is no correlation between carbonyl yield and knock.

POLAROGRAPHIC STUDY OF COOL-FLAME OXIDATION PRODUCTS OF HYDROCARBONS, by W. M. MacNevin, P. F. Urone, and others. [1954] 4p. incl. diagrs. tables. [AFOSR-TN-54-72] [AF 18(600)787] Unclassified

Published in Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y., Reinhold, 1955, p. 402-405.

The use of polarography is considered in this combustion study of oxidation products of n-hexane, 2-methylpentane, 3-methylpentane, and 2,2-dimethylbutane obtained from cool-flame oxidation experiments. From experimental analyses conducted, it was concluded that the polarographic method described provides a relatively rapid procedure for the measurement of some of the oxidation products of the cool-flame combustion of these hydrocarbons. It allows the measurement of 10^{-5} to 10^{-6} mole of reducible substance to be made; however, it is reliable only in that the identification of the constituents in totally unknown samples should be further verified with chromatographic, infrared, or other procedures of chemical identification.

A STUDY OF COOL FLAMES AND ASSOCIATED REACTIONS IN AN ENGINE, by E. W. Malmberg, M. L. Smith and others. [1954] 8p. incl. diagrs. tables, refs. [AFOSR-TN-54-75] [AF 18(600)787] Unclassified

Published in Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y., Reinhold, 1955, p. 385-392.

It has been found that the cool flame does not form in one section of the engine cylinder and move relatively slowly across the combustion chamber as does the normal hot flame. n-C_7H_{16}, n-C_5H_{12}, and isooctane were studied, and it was observed that with each of these compounds, the cool flame persists for about 30°-40° of crank angle. For the n-paraffins, the cool flame results at the same point in the cycle for both stoichiometric and lean mixtures. With rich mixtures, each event shifts to a point later in the cycle. With isooctane as the fuel, the appearance is at the same time, regardless of the mixture strength, the peak intensity is greater with rich mixtures, and the point of peak intensity occurs earlier in the cycle; however, for the n-paraffins, the peak intensity appears with approximately stoichiometric mixtures. The peak intensities of the n-paraffins are about 5-10 times those of isooctane. Evidently the point in the cycle at which the cool flame appears is influenced more by the temperature and pressure in the cylinder than by the structure of the fuel molecule. The rise in carbonyl compounds in the cool-flame reaction parallels the integrated amount of light produced. The chemical study of preflame-reaction product is in agreement with peroxide mechanism of oxidation, with, however, attack occuring primarily at the secondary H atoms. The presence of acrolein and crotonal as primary cool flame products may be explained by means of an intramolecular free radical reaction. This explanation focusses attention on the possible importance of intramolecular attack in oxidation.

The carbonyl yields in the products from cool-flame reactions in flowing systems at atmospheric pressure and in "adiabatically" compressed hydrocarbon-air mixtures in a motored or fired engine were determined qualitatively and quantitatively for the following fuels: diethyl ether; pentane; hexane; heptane; 2-methylpentane; 3-methylpentane; 2, 2-dimethylbutane; and cyclohexane. The carbonyl compounds produced in the stabilized cool flame and the cool-flame reaction in an engine are the same, but are produced in different ratios. The relative importance of the various reactions is probably in agreement with the changes to be predicted from a consideration of the pressure change and the molecularity.

PREPARATION OF SOME SUBSTITUTED ALLYL HYDROPEROXIDES FROM BROMIDES, by J. Hoffman. [1955] [2]p. incl. tables. (AFOSR-TN-55-24) (AF 18(600)787) Unclassified

Presented at meeting of the Organic Div. of the Amer. Chem. Soc., Spring 1955.

Also published in Jour. Org. Chem., v. 22: 1747-1748, Dec. 1957.

Substituted allyl hydroperoxides may be prepared from substituted allyl bromides, which can be obtained by reaction of the appropriate olefin with N-bromosuccinimide and treatment of these bromides with potassium hydroxide-hydrogen peroxide in an aqueous methanol medium at room temperature. Alpha- and β-diisobutylene hydroperoxides were prepared by this procedure: 2-neopentylallyl hydroperoxide from 2, 4, 4-trimethyl-1-pentene and 2, 4, 4, -trimethyl-2-pentenyl hydroperoxide from 2, 4, 4-trimethyl-2-pentene; 2-t-butylallyl hydroperoxide was likewise prepared from 2, 3, 3-trimethyl-1-butene. Evidence was obtained in the bromination of 2, 4, 4-trimethyl-2-pentene for a 85-90% double-bond shift to the α-position with attachment of the bromine to the neopentyl carbon atom as indicated by comparison of infrared spectrograms of the bromide and the α- and β-diisobutylene. During the reaction of this bromide with alkaline hydrogen peroxide, a shift of the double bond back to the β position yielded mainly β-diisobutylene hydroperoxide. The infrared spectrogram of the bromination product of 2, 4, 4-trimethyl-1-pentene indicated little if any double-bond rearrangement. This bromide on reaction with alkaline hydrogen peroxide gave α-diisobutylene hydroperoxide. Further evidence for the position of the double bonds in these two hydroperoxides is given.

THE COOL-FLAME COMBUSTION OF THE ISOMERIC HEXANES, by P. E. Oberdorfer and C. E. Boord. [1955] [3]p. incl. tables. [AFOSR-TN-55-263] [AF 18(600)787] Unclassified

Presented at meeting of the Petroleum Div. of the Amer. Chem. Soc., Minneapolis, Minn., Sept. 11-16, 1955.

Published in Amer. Chem. Soc., Div. Petrol. Chem., General Papers, no. 34. 183-185, Sept. 1955.

The differences in the cool-flame combustion of the isomeric hexanes are particularly significant in view of the known differences of their engine behavior. Cool-flame combustion occurs in the upper range of low temperature oxidation. It is pointed out that alkylhydroperoxides, aldehydes, and olefins are almost certainly precursors of gum formation. When cool-flame combustion of hexane is permitted to operate for a few hr without cessation, a sticky, brownish gummy substance is deposited which becomes a varnish-like resin after a few hr. This substance is very similar to the uncharred residues found on the inner walls of the intake manifold, piston, and entry port of an engine. Tests were conducted using hexane, 2-methylpentane, 3-methylpentane, and 2, 2-dimethylbutane. Data are presented showing initial tube temperatures, maximum temperatures, and ΔT (maximum temperature - tube temperature). Also included are the carbon balances between the intermediate combustion products and hexane.

COOL FLAMES AND THE ORGANIC REACTION MECHANISMS INVOLVED IN THEIR FORMATION (Abstract), by C. E. Boord. [1956] [2]p. [AFOSR-TN-56-63] [AF 18(600)787] AD 81055 Unclassified

Presented at meeting of the Amer. Chem. Soc., Dallas, Texas, Apr. 8-13, 1956.

OSU. 03:016 - OSU. 03:018

Published in 129th meeting of the Amer. Chem. Soc. Abstracts of Papers, 1956, p. 1-G-2-G.

In the oxidation of hydrocarbons the substitution product is an alkyl hydroperoxide. The mechanism is rendered more complex by virtue of the fact that oxygen is divalent. When the alkyl hydroperoxide has been fully formed, only one half of the oxidizing power of the oxygen has been utilized. Alkyl hydroperoxides are therefore unstable, the stability being dependent upon the structure. Tertiary hydroperoxides are the most and primary hydroperoxides the least stable. The degradation reaction, which is essentially a second stage in the oxidation, may be either intra or intermolecular. By the same token the degradation may be either mono- or bimolecular. The rate of degradation is a function of the temperature and is readily subject to catalysis. Free radicals move in the direction of greater stability. Frequently this results in a dismutation reaction which stabilizes a portion of the molecule and produces a smaller free radical. The "stabilized cool flame" tube of Barusch and Payne, as modified by Oberdorfer, and the motored engine provide effective techniques for separating the primary combustion products. Chromatography, polarography, and spectroscopy provide excellent techniques for the analysis of such products. These techniques, when they have been perfected, offer strong promise of making it possible to follow the course of the combustion, step by step, from the hydrocarbon to carbon dioxide and water. (Contractor's abstract, modified)

RELATIONSHIP OF COOL-FLAMES AND ENGINE PERFORMANCE OF HYDROCARBONS, by C. E. Boord. [1956] 21p. incl. diagrs. tables, refs. (AFOSR-TN-56-187) (AF 18(600)787) AD 87060 Unclassified

Cool-flame studies were made of the isomeric hexanes. Each hydrocarbon was characterized by a minimum tube temperature at which a cool-flame formed, and by a maximum or peak flame temperature characteristic of each hydrocarbon at its minimum tube temperature. The difference between these 2 temperatures was designated as the temperature differential Δt. These temperature intervals stand in an inverse relationship to the knock resistance of the hydrocarbons. Both the temperature interval (Δt) and the performance numbers vary inversely as the number of methylene groups. Cool-flame engine studies showed that precombustion products from a motored engine operating without ignition were identical in kind with those obtained from the same engine with spark ignition, but with approximately 10° lag in crank angle. Test results indicated that synergistic mixtures gave low carbonyl yields, and antagonistic ones produced high carbonyl yields. A theoretical discussion of the mechanism by which hydrocarbons burn, and the oxidation of n-hexane by the intermolecular path are given.

THE AUTOXIDATION OF ETHYLCYCLOHEXANE, by J. Hoffman and C. E. Boord. May 3, 1956 [2]p. [AFOSR-TN-56-196] (AF 18(600)787) AD 87069 Unclassified

Published in Jour. Amer. Chem. Soc., v. 78: 4973-4974, Oct. 5, 1956.

A study of the liquid phase oxidation of ethylcyclohexane by molecular oxygen at 120°C was made to determine whether all ring hydrogens are reactive and to what degree. Oxidative attack was discovered to be general for all ring hydrogens, as well as the side-chain secondaries. Most reactive of all was the tertiary hydrogen. The secondary ring hydrogens appeared to be somewhat less reactive than the secondary side-chain hydrogens. The least reactive (most inert) were those ring hydrogens farthest from the ethyl group.

STUDIES ON THE GAS PHASE OXIDATION OF CYCLOHEXENE, by G. H. Hembree and F. H. Verhoek. May 1956, 8p. incl. diagrs. tables. (Technical note no. 1) (AFOSR-TN-56-298) (AF 18(600)787) AD 90010 Unclassified

The gas phase reaction of cyclohexene and oxygen was studied in a static system to determine the rate-reaction effect of the following: (1) changes in oxygen pressure at constant cyclohexene pressure, cyclohexene pressure at constant oxygen pressure, the ratio of reactant pressures at constant total pressure, and temperature, and (2) added inert gas. In all reactions of cyclohexene with an equal amount (pressure) or an excess of oxygen, the pressure decreased slowly to a minimum then rose rapidly at an accelerating rate, passed through a maximum rate, and then increased slowly to a steady value. The reaction of a 7:1 oxygen: hydrocarbon mixture at 250°C in a 100 cc flask caused the pressure to rise rapidly after passing through the minimum; the total change in pressure was more than twice as great as that in the slower reaction; this was indicated as a "cool flame" reaction. The addition of N to a cyclohexene-oxygen reaction mixture did not affect the induction period; the total pressure change and maximum rate increased only slightly above that for a similar reaction without N. When varying reactant pressure ratios at a total pressure of 200 mm and 250°C, the maximum rate, the reciprocal of the induction period, and the total change in pressure showed a maxima in the vicinity of the 3:1 oxygen: cyclohexene mixture.

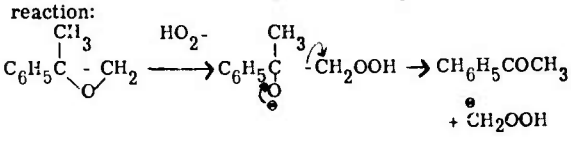
OXIDATIVE STUDIES ON α-METHYLSTYRENE (Abstract), by J. Hoffman. [1956] [1]p. [AF 18(600)787] Unclassified

Presented at meeting of the Amer. Chem. Soc., Atlantic City, N. J., Sept. 16-21, 1956.

Published in 130th meeting of the Amer. Chem. Soc. Abstracts of Papers, 1956, p. 16-O.

In the liquid phase oxidation of α-methylstyrene by molecular oxygen at 100° a large amount of acetophenone was obtained, along with a smaller amount of α-methylstyrene oxide. Chromatographic and polarographic evidence was found for even smaller amounts of α-methylstyrene hydroperoxide in the oxidate. When a sample of pure α-methylstyrene oxide was oxidized by molecular oxygen for 20 hours at 80°, an almost quantitative yield of acetophenone was obtained. A small quantity of a hydroperoxide was isolated from this oxidate by silicic acid chromatography. This material, upon further heating, yielded acetophenone. This indicates that a hydroperoxide derived from α-methylstyrene oxide is an intermediate in the oxidative degradation of the epoxide to acetophenone. Carbon to carbon double bond scission by molecular oxygen (at least in the case of α-methylstyrene) appears therefore to proceed through an epoxide and an epoxide-hydroperoxide; the latter being unstable decomposes to the final product (acetophenone). Evidence for a similar type of unstable intermediate hydroperoxide has been found in the reaction of α-methylstyrene oxide with alkaline hydrogen peroxide in 90% methanol at room temperature. An almost quantitative yield of acetophenone is obtained. This product is most readily explained by the following reaction:



Similarly, α-methylstyrene oxide is cleaved to acetophenone in good yield when refluxed for 48 hours with lithium chloride in acetone.

THE CRYSTAL STRUCTURE OF ONE FORM OF TRINITROTOLUENE, by P. G. Taylor and P. M. Harris. July 20, 1954, 14p. incl. illus. tables. (Technical note no. 2) ([AF]OSR-TN-54-30) (AF 33(616)19) AD 43724 Unclassified

The space group symmetry P_{ba} and rough structure of one form of trinitrotoluene have been determined almost entirely from a three-dimensional "Patterson", or vector, map. The unit cell contains eight molecules of $CH_3C_6H_2(NO_2)_3$ in two sets of four each. The two sets are not symmetry connected. Fourier projections on (001), (010), and (100) have been computed. THE DERIVATION OF THE CRYSTAL STRUCTURE OF TRINITROTOLUENE FROM THE THREE-DIMENSIONAL PATTERSON (Abstract), by P. G. Taylor. [1954] [1]p. [AFOSR-TN-54-60] [AF 33(616)19] Unclassified

Published in Acta Crystallographica, v. 7: 650, Oct. 10, 1954.

Published in Third Congress of the International Union of Crystallography, Paris (France), July 21-28, 1954, p. 37.

Samples of 2:4:6 trinitrotoluene were found to crystallize from chloroform at room temperature in an orthorhombic cell of dimensions 14.85 Å, 19.78 Å, 5.96 Å, containing 8 molecules. The space group was indicated as either D_{2h}^{11} or C_{2v}^{5}. The Patterson synthesis was computed in 3 dimensions using Cu Kα diffraction data. From an examination of the Harker-type vectors, it could be deduced that noncentric space-group C_{2v}^{5} (Pba) was present. Certain features of the Patterson enabled the orientation and relative position of the 2 independent molecules to be deduced. The position of the carbon rings in the cell, and the positions of the remaining atoms were then arrived at by use of Patterson evidence assisted by trial and error work. Agreement of calculated and observed structure factors indicates that the structure is correct, but it cannot be determined with high accuracy until 3-dimensional refinement work is undertaken. Some interesting modifications in the bond lengths, notably those of the carbon ring, appear to be present. (Contractor's abstract)

STRUCTURE DETERMINATION OF PICRYL CHLORIDE, by R. E. Gluyas and P. M. Harris. July 20, 1954 [11]p. incl. diagrs. table (Technical note no. 1) [AFOSR-TN-54-219] (AF 33(616)19) AD 43723 Unclassified

Picryl chloride has been found to have a monoclinic unit containing four molecules with space group symmetry of $P2_1/a$. Three dimensional "Patterson", or vector, maps have been calculated, leading to the orientation of a typical molecule. Parameters (x, z) have been determined, and the (010) projection has been

INVESTIGATION OF STRUCTURE OF CRYSTALS OF NITRO ORGANIC COMPOUNDS, by R. E. Gluyas and P. M. Harris. Final rept. Mar. 1955, 2p. [AFOSR-TR-55-8] (AF 33(616)19) AD 57441
Unclassified

A brief summary is given of the work conducted under contract AF 33(616)19 on the structures of crystalline aromatic vitro compounds. The structures of 2, 4, 6-trinitrotoluene (TNT), and of picryl chloride (TNBC1) have been studied, and an investigation of 1, 3, 5-trinitrobenzene (TNB) has been initiated. Results have been presented on the orthorhombic crystalline modification of TNT having the symmetry Pca and 8 stoichiometric mol/cell. Complete intensity data have been collected on orthorhombic trinitrobenzene, and coefficients for a 3-dimensional Patterson synthesis have been prepared. It is pointed out that TNB contains 16 mol/cell with the symmetry of Pbca. Structural data have also been presented for TNBCl. This crystal possesses a 4-mol monoclinic cell having a symmetry of P^21/a.

THE LAUE-BRAGG SCATTERING AND CHARGE DISTRIBUTION IN LITHIUM METAL (Abstract), by P. L. Splitstone and P. M. Harris. [1955] [2]p. [AF 18(600)769] Unclassified

Presented at the 13th annual Pittsburgh Diffraction Conference, Nov. 3-4, 1955.

Using a Geiger-Müller x-ray spectrometer, measurements of the relative crystal structure factors have been made on small single crystals of metallic lithium at 300° and 100°K. These measurements were spread over some seven different crystals at each temperature. From the results the temperature coefficient of the scattering has been evaluated. Comparison of the form of the scattering factor of lithium as a function of $\frac{\sin\psi}{\lambda}$ with theoretical values from Löwdin's analytic wave function for the lithium ion and of McWeeny for the lithium ion and of McWeeny for the lithium atom is made. Löwdin's results have been used to put the "relative" experimental data on an absolute basis. As a further test direct comparison was made of two (different) lithium crystals with two (different) small spheres ground from rock salt (NaCl). The results are compared with measurements of James and Firth, Renniger, and Brill et al. Calculations of the charge density along the [100], [110], and [111] for the lattice at rest show no significant excess charge concentration between nearest neighbors at (000), (1/2 1/2 1/2) as is suggested by some theoretical models; rather, the best model appears to be one in which lithium ions are immersed in a continuous, uniform charge distribution provided by the valence electrons. The reproducibility of the single crystal measurements is shown by tabulated results. (Contractor's abstract)

THE TRANSFORMATION IN SILVER MERCURIC IODIDE AND THE STRUCTURE OF ONE LOW TEMPERATURE FORM (Abstract), by C. E. Olsen and P. M. Harris. [1955] [2]p. [AF 18(600)769]
Unclassified

Presented at the 13th annual Pittsburgh Diffraction Conference, Nov. 3-4, 1955.

Single crystals of Ag_2HgI_4 have been grown from solution and have been investigated using Weissenberg and precession x-ray diffraction photographs supplemented by spectrometer measurements. This work indicates that the crystal phase (B) grown from solution has a 2-molecule, body-centered tetragonal cell of symmetry $I\bar{4}$ (almost $I\bar{4}$ 2m). This cell has a_o - 6.32 A and c_o = 12.64 A. This cell differs in both symmetry and value of c_o from that reported by Ketelaar. Patterson sections disclose, in addition to Hg at 000; Ag at 1/2, 1/2, 0 and 1/2, 0, 1/4; I at 1/4, 1/4, 1/8; 3/4, 3/4, 1/8; 1/4, 3/4, 3/8; and 3/4, 1/4, 3/8 (all + 1/2, 1/2, 1/2), that there are additional vectors corresponding to silver in octahedral sites but displaced from the center of site. It is postulated that iodine vacancies exist due to replacement of HgI_2 by AgI. These provide a mechanism for this disorder. Density, composition and anomalous dielectric polarization of the crystal support this. Further, the phase produced by cooling the disordered high temperature (a) form through the transition temperature is an apparently cubic (B) phase having eight molecules per cell. Single crystals of Cu_2HgI_4 exhibit a one-molecule, tetragonal cell of symmetry P 4/n mc and dimensions: a_o = 4.29 A and c_o = 12.[illegible] A. This is different from the cell proposed by Ketelaar from powder measurements. (Contractor's abstract)

CHARGE DISTRIBUTION AND CHARACTERISTIC TEMPERATURE OF METALLIC LITHIUM FROM X-RAY SCATTERING AT 300° AND 100°K, by P. L. Splitstone and P. M. Harris. Apr. 1956, 25p. incl. illus. diagrs. tables, refs. (Technical rept. no. 1) (AFOSR-TN-56-235) (Sponsored jointly by Office of Naval Research under N6onr-22517 and Air Force Office of Scientific Research under AF 18(600)769) AD 88355
Unclassified

The Laue-Bragg scattering of single crystals of metallic Li has been measured at 100° and 300°K. These results were placed on an absolute basis by comparison with theoretical atomic form factors for the Li ion and also were compared experimentally with rock-salt. From these results, a characteristic temperature, Θ = 325°K, was derived. Electron density computations suggest no appreciable charge concentration between nearest neighbor atoms. According to the accuracy of the measurements, Li metal may be well represented by the simple model of Li ions immersed in a uniform charge distribution of the valence electrons. These results and the implications of the method of treatment are discussed. (Contractor s abstract)

THE ANALYSIS AND DESIGN OF DENSE ELECTRON BEAMS, by R. P. Anand. Apr. 1955, 23p. incl. diagrs. refs. (Technical note no. 1) ([AF] OSR-TN-55-156) (AF 18(600)980) AD 68367 Unclassified

Problems associated with the design of high density and high perveance electron guns are discussed, and a number of important techniques for the analysis of such guns are briefly reviewed. Among analog methods, the modified electrolytic trough of Musson-Genon, the elastic membrane technique, and the resistor network are described. In the Musson-Genon method, the bottom of the trough is shaped in a special way to take care of space-charge distribution. Calculation of the shape of a 3-dimensional bottom requires extensive computations which have to be repeated a number of times to produce successively better results. The elastic membrane method is limited to 2-dimensional problems. The resistor-network method has been applied successively to solve partial differential equations like Laplace's and Poisson's, and the wave equations. Numerical methods such as relaxation and iteration procedures are discussed. (Contractor's abstract)

AN APPLICATION OF THE RELAXATION METHOD OF ANALYSIS TO THE HEIL ELECTRON GUN, by R. P. Anand. June 1955, 33p. incl. diagrs. tables, refs. (Technical note no. 2) ([AF]OSR-TN-55-250) (AF 18(600)980) AD 74186 Unclassified

The relaxation method was used to obtain an approximate solution of Poisson's equation in a 1/5-size Heil electron gun. A resistance-network analog performed most of the relaxation calculation automatically. The solution was carried to a second approximation. The current flow is not laminar, and the current density is very nonuniform near the nozzle. The first and second approximations agreed fairly well, except in the region near the anode. The trajectories had the same general features. The ones from the cathode edge were so convergent that they appeared to cross the axis; the results indicated the impossibility of determining the precise position of the trajectories, and the current-density distribution in the nozzle. To obtain a better approximation, a network is needed with a finer mesh. The use of a rectangular mesh in the nozzle region and a large number of net points across the beam (not so large as to become excessive) are suggested. The resistance network is capable of giving an accurate numerical solution of the problem in the area near the cathode. The main work involved in this method is that of obtaining the electron trajectories between successive field solutions. This is also the largest source of error. An investigation into the possibility of some kind of automatic trajectory plotter that could be used in conjunction with the network, is suggested.

AN APPLICATION OF THE METHOD OF MUSSON-GENON TO THE HEIL ELECTRON GUN, by T. Kuwabara. Aug. 1955, 49p. incl. illus. diagrs. table, refs. (Technical note no. 3) ([AF]OSR-TN-55-419) (AF 18(600)980) AD 81377 Unclassified

The potential distribution and corresponding electron trajectories in the presence of space charge in the Heil electron gun were studied with the use of the method of Musson-Genon (Ann. Telecommunications, v. 2:298-320, Oct. 1947, and L'Onde Electrique, no. 255:236-242, June 1948). The method involves shaping the electrolytic field plotting tank in such a way as to account for the modification of Laplace's equation by the space charge. The potential distribution with space charge of the gun obtained by M. O. Thurston was used to calculate the depth of the bottom in order to eliminate several approximations. The total cathode emission and the transmission efficiency checked quite closely with experimentally determined values. There is no experimental verification available for the current distribution on paths of electrons.

PINHOLE CAMERA GUN TESTER FOR INVESTIGATION OF ELECTRON BEAMS, by R. M. Campbell. Jan. 1956. 34p. incl. illus. diagrs. (Technical note no. 4) (AFOSR-TN-56-222) (AF 18(600)980) AD 88029 Unclassified

The object of this research was to find a means of making measurements on electron beams to determine whether or not the associated electron gun was performing as expected. From these measurements, it should be possible to determine what must be done in the electron gun to improve or modify the resulting electron

OSU. 07:001 - OSU. 08:001

beam. The method chosen to make these measurements resulted in the design and construction of a pinhole-camera type of gun tester. This type of gun tester is a beam sampling device in which small apertures are moved through the electron beam to determine the current-density distribution of electrons in the beam, and the transverse-velocity distribution of electrons at various points in the beam. Measurements made on a Heil electron gun demonstrated the usefulness of this type of gun tester. It was shown that measurements could be made on an electron gun for which no mathematical analysis was available, and that these measurements could be made relatively rapidly. A MAGNETICALLY FOCUSED RETARDING-FIELD OSCILLATOR OF THE BARKHAUSEN-KURZ TYPE, by M. Uenohara. Sept. 1954, 54p. incl. illus. diagrs. refs. (Technical rept. no. 1) ([AF]OSR-TN-54-330) (AF 18(600)982) AD 50172 Unclassified

An oscillator employing a magnetically focussed electron stream traveling in an electric field resulting from a parabolic potential distribution can be operated as a Barkhausen-Kurz type of oscillator. Electrons perform simple harmonic oscillations across the gap of a cavity resonator. Insofar as an accurate parabolic potential distribution is achieved, the oscillation frequency of the electrons is independent of their amplitudes and they therefore remain in proper phase with the electric field of the resonator and continue to give up energy to that field at successive transits. A preliminary theory of the electronic energy interchange of this oscillator is provided, and the background theory of the oscillator design is discussed. Expressions for electronic admittance, conversion efficiency, starting current, and frequency dependence on accelerating potential have been derived and are in substantial agreement with experimental results. A maximum output power of 1.8 watts has been obtained at 8320 mc with 5.5% efficiency. A maximum efficiency of 13.5% has been obtained at 8400 mc with an output power of 170 milliwatts. Beam starting currents as low as 0.1 ma have been observed at 9800 mc. Tuning over the range 8300 mc to 10,400 mc has been accomplished by varying the position of a movable short in the waveguide. The oscillation frequency of the oscillator can also be adjusted by varying the resonator voltage, and the frequency so controlled is proportional to the square root of the resonator voltage. (Contractor's abstract)

A CENTIMETER-WAVELENGTH OSCILLATOR OF THE BARKHAUSEN TYPE, by D. T. Davis. June 1955, 41p. incl. diagrs. refs. (Technical note no. 2) ([AF]OSR-TN-55-251) (AF 18(600)982) AD 69847 Unclassified

A tube employing simple harmonic electron motion across the interaction gap of a resonant cavity can be operated as a Barkhausen-Kurz oscillator. The d-c potential distribution in which the electrons move is parabolic, and a magnetic field is used to focus the electron beam. A tube utilizing this oscillation mechanism and having symmetry with respect to the axis of the electron beam has been tested. Severe ion bombardment of the cathode occurred, but the effects were minimized by use of a nickel matrix cathode. A maximum efficiency of 7% at 180 mw and a maximum output power of 400 mw at 1.13% efficiency were obtained at 3 cm. Starting currents of less than 0.2 ma have been observed. These results indicate the possibility of developing a highpower, high-efficiency tube if the proper electrode geometry and circuit can be obtained. (Contractor's abstract)

THEORETICAL AND EXPERIMENTAL STUDY ON THE MILLIMETER-WAVE CAVITY BARKHAUSEN-KURZ OSCILLATOR, by M. Uenohara. Aug. 1956, 214p. incl. diagrs. tables, refs. (Technical rept. no. 3) (AFOSR-TN-56-530) (AF 18(600)982) AD 110349 Unclassified

A higher efficiency, a wider electronic tuning range, and a low starting current are the important characteristics of the magnetically-focused Barkhausen-Kurz oscillator. A theoretical and experimental study on the magnetically focused, Barkhausen-Kurz oscillator has been conducted for the purpose of determining its potentialities as a millimeter-wave generator. A section of the report contains a theoretical discussion of the operation of this device ranging from a simple small-signal theory to a large-signal theory under the general high-frequency field distribution in the interaction space. A planar type 3-cm oscillator, 1-cm oscillator, 6-mm oscillator, and an axially symmetrical 3-cm oscillator were constructed. A maximum oscillation frequency of 48,387 mc was obtained. The experimental results are also discussed in detail. The theoretical results are in substantial agreement with experimental results. (Contractor's abstract, modified)

ZEEMAN SPLITTING OF NUCLEAR QUADRUPOLE RESONANCE LINES, by Y. Ting, E. Manring, and D. Williams. [Oct. 21, 1953] 2p. [AF 18(600)772] Unclassified

Also published in Phys. Rev., v. 92: 1581, Dec. 15, 1953.

The Zeeman splitting of Cl^{35} nuclear quadrupole resonance lines in a crystal of sodium chlorate has been observed in external magnetic fields in the range from 0 to 8000 gauss. Theory predicts that at one orientation, in which the 111 plane is normal to the magnetic field there should be 2 symmetrical Zeeman components whose frequency separation from the parent line is strictly proportional to the applied field's strength. In this study, the separation between Zeeman components is approximately 20% of the frequency of the zero-field line at the highest fields employed (8000 gauss). The experimental results show that the splitting is indeed directly proportional to the applied field.

INTENSITIES OF THE ZEEMAN COMPONENTS OF QUADRUPOLE TRANSITIONS IN SODIUM CHLORATE, by Y. Ting and D. Williams. [1954] [1]p. [AFOSR-TN-54-33] (AF 18(600)772) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29, 1954.

Also published in Bull. Amer. Phys. Soc., v. 29: 19, Apr. 20, 1954.

Also published in Phys. Rev., v. 95: 607, July 15, 1954.

The Zeeman pattern of the Cl^{35} nuclear quadrupole transition in a single crystal of sodium chlorate has been studied in a field of 6000 gauss. The shifts of the observed lines from the zero-field frequency for various orientations of the crystal in the external field were in close agreement with theoretical predictions. At orientations in which the angle between I direction and the direction of H field approached 90°, rapid changes in the intensities of the observed components were noted. Two of the 4 Zeeman components diminished in intensity, disappearing at 90°. The other Zeeman components increased in intensity, reaching a maximum at 90°. The transformation matrix, which diagonalizes the total Hamiltonian at this orientation (with zero electric field asymmetry factor), can be obtained in closed form. The calculated probability of magnetic dipole transitions shows that the disappearance of the components in question is to be expected.

ZEEMAN EFFECTS IN THE CHLORINE NUCLEAR QUADRUPOLE RESONANCE IN SODIUM CHLORATE, by Y. Ting, E. R. Manring, and D. Williams. Apr. 1954, 25p. incl. diagrs. tables, refs. (Technical rept. no. 1) [AFOSR-TN-54-125] (AF 18(600)772) AD 31476 Unclassified

Also published in Phys. Rev., v. 96: 408-414, Oct. 15, 1954.

The Zeeman splitting of Cl^{35} nuclear quadrupole resonance lines in a single crystal of sodium chlorate has been studied in a magnetic field sufficiently large to permit detailed investigation of individual Zeeman components for various orientations of the crystal in the applied magnetic field. The observed patterns are in agreement with theoretical predictions based on a Hamiltonian involving an interaction of the nuclear electric quadrupole moment with a crystalline field having axial symmetry, and the interaction of the nuclear magnetic moment with the applied magnetic field. The quadrupole interaction term e^2Qq was found to be 58.806 ±0.002 mc/sec and the effective nuclear magnetic moment was found to be 0.8215 ±0.0001 nuclear magnetons. An upper limit for the electric asymmetry parameter η was found to be 0.0012. The intensity variations of individual Zeeman components for different orientations of the crystal relative to the magnetic field were studied. The line width of individual Zeeman components was of the order of 900 cps. (Contractor's abstract)

THE MICROWAVE SPECTRUM OF OZONE (Abstract), by P. N. Wolfe and D. Williams. [1954] [1]p. [AF 18(600)772] Unclassified

Presented at meeting of the Amer. Phys. Soc., Poughkeepsie, N. Y., Oct. 16-17, 1953.

Published in Phys. Rev., v. 93: 360, Jan. 15, 1954.

OSU. 08:006 - OSU. 08:009

The absorption spectrum of O_3^{16} has been investigated in the microwave region between 20 and 30.3 kmc/sec. Accurate determinations of line frequencies were made between 20 and 26 kmc/sec and approximate measurements were made with a calibrated resonant cavity at frequencies above 26 kmc/sec. The lines observed in this region are in excellent agreement with those observed by Hughes but some improvements in frequency determinations seem to have been achieved. The observed spectrum is readily interpreted in terms of the obtuse-angled isosceles triangular model proposed by Hughes. Splitting of the ground vibrational state due to intramolecular inversions in such a triangular model are found to be negligible within the limits of the frequency discrepancies between observed and predicted lines. If such inversion occurs, its frequency is extremely low.

NUCLEAR QUADRUPOLE TRANSITION IN A SINGLE CRYSTAL OF SODIUM CHLORATE (Abstract), by E. Manring, Y. Ting, and D. Williams. [1954] [1]p. [AF 18(600)772] Unclassified

Presented at meeting of the Amer. Phys. Soc., Poughkeepsie, N. Y., Oct. 16-17, 1953.

Published in Phys. Rev., v. 93: 360, Jan. 15, 1954.

Powdered samples of sodium chlorate have been found to exhibit an extremely narrow absorption line near 30 mc/sec due to nuclear quadrupole transitions involving Cl^{35}. The present work has been concerned with a study of single crystals of sodium chlorate. In the experimental work a single crystal was mounted in the coil of an oscillating detector, and an external magnetic field was employed to produce Zeeman splitting. The observed Zeeman pattern is dependent upon the orientation of the crystal in the external magnetic field. The patterns to be expected can be calculated. The patterns for five orientations will be compared in detail with theoretical predictions. From the observed patterns it is possible to calculate the nuclear magnetic moment of Cl^{35}. The preliminary value of 0.820 ± 0.001 nuclear magnetons compares favorably with the value 0.8210 nuclear magnetons obtained in nuclear magnetic resonance studies of liquid samples and serves as a check on the validity of theory. PROTON LINE SHAPES IN THE MAGNETIC RESONANCE SPECTRA OF AMMONIUM SALTS (Abstract), by R. Carpenter and D. Williams. [1954] [1]p. [AF 18(600)772] Unclassified

Presented at meeting of the Amer. Phys. Soc., Poughkeepsie, N. Y., Oct. 16-17, 1953.

Published in Phys. Rev., v. 93: 360, Jan. 15, 1954.

Proton magnetic resonance line shapes have been observed in the ammonium halides, ammonium sulfate, and ammonium nitrate at room temperature. Measurements were made with an unquenched radio-frequency oscillating detector in a field of approximately 7800 gauss. Frequency measurements were made with a radio receiver and a 10 kc/sec crystal-controlled multivibrator. The line widths in ammonium halides showed a monotonic decrease with increasing atomic number of the halide. The proton resonance line in ammonium fluoride was the widest observed in this study. Ammonium sulfate and ammonium nitrate both showed comparatively narrow proton absorption lines, the ammonium nitrate line showing the narrowest width of any of the salts studied. The second moments of the proton line for the different salts were computed from the observed line shapes and were found to be smaller than would be expected for a rigid lattice structure. QUADRUPOLAR SPLITTING OF THE Al^{27} AND Be^9 MAGNETIC RESONANCES IN BERYL CRYSTALS, by L. C. Brown and D. Williams. June 3, 1955 [17]p. incl. diagrs. [Part 1 of Technical rept. no. 2] (AFOSR-TN-55-345, Pt. 1) (AF 18(600)772) AD 100978 Unclassified

Also published in Jour. Chem. Phys., v. 24: 751-756, Apr. 1956.

The quadrupolar hyperfine structure of the Al^{27} and Be^9 nuclear magnetic resonance peaks in beryl crystal at 300°K have been examined. From the observed spectra, the following values were obtained for the nuclear spins I, the effective nuclear magnetic moments μ, the nuclear quadrupole coupling constants eQ $\cdot$ zz and the electric field asymmetry parameters η:

Al^{27}: I = 5/2, $|\mu|$ = 3.6385 ± 0.0003 n. m., $eQ \cdot zz$ = 3.093 ± 0.015 mc/sec, η = 0.000 ± 0.005.
Be^9: I = 3/2, μ = 1.174 ± 0.0002 n. m., $eQ \cdot zz$ = 0.504 ± 0.004 mc/sec, η = 0.090 ± 0.005.

NUCLEAR MAGNETIC DIPOLE AND ELECTRIC QUADRUPOLE ENERGY RELATIONS, by L. C. Brown and P. M. Parker. Aug. 31, 1955 [4]p. incl. refs. [Part 2 of Technical rept. no. 2] (AFOSR-TN-55-345, Pt. 2) (AF 18(600)772) AD 100978(a) Unclassified

Also published in Phys. Rev., v. 100: 1764-1767, Dec. 15, 1955.

Calculations based on existing theory of nuclear magnetic dipole and electric quadrupole transitions provide general expressions in closed form relating I, μH_0, e^2Qq, η, θ, and Φ to experimentally determined frequencies ν_{ij}. The angles θ and Φ determine the orientation of H_0 in the principal axis system of ∇E. Methods of applying the expressions in specific situations are discussed. Application of the procedure to similar systems, such as the asymmetric rotator, is pointed out. (Contractor's abstract)

NUCLEAR QUADRUPOLE LEVELS IN SINGLE CRYSTALS, by P. M. Parker. May 1956 [7]p. incl. diagrs. tables, refs. [Part 3 of Technical rept. no. 2] (AFOSR-TN-55-345, Pt. 3) (AF 18(600)772) AD 100978(b) Unclassified

Also published in Jour. Chem. Phys., v. 24: 1096-1102, May 1956.

Numerical methods are used to study the behavior of the energy levels of a nucleus, having nonzero quadrupole moment and spin I = 1 or 3/2, under the influence of a constant uniform external magnetic field and an electric crystalline field of axial symmetry. These numerical results are of use when experimental conditions are such that perturbation theory cannot be applied in data analysis. (Contractor's abstract)

PROTON POSITIONS IN BRUCITE CRYSTALS, by D. E. Elleman and D. Williams. Nov. 7, 1955 [3]p. incl. diagrs. tables, refs. [Part 1 of Technical rept. no. 4] [AFOSR-TN-55-399] [AF 18(600)772] AD 115057 Unclassified

Also published in Jour. Chem. Phys., v. 25: 742-744, Oct. 1956.

The proton positions in brucite ($Mg(OH)_2$) have been determined by comparison of nuclear magnetic resonance spectra with existing x-ray data. The protons are located in parallel planes in each of which the protons are arranged in a pattern having hexagonal symmetry. The distance between adjacent protons in a given plane is 3.12 ± 0.01 Å, while the distance between a given proton and its nearest neighbors in the next plane is

OSU. 08:015 - OSU. 08:019

1.93 ±0.02 Å. The distance between adjacent proton planes is 0.69 ±0.02 Å. The internuclear distance in the OH bond is found to be 0.98 ±0.02 Å. (Contractor's abstract)

MICROWAVE SPECTRUM OF CHLOROFORM, by P. N. Wolfe. Nov. 15, 1955 [6]p. incl. diagrs. tables, refs. [Part 2 of Technical rept. no. 4] [AFOSR-TN-55-416] [AF 18(600)772] AD 115057(a) Unclassified

Also published in Jour. Chem. Phys., v. 25: 976-981, Nov. 1956.

A theoretical and experimental examination of the J=2 ⟶ 3 transition in $CHCl_3^{35}$ permits the evaluation of the quadrupole coupling constant of the molecule as eQV_{zz}=28.70 ±.08 mc, and provides an improved value of the rotational constant, B=3302.41 ±.03 mc. Two centrifugal distortion coefficients are also obtained: Dj=4.12 ±.43 kc and Djk = 55 ± 7 kc. The J=2 ⟶ 3 transitions in $CHCl_2^{35}Cl^{37}$ yield the following, revised structural parameters for chloroform: C — H = 1.073 Å, C — Cl = 1.762 Å, and Cl — C — Cl = 110°55'. With the assumption of axial charge symmetry about the C — Cl bond direction, a, the revised bond angle gives eQV_{aa} = -80.39 ±.22 mc for the quadrupole coupling constant of $CHCl_3^{35}$. NUCLEAR MAGNETIC MOMENT OF POTASSIUM (Abstract), by L. C. Brown and D. Williams. [1955] [1]p. [AF 18(600)772] Unclassified

Presented at meeting of the Amer. Phys. Soc., Baltimore, Md., Mar. 17-19, 1955.

Published in Phys. Rev., v. 98: 1537, June 1, 1955.

The nuclear magnetic resonance peak due to K^{39} in a saturated solution of KF has been observed in a field of approximately 7800 gauss. The K^{39} resonance frequency has been compared with that of N^{14} in a solution of HNO_3. The ratio obtained is $\nu(K^{39})/\nu(N^{14})$ = 0.64588, a value in agreement within the limits of experimental error with the value obtained by Collins, who observed the K^{39} resonance in a solution of KNO_2. A comparison of the experimental errors will be given and a "best value" for the magnetic moment will be proposed.

HYPERFINE STRUCTURE IN THE PARAMAGNETIC RESONANCES IN SOLUTIONS OF MANGANOUS SALTS (Abstract), by J. E. Geusic and D. Williams. [1955] [1]p. [AF 18(600)772] Unclassified

Presented at meeting of the Amer. Phys. Soc, Washington, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 99:612, July 15, 1955.

Studies of paramagnetic resonance absorption by the Mn^{++} ion in solutions of manganese salts have revealed well resolved hyperfine structure. The observed line pattern is predicted by the expression,

$$H = h\nu/g - Am\frac{A^2g^2}{2h\nu}\{1(1+1) - M^2 + M(2M-1)\},$$

in which the symbols have their usual meaning. The value for the hyperfine splitting parameter A=95.3 ±1.0 gauss is in agreement with the value previously obtained by Tinkham, Weinstein, and Kip but in disagreement with the value reported by Schneider and England. The variation of line width with concentration will be discussed. (Contractor's abstract)

SUSCEPTIBILITY AND ENTROPY OF F-CENTERS (Abstract), by J. Forringa and J. G. Daunt. [1955] [1]p. ([AF]OSR-TN-55-34) [AF 18(600)1003] Unclassified

Presented at meeting of the Amer. Phys. Soc., Baltimore, Md., Mar. 17-19, 1955.

Published in Phys. Rev., v. 98: 1550, May 15, 1955.

The entropy S and the paramagnetic susceptibility χ of F-centers in alkali halides have been computed using the model of Kip, Kittel, Levy and Portis. With the hyperfine coupling between the F-center electron and the six equivalent nearest alkali nuclei as the only interaction, the eigenvalues of the energy of the center in a weak magnetic field were calculated up to 2nd order in H. The sum of states then yields an expression for S and χ as a function of a reduced temperature $T^*=kT/E_c$, where E_c is twice the hyperfine coupling constant. The calculations have been limited to nuclei with spin 3/2. The influence of the hfs on χ amounts to 7.5 per cent for $T^*=10$, corresponding to $T\approx 0.01°K$ for Li^6 and up to $T\approx 0.4°K$ for Cs^{133}. In a magnetic cooling experiment starting in a strong magnetic field $T_i=1°K$ at most the electronic entropy R ln 2 can be removed, leading to a final temperature $T_f^*\approx 3$. MAGNETIC PROPERTIES OF DEFECTS AND IMPURITIES IN SOLIDS, by C. V. Heer and C. J. Rauch. July 1955, 5p. incl. table. (Technical note no. 1) ([AF]OSR-TN-55-187) (AF 18(600)1003) AD 74067 Unclassified

Presented at the International Conference on Low Temperature Physics, Paris (France), Sept. 2-8, 1955.

Study was initiated on the magnetic properties of defects and impurities at liquid He temperatures. The correlation between the number of F-centers in the alkali halides determined by optical and magnetic techniques was selected for the initial phase. KCl and KBr crystals were colored by heating to 600° to 700°C in the presence of K vapor for several hours and quenching to room temperature in an AcOH bath. The quench provides rapid cooling, yielding uniformly colored crystals with pure F-band absorption. Magnetic susceptibility measurements of the colored crystals were made between 1° and 300° K by the Gouy method (Phys. Rev., v. 90: 530, 1953). The susceptibility followed Curie's law down to the lowest temperature, and the saturation of the magnetic movement in strong magnetic fields was consistent with a free electron spin. The number of F-centers was determined from the Curie constant. Optical absorption curves were obtained for a series of positions in the crystal, and the number of F-centers was determined by applying Smakula's equation which relates the number of absorption centers to the absorption constant, α, and the half-width of the absorption line. The ratio of the number of centers measured optically to the number measured magnetically is assumed to be the f-value or oscillator strength. The magnetic properties of synthetic ruby (Al_2O_3) with a small amount of Cr^{3+} was examined between 1° and 300°K. The crystal with the magnetic field oriented at 30° with the hexagonal c axis followed a Curie-Weiss law in the He temperature region, $x=\frac{2.77 \times 10^{-3}}{T+0.05}$ emu/cc.

SOME F-BAND OPTICAL OSCILLATOR STRENGTHS IN ADDITIVELY COLORED ALKALI HALIDES, by C. J. Rauch and C. V. Heer. July 26, 1956 [7]p. incl. diagrs. tables, refs. (Technical note no. 3) (AFOSR-TN-56-352) (AF 18(600)1003) Unclassified

Also published in Phys. Rev., v. 105: 914-920, Feb. 1, 1957.

OKA. 01:001 - OKA. 02:002

The number of magnetic centers in alkali halides additively colored in the alkali vapor were determined by measuring the static magnetic susceptibility. Curie's law was followed, and the measurements were extended to liquid He temps. to increase the sensitivity. The number of centers was compared with the optical absorption of the F band. Under the assumptions that the F-center electron wave function depends parametrically upon the coordinates of the surrounding nuclei, the electric dipole matrix element is independent of the nuclear coordinates, and the electric field at the electron is the Lorentz local field, the optical oscillator strengths for a Lorentz, Gaussian, and observed line shape were determined. The average for a series of experiments yielded $f_L = 0.66$ for KCl, $f_L = 0.71$ for KBr, and $f_L = 0.46$ for KI. Values for CsBr and NaCl are discussed. (Contractor's abstract)

OPTICAL ABSORPTION, PHOSPHORESCENCE, AND BIREFRINGENCE IN SEMI-CONDUCTING DIAMOND (Abstract), by W. J. Leivo and H. J. Stein. [1956] 1p. [AFOSR-TN-56-461] (AF 18(603)40) AD 97079 Unclassified

Presented at Color Center Symposium, Argonne National Lab., Lamont, Ill., Oct. 31-Nov. 2, 1956.

A type IIb diamond was studied in which the opposite ends show different properties. One half of the crystal has a slight bluish color and has an electrical conductivity considerably greater than the other half. The clear portion, however, would still be classified Type IIb from a conductivity standpoint. A double set of intersecting birefringent lines can be observed at the blue end, whereas the clear side shows only a single set. Both sides show phosphorescence, but the phosphorescent color, lifetime and excitation wavelength are different. There are also changes in the optical absorption in the 2 sides. In particular, the major absorption peaks at 2.43 and 3.56 in the blue end are not observed in the clear end. The absorption at 3.56 (0.35 ev) corresponds to the activation energy for a Group III impurity using the simple hydrogen atom model. A value of about 0.35 ev has also been previously obtained for the slope of the curve k ln R vs 1/T in the low temperature region. The absorption peaks characteristic of the blue side are temperature dependent, increasing with decreasing temperature. Changes in the ultraviolet cut-off region with temperature are are also observed. The investigations on this diamond give some support to Custers' (Physica, v. 20: 183-184, Mar. 1954) proposal that the conductivity may be the result of lattice imperfections other than impurities. PHOTOCONDUCTIVITY IN TYPE IIb DIAMOND (Abstract), by M. D. Bell and W. J. Leivo. [1956] [1]p. [AFOSR-TN-56-504] [AF 18(603)40] AD 110319 Unclassified

Presented at meeting of the Amer. Phys. Soc., Monterey, Calif., Dec. 1956.

The photoconductivity of two specimens of semiconducting diamond has been studied. The diamonds are photoconducting in the visible and near infrared with a major peak occurring at 660 mμ and a slight peak at 890 mμ. The photoconductivity is obtained without previous irradiation with ultraviolet light. Maxims of photoconductivity in the ultraviolet occur at 223 mμ and 228 mμ. The peak at 223 mμ was not observed in all parts of the diamonds. Also, the portion of one specimen which had the highest dark conductivity had no detectable photoconductivity in the ultraviolet above 190 mμ, the lower limit measured, but it did show the visible and near infrared photoconductivity. The photoconductivity was also dependent upon the direction of current flow through the crystal. (Contractor's abstract)

ACTIVITIES OF ELECTROLYTES IN THREE-COMPONENT SYSTEMS, by T. E. Moore. [Aug. 25, 1955] 3p. ([AF]OSR-TN-55-288) (AF 18(600)478) Unclassified

Equations are derived from the Gibbs-Duhem equation for 3 components which are particularly useful in determining the effect of a second electrolyte (at varying concentrations) upon the activity of a given electrolyte at some arbitrary concentration (as might be the case in studying extraction-promoting electrolytes in the liquid-liquid extraction of salts). The results are usually most useful if all activities are referred to the conventional standard states in binary solutions.

RESEARCH STUDY OF THE MECHANISM OF ACTION IN THE SYNTHESIS OF CELLULOSE, by G. A. Greathouse, D. E. Barnes, and W. Borysewich. Final technical rept. Mar. 1, 1955 - Feb. 29, 1956, 32p. incl. diagr. tables, refs. (AFOSR-TR-56-16) (AF 18(600)1389) AD 86600 Unclassified

Experimental data are presented on C^{14}-cellulose formation by Acetobacter xylinum or cell-free enzyme systems from D-glucose-1-C^{14}, D-glucose-2-C^{14}, D-glucose-6-C^{14}, and glycerol-1, 3-C^{14}. There are at least 2 mechanisms of cellulose synthesis indicated by these data. One, a prior cleavage of hexoses to trioses and then resynthesis to hexoses, probably hexose phosphates and then polymerization to cellulose; 2nd, a direct polymerization of hexoses, probably through the phosphates, to cellulose. Identification was made of hexose monophosphates, diphosphates, and dihydroxyacetone phosphates as intermediates between glycerol and hexose biosynthesis of cellulose. (Contractor's abstract)

CARBON DIOXIDE FIXATION DURING PROTEIN SYNTHESIS FROM AMMONIUM ACETATE, by H. L. Kornberg. [1956] [3]p. incl. diagrs. table. (AF 61(514)1180) Unclassified

Published in Biochem. et Biophys. Acta, v. 22: 208-210, Oct. 1956.

It is shown that in the growth of Pseudomonas KB_1 on acetate as the sole source of C, CO_2-fixation reactions other than those now known must play a major role in the synthesis of proteins, and that most of the C of the amino acids synthesized passes through the stage of CO_2 or compounds in ready equilibrium with CO_2. Both $C^{14}H_3CO_2Na$ and $NaHC^{14}O_2$ were incorporated into the acid-solution and protein fractions of the organism, but this result suggested only minimum value of about 17% incorporation of label from $NaHC^{14}O_2$. By the use of the isotope competition technique, however, it was found that of the order of 70% of the C of amino acids synthesized by the organism growing on acetate as sole source of C could be derived from CO_2.

THE DENSITY OF LIQUID FLUORINE BETWEEN 67° AND 103°K, by R. L. Jarry and H. C. Miller. Nov. 4, 1955, 10p. incl. diagrs. tables. ([AF]OSR-TN-55-286) (AF 18(600)761) AD 77193 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 1552-1553, Apr. 20, 1956.

In this study, the density of liquid fluorine has been determined over the temperature range from 66° to 103°K. A description is given of the all-metal system which was used to avoid the danger of contamination resulting from the action of fluorine on glass equipment. The data obtained have been fitted to the equation $d = 1.907 - 2.201 \times 10^{-3}T - 2.948 \times 10^{-5}T^2$, where d is the density in g/cu cm at temperature T. The estimated uncertainty in the density is ± 0.1%. The results are presented in a table, and a comparison is made with fluorine density values collected from other sources.

THE LIQUID DENSITY, VAPOR PRESSURE, AND CRITICAL TEMPERATURE AND PRESSURE OF NITROGEN TRIFLUORIDE, by R. L. Jarry and H. C. Miller. June 11, 1956, 12p. incl. diagrs. tables, refs. (AFOSR-TN-[56-138]) (AF 18(600)761) AD 86015 Unclassified

Presented at Delaware Valley regional meeting of the Amer. Chem. Soc., Philadelphia, Pa., Feb. 16, 1956.

Also published in Jour. Phys. Chem., v. 60: 1412-1413, Oct. 1956.

The liquid density of NF_3 has been measured from 78° to 170°K. These data have been fitted to the equation, $d(g/cc) = 2.103 - 3.294 \times 10^{-3}T - 4.675 \times 10^{-6}T^2$. The estimated uncertainty in the measured values is ± 0.1%. Vapor pressures measured to the critical point are represented to a precision of ± 0.17 atm by the equation, $\log_{10}P(atm) = 4.27264 - 613.330T^{-1}$. The vapor pressures to 1 atm have been measured to a precision of 0.01° in T and the data have been fitted to the Antoine equation, $\log_{10}P(mm) = 6.77966 - 501.913/T - 15.37$. The normal boiling point calculated from the Antoine equation is 144.10°K. Temperature was known in all cases to ± 0.05°. The critical temperature is 233.90 ± 0.10°K, and the critical pressure is 44.72 ± 0.17 atm. (Contractor's abstract)

THE LIQUID DENSITY, VAPOR PRESSURE AND CRITICAL TEMPERATURE AND PRESSURE OF PERCHLORYL FLUORIDE, by R. L. Jarry. Aug. 3, 1956, 8p. incl. tables. (AFOSR-TN-56-251) (AF 18(600)761) AD 88971 Unclassified

Also published in Jour. Phys. Chem., v. 61: 498-499, Apr. 1957.

The liquid density of perchloryl fluoride has been measured from 131° to 234°K, and the data have been fitted to the equation, $d(g/cc) = 2.266 - 1.603 \times 10^{-3}T - 4.080 \times 10^{-6}T^2$. The estimated uncertainty in the values of density is ± 0.1%. Vapor pressures have been measured to the critical point. The vapor pressure data to 2 atm are represented by the equation, $\log_{10}P(mm) = 18.90112 - 1443.467T^{-1} - 4.09566 \log_{10}T$. The normal boiling point calculated using this equation is 226.40°K. Vapor pressure data to the critical point are represented to a precision of ± 0.17 atm by the equation, $\log_{10}P\ atm = 4.46862 - 1010.81T^{-1}$. The critical temperature is 368.33 ± 0.10°K and the calculated critical pressure is 53 atm absolute. (Contractor's abstract)

AN ALL METAL APPARATUS FOR THE DETERMINATION OF THE DENSITIES OF LIQUEFIED GASES, by R. L. Jarry. Dec. 10, 1956, 6p. incl. diagr. (AFOSR-TN-56-497) (AF 18(600)761) AD 110312 Unclassified

Also published in Rev. Scient. Instruments, v. 28: 641-642, Aug. 1957.

An all metal apparatus designed for density measurements on liquefied gases is described. The metal construction enabled its use with corrosive materials, and also allowed measurements to be made to moderate pressures. It consists of a pycnometer, temperature control device and gas handling system. While this apparatus was particularly designed for density work it could be adapted for PVT measurements with slight modifications. The design and construction is detailed and its use with liquid fluorine outlined. (Contractor's abstract)

THE VISCOSITY AND SURFACE TENSION OF PERCHLORYL FLUORIDE, by J. Simkin and R. L. Jarry. Technical rept. Dec. 10, 1956, 3p. incl. tables. (AFOSR-TN-56-498) (AF 18(600)761) AD 110313
Unclassified

Also published in Jour. Phys. Chem., v. 61: 503-506, Apr. 1957.

Relative viscosity measurements of perchloryl chloride were made with acetone as the reference material. Surface tension measurements were based on the capillary rise in a Scarpa viscometer. Viscosity values are reported in centipoise at various temperatures (C) as follows:

t, °C	n, centipoise
-76.5	0.572
-75.0	0.563
-65.9	0.500
29.9	0.173
53.8	0.142

Surface tension in dynes /cm is reported as follows:

t, °C	Surface tension
-75.2	24.1
-65.8	22.3
-55.6	21.3

This research project was concerned with the determination of various physical properties of liquid fluorine, nitrogen trifluoride and perchloryl fluoride. The densities of liquid fluorine were measured over the temperature range 67 to 103°K. For nitrogen trifluoride and perchloryl fluoride, determinations were made of the liquid density over the temperature ranges 78 to 170°K and 131 to 234°K respectively. Vapor pressure for these two compounds were measured to the critical region, and their critical temperatures determined. In addition for perchloryl fluoride, data on the viscosity and surface tension were taken over a limited range. During this program apparatus and techniques were adapted or developed for the various measurements. As an example an all metal device was designed and successfully operated for measuring liquid densities of corrosive materials to a precision of ± 0.1%. (Contractor's abstract)

BOUNDARY LAYER CONTROL BY POROUS SUCTION, by H. G. Lew and R. D. Mathieu. June 1954, 117p. incl. diagrs. table, refs. (Technical rept. no. 3) ([AF]OSR-TN-54-203) (AF 18(600)575) AD 41436
Unclassified

The status of the investigation of the laminar boundary layer with a normal velocity at the wall, especially suction, was surveyed. Certain simple exact solutions of the boundary layer equations with continuous porous suction are given. Among these are the exact asymptotic profile, the circulatory flow about a circular cylinder with constant suction, and the similar profiles in the appropriate coordinate system. The method of Trilling uses (x, u) coordinates and an expansion in terms of the velocity u. Ringleb's solution approximates the velocity profile by an exponential function of a polynomial of the fourth power. The expansion in series method was useful in obtaining an exact solution, but a considerable expenditure of time was required in performing the calculations. Thwaites' new method of unlparametric calculation of the boundary layer with constant suction and an adverse pressure gradient by the use of the momentum equation simplified the calculation by allowing the easy addition of profiles. The approximate momentum method of Schlichting avoided the difficulty by Preston by representing the Blasius profile by a combination of sine curve and an exponential curve. Yuan's method is based essentially on the same profile of Schlichting. The emphasis of theoretical studies of boundary layer control problems by porous means should be placed on 3 dimensional flows and on turbulent flow.

ON THE LAMINAR COMPRESSIBLE BOUNDARY LAYER OVER A FLAT PLATE WITH SUCTION OR INJECTION, by H. G. Lew and J. B. Fanucci. July 1954, 50p. incl. diagrs. tables, refs. (Technical rept. no. 4) ([AF]OSR-TN-54 255) (AF 18(600)575) AD 44624
Unclassified

Also published in Jour. Aeronaut. Sciences, v. 22: 589-597, Sept. 1955.

Exact solutions are calculated for the flow of a compressible laminar boundary layer over a flat plate for the cases of homogereous suction and injection. The characteristics of these flows are given in detail. The solutions of the momentum method given by H. G. Lew (Reissner Anniversary Volume, p. 43-60, 1949, J. W. Edwards, Ann Arbor, Michigan, and PIBAL Rept. no. 131 of the Polytechnic Institute of Brooklyn, Sept. 1948) and by H. G. Lew and F. Romano (PIBAL Rept. no. 132, Sept. 1948) compare favorably with the present results. Asymptotic solutions are developed which are valid for

flows which are large distances from the leading edge of the plate or for flows over arbitrary bodies with large suction. The exact solutions for the flow over a flat plate with homogeneous suction approach the asymptotic solution downstream of the leading edge, and for practical purposes, this occurs at a rather short distance from the leading edge. The asymptotic solutions are given in closed form for several cases, and they may be used as first approximations for the above flows. The method of Lighthill (Proc. Roy. Soc. London, A 202, no. 1070:359-377, 1950) for the approximate calculation of heat transfer at the wall is exact for the asymptotic solution.

AN EXACT SOLUTION OF THE LAMINAR BOUNDARY LAYER WITH ZERO PRESSURE GRADIENT AND HOMOGENEOUS INJECTION, by H. G. Lew and J. B. Fanucci. July 1955 [46]p. incl. diagrs. tables. (Technical rept. no. 6) ([AF]OSR-TN-55-273) (AF 18(600)575) AD 72720 Unclassified

The laminar boundary layer equations with the effects of injection have been transformed to a form such that all equations and boundary conditions are independent of the injection velocity at the wall. The resulting momentum equation, which is independent of the injection velocity, has been integrated along the plate length to almost the vanishing of the wall shear stress. Characteristics of the flow for the incompressible case for homogeneous injection have been evaluated. The velocity profiles have an inflection point, and the wall shear stress rapidly approaches zero. It is determined in the case of injection that results of momentum integral methods (quartic profile) agree favorably for small values of $|v|$ and, may be in considerable error for larger values of $|v|$. For example, for $-0.2 < v < 0$, the error of the wall shear stress is within 10%.

THE ASYMPTOTIC SUCTION CHARACTERISTICS OF THE BOUNDARY LAYER ON A CIRCULAR CYLINDER, by H. G. Lew. Jan. 1956 [35]p. incl. diagrs. (Technical rept. no. 7) (AFOSR-TN-56-293) (AF 18(600)575) AD 96005 Unclassified

The asymptotic suction characteristics of the boundary layer over a circular cylinder are considered for a rotating and nonrotating cylinder. Both the incompressible and compressible cases are treated. In the nonrotating case, the assumption that the radius may be of the same order as the boundary layer thickness is retained thus, increasing the displacement thickness when suction is present. The effect of suction on the circular cylinder as compared to the flat plate case is minimized by the small radius and is reflected by the parameter $(-v_0 a/\nu)$. For the rotating cylinder, the axial velocity field is coupled to the rotational velocity field and the temperature field by the variable viscosity coefficient. The effect of rotation on the characteristics of the flow is contained in a factor multiplying the Mach number and is small for small rotation. In all cases, the skin friction intensity in the axial direction is independent of the rotation and the transverse curvature. (Contractor's abstract)

ASYMPTOTIC SUCTION CHARACTERISTICS OF THE BOUNDARY LAYER OVER A CIRCULAR CYLINDER, by H. G. Lew. May 11, 1956, [2]p. [AF 18(600)575] AD 117607 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 23: 895-897, Sept. 1956.

The means of calculating the displacement area and momentum defect area are described. Expressions are given for the displacement thickness and for the ratio of this displacement thickness to that of the two-dimensional asymptotic suction profile. Effects of skin friction are pointed out. These findings are extended to the flow of a compressible heat-conducting boundary layer over a porous circular cylinder with uniform suction. Means for determining the effect of compressibility and velocity profile are given.

WORK FUNCTION OF TUNGSTEN SINGLE CRYSTAL PLANES MEASURED BY THE FIELD EMISSION MICROSCOPE, by E. W. Müller. Sept. 1954. 15p. diagrs. table, refs. ([AF]OSR-TN-54-257) (AF 18(600)672) AD 47613 Unclassified

Also published in Jour. Appl. Phys., v. 26: 732-737, June 1955.

The work functions of the low-emitting crystallographic planes of tungsten, (011) and (112), are not well known. In previous experiments scattered secondaries and some other disturbing effects covered the spurious emission particularly of the (011) plane. A method combining the field emission microscope with a probe collector has been applied. The current density in the (011) plane turned out to be 4 to 5 orders of magnitude smaller than in strongly emitting planes. Applying the Fowler-Nordheim theory, φ_{011} was found between 5.70 and 6.17 ev and φ_{112} between 4.65 and 4.97 ev depending on the temperature at which the tungsten crystal has been annealed previously. This is not a temperature effect of the work function, but the result of freezing in thermal imperfections of the planes. The work function of the ideal (011) plane appears to be as high as 6.17 ev. The existence of such a high value is further suggested by the ionization of aluminum on a hot polycrystalline tungsten wire, indicating that about 10% of the surface has a work function higher than the 5.98 ev ionization potential of aluminum. (Contractor's abstract)

WORK FUNCTIONS OF TUNGSTEN SINGLE CRYSTAL PLANES (Abstract), by E. W. Müller. [1954] [1]p. [AF 18(600)672] Unclassified

Presented at meeting of the Amer. Phys. Soc., Ohio U., Athens, Apr. 16-17, 1954.

Published in Bull. Amer. Phys. Soc., v. 29: 26, June 28, 1954.

Published in Phys. Rev., v. 96: 837, Nov. 1, 1954.

Electron emission from the 110 plane has been measured as a spurious effect only. The method of a field emission microscope with a probe hole in the screen and behind it a suppressor and a collector has been improved. The current density in the 110 plane was found to be 4 to 5 orders of magnitude smaller than in the strongly emitting planes. Applying the Fowler-Nordheim theory and assuming φ_{111} = 4.38 ev according to M. H. Nicols and G. F. Smith, NRL rept. no. 24433, 1952, one finds φ_{110} between 5.80 and 6.15 ev, depending on the temperature at which the crystal has been annealed previously (2500°K and 1200°K, respectively, vacuum 10^{12} mm). The same effect at the 112 plane yields work functions between 4.80 and 5.05 ev. It is caused by freezing in the thermal imperfections. The data of all strongly emitting planes agree with those obtained by thermionic methods. (Contractor's abstract)

FIELD ELECTRON EMISSION. PART I. STUDY OF ADSORPTION OF BORON ON TUNGSTEN, by R. D. Young. PART II. STUDY OF SILICON DEPOSITS ON MOLYBDENUM, by E. C. Cooper. July 1956 [87]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 2) (AFOSR-TN-56-317) (AF 18(600)672) AD 94853 Unclassified

Part I. The adsorption of B on W was studied with the field electron microscope. Boron was strongly bonded to the W substrate as indicated by activation energies of 2.8 ev for surface migration and 6.2 ev for disappearance. The crystallographic planes which are darkened by the presence of a few B layers have either a zero in the plane's index or each plane has 2 identical indices. A monolayer was defined for B adsorption by noting the degree of covering of the last stable layer as the tip temperature increases. Spiral growths were discovered which have a form similar to that of a screw dislocation. A pole figure for the cubic system and a standard tip temperature vs tip loop current calibration curve are included. Part II. In a second study, the effect of Si deposits on a Mo surface was observed using a field emission microscope. The activation energy of pure Mo for surface migration is 3.1 ev and for the Si deposit ranges from 4.0 to 0.8 ev with a straight line average of about 2.5 ev. The activation energy for the Si deposit is about 4.0 ev for evaporation. It is said that small traces of O hinder the migration of the Si deposit and enhance the migration for pure Mo. SEEING ATOMS IN A MICROSCOPE, by E. W. Müller. [1956] [3]p. incl. illus. diagrs. (AF 18(600)672) Unclassified

Published in Armed Forces Chem. Jour., v. 10: 13, 36, 38, Nov.-Dec. 1956.

A new low temperature field ion microscope has made it possible to photograph single atoms on the surface of a solid (tungsten). Tungsten atoms are approximately 5 one-thousandths of one-millionth of an inch in diameter. This microscope consists of an evacuated glass tube containing a minute quantity of helium. Sealed in the middle and pointing toward a fluorescent screen is an extremely fine tungsten needle. A very high voltage is applied between the point of the needle and the screen.

PSU. 06:001 - PSU. 06:005

The helium gas is ionized very close to the tip, and these ions stream radially from the point to the screen, giving an enlarged projection of the tip surface. The microscope is a useful tool for investigating the influence of surface films such as oxygen, water vapor, and hydrogen on atomic surface migration, creep of metals at high temperatures, corrosion, and the effects of nuclear radiation on the individual atoms in a solid material. It also has proved useful in studying important problems of the production of high temperature alloys, cathode sputtering, effects of temperature and electric field strength on work functions of single crystal planes, optical and field excitation of absorbed atoms and field emission into liquid and solid insulators.

FIELD IONIZATION. PART I. FIELD DESORPTION, by E. W. Müller. Sept. 1955 [20]p. incl. illus. diagrs. refs. ([AF]OSR-TN-55-307 (pt. 1)) (AF 18(600)673) AD 75120 Unclassified

Also published in Phys. Rev., v. 102: 618-624, May 1, 1956.

Field desorption of barium, thorium, oxygen and some other adsorbates is studied in a field emission microscope with reversed polarity as a function of field strength, temperature, and degree of coverage. The desorption occurs in the 100, 200 and 500 million v/cm range, for the 3 substances, respectively. At the highest fields, the tungsten substrate itself evaporates at room temperature. The quantitative interpretation of the measurements suggests that field desorption be considered as an evaporation of ions in which the energy hump is reduced by the Schottky effect.

FIELD IONIZATION. PART II. FIELD IONIZATION OF GASES AT A METAL SURFACE AND THE RESOLUTION OF THE FIELD ION MICROSCOPE, by E. W. Müller and K. Bahadur. Sept. 1955 [31]p. incl. illus. diagrs. refs. ([AF]OSR-TN-55-307 (pt. 2)) (AF 18(600)673) AD 75120(a) Unclassified

Also published in Phys. Rev., v. 102: 624-631, May 1, 1956.

The mechanism of field emission of positive ions is considered to depend upon the supply of molecules and their ionization probability in a field up to 500 million v/cm. Experimental current-field characteristics match the theoretical curves. The velocity distribution, measured in a retarding potential tube, shows that the ions originate some 5 to 100 Å above the surface, depending upon the field. A simple mass spectrometer is described which uses the field emitter as a point ion source. The resolution of the field ion microscope is found to depend upon tip radius, polarizability, and ionization potential of the gas, and possibly upon the accommodation coefficient and the temperature. Helium seems to give the best resolution of about 4 Å. The possibility of operating a field desorption microscope with sufficient resolution to show the lattice structure of the surface is discussed. FIELD ION EMISSION. PART I. EXPERIMENTAL INVESTIGATION OF FIELD ION EMISSION, by K. Bahadur. Mar. 1956 [30]p. incl. diagrs. tables. (Technical rept. no. 2, pt. 1) (AFOSR-TN-56-118) (AF 18(600)673) AD 82514 Unclassified

A gas source and means for measuring amounts of various gases were added to the apparatus used previousiy in the study of field ion emission. The vacuum system employs a Hg cutoff valve to isolate the tube from the vacuum pumps. He, A, Kr, and Xe were used. A Pd tube was the source of H, $KMnO_4$ was the source of O, and NaN_3 was the source of N. ZnS activated with Ag was used as the fluorescent material for the screens. The screens tended to be deactivated under intense bombardment by a 10- to 20-kv ion beam. A partial recovery was achieved by baking the tube at about 480°C for several hours. Preliminary measurements were made of the ion current in a simple 2-electrode emission microscope which consisted of a W emitter sealed in a glass envelope. The inside walls of the tube were coated with SnO and kept at a high voltage to serve the purpose of the accelerating electrode and of preventing any undesirable and uncontrolled charging up of the walls. The ic -current characteristics for the various gases were in good agreement with the theoretical data. The increase in the ion-current value was ascribed to secondary electrons produced at the accelerating electrode and partly to spatial ionization of gas molecules by high-velocity ions. Space ionization occurred to some extent. Measurements were made of the apparent ion current drawn by the accelerating electrode and the collector together. Field-ion mass-spectroscopy experiments were conducted with a symmetrical 3-element electrostatic lens for focusing the ion beam. Measurements showed an equal abundance of H^+ and H_2^+ for various fields at the emitter and for different gas pressures.

FIELD ION EMISSION. PART II. RESOLUTION OF THE ATOMIC STRUCTURE OF A METAL SURFACE BY THE FIELD ION MICROSCOPE, by E. W. Müller. [Mar. 1956] [12]p. incl. illus. diagr. refs. [Technical rept. no. 2, pt. 2] [AFOSR-TN-56-157] (Bound with its AFOSR-TN-56-118; AD 82514) [AF 18(600)673] AD 82514(a) Unclassified

Also published in Jour. Appl. Phys. v. 27. 474-476, May 1956.

Experiments were conducted with a new field emission microscope especially designed for low-temperature work. Cooling the emitter tip with liquid N greatly improved the resolution. Sufficient accommodation of the He atoms apparently was reached at the temperature of solid N. The use of liquid H increased the intensity but did not improve the resolution. Cooling by liquid He gave a slightly more blurred image. The advantage in using the low-temperature ion microscope become apparent when the conventional field electron emission pattern of a W tip is compared with an ion image of a similar single crystal tip. In many parts of the picture, the individual atoms constituting the concentric edges of the 011 net planes are resolved. The individual atoms along many lattice steps are resolved. The atoms are not clearly oriented in a regular network, but rather along a slightly staggered and almost evenly curved line. A study of a cork ball model of a hemispherical single crystal tip showed that the ion images reveal exactly what would be expected under the restriction of visualizing only the protruding atoms along the net plane edges. The model also indicated that 2 adjacent lattice sites along the steps are very rarely occupied in such a manner as to have both atoms protrude equally. The actual observing of the arrangement of the atoms in the surface lattice apparently will give additional information on surface problems in the future.

In a reinvestigation of the optical, dielectric and structural properties of a large number of alums, ferroelectric behavior was discovered in a number of these, and antiferroelectricity in others. A striking property of these ferroelectrics is that the coercive field is unusually large and increases rapidly with decreasing temperature. The behavior of methyl-ammonium aluminum sulfate dodecahydrate is reported in detail. Comments are also made concerning urea chromium alum and guanidinium aluminum alum.

CRYSTAL STRUCTURE OF CHOLINE REINECKATE (Abstract), by Y. Takeuchi and R. Pepinsky. [1956] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1556 and Office of Naval Research under N6onr-26913) Unclassified

Published in Programs and Abstracts, Amer. Crystallographic Assoc., French Lick, Ind., June 1956, Paper C-5.

The structure of choline reineckate has been determined, as a further illustration of the method of "crystal engineering." Excellent crystals were prepared by the method of diffusion of choline chloride and Reinecke's salt, in opposite arms of a U-tube, into a silicic acid gel in the bend of the tube. Optical observations revealed holohedral orthorhombic symmetry. Weissenberg photographs with Cu Kα radiation showed the space group to be Icma, with a = 12.69 ± 0.03 A; b = 22.80 ± 0.03 A; c = 6.75 ± 0.03 A. There are four formula units of $[C_5H_{13}NOH] \cdot [Cr(NCS)_4(NH_3)_2]$ per cell. The calculated specific gravity of 1.48 compares with the measured value of 1.475. Patterson map revealed that Cr atoms lie on centers with point symmetry 2/m, and Cr-S vectors were found from these maps. Cr and S positions sufficed to determine phases for a Fourier syntheses. The Cr-N-S angle is not 180° as in other reineckates studied, but is 150° on the (001) projection. This affords extra space for the choline ion, the nitrogen atom of which is at (0, 1/4, z). The choline group is randomly oriented in four positions. Atoms of the group could be located from packing considerations, and were clearly revealed in (100) and (001) projections. The structure was refined via these projections and a subsequent three-dimensional synthesis. The R-factors are 11.2 for F(hk0) and 11.8 for F(0kl); B = 2.8A^2. The choline configuration is gauche. In ammonium and pyridine reineckates the N ≡ C-S isothiocyanate structure appears, with N-C distances 1.14 and 1.15 A, and C-S distances 1.80 and 1.76 A, respectively; and the N-C-S groups are on Cr-N = 1.94 A, N-C = 1.27 A, C-S = 1.64 A. The isothiocyanate group is predominately -[N = C = S], therefore. A possible explanation of the differences in the isothiocyanate group in these three structures is offered. (Contractor's abstract)

SOME EXPERIENCE WITH THE CRYSTAL ENGINEERING TECHNIQUE (Abstract), by R. Pepinsky, Y. Takeuchi and others. [1956] 2p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18-(600)1556 and National Inst. of Health) Unclassified

Published in Program and Abstracts, Amer. Crystallographic Assoc., French Lick, Ind., June 1956, Paper no. F-6.

The method of control of crystal symmetry designated as "crystal engineering," for studies of organic ion structures via the preparation of salts with complex ions, has been explored further during the past year. Several hundred complex ion-organic ion salts have been prepared, and many of these examined by single-crystal x-ray diffraction. In all cases where the complex ion locations have been established, these outline the unit cells, and organic ions are in spaces between the complex ions. A number of examples are presented. Where the spaces between the complex ions are so large as to permit disorder in the organic ion arrangement, this disorder can often be eliminated by the use of a complex ion having a polar structure (such as nitroprusside or cobaltpentaminochlor ions). The crystal engineering technique can be extended via the use of large ions such as chlorostannates or silicofluorides. As previously pointed out, use of optically-active complex ions of known hand permits determination of the hand of an optically active organic ion. Temperature-induced crystal transitions have been observed in a number of these compounds. Some interesting features of complex ion structures are reported. (Contractor's abstract)

CRYSTAL STRUCTURE AND DISORDER IN $K_3Co(CN)_6$ AND RELATED COMPLEX ION SALTS (Abstract), by Y. Okaya and R. Pepinsky. [1956] 3p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1556 and Office of Naval Research under N6onr-26916) Unclassified

Published in Program and Abstracts, Amer. Crystallographic Assoc., French Lick, Ind., June 1956, Paper no. 1-6.

Crystals of compounds of the type $K_3M(CN)_6$, with M = Cr, Mn, Fe and Co, have been examined as a part of our program for the investigation of complex ion salts of organic ions. $K_3Co(CN)_3$ is orthorhombic, with a = 10.53 A, b = 13.26 A, c = 8.32 A; $\rho_{obs.}$ = 1.906 gr/cc, $\rho_{calc.}$ for Z = 4 is 1.900 gr/cc. Space group extinctions correspond to Pcnb, showing isomorphism with the corresponding Fe, Cr, Mn and Ir salts whose crystallography was reported by Gottfried and Nagelschmidt. No definitive structure analysis of the series of salts has been published, and several other workers have reported other symmetries for the series. Oscillation and Weissenberg patterns, taken with Co Kα radiation, show that all (hkl) reflections with l even have integral indices; but for l odd the reflections are linked by diffuse streaks parallel to b^*, with integral h indices. For some rapidly-grown crystals no sharp reflections appear, and only streaks parallel to b^* are obser[illegible]e. In addition to space group extinctions, (h, k, 2n) [illegible]sent only for k + n even. A c-axis Patterson projection aided in the location of all atoms. Positions were refined by electron density and structure factor iterative calculations on X-RAC and

S-FAC in two and three dimensions. Interatomic distances are Co - C_1 = 2.07 A; C_1 - N_1 = 1.16 A; Co - C_2 = 2.0**A; C_2 - N_2 = 1.16**; about K_1 at 0, 1/4, 1/8: 2N at 2.57 A and 4N at 2.77 A; about K_2 at 1/4, 0, 1/8: 2N at 3.02 A, 2N at 2.87 A, 2N at 3.14 A. R factors are 0.15 for (hk0) and 0.16 for (hk2) reflections. The reflection anomalies for odd-l layer indicate one-dimensional disorder along b. This is due to the fact that layers perpendicular to b are occasionally displaced by $\frac{c}{2}$. The disorder is permitted because of the particular z-coordinates of K ions on planes x = 1/4, which permit random location of Co atoms at either z = 3/8 or 7/8 without configuration changes. Similar disorder is found in the Cr, Fe, and Mn salts. The disorder probably accounts for the incorrect symmetries reported by Barkhatov and Zhdanov. (Contractor's abstract)

ON THE DESIGNING OF CRYSTAL STRUCTURES (Abstract), by R. Pepinsky. [1956] 2p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1556 and National Insl. of Health) Unclassified

Presented at meeting of the Wilmington Section of the Amer. Chem. Soc., Dec. 12, 1956.

Crystallization of organic ions with complex ions of suitable sizes, charges and solubilities results in structure with cells and symmetries determined chiefly by packing of the complex ions. These cells and symmetries are to a good extent controllable; hence crystals with advantageous properties can be designed or "engineered." X-ray examination of a large number of such structures show the complex ions ideally placed for crystal structure analysis, since structure factor phase determination is facilitated both by direct contribution of the ions to the structure factors and through image-seeking in interatomic vector maps. Locations of the complex ions are readily established from such maps. Use of the optically-active complex ions of known hand permits direct establishment of the absolute configuration of optically-active organic ions included in the lattice, and conversely. Use of complex ion salts also facilitates introduction of anomalous scatterers into non-centrosymmetric crystals, to permit application of a new, direct method for structure determination. This method also reveals the absolute configurations of optically-active components in such a crystal, and hence is of profound stereochemical importance. Examples of structures of a number of complex ion salts with organic ions are presented, to illustrate these concepts. (Contractor's abstract)

X-RAY STUDY OF THE FERROELECTRIC LOW-TEMPERATURE PHASE OF SODIUM NIOBATE, $NaNbO_3$ (Abstract), by G. Shirane, J. Johns and others. 1956, 2p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs. under DA 36-039-sc-63233) Unclassified

Published in Program and Abstracts, Amer. Crystallographic Assoc., French Lick, Ind., June 1956, Paper no. E-3.

The room-temperature structure of sodium niobate, $NaNbO_3$, was first studied by Vousdan. The unit cell is orthorhombic with lattice parameters a = 5.505 A, b = 5.568 A, c = 15.518 A, and space group $P222_1$. At higher temperatures the crystal is cubic of the perovskite type. The room-temperature structure can be obtained from the perovskite phase through antiparallel shifts of the Nb atoms along the cubic (110) direction, which becomes the orthorhombic b axis. A superstructure is

PSU. 08:003 - PSU. 08:005

developed, the periodicity along the c axis being four times greater than that along the original cubic (001) axis. Dielectric observations and the structural study indicate that this phase is antiferroelectric. Recently Cross and Nicholson have reported another phase change at about -150°C. Dielectric measurements reveal ferroelectric behavior in this phase. In order to understand the mechanism of this lower transition, an x-ray study of the ferroelectric phase of $NaNbO_3$ has been carried out. The analysis was accomplished on single crystals grown by using an excess of sodium carbonate as flux. At -170°C. the symmetry is monoclinic, with lattice parameters a = 7.812 A, b = 5.564 A, c = 5.484 A, $\gamma = 80° 51'$ where c is the unique axis. The ferroelectric axis is along a, which is now only twice as long as the original cube axis. Examination of rotation and Weissenberg pictures indicates that the antiparallel shifts of the Nb atoms disappear in the ferroelectric range. The monoclinic cell is approximately rhombohedral with parameters (T= -170°C): $a_R = 3.906$ A, $\alpha = 89° 11'$. Both optical and x-ray observations of the twinning exclude the possibility of true rhombohedral symmetry. X-rays reveal a large volume increase ($\Delta V = 0.31$ A^3) when the transition point is passed from above. (Contractor's abstract)

Published in Phys. Rev., v. 105: 849-856, Feb. 1, 1957.

The room-temperature structure of antiferroelectric lead zirconate, $PbZrO_3$, has been studied by x-ray and neutron diffraction. The symmetry is orthorhombic (pseudo-tetragonal) with lattice parameters a = 5.88 A, b = 11.77 A, c = 8.22 A. The space group is Pba2 and there are 8 formula units in the unit cell. The structure results from slight distortions of the cubic perovskite lattice, which the crystal assumes above 230°C. With respect to the ideal perovskite structure, Pb atoms suffer antiparallel shifts along the former cubic [110] direction; oxygen atoms also suffer antiparallel shifts within the (0, 0, 1) plane and, in addition, unbalanced antiparallel shifts along the c direction. The non-centric symmetry is in accord with the presence of a small piezoelectric effect as reported by Roberts. The oxygen octahedra surrounding the Zr atoms appear to be distorted, and it is possible to explain the strong optical anisotropy within the (0, 0, 1) plane as well as the pseudo-tetragonality (b = 2a). Published in Program and Abstracts, Amer. Crystallographic Assoc., French Lick, Ind., June 1956, Paper no. E-5.

An investigation of the optical, dielectric, thermal, and structure properties of the alum family has resulted in the discovery of a large number of ferroelectrics in this group. A variety of known and new types alums have been prepared and examined, and some debated points in alum chemistry clarified. The dielectric behavior of these crystals is exemplied by that of methylammonium aluminum alum, $(CH_3NH_3)Al(SO_4)_2 \cdot 12H_2O$. This has Curie point at 176°K, with the dielectric constant following a Curie-Weiss law as a function of temperature for a range of about 25° above the transition point. The Curie constant is about 1000°K; the dielectric constant climbs from about 9 at room temperature to about 60 at the Curie point; the coercive field is about 5KV/cm at 2° below the Curie point, and climbs to 15KV/cm 25° below that point; saturated hysteresis loops can be observed only in the temperature range from Curie point to about 20° below it; and the spontaneous polarization is about 0.6 μ-coulombs/cm^2 at 166°K. It has been possible to prepare guanidinium aluminum sulfate and the corresponding chromium salt as an alum. Normal preparation of these salts lead to the hexahydrates, the ferroelectric activity of which was discovered by Holden et al. The structure of chromium guanidinium sulfate hexahydrate was determined in order to permit comparison with the alum structure. Modifications of published alum structures appear to be required. The high- and low-temperature symmetries of the methylammonium alums are discussed. (Contractor's abstract)

FERROELECTRICITY IN THE LANGBEINITE SYSTEM (Abstract), by F. Jona and R. Pepinsky. [Aug. 15, 1956] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs. under DA 36-039-sc-63233)
Unclassified

Published in Phys. Rev., v. 103: 1126, Aug. 15, 1956.

Optical examination of $(NH_4)_2Cd_2(SO_4)_3$ over the range from room temperature to 77°K revealed a crystal

transition about 10° above the lowest temperature. The material is cubic above the transition point, and belongs to the langebeinite [$K_2Mg_2(SO_4)_3$] family. An x-ray powder pattern establishes the lattice constant as $a = 10.35_0 \pm 0.005$ A at room temperature. Growth from water solution at 80°C results in predominance of octahedral (111) faces. Dielectric measurements were made on plates cut perpendicular to the cubic [111] direction. The behavior of the low-field dielectric constant ϵ_{111} as a function of temperature is depicted. The room temperature value of ϵ_{111} is about 9.5; the constant begins to climb slightly at -160°C, and reaches a peak of 10.2 at -184°C. Below this point, ferroelectric hysteresis loops are observed. The coercive field at -190°C is approximately 15 KV/cm for an applied field of 25 KV/cm, and the spontaneous polarization above the former [111] cube direction is about 0.3 microcoulombs/cm^2. The hysteresis loops sometimes appear with noncentric symmetry, as in the case of guanidinium aluminum sulfate hexahydrate as reported by Holden et al. Detailed dielectric, optical, thermal and x-ray measurements on this and isomorphous crystals are in progress. (Contractor's abstract)

DIELECTRIC AND THERMAL STUDY OF THE FERROELECTRIC TRANSITION IN METHYLAMMONIUM ALUMINUM ALUM (Abstract), by F. Jona, S. Vidulich and R. Pepinsky. [1956] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)35 and Signal Corps Engineering Labs. under DA 36-039-sc-63233) Unclassified

Presented at the Fourteenth Pittsburgh Diffraction Conference, Oct. 31-Nov. 2, 1956, Paper no. 22.

The dielectric and thermal properties of the alum MASD, $(CH_3NH_3)[Al(H_2O)_6](SO_4)_2 \cdot 8H_2O$, which has recently been found to be ferroelectric, have been examined. A dielectric constant versus temperature study has determined the transition temperature as 177.2°K. The maximum value of ϵ at this temperature is 60. For the chromium isomorph MCrSD, $(CH_3NH_3)[Cr(H_2O)_6](SO_4)_2 \cdot 6H_2O$, the transition temperature is 185°K, at which point ϵ reaches a maximum of about 70. The Curie-Weiss law appears to be followed over a short temperature range (about 6°). The transition temperature is raised by appoximately 1 percent, and the dielectric constant lowered by about 2%, by a dc biasing field. The original cubic [100] direction becomes the polar axis below the transition temperature. P_s drops very sharply at the transition temperature. The heats of transition of MASD and MCrSD are large, and are comparable to the heat of transition in KH_2PO_4. The transition is probably of first order. X-ray and optical observations indicate that the symmetry of the low-temperature phase is probably monoclinic. (Contractor's abstract)

CORRELATION ENERGIES AND ANGULAR COMPONENTS OF THE WAVE FUNCTIONS OF THE GROUND STATES OF H^-, He I, AND Li II, by L. C. Green, M. N. Lewis and others. [1953] [22]p. incl. tables, refs. [In cooperation with Haverford Coll., Strawbridge Observatory, Pa.] (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)660 and Office of Naval Research) Unclassified

Also published in Phys. Rev., v. 93: 273-279, Jan. 15, 1954.

A 3-parameter variational function involving a symmetrized exponential in the nuclear distances and a linear factor in the interelectron distance has been obtained for He I and Li II to examine the effects of configuration interaction in the ground state of the 3 simple atomic systems, H^-, He I, and Li II. These functions together with the one of the same type already in existence for H^- have been expanded in series of Legendre functions of the cosine of the angle between the 2 radius vectors. The coefficients in these expansions are functions of the nuclear distances of the 2 electrons. The various component functions are presented, together with the coefficients with which they enter the expansions, and their contributions to the total energies. A discussion is given of the method of estimating the magnitude of the total correlation, or configuration interaction, energy and its radial, angular, and mixed parts. A table is given of the values of the correlation energy, and its various parts for H^-, He I, and Li II. (Contractor's abstract)

A DISCUSSION OF ANALYTIC AND HARTREE-FOCK WAVE FUNCTIONS FOR $1s^2$ CONFIGURATIONS FROM H^- TO C v, by L. C. Green, M. M. Mulder and others. [Oct. 30, 1953] [19]p. incl. tables, refs. [In cooperation with Haverford Coll., Strawbridge Observatory, Pa.] (Sponsored jointly by [Air Force] Office of Scientific Research under AF 18(600)660 and [Office of Naval Research]) Unclassified

Also published in Phys. Rev., v. 93: 757-761, Feb. 15, 1954.

Two simple analytic expressions are presented, both of which are excellent approximations to a Hartree-Fock 1s wave function in a $1s^2$ configuration. One of these expressions is a 2-parameter function and the other a 3-parameter one. The parameters were chosen variationally, and their values are given for the various members of the isoelectronic sequence from H^- to C v. The energies were also computed, and the energies and the wave functions are compared with the corresponding Hartree-Fock quantities, where the latter are known. Both the 2- and the 3-parameter functions approximate the numerical functions closely, and give energies as low, or almost as low, as the more reliable of the Hartree-Fock energies. The 3-parameter wave function proves to be the better, particularly in the case of H^-. Some comments are made on the existing numerical functions and their energies. (Contractor's abstract)

AN ANALYSIS OF THE THREE-PARAMETER WAVE FUNCTION OF HYLLERAAS FOR THE He I GROUND STATE IN TERMS OF CENTRAL FIELD WAVE FUNCTIONS, by L. C. Green, M. M. Mulder and others. [June 8, 1954] [22]p. incl. diagrs. tables, refs. [In cooperation with Haverford Coll., Strawbridge Observatory, Pa.] [AFOSR-TN-54-366] (Sponsored jointly by [Air Force] Office of Scientific Research under [AF 18 (600)660], Office of Naval Research, and Research Corp.) Unclassified

Also published in Phys. Rev., v. 96: 319-325, Oct. 15, 1954.

A study of configuration interaction in the ground state of He I has been carried through by expanding the various angular components of the 3-parameter wave function of Hylleraas in orthonormal sets of functions. The different sets have been constructed from symmetrized products of hydrogenic wave functions with different values of the parameter Z. The importance of the various configurations for Z = 2 is commented upon at some length. Configurations involving a free electron are shown to make surprisingly large contributions. The changing importance of the various components with changing Z is illustrated. In particular, the minimum with respect to Z of the contribution of configurations containing a free electron is pointed out. The implications of the results of these expansions for attempts to obtain wave functions for both normal and excited states of 2-electron systems by the minimum principle from linear combinations of products of hydrogenic functions of the proper symmetry are discussed. Presented at meeting of the Amer. Phys. Soc., Providence, R.I., Apr. 2, 1955.

Also published in Phys. Rev., v. 98: 1020-1028, May 15, 1955.

The rate of change of the oscillator strength at the K-edge of ionized potassium has been computed in a number of ways, and a few computations have been made on the L-edge. The work has been carried through by using both hydrogenic and Hartree wave functions at the level of the single-electron approximation and Hartree and Hartree-Fock wave functions when the single-electron approximation was not used. Calcium wave functions both with and without exchange have also been employed. The moment, momentum, and acceleration matrix elements have been computed. The momentum matrix element gives values most closely in agreement with experiment, and is most stable with respect to changes in the wave functions. It is followed by the acceleration and the moment in that order. The single electron approximation gives good results. If the single-electron approximation is not used, it is essential that exchange effects be included by employing the determinant form of the wave functions, and the Hartree-Fock 1-electron wave functions then give considerably better results than the ordinary Hartree functions. It also proves to be possible to substitute the wave functions of the unexcited ion of next higher atomic number, calcium, for the wave functions of potassium excited in an x-ray level without noticeable deterioration in the results. THERMOELASTIC DAMPING AT THE BOUNDARY BETWEEN DISSIMILAR SOLIDS, by M. Lessen. [Oct. 19, 1956] [3]p. [AF 18(603)124] Unclassified

Published in Jour. Appl. Phys., v. 28: 364-366, Mar. 1957.

The problem of thermoelastic damping at the boundary between dissimilar solids is investigated for the case of small sinusoidal, longitudinal disturbances of long wavelength, propagating normally through the interface. The relevant equations are derived from thermodynamic considerations, and it is found that the mechanical energy absorption per unit time is proportional to the square root of the disturbance frequency. CHARACTERIZATION OF ALMOST PERIODIC TRANSFORMATION GROUPS, by W. H. Gottschalk. Dec. 1955, 5p. ([AF]OSR-TN-55-217) (AF 18(600)1116)
AD 85550 Unclassified

Also published in Proc. Amer. Math. Soc., v. 7: 709-712, Aug. 1956.

Let X be a compact, uniform space and let T be a multiplicative topological group operating as a (right) transformation group on X. The author treats interconnections between almost periodicity, local almost periodicity and equicontinuity of T (for definitions of terms, see Gottschalk and Hedlund, Topological Dynamics, Amer. Math. Soc. Colloq. Publ., v. 36, Providence, R.I., 1955; MR 17, 650). It is proved that T is almost periodic if and only if T is locally almost periodic and T is distal; the transformation group T is said to be distal on X provided that if $x, y \in X$ with $x \neq y$, then there is an index α of X such that $(xt, yt) \notin \alpha$ for all $t \in T$. It is also proved that if T is locally almost periodic on X, then T is not equicontinuous on X if and only if there exists a pair of distinct points of X which is syndetically proximal under T; here the pair (x, y) is said to be syndetically proximal provided that if α is an index of X, then there exists a syndetic subset A of T such that $(xa, ya) \in \alpha$ for all $a \in A$. TOPOLOGICAL DYNAMICS, by W. H. Gottschalk and

PEN. 04:001 - PEN. 04:003

G. A. Hedlund. American Mathematical Soc. Colloquium Publications, v. 36. Amer. Math. Soc., Providence, R. I., 1955, 151p. incl. refs. (AF 18(600)-1116 and AF 18(600)667) Unclassified

A topological transformation group is defined to be a triple consisting of a topological space X, a topological group T and a continuous mapping $(x, t) \longrightarrow xt$ from $X \times T$ into X such that $(xt)s = x(ts)$ and $xe = x$, where e is the identity in T. In part 1, which consists of 11 sections, various concepts and theorems of dynamical systems are generalized to suitably extensive classes of topological transformation groups. Isomorphisms, homomorphisms, orbits, orbit closures, invariant subsets, etc., of topological transformation groups are defined, as are partitions and decompositions of spaces. Theorems are given stating when the orbit closures constitute a partition of X. A subset A of T is called left syndetic in T if $T = AK$ for some compact subset K of T. The period of T at x is defined to be the greatest subset P of T such that $xP = x$. The group T is said to be periodic at x if P is a syndetic subset of T. The group T is said to be recursive at x if for each neighborhood U of x there is an "admissible" subset A of T such that $xA \subset U$. Various generalizations of periodicity such as almost periodicity, regular almost periodicity and recurrence are obtained as special cases of recursion by choosing suitable classes of admissible sets. Thus many theorems can be stated and proved for all these kinds of recursions at once. In sections 4 and 5 numerous theorems on almost periodicity and regular almost periodicity, are proved under conditions on X and T which vary from theorem to theorem. In sections 7 and 8 recurrence and incompressibility are studied under the condition that T is generative, that is, T is Abelian and is generated by some compact neighborhood of the identity. It is shown that the recurrence properties are essentially equivalent to incompressibility properties. The group T is said to be transitive at x if for every open set U of X there exists $t \in T$ such that $xt \in U$. The group is said to be regionally transitive if for every two open sets U and V of X there exists $t \in T$ such that $Ut \cap V \neq \emptyset$. Transitivity is studied in section 9. In section 10 asymptoticity is studied under the condition that X is a compact metric space and T is the cyclic group generated by a homeomorphism ϕ of X onto itself. A point x is said to be (positively) asymptotic to a closed invariant set B if $x \in \mathfrak{B}$ and $\lim \varrho(x\phi^n, B) = 0$. Section 11 deals with function spaces with a view to the properties needed elsewhere. Part I is written in a very precise terse style, and definitions and theorems are given under most general conditions. It contains a fully organized presentation of topological dynamics from a certain point of view. Part II consists of three sections dealing with some specific examples of flows and has a much more classical approach to the subject. Sections 12 and 13 are respectively on symbolic dynamics and geodesic flows, subjects with which one of the authors has been intimately associated. The theorem on the topological transitivity of a geodesic flow on surfaces of constant negative curvature is proved. Section 14 is on cylinder homeomorphisms. (See also item no. IAS. 02:002) (Math. A NOTE ON MULTIPLY POSITIVE SEQUENCES AND THE DESCARTES RULE OF SIGNS, by I. J. Schoenberg. [1955] [9]p. (AFOSR-TN-55-434) [AF 18(600)1158] Unclassified

Published in Rend. Circ. Matem. Palermo, Series II, v. 4: 123-131, Jan.-Apr. 1955.

It is demonstrated how multiply positive sequences and their variation-diminishing property furnish a seemingly very natural proof of Obreschkoff's extension of Descartes' rule of signs to include complex zeros in a sector. So far only Obreschkoff's original proof of this extension has been available. It is considered desirable to have at least two avenues of approach to this proposition. A theorem of S. Lipka states the following: Let k be an integer, $0 \leq k \leq n$. If the polynomial $P(x)$ has the property

$$Z\left(|\arg x - \pi| \leq \frac{\pi}{k+2}\right) \geq n-k,$$

$$v(a) \leq k.$$

This theorem is generalized, and this generalization leads easily to the Obreschkoff-Descartes rule.

ON MULTIPLY MONOTONE FUNCTIONS AND THEIR LAPLACE TRANSFORMS, by R. E. Williamson. June 1955, 2tp. incl. refs. ([AF]OSR-TN-55-436) (AF 18-(600)1158) AD 85546 Unclassified

Also published in Duke Math. Jour., v. 23: 189-207, June 1956.

Ths analog of the Bernstetn-Widder reprssentation of completsly monotone functions on $(0,\infty)$: $f(t) = \int_0^\infty e^{-tu}\, d\beta(u)$, where $\beta(u)$ ts nondecreasing, ts given as the n-times monotons function $f(t) = \int_0^\infty [(1-ut)_+]^{n-1} d\beta(u)$, where $\beta(u)$ ts nondscreasing and bounded below and $(t)_+ = \begin{cases} t, & t \geq 0 \\ 0, & t < 0 \end{cases}$. The Laplacs transforms of these functions are characterized by ths following theorem. Let $\alpha \geq 1$ be a real number. Necessary and sufftctent condttions that the nonnsgativs function $f(s)$, $0 < s < \infty$, be the Laplace transform of a function $\varphi(t)$, such that $\varphi(t)$ tε α-times monotone and summable tn every ftnite tnterval, are that (1) $D^\alpha[s^\alpha f(s)]$ be completsly monotone and summable at the origin, (2) $\lim_{s\to\infty} f(s) = 0$, and (3) $\lim_{s\to 0} sf(s)$ exists. Transforms of 3-times monotone functions are shown to be univalent for $Re(s) > 0$.

ON HAAR'S THEOREM CONCERNING CHEBYCHEV APPROXIMATION PROBLEMS HAVING UNIQUE SOLUTIONS, by J. C. Mairhuber. June 1955, 8p. refs. ([AF]OSR-TN-55-437) (AF 18(600)1158) AD 85545 Unclassifted

Also publtshed in Proc. Amer. Math. Soc., v. 7: 609-615, Aug. 1956.

A principal result is given by the following theorem. A compact subset M of a k-dimensionat Euclidean space containing at least n potnts, $n \geq 2$, may serve as the domain of definition of a set of real conttnuous functions $f_t(x), \ldots, f_n(x)$ with property D, tf and only tf M ts homeomorphic to a closed subset of the circumference of a ctrcle. The proof is obtained by use of the auxiliary theorem that a compact set M in E_n wtth the property that at most n potnts of M lte on any hyperplane of E_n is the homeomorplic tmage of a closed subset of the circumference of a circle. Property D states that the determtnant

$$\begin{vmatrix} f_1(x_1)\ f_2(x_2) \ldots f_n(x_t) \\ f_1(x_n)\ f_2(x_n) \ldots f_n(x_n) \end{vmatrix} \neq 0$$

for every set of n distinct points $x_t, \ldots, x_n$ of M.

PHOTOPROTONS FROM BISMUTH (Abstract), by M. E. Tonis and W. E. Stephens. [1952] [1]p. (Sponsored jotntly by [Air Force Offtce of Sctentiftc Research under AF 33(038)20381], Atomtc Energy Commtssion, and Office of Naval Research) Unclasstfied

Presented at meeting of the Amer. Phys. Soc., Chtcago, Ill., Oct. 24-27, 1951.

Published in Phys. Rev., v. 85: 728, Feb. 15, 1952.

The high energy photoprotons from some medtum weight elements have seemed to show an angular vartation whtch suggests that they were produced by a direct photoprocess. To check tf this mechanism were present tn heavy nuclei, for which the coulomb barrter would suppress lower energy evaporated photoprotons, we have looked for photoprotons from a one-mil foil of bismuth irradiated wtth x-rays from a 24-mev betatron and recorded in nuclear emulstons. The photoproton yield observed is about 3×10^4 protons/mole/r, whtch ts smaller than the anisotropic protons observed tn Rh, Ag, and Cu. This yield is of the order of magnitude of or somewhat smaller than the yield calculated with reasonable assumptions on the Weisskopf-Ewing model. The photoproton energy distributton has a peak near 11 mev, somewhat higher than that calculated on thts model. The angular distribution seems isotropic, within the rather poor statistical uncertainties of 20 percent. Thus no evidence was found for any direct photoeffect for protons from bismuth in this energy range. (Contractor's abstract)

ANGULAR DISTRIBUTION OF PHOTOPROTONS, by A. K. Mann, J. Halpern, and M. Rothman. [1952] [4]p. incl. diagrs. table. (Sponsored jointly by [Air Force Office of Scientific Research under AF 33-(038)20381], Office of Naval Research, and Atomic Energy Commission) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 31, Feb. 1-2, 1952.

Abstract published in Phys. Rev., v. 86: 629, May 15, 1952.

Published in Phys. Rev., v. 87: 146-149, July 1, 1952.

The angular distributions of photoprotons from Cu, Ni, and Co targets irradiated with bremsstrahlung of 23-mev maximum energy have been measured. Protons from Cu and Co show a large asymmetric component which is described by the expression $(\sin\theta + 0.5 \sin\theta \cos\theta)^2$. Absorption experiments on the protons are consistent with the assignment of the asymmetric component to transitions involving discrete levels in the vicinity of the ground state of the residual nucleus. The angular distributions observed are interpreted as resulting from interference between electric dipole and quadrupole absorption of the initial photons with the relative quadrupole intensity equal to 5 percent. PHOTO PROTONS FROM HEAVY ELEMENTS (Abstract), by W. E. Stephens and M. E. Toms. [1952.] [1]p. (Sponsored jointly by [Air Force Office of Scientific Research under AF 33(038)20381.], Office of Naval Research, and Atomic Energy Commission.) Unclassified

Presented at meeting of the Amer. Phys. Soc., Denver, Colo., June 30-July 3, 1952.

Published in Phys. Rev., v. 88: 160, Oct. 1, 1952.

The photoprotons ejected from bismuth, cerium, and barium by the 24-mev bremsstrahlung from the University of Pennsylvania betatron have been measured in nuclear emulsions. Preliminary results give yields of approximately 16×10^4 and 23×10^4 protons per mole per roentgen unit for Ce and Ba, respectively. A second run with better statistics than our previous data gives 4×10^4 p/m/r from bismuth. The yields calculated from an evaporation process are roughly 0.4×10^4, 0.07×10^4, and 0.09×10^4 p/m/r for Bi, Ce, and Ba, respectively. The angular distribution of the bismuth photoprotons is markedly asymmetric with three times as many protons at 30° and 50° as at 130° and 150°. If these asymmetric protons are ascribed to a direct photoelectric effect, then at least half of the bismuth yield is due to such an effect. It would seem reasonable then to associate the high yields from Ce and Ba also with a direct effect. The angular distribution of the photoprotons from Ce and Ba will be measured to examine this further.

A DILATOMETRIC STUDY OF THE ORDER-DISORDER TRANSFORMATION IN Cu-Au ALLOYS (Abstract), by W. W. Sanvitle, F. C. Nix, and F. E. Jaumot, Jr. Mar. 27, 1953 [2]p. [AF 33(308)20381] Unclasstfied

Presented at meeting of the Amer. Phys. Soc., Durham and Chapel Hill, N. C., Mar. 26-28, 1953.

Published in Phys. Rev., v. 91: 220-22t, July 1, t953.

The order-disorder transformation in Cu-Au alloys tn the composttion range from 10 to 32.2 atomtc % Au was studied by dilatometrtc means. An interferometrtc dtlatometer was used. All samples containing greater than 17.5 atomtc % Au exhibited an anomalous peak in the curve of the coefftcient of thermal expansion as a function of temperature. A plot of the critical ordering temperature, T_C, as a function of composttion deftnes an ordered region about 25 atomtc % Au which is in agreement with that defined by resistivity. The coefficient of thermal expansion was rigorously constant above the ordering temperature (to 500°C). The data indicate that the volume expansion is sensttive to small changes in the degree of long-range order, since in all cases the region of anomalous expansion begins at temperatures from 200 to 250°C. SHORT-RANGE-ORDER tN A Cu-Au ALLOY (Abstract), by C. H. Sutcliffe and F. E. Jaumot, Jr. Mar. 27, 1953 [1]p. [AF 33(038)20381] Unclasstfied

Presented at meeting of the Amer. Phys. Soc., Durham and Chapel Hill, N. C., Mar. 26-28, 1953.

Published in Phys. Rev., v. 91: 221, July 1, 1953.

Short-range-order parameters have been measured ustng x-ray diffraction techniques, at three tempera tures above the crttical temperature of ordertng, for a Cu-Au alloy containing 23 atomtc % gold. The expertmental technique used was similar to that employed by J. M Cowley (Jour. Appl. Phys., v. 21:24, t950). The diffuse scattered tntensity was measures at approximately 900 potnts wtthin 1/32 of a unit cell, and corrected for the tntenstty due to factors other than short-range order. A three-dtmensionat Fourier analysts was made on the short-range order intensities. The Fourier coefficients are tnen interpreted as short-range order parameters. The data tndtcate that an alloy contatning less than 25 atomtc % Au exhibtts a greater tendency to short-range order than does an alloy at the stotchiometrtc composttion. The tendency to what Cowley has referred to in a "liquid-like distribution about an origin atom in a Cu_3Au alloy, although present, is considerably less in the 23 percent Au sample. Also published in Phys. Rev., v. 92: 362-366, Oct. 15, 1953.

The charged particles ejected from In, Ce, and Bi foils by 24-mev-betatron x-rays were observed in nuclear emulsions. The yields of photo protons, photo deuterons, and photo α particles were determined, and the energy and angular distributions of the photo protons were measured and compared with theoretical calculations based on the evaporation process and on the direct photo effect. The energy distributions observed indicate a large fraction of direct photo effect. A marked forward asymmetry was observed in the angular distributions from In and Bi.

[INTERACTION OF HIGH ENERGY RADIATION] by W. E. Stephens, A. K. Mann, and D. H. Wilkinson. Final rept. Nov. 30, 1954, 16p. incl. diagrs. refs. ([AF]OSR-TR-54-37) (AF 33(038)20381) AD 51765 Unclassified

A summary is presented of the nuclear research conducted under this task. Some of the highlights of the work are listed. These include: (1) the construction of a thin lens spectrometer; (2) the investigation of electron-electron scattering using a cloud chamber; (3) the measurement of the angular distribution of photoprotons; (4) the fabrication and testing of a pulse height analyzer; (5) the testing of an anthracene crystal, coupled with a scintillation counter, for detecting protons; and (6) production of photoneutrons in Bi using Li γ rays from a stalliron.

ENERGY SPECTRUM OF PHOTOPROTONS FROM CARBON, by W. E. Stephens and A. K. Mann. [Nov. 30, 1954] 3p. incl. diagrs. [AFOSR-TR-54-37(A)] (AF 33(038)20381) (Also bound with its AFOSR-TR-54-37; final rept.; AD 51765 as Appendix A) AD 51765(a) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 26-27, 1954.

Abstract published in Bull. Amer. Phys. Soc., v. 29: 26, Nov. 26, 1954.

Abstract published in Phys. Rev., v. 98: 241, Apr. 1, 1954.

The photoprotons ejected from a 6 mg/sq cm thick C foil by 23-mev bremsstrahlung [braking radiation] have been observed in nuclear emulsions. The ranges of 408 protons which entered the emulsions in the proper direction were measured. The proton energy distribution has a peak at 5.5 mev and a width at half maxium of about 2.8 mev. These values confirm the previous determination of the giant resonance in C which had been obtained from yield curve data. The width of the proton spectrum is consistent with transitions from a single broad level in C^{12} to the ground state of B^{11}, but transitions to the first excited state of B^{11} appear to be inhibited. SYSTEMATICS OF PHOTONEUTRON REACTIONS, by R. Nathans and J. Halpern. [1953] [1]p. incl. diagrs. table. (AF 18(600)472) Unclassified

Published in Phys. Rev., v. 92: 207, Oct. 1, 1953.

Photoneutron yields were measured using a direct neutron detection method, of thirteen singly isotopic elements (C, P, V, Mn, Co, As, Nb, Rh, I, Ta, Au, Bi, U) when irradiated with betatron bremsstrahlung at energies from threshold to 24 mev. Excitation functions constructed from the total neutron yield data by the successive subtraction method show the characteristic large dipole resonance behavior for all the elements investigated. Significant parameters for the resonances are tabulated. The log-log plot is included of the bremsstrahlung energy where maximum cross section values occur ($E\sigma_m$) against mass number. The least-squares straight line through experimental points yields $E\sigma_m = 38.5A^{-0.19}$, in close agreement with previous determinations and predictions. A plot of the dipole resonance half-widths against neutron number shows a slow decrease in half-widths as N increases, with the exception of four elements having unusually narrow resonances. The correlation of these elements, C^{12} (N 6), V^{51} (N 28), Nb^{93} (N 52), and Bi^{209} (N 126), with the shell model is unusual for phenomena concerned with such high excitation energies.

STUDIES IN PHOTONUCLEAR REACTIONS. Annual rept. Oct. 15, 1953 [8]p. incl. illus. (AF 18(600)-472) AD 19603 Unclassified

Progress in efforts directed to increasing the beam spread of a betatron, eliminating particle pile-up in counters, and developing a high-speed discriminator is briefly reviewed. The completed research is summarized. A large paraffin-BF_3 counter house was used to determine the (γ, n) yields and excitation functions of 14 singly isotopic elements. The parameters of the giant dipole γ-ray adsorption resonance were studied. Systematic trends in half width, position of the resonance maximum, the integrated cross section, and the value of the maximum cross sections were in accordance with the sum-rule predictions of Levinger and Bethe. The energy at peak cross section varied as $38.5A^{-0.186}$; the widths of the giant resonances showed a slowly decreasing behavior with atomic no. Ta, Pt, Pb, W, and Au showed photo-proton yields of 5.7×10^4, 2.9×10^4, 5.8×10^4, 5.2×10^4, and 1.9×10^4 protons/mol/roentgen, respectively, in measurements using ZnS screens and a spread x-ray beam at 22 mev. These yields were consistent with those obtained for heavy elements by Stephens with photographic plates. A rough determination of the (γ, p) angular distribution of Ag showed the same general features as the distributions from Cu and Co which were previously reported, but a larger quadrapole-interference term was obtained. A block diagram and the circuit of the fast pulse discriminator are presented.

SYSTEMATICS OF PHOTOPROTON REACTIONS, by E. V. Weinstock and J. Halpern. [1954] [4]p. incl. diagrs. table. refs. (Sponsored jointly be [Air Force Office of Scientific Research under [AF 18(600)472], Office of Naval Research, and Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 94: 1651-1654, June 15, 1954.

The photoproton yields from the elements Ta, Pt, Pb, W, and Au have been determined for betatron bremsstrahlung bombardment at 22-mev peak energy by the use of zinc sulfide detectors and a 40-μsec betatron pulse duration. The yields, as measured in photoprotons per mole per roentgen are as follows; Ta, 5.7×10^4; Pt, 2.9×10^4; Pb, 5.8×10^4; W, 5.2×10^4; and Au, 1.9×10^4. These values, along with previous determinations, permit a study of general behavior of photoproton yields for all Z values throughout the periodic table. Compartsons with calculations based on the evaporation model show good agreement with experimental trends up to a Z of 50, after which the measured yields are too high by factors ranging from 10 to 10^4. Calculations based on the direct photoelectric process give better agreement. (Contractor's abstract)

PHOTONEUTRON ANGULAR DISTRIBUTIONS (Abstract), by K. Geller, J. Halpern, and P. F. Yergin. [1954] [1]p. [AF 18(600)472] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C. Apr. 29-30, and May 1, 1954.

Published in Phys. Rev., v. 95: 659, July 15, 1954.

The angular distributions of photoneutrons produced by 22 mev bremsstrahlung on Pb, Ag, and Cu have been measured using a lucite-zinc sulfide fast neutron detector. The results do not show any significant nonisotropy. If the distributions are fitted to the form $A + B \sin^2\theta$, the value of B/A consistent with the data for any of the elements could not exceed 0.12. If we make approximate estimates of the neutron energy distributions for two different models, the evaporation model and Courant's direct photoeffect model, and if we assume that all of the nonisotropic component is the result of direct photoeffect, and take into account the measured energy sensitivity of the type of detector used, then the cross section for direct photoeffect production of the nonisotropic component is not more than 1 percent of the total cross section for Cu, and must be considerably less for Ag and Pb, for which the data is better. (γ, n) CROSS SECTIONS IN Mg ^{24} and Mg ^{25} (Abstract), by R. Nathans and P. F. Yergin. [1955] [1]p. [AF 18(600)472] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 27-29, 1955.

Published in Phys. Rev., v. 98:1198, May 15, 1955.

The cross sections have been measured by neutron detection using separated isotope targets from ORNL (1.77 and 0.50 g of isotope, respectively). Both "giant resonance" peaks occur at about 20 mev, as does the previously reported Mg^{25}(γ, n) peak. An unusual feature of our results is that both the peak and integrated (to 24 mev) cross sections for Mg^{25}(γ, n) are about twice those for Mg^{24}(γ, n). About ¾ of the integrated cross section for Mg^{24}(γ, n) is between threshold and the onset of the giant resonance. Our results are in contradiction to the report that the peak of the giant resonance for Mg^{25}(γ, n) is about 13 mev, which would result in far more protons than neutrons being emitted at the higher energies. These observations were described to threshold differences. The thresholds involved are: Mg^{24}(γ, n)16.6 mev, Mg^{25}(γ,p)12.1 mev; Mg^{25}(γ, n)7.3 mev. No such threshold effect was found.

(γ, n) CROSS SECTIONS IN Zr ^{90} and Zr ^{91} (Abstract), by R. Nathans and P. F. Yergin. [1955] [1]p. [AF 18(600)472] Unclassified

Presented at meeting of Amer. Phys. Soc., New York, Jan. 27-29, 1955.

Published in Phys. Rev., v. 98: 1197, May 15, 1955.

The (γ, n) thresholds of these isotopes are widely separated (12.1 and 7.2 mev respectively) because Zr^{90} has a "magic number" (50) of neutrons. By direct neutron detection, using separated isotopes from ORNL, it was found that despite this the location and magnitude of the peak of the giant resonance is the same for each isotope and agrees well with the previously reported photoneutron systematics. The half-widths of the Zr^{90}, Zr^{91} and the previously measured Nb^{93} resonances increase progressively with the neutron numbers (50, 51, and 52 respectively) but all are narrower than expected from the systematics. This reinforces the previous observation that nuclides at or near the magic neutron numbers 28, 50, 82 and 126 have unusually narrow giant resonances.

PHOTONEUTRON CROSS SECTIONS IN Mg ^{24}, Mg ^{25}, Zr ^{90}, Zr ^{91}, by R. Nathans and P. F. Yergin. [1955] [4]p. incl. diagrs. tables, refs. (Sponsored jointly by [Air Force Office of Scientific Research under AF 18(600)472], Office of Naval Research, and Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 98: 1296-1299, June 1, 1955.

The variation of σ(γ, n) with E_γ from threshold to 2 mev has been measured by detecting neutrons produced from betatron bremsstrahlung irradiation of separated isotope samples in oxide form. Despite the large threshold differences (9.3 mev for the Mg isotopes and 5.0 mev for the Zr isotopes) the peaks of the giant dipole resonances are very close for each pair of adjacent isotopes: Mg^{24}, 19.5 mev; Mg^{25}, 20.3 mev; Zr^{90}, 16.4 mev; Zr^{91}, 16.3 mev. The half-widths of the Zr resonances are unusually small, 4.1 and 5.4 mev, compared to 8 mev for nearly nuclei observed previously. This is apparently a "magic number" effect. and B. P. Fabricand. [1955] [1]p. [AF 18(600)472] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 25-26, 1955.

Published in Phys. Rev., v. 100: 1249, Nov. 15, 1955.

The published data for natural Mg and for Mg^{25} disagree somewhat in the energy region below 11 mev where only $Mg^{25}(\gamma, n)$ can contribute to the neutrons detected. Above the $Mg^{26}(\gamma, n)$ threshold at 11.1 mev, however, a more serious disagreement occurs. If the measured Mg^{25} yield is subtracted from the published natural Mg yield, the resulting "$Mg^{26}(\gamma, n)$" cross section from its threshold to the $Mg^{24}(\gamma, n)$ threshold at 16.6 mev, is extremely different from that of Mg^{25} in the same region. This has been investigated by remeasuring the natural $Mg(\gamma, n)$ cross section, using a sample of MgO. Our yields disagree with the published values in the region in question. If the Mg^{25} yield is subtracted from our measured natural Mg yield, the resulting "$Mg^{26}(\gamma, n)$" yield resembles very closely that of Mg^{25} in the same region. Spectroscopic analysis of our sample showed no significant impurities. (Contractor's abstract)

PHOTONEUTRON ANGULAR DISTRIBUTION FROM CARBON (Abstract), by B. P. Fabricand, B. Allison, and J. Halpern. [1955] [1]p. [AF 18(600)472] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 25-26, 1955.

Published in Phys. Rev., v. 100: 1249, Nov. 15, 1955.

Previous measurements of the photoproton angular distribution arising from the giant dipole resonance in the reaction $C^{12}(\gamma, p)B^{11}$ have yielded a distribution of the form $2 + 3 \sin^2\theta$. This has been interpreted as evidence for an independent particle description of the giant resonance and for the LS coupling scheme. In the hope of studying the process of the direct emission of photoneutrons, the angular distribution was measured of neutrons from the giant dipole resonance in the reaction $C^{12}(\gamma, n)C^{11}$ using a zinc sulfide-paraffin-plastic scintillator as the neutron detector. In contrast to the results for photoprotons from carbon, the photoneutrons show a dip at 90° and a distribution that can be fitted by an expression of the form $a + b\cos^2\theta$. The results are analyzed from the standpoint of distributions expected from the possible channel spins involved. (Contractor's abstract)

$Sr^{86, 87, 88}$, Y^{89}, $Zr^{92}(\gamma, n)$ CROSS SECTIONS (Abstract), by P. F. Yergin and B. P. Fabricand. [1955] [1]p. [AF 18(600)472] Unclassified

Presented at meeting of Amer. Phys. Soc., Chicago, Ill., Nov. 25-26, 1955.

Published in Phys, Rev., v. 100: 1269, Nov. 15, 1955.

These cross sections were measured from threshold to 23 mev. All show the usual giant resonance, at about 16 mev. The width of the resonances show systematic variation not attributable to $(\gamma, 2n)$ or (γ, pn) contributions. They provide further evidence of the effect of the magic neutron number, 50, on the giant resonance width. The lesser widths are not associated with greater heights; instead the integrated cross section decreases substantially when the peak becomes narrower. It was also observed that the rise of the cross section into the peak, from 12.5 to 15.5 mev, is almost exactly the same in shape and magnitude for all 5 isotopes, as well as for the previously measured Zr^{90} and Zr^{91}. In agreement with the conjecture of Wapstra the $Sr^{86}(\gamma, n)$ threshold was found to be about 11.5 mev, not at 9.5 mev as previously reported. (Contractor's abstract)

BREMSSTRAHLUNG SPECTRUM FROM THE INTERNAL TARGET OF A 22-MEV BETATRON, by E. V. Weinstock and J. Halpern. [1956] [6]p. incl. diagrs. table, refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)472], Office of Naval Research, and Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 100: 1293-1298, Dec. 1, 1955.

The intensity and energy distribution of the bremsstrahlung photons produced in a betatron operating at 22 mev have been determined by measurement of the energy spectrum of photoprotons ejected from deuterium. The protons were detected using a 0.15 cm thick NaI crystal followed by a 100-channel pulse-height analyzer. The photon beam was highly collimated in the forward direction. If one assumes the energy dependence of the cross section for the photodisintegration of deuterium as given by Hulthén, the computed bremsstrahlung energy distribution is in excellent agreement with the theoretical thin-target spectrum. The observed total intensity is that indicated by monitoring using an "R" thimble imbedded in 3.9 cm of Lucite. (Contractor's abstract)

(γ, n) CROSS SECTIONS OF NUCLIDES NEAR NEUTRON NUMBER 50, by P. F. Yergin and B. P. Fabricand. [1956] [6]p. incl. diagrs. tables, refs. (Sponsored jointly by [Air Force Office of Scientific Research under AF 18(600)472], Office of Naval Research, and Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 104: 1334-1339, Dec. 1, 1956.

Measurement of the (γ, n) cross sections of the nuclides Sr^{86}, Sr^{87}, Sr^{88}, Y^{89}, Zr^{92}, together with earlier measurements for the nuclides Zr^{90}, Zr^{91}, and Nb^{93}, show a pronounced narrowing of the giant dipole resonances in the region of neutron number 50, the narrowest resonances being those for the 50-neutron nuclides. Possible confusion of the interpretation of the data due to (γ, 2n) and (γ, pn) processes is shown to be inadequate to explain the observed effects, and the narrowing is concluded to be real, in agreement with the prediction of the prediction of the single-particle model of Wilkinson. The changes in widths are observed to occur entirely on the high-energy sides of the curves, the low-energy sides being remarkably similar for all 8 nuclides. A regularity in the behavior of the peak values of the cross sections is also observed. The (γ, n) threshold of Sr^{86} is observed to be at about 11.5 mev, in agreement with other reaction data, but in disagreement with an earlier tentative assignment based on neutron yield measurements on natural Sr. (Contractor's abstract)

PHOTONEUTRON YIELDS FROM NATURAL MAGNESIUM, by P. F. Yergin. [1956] [3]p. incl. diagrs. (Sponsored jointly by [Air Force Office of Scientific Research under AF 18(600)472], Office of Naval Research, and Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 104: 1340-1342, Dec. 1, 1956.

Published measurements of the cross sections of the (γ, n) reaction in natural Mg and in Mg^{25} are in disagreement in the energy region where the other Mg isotopes do not contribute to the cross section of the natural sample, and imply a most unusual cross-section curve for the Mg^{26} isotope at slightly higher energies. A new measurement of the cross section for natural Mg is reported which disagrees strongly with the published data, but agrees with the Mg^{25} values, and implies a not-surprising cross-section curve for Mg^{26}. The origin of the disagreement in the natural-sample cross-section values is unknown. (Contractor's abstract)

Studies made on low frequency fluctuations (less than 300 kcps) in electrical discharges through gases at low pressure are described. Single- and double-probe techniques were applied to cold cathode glow discharges, hot cathode arc discharges, and radio-frequency electrodeless discharges. The fluctuations in positive ion beams from radio-frequency electrodeless discharge sources were examined, with the primary result being that ion-beam noise is very close to shot-effect noise. Some theoretical considerations of random effects are included. (Contractor's abstract)

EFFECT ON DISTRIBUTION OF LATTICE DEFECTS WITHIN CRYSTALS OF LINEAR EXPANSION AND X-RAY LATTICE CONSTANT, by P. H. Miller, Jr. and B. R. Russell. [1953] [2]p. (AF 18(600)561)
Unclassified

Published in Jour. Appl. Phys., v. 24: 1248-1249, Sept. 1953.

It is asserted that for randomly distributed Frenkel defects the relative changes in x-ray lattice constant and in linear dimensions are virtually the same. The only cases in which Frenkel defects might give rise to an x-ray expansion differing from the macroscopic linear expansion are those for which the distribution of defects is spatially non-uniform within the crystal.

The coefficient of thermal expansion of LiF and KI crystals was determined in the 20° to 300°C range with a capacitance type dilatometer. The instrument operates by measuring the variation in capacitance between a fixed and a movable plate. The device uses the variation in capacitance to change the resonant frequency of a HF oscillator, and a discriminator to convert the frequency changes into current changes; the latter are indicated by the deflection of a galvanometer. A limiting amplifier is used to free the instrument from errors which might otherwise be caused by amplitude variation in the discriminator input. The average values of the expansion coefficients agree within 1% in most cases to the dilatometer measurements made by Gott (Ann. Phys., v. 41: 520, 1942) for the same crystals. The x-ray measurements which Gott made of the thermal expansion of these crystals are believed to be in error by several percent.

EFFECT OF DISTRIBUTION OF LATTICE DEFECTS WITHIN CRYSTALS UPON X-RAY LATTICE CONSTANT AND MACROSCOPIC LINEAR EXPANSION, by B. R. Russell. July 24, 1953 [14]p. incl. diagr. tables. (Technical rept. no 1) (AFOSR-TN-54-48) (AF 18(600)-561) AD 19715 Unclassified

Owing to a discrepancy between the results obtained by P. H. Miller and B. R. Russell (item no. PEN. 08:001) and those found by J. D. Eshelby, the original calculations were reviewed and new calculations were made. The original calculations involved the assumption of simple superposition of the effects produced by single defects; the new calculations consider the whole distribution of defects (in first approximation at least), andthe results indicate the effects of nonuniformity of the distribution quite clearly. By interpolating, it is concluded that for uniform distributions of Frenkel defects there is little, if any, difference betwenn the expansion measured by means of x-rays and that observed by means means of x-rays and that observed by means of a dilatometer. A check of the original calculations disclosed an error in 1 important case which was sufficient to account for the discrepancy first noted. All of the results now seem to be in substantial agreement.

CHANGE IN LENGTH OF ALKALI HALIDE CRYSTALS CAUSED BY X-RAY IRRADIATION (Abstract), by L.-Y. Lin and B. R. Russell. [1955] [1]p. [AFOSR-TN-55-53] [AF 18(600)561] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 99: 657, July 15, 1955.

Potassium and sodium chloride crystals (about 12mm x 7mm x 1.5mm) at room temperature were irradiated with x-rays in a thermostated enclosure regulated to 10^{-2} °C. The crystals were about 2¼ inches from the x-ray tube beryllium window. The change in length of the largest dimension of the crystal was measured during the irradiation by a capacitance-type dilatometer with sensitivity 10^{-8}cm. The F center density calculated from the increase in length per unit length (assuming one ion pair at the surface for each pair of lattice vacancies) agreed within 5 percent with the number of color centers determined subsequently by optical absorption measurement. For example: $\Delta l/l = 6.1 \times 10^{-7}$, n (calculated) = 4.1×10^{16} cm^{-3}, n (optical, colored portion) = 3.9×10^{16} cm^{-3} for NaCl; $\Delta l/l = 1.36 \times 10^{-8}$, n (calculated) = 6.6×10^{16} cm^{-3}, n (optical) = 6.7×10^{16} cm^{-3} for KCl. These crystals were uncolored in about 30 percent of their volume as they were larger than the x-ray beam. Using a slightly smaller crystal to get uniform coloration throughout the whole crystal, $\Delta l/l = 4.3 \times 10^{-7}$, n (calculated) = 2.1×10^{16} cm^{-3}, n (optical) = 2.0×10^{16} cm^{-3} for KCl. THE CHANGE OF LENGTH OF IONIC CRYSTALS DUE TO X-RAY IRRADIATION, by L.-Y. Lin. June 1955, iv. incl. diagrs. tables, refs. (Technical rept. no. 3) ([AF]OSR-TN-55-103) (AF 18(600)561) AD 64017 Unclassified

In this study, the potassium chloride and sodium chloride crystals (about 12 mm by 8 mm by 1.5 mm) at room temperature both in air and in helium atmosphere are irradiated up to 3 hr with x-rays (48 kv at 18 ma). The crystals are placed in a thermostated enclosure regulated to 0.01°C, 2.5 in. from the x-ray tube beryllium window. The change in length of the largest dimension of the crystal is measured during the irradiation by a capacitance type dilatometer with sensitivity 10^{-8} cm. It is found that the number of F-centers/unit volume calculated from the increase in length/unit length agrees within 5% with the number of color centers/unit volume determined subsequently by optical absorption measurement. A series of measurements has been carried out with different irradiation times, and it is found that the relation between the relative expansion of crystal and the density of F-centers is linear. It is also found that the relative expansion of the crystal does not depend on the dimensions of the colored part of the crystal. Supplementary experiments indicate that this is caused by the formation of defects throughout the crystal even though only a small fraction of the volume is directly exposed to the x-ray beam. In all cases, a short time lag occurs between the start of the irradiation and the initial expansion of the crystal: for KCl the lag is about 20 min, and for NaCl it is about 30 min. In addition, the expansion is always found to continue for about 6 min

after the x-rays are turned off. Bleaching experiments have also been performed on crystals prevtously colored using light wave-length of 560 mμ for KCl and 450 mμ for NaCl. The crystats neither contract nor expand when the density of F-centers is reduced from about 10^{17} cm^{-3} to less than 10^{15} cm^{-3}. The time for bleaching is aboul 30-40 mtn. RATE OF FORMATION OF F-CENTERS IN PARTIALLY X-RAY IRRADIATED ALKALI HALIDE CRYSTALS (Abstract), by L.-Y. Lin and M. E. Caspari. [1956] [1]p. [AF 18(800)561] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 213, Apr. 28, 1958.

The over-alt relative linear expansion of partially x-ray irradiated potassium and sodium chtoride crystals was found to be proportional to the average F-center concentration in the trradiated portion, but not to the F-center concentration averaged over the whole crystat. Further experiments have shown that the rate of formation of F-centers in partially x-ray irradiated crystats is directly proportional to the fraction of the votume which is exposed to the irradiation and that the F-center concentration after a certain period of irradiation in a previousty uncolored part is greatly increased by first irradiating an adjacent part. These experiments indicate the presence of a targe number of vacancies in the nontrradiated portion of the crystal. The diffusion of vacancies in alkali hatide crystals is not large enough to account for this rapid transfer of vacanctes, but slip processes may possibly explain the effects. (Contractor's abstract)

EXPANSION OF POTASSIUM AND SODtUM CHLORIDE CRYSTALS DUE TO X-RAY IRRADIATION OF WEAK INTENSITIES, by L.-Y. Lin. [1956] [7]p. incl. illus. diagrs. tables, refs. [AF 18(800)581] Unclassifted

Published in Phys. Rev., v. 102: 988-974, May 15, 1956.

Rectangular cteaved samples of potassium and sodium chloride crystals having dimensions of about 12 x 10 x 15 mm were irradiated for times up to three hours with x-rays (48 kv at 18 ma) from a molybdenum target tube passing through a beryllium window at room temperature in air and in helium atmospheres. The crystals were placed tn a thermostatted enclosure regutated to within 0.01°C. The crystals were about 2¼ tn. from the x-ray tube beryllium wtndow. The change in length of the largest dtmenston of the crystal was measured during and after the irradiation by a capacitance-type dilatometer with a senstttvity of 10^{-8} cm. A series of measurements were carrted out emptoying different times of irradiation and it was found that the relation between the relative linear expansion of the crystat and the optically determtned average concentration of F-centers was linear with a constant of proportionality remarkably close to the value of $d^3/12$, where d is the tattice constant of the crystal. There was a time delay o' about 20-30 minutes before the expansion could be detected. This time delay was increased by ptastic deformation. The results did not depend on the fraction of the crystal volume which was irradtated. The rate of formation of a certain P-center concentration in the irradiated portion of the crystal was directly proportional to the fraction of the votume exposed to the irradiation. In partially irradiated crystats, the rate of formation of F-centers in the nonirradiated portion upon subsequent trradiation was greatly increased by the presence of the adjacent irradiated part. The merits of possible models to explain these results are discussed. (Contractor's abstract)

Collimated beams of 0.41 and 0.66 mev gamma rays

PEN. 09:003 - PEN. 09:006

were scattered from tin and lead targets and the absolute differential cross sections for elastic scattering measured at five angles between 15 and 75 degrees. The scattered radiation was detected with a NaI scintillation counter to select only the energy region of elastic scattering. At the smaller angles, the degraded radiation from Compton scattering was subtracted empirically by comparing the tin and lead scattering with that from an aluminum target containing the same number of electrons. At these energies the predominant mode of elastic scattering should be Rayleigh scattering from the tightly bound electrons. Within the experimental error of about 10 percent the measured differential cross sections for lead at both 0.41 and 0.66 mev do not differ significantly from the calculation of Rayleigh scattering made by Franz using the Thomas-Fermi model. For tin at 0.66 mev the measured values at large angles appear to be less than those given by Franz, but no such disagreement is evident at 0.41 mev.

ENERGY SPECTRUM OF PHOTOPROTONS FROM CARBON (Abstract), by W. E. Stephens and A. K. Mann. [1955] [1]p [AF 18(600)894] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 26-27, 1954.

Published in Phys. Rev., v. 98: 241, Apr. 1, 1955.

The photoprotons ejected from a 6 mg per cm^2 thick carbon foil by 23-mev bremsstrahlung have been observed in nuclear emulsions. The ranges of 408 protons which entered the emulsions in the proper direction were measured. The proton energy distribution has a peak at 5.5 mev and a width at half-maximum of about 2.8 mev. These values confirm the previous determination of the giant resonance in carbon which had been obtained from yield curve data. The width of the proton spectrum is consistent with transitions from a single broad level in C^{12} to the ground state of B^{11} but transitions to the first excited state of B^{11} appear to be inhibited. ELASTIC SCATTERING OF GAMMA RAYS, by A. K. Mann. [1955] [16]p. incl. diagrs. refs. (AF 18-(600)894) Unclassified

Also published in Phys. Rev., v. 101. 4-8, Jan. 1, 1956.

Gamma rays of 0.411, 0.662, and 1.33 mev were scattered from tin and lead targets and the absolute differential cross sections for elastic scattering were measured at six angles between 15 and 90 degrees. At 0.411 and 0.662 mev, the scattering is expected to be almost entirely Rayleigh scattering from the tightly bound electrons, and these data should therefore provide a reasonably stringent test of the theory of that process. However, the only calculations of Rayleigh scattering presently available are form-factor calculations which are expected to be inadequate for several reasons — in particular, for neglect of electron binding in the intermediate state of the scattering process, and for certain nonrelativistic approximations — and consequently comparisons of experiment with the form-factor results are inconclusive. Nevertheless, for the scattering from tin at both 0.411 and 0.662 mev, there is fair but possibly fortuitous agreement between experiment and form-factor calculations using Dirac wave functions for the electrons; for lead at the same energies there are appreciable discrepancies particularly at the larger angles between the experimental results and similar calculations. In view of the latter discrepancies, it appears that unambiguous identification of the elastic scattering of gamma rays by the electric field of a nucleus, i.e., potential scattering, cannot be obtained from measurements of the total elastic scattering by lead at 1.33 mev without improvements in the theory of Rayleigh scattering. DISPERSION RELATIONS FOR FIXED SOURCE MESON THEORIES, by A. Klein. June 1956, 20p. incl. diagr. refs. (Technical note no. 1) (AFOSR-TN-56-256) (AF 18(603)60) AD 88976 Unclassified

Also published in Phys. Rev., v. 104: 1131-1136, Nov. 15, 1956.

A study is being made to obtain exact consequences of ihe most general postulates of local field theories without making laborious calculations. Dispersion relations for a class of Hamiltonian operators describing meson theories with a fixed, extended source are derived for meson-nucleon scattering. The assumption is made that each meson field operator is coupled to its own source, and a restriction is imposed on the maximum number of temporal or spatial derivatives of the field operator that can occur in any one term; the interaction is not necessarily linear in the meson field. With these assumptions, nonrelativtstic verstons of all proposed relativisttc dtspersions are derived rigorously. In particular, the P-wave equattons of Chew and Low (Phys. Rev., v. 101: 1570, 1956) were obtained as well as a set of equations for the S-waves. Discusstons are presented on the forward scattering of neutral mesons and of symmetrical pseudoscalar mesons. The symmetry pseudoscalar theory is described.

DISPERSION RELATIONS FOR FIXED SOURCE MESON THEORIES. II. EFFECTIVE RANGE RELATIONS, by A. Klein. July 1956 [20]p. incl. diagrs. (Technical note no. 2) (AFOSR-TN-56-288) (AF 18(603)60) AD 89499 Unclassified

Also published in Phys. Rev., v. 104: 1136-1141, Nov. 15, 1956.

Dispersion relations for boson-fermion scattertng have been shown to yield, tn the static limit, coupled tntegral equations for the scattering amplitudes of a definite orbtial angular momentum. The present investigation is devoted to the search for the "solutions" of these equations, or more accurately, to the problem of obtaining essentially real integral equations for the reciprocals of the scattering amplitudes, since such equations would form the basis for effective range approximations. The mathematical problem ts that of determining an analytic continuatton of the scattering amplitudes which has no zeros in the complex plane. It ts shown that for all cases constdered tn I, an analytic conitnuatton can be deftned, either for the scattering amplitude in a deftnite channel, or for a simple ltnear combtnation of these, which has the basic properties of Wtgner's R-functions and yields the required equations upon inversion. These inverstons contain as many arbitrary constants (or in some tnstances functions) as there are zeros in the ortginal amplitudes. It is shown that the procedures apply, without essential change, to the case where inelastic processes are permitted. No attempt is made to apply the resultant formulas to experiment.

CONSTRUCTION OF THE ADIABATIC NUCLEAR POTENTIAL. 1. FORMALISM, by A. Klein and B. H. McCormick, July 1956, 38p. refs. (AFOSR-TN-56-419) (AF 18(603)60) AD 96228 Unclassified

Also Published in Phys. Rev., v. 104: 1747-1757, Dec. 15, 1956.

A new formalism is presented for the construction of the 2-nucleon potential, whose salient characteristic is that it involves an expansion only in the number of mesons exchanged, the self-mesic field of each nucleon being treated, in principle, exactly. Access to the potential is achieved through the intermediary of the scattering matrix. Alternative versions of the latter are derived with the neglect either of nonlinear meson propagation or of closed loops entirely. Only the form obtained under the second, more drastic assumption is exploited in this study. The connection between the scattering matrix and the potential is discussed; it is emphasized again that the transition between the 2 requires knowledge of nonenergy conserving matrix elements of the potential, which can be obtained only if the underlying Schrödinger equation is known. The potential involving the exchange of at most 2 P-wave mesons is computed and it is shown to depend on the renormalized coupling constant, the single-nucleon source function, and the total cross-sections for pion [π meson]-nucleon interaction. The numerical evaluation of these formulas is not attempted. (Contractor's abstract)

THE AERODYNAMICS OF BODIES IN NON-UNIFORM FLOW, by E. Pistolesi and M. Marini. [1956] 1v. incl. diagrs. tables. (AFOSR-TR-56-37) (AF 61-(514)872) AD 96513 Unclassified

A study is made of the aerodynamics of airfoils immersed in a subsonic stream of compressible fluid adjacent to another similar stream of different subsonic velocity. The following cases are examined: (1) two semi-infinite streams; (2) a semi-infinite stream adjacent to a stream bounded by a rigid wall; and (3) a semi-infinite stream adjacent to a jet. Each case is explained for an airfoil of zero thickness disposed at some angle of attack and for an airfoil of finite thickness-chord ratio at zero angle of attack. The problem is defined by two restrictions: (1) the perturbation pressure must be the same on both sides of the interface between the streams; and (2) the flow inclination must be the same on both sides of the interface. By the use of the theory of small disturbances and Fourier integral representation, the values of the induced axial and transverse velocities on the airfoil are obtained. Consideration is also given to the problem of two semi-infinite streams of compressible fluid when one has a subsonic velocity and the other has a supersonic velocity.

THE ZEEMAN SPLITTING OF NUCLEAR

QUADRUPOLE RESONANCES, by C. Dean. [1954] ([AF]OSR-TN-54-172) (AF 18(600)892) Unclassified

Also published in Phys. Rev., v. 96: 1053-1059, Nov. 15, 1954.

The theory of the Zeeman splitting of the pure quadrupole energy levels for nuclei of half integral spin is given in a form that is correct for any electric field gradient. The splitting of the spectra is discussed, and also the simplications that can be made in the theory when the magnetic field is parallel to any of the three principal axes of the electric field gradient. For spin 3/2 it is shown that the deviation of the gradient from cylindrical symmetry can be determined from the Zeeman spectrum, and detailed calculations are given for this case, along with a discussion of their experimental application. EFFECTS OF ANISOTROPY ON THERMODYNAMIC PROPERTIES OF ANTIFERROMAGNETS, by J. A. Eisele and F. Keffer. [Aug. 13, 1954] [21]p. incl. diagrs. table, refs. ([AF]OSR-TN-54-197) (AF 18-(600)892) Unclassified

Presented at meeting of the Amer. Phys. Soc., Detroit, Mich., Mar. 18-20, 1954.

Also published in Phys. Rev., v. 96: 929-933, Nov. 15, 1954.

In antiferromagnets, because of interplay with exchange energy, a small anisotropy can have a huge effect on thermodynamic properties. Detailed calculations are given, using spin-wave theory, of the effects of anisotropy on sublatlice magnetization, specific heat, and parallel susceptibility of a cubic antiferromagnet. Specific heat data are discussed and experiments are suggested on the relatively large spin specific heats of antiferromagnets with low Curie points. The theory is extended to orthorhombic symmetry, and reasonable agreement is found with existing experimental data on $CuCl_2 \cdot 2H_2O$. (Contractor's abstract)

DIPOLAR FERROMAGNETISM AT O°K, by M. H. Cohen and F. Keffer. [Mar. 11, 1955] 24p. incl. table. ([AF]OSR-TN-55-86) [AF 18(600)892] AD 111075 Unclassified

Also published in Phys. Rev., v. 99: 1135-1140, Aug. 15, 1955.

A critical examination of the Holstein-Primakoff spin-wave technique has yielded explicit criteria for the stability of ferromagnetic arrays. These criteria have been applied to point dipoles on the 3 primitive cubic lattices for the shape most favorable to ferromagnetism that of a long, thin sample. The results show that: (1) dipolar ferromagnetism cannot occur in the simple cubic lattice; (2) the ferromagnetic state can be the lowest, or at least a metastable, state on the face-centered cubic and body-centered cubic lattices. The zero-point energies of ferromagnetic states are calculated for the $\langle 100 \rangle$, $\langle 011 \rangle$, and $\langle 111 \rangle$, directions, yielding 2 anisotropy constants, K_1 and K_2, for each lattice. The Holstein-Primakoff Hamiltonian is shown not to be diagonal for spin waves in the pathological region, i.e., of wavelengths comparable to the dimensions of the specimens. The properties of this region are shown to be unimportant in energy considerations but may effect stability. They are of great importance in effects such as ferromagnetic resonance which involve long-wavelength spin waves. (Contractor's abstract)

CHLORINE NUCLEAR QUADRUPOLE RESONANCES IN SOLID SOLUTIONS, by C. Dean. June 8, 1955 [1]p. ([AF]OSR-TN-55-190) (AF 18(600)892) AD 110912 Unclassified

Published in Jour. Chem. Phys., v. 23: 1734-1735, Sept. 1955.

A study is reported briefly of the Cl^{35} nuclear quadrupole resonance in p: bromochlorobenzene (p: $Br\phi Cl$). Observations have been made at room temperature in several solid solutions of the above substance with p: dibromobenzene (p: $Br_2\phi$). At the lowest concentration utilized (2 mol-% p: $Br\phi Cl$), the narrowest resonance was found. As the concentration was increased, the resonances became broader, being too broad for positive identification in p: $Br\phi Cl$. For comparison, the Cl^{35} resonance was studied in a series of solid solutions of p: $Br_2\phi$ with the mol-% of p: $Cl_2\phi$ ranging from 1 to 50. These results indicate that relatively minute local variations in crystal structure are an important factor in broadening the quadrupole resonances.

Two theories of the temperature dependence of ferromagnetic anisotropy in cubic crystals, the nearest-neighbor quadrupole-quadrupole coupling theory of

PIT. 02:006 - PIT. 02:009

Van Vleck, and the more recent classical theory of Zener, seem to be contradictory. It is shown that these are, respectively, high- and low-temperature approximations to the same physical picture, i.e., an anisotropy which decreases with rising temperature due to statistical fluctuations from alignment of anisotropically-coupled neighbor spins. Zener's low-temperature approximation shows that the anisotropy decreases as the tenth power of the magnetization. Van Vleck's high-temperature approximation yields a lower power law. It is argued that most of the anisotropy has vanished before sufficiently high temperatures are reached for Van Vleck's approximation to be appropriate. Van Vleck's nearest-neighbor dipole-dipole coupling theory, which has no classical analog and cannot be compared with Zener's theory, is discussed from a spin-wave picture. (Contractor's abstract)

RAPID PASSAGE EFFECTS IN ELECTRON SPIN RESONANCE, by A. M. Portis. Sept. 26, 1955 [2]p. incl. diagrs. ([AF]OSR-TN-55-341) (AF 18(600)892) AD 110914 Unclassified

Also published in Phys. Rev., v. 100: 1219-1221, Nov. 15, 1955.

Using the rapid passage theory of Bloch (Phys. Rev., v. 70: 460, 1946), relaxation effects which have been observed in electron spin resonance from F centers in alkali halides and from donor states in silicon are interpreted. The distinguishing characteristic of the 2 cases is that the line broadening is of the inhomogeneous type, arising from hyperfine interaction. The dispersion signal, obtained at room temperature from a sample of LiF irradiated with 220-kev x-rays for 18 hr, is plotted as a function of the magnetic field for several values of θ, the phase angle between modulation field and reference signal. An examination of these curves reveals 2 surprising results: (1) the LiF signal lags the modulation field by nearly 90°; and (2) the line shape of the LiF resonance more closely resembles an absorption curve than it does the derivation curve. In comparison, the copper sulfate signal appears quite normal. Bloch shows that under rapid passage, the sense of the dispersion line reverses with the direction of travel, and the intensity of the line is proportional to the value of S_z associated with the line. The observed phase shift of 90° and a line shape which reflects the local field distribution may be inferred directly from Bloch's results. Graphical plots are also presented of the absorption signal and dispersion signal in KCl.

ELECTRON SPIN RESONANCE IN IRRADIATED ALKALI HALIDES (Abstract), by A. M. Portis and D. Shaltiel. [1955] [1]p. (AF 18(600)892) Unclassified

Presented at meeting of the Amer. Phys. Soc., Berkeley, Calif., Dec. 28-30, 1954.

Published in Phys. Rev., v. 98: 264, Apr. 1, 1955.

Electron spin resonance has been observed in samples of LiF and LiCl irradiated for a period of 36 hr with 220 kev x-rays. Both samples show inhomogeneous saturation of the resonance similar to that already reported for F centers in KCl, KBr, and NaCl. The g factors for both lines are within experimental error of the free electron g. Both resonances show a surprising response to the magnetic field modulation in that the signal lags the modulating field by nearly 90°. This effect can be understood in a direct way on the basis of hyperfine broadening of lines which are narrow compared with the modulation frequency. We find no resonance in the crystals before irradiation or after the F band has been bleached. The intensity of the resonance is in general agreement with the strength of the F band. We conclude from this evidence and the similarity with the F center resonances in other alkali halides that we are observing genuine F center resonances. We find no evidence for either the resolved spectrum of 19 lines or the broad peak with a g of 2.018 reported by Schneider (Phys. Rev., v. 93: 919, 1954). (Contractor's abstract)

MAGNETIC RESONANCE IN SYSTEMS WITH SPECTRAL DISTRIBUTIONS, by A. M. Portis. Nov. 15, 1955, 44p. incl. diagrs. table, refs. (Technical note no. 1) (AFOSR-TN-56-7) (AF 18(600)892) AD 85870 Unclassified

A study is made of effects in magnetic resonance peculiar to situations where the conditions of excitation change rapidly compared with the relaxation time. The excitation of single resonance line and of a spectrum of resonance lines is discussed. The analysis shows that the amplitude, shape, and phase of the resonance line depend on the rate of relaxation to the lattice. Spin-spin relaxation for such systems is also considered by studying the effect of dipolar interaction on a system of spins distributed over a range of local fields that are large compared with their dipolar fields. The dipoles are assumed to be randomly distributed over some regular lattice, and no correlation is assumed to exist between the dipolar position and the magnitude of the local field.

SPIN-SPIN RELAXATION IN SYSTEMS WITH TWO MAGNETIC INGREDIENTS (Abstract), by A. M. Portis. [1956] [1]p. [AF 18(600)892] Unclasstfied

Presented at meeting of the Amer. Phys. Soc., Pittsburgh, Pa., Mar. 15-17, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 124, Mar. 15, 1956.

Spin-spin relaxation has been investigated theoretically for systems like F-centers in alkali halides or donor centers in semiconductors, which have the following salient features: (1) the effect of the nuclear spins on the electron spins may be described by a resonance spectrum; (2) each electron spin may be identified with a definite position in the spectrum; (3) the electron spins are randomly distributed through the lattice; and (4) the position of an electron in the lattice and its position in the resonance spectrum are completely uncorrelated. The interaction between electron spins is treated by time-dependent perturbation theory and an expression for the life of an individual spin state is found. This time, τs equals $\Delta\omega/\Delta^2$, where Δ is a measure of the strength of the spin-spin interaction and $\Delta\omega$ is related to the width of the resonance spectrum. Macroscopic spin-spin relaxation is described in terms of the diffusion of spin excitation through the resonance spectrum. The behavior of the spin system in an rf field has been investigated by the substitution of a diffusion term for the usual spin-spin term in the Bloch equations. A characteristic diffusion time $\tau D = (\gamma H_1 \tau s)^2 \tau s$ is found. (Contractor's abstract)

SPECTRAL DIFFUSION IN MAGNETIC RESONANCE, by A. M. Portis. [1956] [5]p. (Also bound with its AFOSR-TR-58-46; AD 154185) (AF 18(600)892)
Unclassified

Published in Phys. Rev., v. 104: 584-588, Nov. 1, 1956.

Electron spin-spin interaction is discussed for the case of strong hyperfine broadening. The hyperfine interaction is represented by a resonance spectrum of width $\Delta\omega$ and the electron interactions, which are taken to be dipolar, are treated by time-dependent perturbation theory. A characteristic relaxation time for electron spins, $\tau_3 = \Delta\omega/\Delta^2$, is found, where Δ is a measure of the strength of the dipolar interaction. The time-dependent theory suggests a modification of the Bloch equations to give a phenomenological description of systems of this kind. Spin-spin relaxation is represented by a term which gives diffusion of spin excitation through the resonance spectrum. Slow passage, rapid passage, and free relaxation are considered by using the modified equations. (Contractor's abstract)

Also published in Phys. Rev., v. 97: 1671-1679, Mar. 15, 1955.

Cross-sections are calculated for rotational excitation of a homonuclear diatomic molecule by collisions with very slow electrons. The mechanism is assumed to be the long range quadrupole interaction. The Born approximation is shown to be correct in the low energy limit. The results are applied to calculation of energy losses in N_2, and comparison is made with values inferred from swarm and cross-modulation experiments. At energies below .29 ev, the threshold for vibrational excitation, losses are ~ twice the experimental values, but many times larger than the value (2m/M), where m = the electron mass and M = the molecular mass, for elastic losses only. Also published in Phys. Rev., v. 98: 1848-1851, June 15, 1955.

Theoretical cross sections for the rotational excitation of homonuclear molecules by slow electrons are applied to calculation of the fractional energy loss/collision (λ) in H_2. The theoretical losses are not more than 2.5(2m/M) and except at the lowest energies studied (~0.1 ev) are smaller than observed. It would be desirable to have more direct experimental evidence of

PIT. 03:003 - POL. 01:003

rotational excitation. For this reason, λ has been calculated at 77°K in pure p-hydrogen and in normal hydrogen at that temperature. At electron energies ~0.075 ev, the 2 λ's should differ by about 50%. Similarly, because of the altered rotational distribution, λ for deuterium differs from λ for H_2. Such differences, if observed, could hardly be accounted for on any other basis than rotational excitation. (Contractor's abstract)

ROTATIONAL EXCITATION OF HOMONUCLEAR MOLECULES (Abstract), by S. Stein, E. Gerjuoy, and T. Holstein. [1954] [1]p. (AF 18(600)897) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 27-28, 1953.

Published in Phys. Rev., v. 93: 934, Feb. 15, 1954.

Cross sections are calculated for excitation of rotation of diatomic homonuclear molecules by very slow electrons (energy ~0.1 ev) with neglect of exchange. It is assumed that the excitation results from interaction of the electron with the quadrupole field of the molecule; for this type of potential, use of the Born approximation is defensible at these low energies. For kinetic energies large compared to the separation of rotational levels, the cross section approaches a constant value ~10^{-17} cm^2, using measured quadrupole moments. The average fractional energy losses per collision in N_2 and H_2 are evaluated and are in moderately good agreement with recent measurements. (Contractor's abstract)

Published in Rend. Ist. Lombardo Sci. e Lett., v. 88: 51-71, 1955.

Some general aspects of the overvoltage measurements by means of tensiometric cells are discussed, with consideration of the systematic errors involved in the arrangements shown by Delahay (New Instrumental Methods in Electrochemistry, 1954, p. 393) who asserted that these errors did not exceed 10 mv. The devices used to avoid the errors for the tensiometric measurement in the thin strata (20-30μ) of solution around the electrodes, are described. The principles of new arrangements with probes of various kinds (isoelectrodic, 2nd-class electrodes, for pH-, or oxidation-reduction potentials of electrode stratum) are given together with those of the possible types giving compound-tensiometric cells. The meaning of the various voltages, with particular reference to the practically stationary condition, is discussed. (C. A., 1956:5428h)

IMPROVED APPARATUS FOR CUTTING SINGLE CRYSTALS, by R. Piontelit, B. Rtvolta, and G. Sternheim, [1955] [1]p. (AF 61(514)733-C) Unclassified

Published in Rev. Scient. Instruments, v. 26: 1206, Dec. 1955.

The mechanical methods for cutting single crystals though followed by metallographtc polishing and etching, are unable togtve strain-free specimens as a consequence of the deep penetration of the deformation. A very tnteresting method of cutting stngle crystalltne dtsks from a rod, by means of chemical attack to avoid tntroductng strains, has been developed by Maddtn and Asher. This method uses an endless plastic thread (Saran) which ts led with the aid of pulleys through a bath containing the etchtng solution and over the specimen to be cut. This method has been applted tn this laboratory wtth good results on single crystals of Zn, Sn, and other metals. To shorten the time-consuming operation of cutting, the rate of attack has been tncreased by means of an electrolytic process. The rod to be cut is made the anode of a cell tn which the cathode (in form of a plattnum plate) is tmmersed tn the bath traversed by the plastic thread. The solutton carrted on the thread ts sufftctent to matntatn the conttnutty of the electrtc ctrcutt. Excellent results on cuttng rates and surface ftnish have been obtained on stngle crystals of tin, havtng a dtameter of the order of 20 mm, with a current of about 30 ma, ustng a 1.1 bath of HNO_3. The voltage applied depends tn practice on the length of thread between the bath and the rod. (Contractor's abstract)

OVERVOLTAGE MEASUREMENTS ON ALUMINUM ELECTRODES IN CRYOLITE-ALUMINA BATHS, by G. Montanelit. Mar. t956 [34]p. incl. dtagrs. tables, refs. (Technical note no. 3) (AFOSR-TN-56-217) (AF 6t(514)733-C) AD 88023 Unclasstfied

By means of improved expertmental methods, the cathode and anode overvoltages have been determined at Al electrodes tn cryolite-alumtna bath with or without additives in conditions correspondtng to those of the industrial productton of the metal. The "exchange overvollage" tn the Al separation at 1000°C is as a maximum of the order of some mV even at c.d. of 100 A/dm^2. The concentration overvoltage depends essentially upon the decrease of AlF_3 concentration in the

POL. 01:008 - POL. 01:012

electrode layer and may correspond to some tenth of volt. These results support the hypothesis of the primary discharge of Al from "donors" in the cells, and explain the conditions in which the Na discharge may intervene as a "parasitic" process. (Contractor's abstract)

ELECTROCHEMICAL BEHAVIOR OF TIN, by U. Bertocci and G. Serravalle. Apr. 1956 [37]p. incl. diagrs. tables, refs. (Technical note no. 4) (AFOSR-TN-56-271) (AF 61(514)733-C) AD 89481 Unclassified

The electrochemical behavior of Sn in aqueous solutions, especially those containing fluoride ions was studied. The electrochemical kinetic behavior of Sn was "normal" in solutions containing either fluoride or other anions. Anodic and cathodic ionic exchange overvoltages of Sn were very low in all solutions. The high polarizations obtained in some cases apparently resulted from activity changes (concentration polarization). At sufficiently high current density, the most efficient stirring failed to overcome these changes. In cases where the excess of the constituent which leads to complexes is not too great, the overvoltage may attain very high values (over 100 mV) in the absence of stirring. The presence of free strong acids decreased the Sn complexity degree concurring with it to bond fluoride ions to form HF and HF_2^-. The anodic and cathodic dissolutions take place with practically theoretical efficiency with respect to Sn^{++}. The deposits were mainly macrocrystalline and often in the form of dendrites and plates. (Contractor's conclusions)

ELECTROCHEMICAL BEHAVIOR OF POLYCRYSTALLINE CADMIUM, by U. Bertocci and C. Tantardini. May 1956 [29]p. incl. diagrs. tables. (Technical note no. 5) (AFOSR-TN-56-303) (AF 61(514)733-C) AD 90017 Unclassified

Anodic and cathodic overvoltage measurements of polycrystalline Cd were carried out in perchlorate, sulfate, and chloride solutions having different free acid contents. The results of these experiments prove that the Cd has a "normal" electrochemical behavior, showing low overvoltages, both anodic and cathodic, at 25°, 40° and 55°C. Since the anodic attack and the cathodic deposition are limited to well defined regions of the surface, the actual Ci on the active surfaces is much higher than the apparent one, without leading to high overvoltages. The behavior of Cd, as an electrode, seems to be determined by the crystallographic factors, with probable inhibitive influences deriving from the H^+ or from the OH^- ions. The more deformable anions (in this case Cl^-) are especially efficient in activating the ion exchanges. The temperature increase exerts the usual activating influence. The law of the dependence of the overvoltages upon the apparent Cd does not agree with the usual formulations (as Tafel's law or combined exponential laws). (Contractor's abstract)

RESEARCH ON ANODIC AND CATHODIC BEHAVIOR OF METALS, by R. Piontelli. Sept. 1956 [10]p. refs. (Tecnical note no. 7) (AFOSR-TN-56-546) (AF 61(514)733-C) AD 110365 Unclassified

The purposes of the research were the completion and realization of improved methods and apparatus for measuring electrode overvoltages of metals in aqueous solutions and fused salts by the "direct method," but avoiding the usual sources of systematic errors; the conduction of systematic experiments on the anodic and cathodic behavior of a group of metals in form of polycrystalline electrodes in aqueous solutions, of a group of solid and melted metals in melted salts (in particular of melted aluminium in cryolite-alumina baths), and of a selected group of metals in the form of single crystals in aqueous solutions.

RESEARCH ON THE ELECTROCHEMICAL BEHAVIOR

OF POLYCRYSTALLINE ZINC, by U. Bertocci. Nov. 1956 [23]p. incl. diagrs. tables, refs. (Technical note no. 8) (AFOSR-TN-56-596) (AF 61(514)733-C)
AD 115023 Unclassified

Also published in Rend. Ist. Lombardo Sci. e Lett., v. 91: 39-54, 1957.

The electrochemical behavior of Zn is investigated in order to determine the individual anodic and cathodic overvoltages by good approximation through a choice of techniques and the choice of a zero value of the electrode voltage near the equilibrium voltage. The cause of the lack of symmetry between the anodic and cathodic overvoltages is investigated and found to disappear when the value, agreeing with the simple Zn electrode at equilibrium, is set equal to zero in the evaluation of overvoltages. Differences, corresponding to those of the anode overvoltage values of Zn, between the electrode voltages in absence of current and the equilibrium value of the simple Zn electrode are found to be greater in sulphate and especially, in perchlorate solutions than in chloride.

[BEHAVIOR OF ELECTRODES IN FUSED SALTS] Comportement d'électrodes en milieu de sels fondus, by R. Piontelli, G. Sternheim, and M. Francini. [1956] [3]p. incl. diagr. [AF 61(514)733-C] Unclassified

Published in Compt. Rend. Acad. Sci., v. 242: 1301-1303, Mar. 5, 1956.

The apparent overpotentials, relative to a reference electrode, as a function of current were determined for the following electrodes: Mg (solid) | $MgCl_2$ (35%) + KCl (47%) + NaCl (18%) (by weight) at 550°; Al (solid)| $AlCl_3$ (70%) + NaCl (30%) at 220°. The overpotential was due entirely to an ohmic drop in the bath and not to exchange of ions between the bath and the metal. The graphs were linear, and the anodic and cathodic branches were symmetrical. This was true only when the bath was very pure (especially free from H_2O), the metal surfaces very clean, and passage of current limited and brief. This avoided passivating layers of oxide or oxychloride.

DESIGN AND OPERATION OF INTERMITTENT SUPERSONIC WIND TUNNELS, by A. Ferri and S. M. Bogdonoff. May 1954, 108p. incl. illus. diagrs. refs. (NATO AGARDograph rept. no. 1) [AF 18(600)796] Unclassified

A study has been made of the operating characteristics of intermittent wind tunnels, particularly of the blow-down type. Considerations of low cost and flexibility are pointed out. Detailed performance of the components of such equipment are presented from calculation and experience. Typical construction, test set-up, instrumentation, and extension to the transonic and hypersonic region are discussed. Some examples of operating intermittent tunnels are also given.

The coefficients of thermal expansion of powdered cubic sodium tungsten bronzes (Na_xWO_3; $0.9 > x > 0.3$) from room temperature to 600°C have been determined. The expansion coefficients for all compositions studied are constant and essentially identical below transition temperatures (near 200°C) which vary with sodium content. At the transition temperatures, the expansion coefficients change sharply to lower values which vary with composition, going through a minimum near $x = 0.5$. The relation between these changes and a similar change in pure WO_3 is pointed out. (Contractor's abstract)

SUPERSONIC FLOW OVER CONICAL BODIES WITHOUT AXIAL SYMMETRY, by A. Ferri, N. Ness, and T. T. Kaplita. Nov. 1952, 26p. illus. (PIBAL rept. no. 213) (AF 18(600)186) AD 201 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 20: 563-571, Aug. 1953.

The method of superposing linear solutions to a nonlinear nonuniform flow field was applied to the analysis of conical flows without axial symmetry. The aerodynamic properties of cones with elliptical, drop-shape, and triangular cross sections were determined from these linearized solutions. For elliptical cones, the results indicated that at a constant free-stream Mach no. the shock-drag ratio decreases as the ratio of the minor to major axis of the ellipse decreases. For a given elliptical body at zero angle of attack, the drag ratio remained practically constant and less than unity for the Mach range considered. The effect of angle of attack was also analyzed, and the lift coefficient determined. The lift coefficient was similar to that of a triangular flat plate of the same plan form. For cones having drop-shape and triangular cross sections, the drag ratio remained practically constant and less than unity for a wide range of Mach nos. Some gain on the shock drag appeared obtainable with bodies having cross sections different from circular.

The supersonic flow over conical bodies without axial symmetry may be obtained by superposing linear conical flows upon a basic nonlinear axially symmetric conical flow. The basic nonlinear axially symmetric conical flow was investigated, and tabulated values for this flow are given in Tables of Supersonic Flow Around Cones, technical report no. 1, MIT (1947). The superposed linear conical flow may be determined with the aid of the perturbation velocity components that are tabulated. A description is presented of the method for obtaining these components. The components are tabulated from the surface of the basic circular cone to the axially symmetric shock front produced by the basic circular cone, and are expressed by five digits. (ASTIA abstract)

SUPERSONIC FLOW AROUND POINTED THREE-DIMENSIONAL BODIES. PART I. DESCRIPTION OF THE METHOD, by M. Vistch, Jr. July 1955 [33]p. incl. dtagr. refs. (PIBAL rept. no. 280-A) ([AF]-OSR-TN-55-266) (AF 18(600)693) AD 75347 Unclassifted

The methods of Ferrt, Ness, and Kapltta (Jour. Aeronaut. Sctences, v. 20: 563-571, 1953) and of Broglto are extended in order to determine the flow fteld about potnted 3-dtmenstonal bodtes represented by

$$\psi_B = \psi_{o_c} + \sum_{t=o}^{\infty}\sum_{n=o}^{\infty} \Lambda_{nl}\, r^t \cos n\theta;$$ r, θ, and ψ are

spherical coordtnates; the subscrtpts o and c refer to properties of the bastc axially symmetrtc conical flow and properties at the surface of the basic axially symmetrtc cone, respectively; B refers to properties at the surface of the actual body. The analysts ts based on the superposttion of ltnear conical soluttons on a nonltnear axially symmetrtc conical flow. Two methods

are presented for determining the body coefftctents Λ_{nl}.

The ftrst method entails spectfytng the coordtnates of the body at (N + 1)(I + 1) potnts to obtain an equation that deftnes the body exactly at the potnts specified. The second method assumes that a cross section of the body ts spectfted on the surface of a sphere of radtus r = k so that

$$\psi_{B_{r=R}} = \psi_{o_c} + \sum_{t=o}^{I}\sum_{n=o}^{N} \Lambda_{nl} R^t \cos n\theta$$

represents the body by a ftntte number of terms. The Λ_{nl} are then deftned as

$$\psi_{o_c} + \sum_{t=o}^{I} \Lambda_{ol} R^t = \frac{1}{\pi}\int_0^{\pi} \psi_{B_{r=R}}\, d\theta,$$

$$\sum_{t=o}^{t} \Lambda_{nl} R^t = \frac{2}{\pi}\int_0^{\pi} \psi_{B_{r=R}} \cos n\theta\, d\theta, \quad n = 1, 2, \ldots, N.$$

DIFFRACTION OF DtSTURBANCES AROUND A CONVEX RIGHT CORNER WITH APPLICATIONS IN ACOUSTICS AND WING-BODY INTERFERENCE, by L. Ting. Aug. 1956 [31]p. incl. diagrs. (PIBAL rept. no. 307) (AFOSR-TN-56-428) (AF 18(600)693) AD 96510 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 24: 821-844, Nov. 1957.

An integral equation is set up for the problem of finding the pressure disturbance when a given small disturbance passes around a 90° convex corner. The solution is obtained by the method of successive substitution. It is shown that the series given by this procedure converges faster than the power series of 1/2. The convergence of the series is accelerated by regrouping the terms so that the solutions corresponding to any one of the ordinal numbers of substitution possesses the correct behavior at the boundary of the domain. When the given disturbance is a plane weak (acoustic) shock, the solution corresponding to the second substitution is already in good agreement with the linearized conical solution. For the problems considered in this study, the series converges so fast, that there is no necessity to go beyond the second substitution. Based upon this solution and the procedure outlined previously (Jour. Math. and Phys., v. 32: 102-116, July-Oct. 1953), the pressure distribution on a rectangular barrier after it is hit by a weak shock is obtained. The problem of interference of a cylindrical body of rectangular cross section with a planar wing in supersonic flight can be reduced to the problem presented here and the one solved by Evvard's method (NACA Technical note no. 1382, July 1947). The pressure distrtbution is obtained for a body of square cross section mounted on a semi-infinite wedge. The numerical results agree with the tntegral relationship.

AN ASSESSMENT OF BODY LIFT CONTRIBUTtONS AND OF LINEARIZED THEORY FOR SOME PARTtCULAR WING-BODY CONFtGURATIONS, by J. W. Reyn and J. H. Clarke. June t956 [71] p. incl. diagrs. tables, refs. (PIBAL rept. no. 305) (AFOSR-TN-56-429) (AF 18(600)693) AD 96511 Unclassified

A configuration composed of a circular half cone mounted beneath a swept wing with zero thickness is studied to determine whether the lift induced in the system by the cone in supersonic flow ts produced effictently enough to provide, at practical values of the lift coefficient, significant reductions in the pressure drag. The drag of this configuration is compared, at equal lift coefficient and Mach number, to tts inverted counterpart, to a configuration composed of the same wing and a symmetrically disposed cone with equal volume, and to the wing alone. For given values of the cone angle parameter and the sweep parameter, the drag of the high-wing configuration ts less than that of the low-wing configuration for all positive values of the lift coefficient. The drag of the high-wing configuration becomes successively less than that of the midwing configuration and that of the wing alone at certain critical values of the lift coefficient. The relative drag reductions in the three cited comparisons are a maximum at certain optimum values of the lift coefficient. Compared to the high delta wing-cone configuration, the high swept wing-cone configuration results in greater relative drag reductions at lower values of the lift coefficient, and therefore appears to be of much greater practical interest. Compared to the corresponding low-wing configuration, midwing configuration, and wing alone, the high swept-wing system can give drag reductions up to 36%, 10%, and 5%, respectively. Numerical calculations are reported of the supersonic flow field around cones and cone-cylinders at zero angle of attack which were made to assess the accuracy of the ltnearized theory tn wtng-body tnterference problems.

A PROVISIONAL ANALYSIS OF TURBULENT BOUNDARY LAYERS WITH INJECTION, by J. H. Clarke, H. R. Menkes, and P. A. Libby. [1955] [6]p. incl. illus. diagrs. table. [AF 18(600)694] Unclassified

Published in Jour. Aeronaut. Sciences, v. 22: 255-260, Apr. 1955.

Prandtl's analysis of the incompressible turbulent boundary layer over a flat plate is extended in this report to include the effect of uniform, transverse fluid injection. The nondimensional parameters characterizing such a flow are deduced by dimensional reasoning. A velocity profile is generated by considering the flow over a plane wall; this distribution reduces to the universal log law when the mass transfer is zero. The expression also serves to relate the local skin friction to the boundary-layer thickness. When these relationships are used in conjunction with the von Kármán integral, the problem becomes mathematically specified. Since only a limited amount of experimental data is available, it is necessary to assign to certain parameters that arise in the velocity profile the constant values they have for no mass transfer. When more measurements are completed, it may be possible to adjust these parameters as or if required. The results give the variation of average skin-friction coefficient with the injection ratio and the Reynolds number based on the streamwise coordinate. The agreement between these results and the experimental data available is found to be satisfactory. The significant reductions in skin friction, and therefore in heat transfer, to be realized with small rates of injection are indicated.

Unclassified

Also published in Jour. Aeronaut. Sciences, v. 24: 1-18, Jan. 1957.

A general outline has been given of possibilities for favorable interference between supersonic aircraft components. The interference between a 3-dimensional wing and a small reflecting surface in biplane arrangement has been discussed in terms of the linearized flow theory. Relationships have been developed which permit the analysis of such biplane configurations without the need for determination of the flow field. These relations apply in the linear approximation to a large class of such configurations. The method has been applied to several biplane arrangements of practical interest. It has been shown that the drag of the wing can be greatly reduced or that the volume near the root section of the wing can be considerably increased without penalty in drag. A discussion of the biplane from the engineering point of view indicated that the configuration appears to have some practical application, particularly in the higher Mach number range. DRAG OF A THIN BODY FAVORABLY INTERFERING WITH A WING IN SUPERSONIC FLOW, by J. H. Clarke and F. D. Hains. Oct. 1956 [57]p. incl. diagrs. refs. (PIBAL rept. no. 310) (AFOSR-TN-56-496) (AF 18-(600)694) AD 110310 Unclassified

A comparison is made between the drags of thin, wing-like bodies and slender bodies of revolution when these bodies enclose the same volume and immersed in the same supersonic stream. It appears that the sum of the wave drag and the viscous drag can be of comparable magnitude in each case when the chords are equal and the enclosed volume is sufficiently large. Interference of the biplane type between a high aspect ratio wing and a thin, wing-like body with pentagonal planform is analyzed. The body is considered to represent an external installation, such as a store or winged vehicle, which is placed in proximity to the wing. Solutions are found through employment of diaphragms and images and it is shown that interplanar induction is quasi two-dimensional in nature, for the problem considered, so that all detailed calculations required are of the planar type. The difference between the wave of the configuration and the wave drag of the isolated wing is presented as a function of the body planform parameters for given values of the volume enclosed by the body. This drag is always much less than the wave drag of the corresponding isolated body, and becomes zero and then increasingly negative as the span of the body is increased indefinitely. The values also compare favorably with the wave drag of Sears-Haack bodies, exhibiting small fineness ratios and containing equal values, over a range of the body planform parameters. A skin friction estimate, for a particular case, yields results which do not materially alter the latter comparison. (Contractor's abstract)

ANALYSIS OF FRAMEWORKS IN THE PRESENCE OF STEADY CREEP, by P. G. Hodge, Jr. and B. Venkatraman. Nov. 1955 [28]p. incl. diagrs. tables, refs. (PIBAL rept. no. 333) ([AF]OSR-TN-55-455) (AF 18(600)1381) AD 81597 Unclassified

An analysis is presented of pinjointed frameworks in which the deformations are caused exclusively by steady creep. By means of the elastic analogue, the creep problem is first reduced to one in nonlinear elasticity. The elastic analysis is then shown to depend upon the solution of one or more nonlinear algebraic equations. Next, 2 distinct methods of finding approximate solutions are presented. These are based upon the 2 minimum principles of elasticity, and also upon the behavior of a rigid-perfectly plastic material. Finally, some examples are worked out by the exact and approximate analyses, the results being compared. (Contractor's abstract)

APPROXIMATE SOLUTIONS OF SOME PROBLEMS IN STEADY CREEP, by P. G. Hodge, Jr. and B. Venkatraman. Aug. 1956 42p. incl. tables, refs. (AFOSR-TN-56-361) (AF 18(600)1381) AD 95447 Unclassified

If the elastic and primary creep strains in a structure can be neglected, than it can be shown that the resulting mathematical problem is equivalent to a problem in nonlinear elasticity. Further, if the creep strain rates satisfy a power law, then the classical minimum principles of elasticity are valid for the analogous elastic problem. Therefore, approximate solutions can be obtained by choosing appropriate functions containing certain arbitrary parameters and minimizing either the potential or complementary energy with respect to these parameters. If the exponent in the power law for creep strain rates is large, the stress-strain rate curve is very similar to that which characterizes a rigid-perfectly plastic material. This fact can be used to advantage in choosing appropriate functions for applications of the minimum principles. This concept is illustrated with respect to pin jointed frameworks and jointed plane frames. Exact and approximate methods are compared for some simple examples, and the power of the approximate methods is illustrated in more complex problems. (Contractor's abstract)

BENDING OF RIGID FRAMES IN THE PRESENCE OF STEADY CREEP, by B. Venkatraman and P. G. Hodge, Jr. May 1956 [22]p. incl. diagrs. tables, refs. (PIBAL rept. no. 346) (AFOSR-TN-56-455) (AF 18-(600)1381) AD 97071 Unclassified

This paper is concerned with the creep behavior of rigid frames made of a material obeying a steady creep law. The creep problem is first reduced to one in nonlinear elasticity by means of the elastic analogue. The elastic problem is shown to depend upon the solution of one or more nonlinear algebraic equations. Next,

various methods of finding approximate solutions are presented. These stem from the behavior of a rigid-perfectly plastic material and are based upon potential energy analysis. Finally, some examples are worked out by the exact and approximate analyses to show the qualitative effect of creep in bending. (Contractor's abstract)

STRESS DISTRIBUTION IN THE PRESENCE OF CREEP, by N. J. Hoff. Sept. 1956 [18]p. incl. diagrs. refs. (PIBAL repl. no. 362) (AFOSR-TN-56-456) (AF 18(600)-1381) AD 97072 Unclassified

Also published in Proc. Ninth International Congress of Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956), v. 8: 211-218, 1957.

When the material of a structure creeps, the law governing the creep deformations, or a law combining elastic and creep deformations, takes the place of Hooke's law in the statement of the problem of stress distribution. The creep laws obtained from creep tensile tests, and their generalizations applicable when the state of stress is biaxial or triaxial and when the stress varies, are discussed. The existence of elastic and plastic analogues for steady and for transient creep is shown and the use of the analogues in stress analysis is explained. The theory of the buckling of columns whose material is subject to creep is presented.

LONG-LIVED STATES IN PHOTOCHEMICAL REACTIONS: II. PHOTOREDUCTION OF FLUORESCEIN AND ITS HALOGENATED DERIVATIVES, by A. H. Adelman and G. Oster. [Mar. 1956] [17]p. incl. diagrs. tables, refs. (AFOSR-TN-56-130) [AF 18-(600)1182] AD 86007 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 3977-3980, Aug. 20, 1956.

A comparison is made among the constants characterizing the photoreduction of fluorescein and several of its halogenated derivatives in the presence of allyl thiourea. The quantum yield of production of the long-lived excited state changes slightly with halogenation. Similarly, the lifetimes of these states do not vary among the halogenated members and are about 10^{-4} sec in water at room temperature. Internal conversion from the first singlet excited state to the ground state increases with halogenation. There is extensive quenching of the metastable state by the dye in the ground state as well as by a wide variety of foreign substances. The diversity of effective substances suggests that a diffusion-controlled quenching mechanism is operative as opposed to an energy transfer mechanism. Comparison of phosphorescence quenching in a highly viscous medium with the retardation of photoreduction indicates that the metastable state is the triplet state. (Contractor's abstract)

LONG-LIVED STATES IN PHOTOCHEMICAL REACTIONS. I. PHOTOREDUCTION OF EOSIN, by G. Oster and A. H. Adelman. [1956] [4]p. incl. diagrs. refs. (AF 18(600)1182) Unclassified

Published in Jour. Amer. Chem. Soc., v. 78: 913-916, Mar. 5, 1956.

A mechanism for the photoreduction of eosin Y with allyl thiourea is presented which necessitates the postulation of a long-lived excited state of the dye. Extensive quenching of this metastable state by dye in the ground state is shown to occur. Kinetic and quenching data are used to evaluate the extent to which the unexcited dye, reducing agent, potassium iodide and p-phenylenediamine interact with the metastable excited state of the dye. Further, these data are used to calculate an approximate lifetime of the long-lived excited state which was found to be about fifty thousand times greater than that of the first excited singlet state. FLUORESCENCE AND INTERNAL ROTATION: THEIR DEPENDENCE ON VISCOSITY OF THE MEDIUM, by G. Oster and Y. Nishijima. [1956] [4]p. incl. diagrs. refs. (AF 18(600)1182) Unclassified

PIB. 07:004 - PIB. 08:001

Presented at meeting of the Amer. Chem. Soc., Dallas, Tex., Apr. 1956.

Published in Jour. Amer. Chem. Soc., v. 78: 1581-1584, Apr. 20, 1956.

Substances possessing substituted phenyl groups which are capable of internal rotation increase their fluorescence with increasing viscosity of the medium. The fluorescence yield ϕ of auramine 0, a substituted diphenylmethane dye, measured in glycerol at various temperatures and in dextrose-glycerol-water mixtures at room temperature followed the relation $\phi = (\eta/T) / [\alpha + \beta (\eta/T)]$ where α and β are constants, η is the viscosity and T is absolute temperature. The results are interpreted as being due to one of the fluorescence quenching steps passing via a rotational diffusion process. We calculate that this step takes place if during the period of excitation of the light-excited dye the groups on the molecule have rotated relative to one another by more than 2°. PHOTOREDUCTION OF TRIPHENYLMETHANE DYES IN THE BOUND STATE, by G. Oster and J. S. Bellin. [June 26, 1956] [5]p. incl. diagrs. refs. (AF 18-(600)1182) Unclassified

Published in Jour. Amer. Chem. Soc., v. 79: 294-298, Jan. 20, 1957.

Triphenylmethane dyes do not undergo photoreduction unless they are bound to water-soluble high polymers. In contrast to their behavior in the light, the reduction of these dyes in the dark by strong reducing agents is actually inhibited when the dyes are bound. In several respects the photochemical behavior of the bound dyes is different from that of free fluorescein-type dyes. Whereas, with the latter, when free, the quantum yield increases with increasing dye concentration. Nitrobenzene retards the rate of fading of free dyes, while in the case of bound dyes, the reaction is inhibited until all the nitrobenzene is consumed, after which the reaction proceeds at a rate equal to that for the inhibitor-free system. Analysis of t e kinetic data shows that bound long-lived excited dye molecules react with the reductant to give colorless products. Interaction between bound dye molecules in the ground state and those in the first electronically excited singlet state is the principal mechanism for the formation of long-lived excited dye molecules. Confirmation of this reaction step is the fact that self-quenching of the fluorescence of bound dye molecules occurs at abnormally low concentrations. An analogy is drawn between these systems and those occurring in photosynthetic systems.

PHOTOREDUCTION OF EOSIN IN THE BOUND STATE, by J. S. Bellin and G. Oster. [Nov. 30, 1956] [4]p. incl. diagrs. refs. (AF 18(600)1182) Unclassified

Published in Jour. Amer. Chem. Soc., v. 79: 2461-2464, May 20, 1957.

The spectral and photochemical properties of eosin Y bound to polyvinylpyrrolidone differ considerably from those of the free dye. The bound dye exhibits self-quenching of phosphorescence (in rigid media) the opposite is true. Furthermore, p-phenylenediamine which quenches the phosphorescence of the free dye is without effect on the bound dye. Nitrobenzene retards the photoreduction of free eosin but inhibits the photoreduction of bound eosin, the duration of the inhibition period being proportional to the concentration of the inhibitor. p-Phenylenediamine both inhibits and retards the photoreduction of bound eosin while it only retards the reaction for free dye. For small dye concentrations the quantum yield of photoreduction of bound eosin increases with increasing dye concentration while for free dye the opposite is the case. These rate studies suggest that a bound dye molecule in the first electronically excited state rapidly exchanges energy with a bound dye molecule in the gound state to produce a long-lived excited species which reacts with the reducing agent (here ascorbic acid). A mechanism is proposed for dye-sensitization in silver halide photography based on photoreduction of bound dye. (Contractor's abstract)

IONIC POLYMERIZATION, by C. G. Overberger and A. B. Finestone. June 1955, 27p. incl. tables, refs. (Technical note no. 2) ([AF]OSR-TN-55-191) (AF 18-(600)970) AD 68543 Unclassified

An attempt was made to synthesize from vinyl monomers an asymmetric polymer which would be capable of producing asymmetric polymers by ionic polymerization. The use of optically active cocatalysts, l-menthoxyacetic acid and d-π-camphorsulfonic acid, in the cationic-catalyzed copolymerization of styrene and p-chlorostyrene, failed to give an asymmetric polymer synthesis. Ammonium p-toluenesulfinate, Na p-toluenesulfinate, and triethylsulfonium bromide were studied with vinyl monomers containing electron-withdrawing groups to explore their use as anionic catalysts in vinyl polymerization. The catalyst did not initiate polymerization. The use of active amylmagnesium bromide in the anionic-catalyzed polymerization of methyl methacrylate failed to give an asymmetric polymer synthesis. This Grignard reagent was not a catalyst for the polymerization of sec-butyl methacrylate. X-ray diagrams demonstrated that polystyrene and polymethyl methacrylate obtained by Alfin-catalyst polymerization were completely amorphous. The use of an optically active alcohol, d-sec-butanol, as one of the components of the Alfin catalyst also failed to give any

increased orientation in the polymer. The Alfin catalysis failed to polymerize sec-butyl methacrylate. (ASTIA abstract)

DESIGN OF FEEDBACK SYSTEMS, by E. J. Angelo, Jr. Jan. 31, 1956 [22]p. incl. diagrs. refs. (Repl. no. R-449-55; PIB-379) (AFOSR-TN-56-146) (AF 18-(600)1505) AD 86305 Unclassified

An examination is made on the relationship between system configuration and system performance with the objective of establishing practical guides to aid in choosing the configuration to be used. This study revealed that the dynamic performance of a linear feedback system depends primarily on the over-all transmission (closed-loop transfer function), T_0, and the sensitivity function, S; it is independent of the system configuration used to realize these functions. In order to achieve an optimum design, attention should be directed toward the choice of optimum transfer and sensitivity functions; the system configuration can then be chosen for greatest convenience in realizing these functions. This statement implies a design procedure consisting of 2 parts: (1) the choice of optimum functions for T_0 and S, and (2) the choice of system components and configuration to realize these functions when certain components (such as the servo motor) are specified. R-C TRANSISTOR NETWORK SYNTHESIS, by I. M. Horowitz. [1956] [12]p. (AF 18(600)1505; continued by AF 18(603)105) Unclassified

Presented at National Electronics Conference, Chicago, Ill. Oct. 1-3, 1956.

Published in Proc. National Electronics Conference, v. 12: 818-829, 1956.

The transistor with its numerous attractive features lends itself readily to exploitation as a circuit element. In conjunction with resistors and capacitors, it may be used to synthesize transfer functions otherwise requiring inductors. Synthesis procedures for this purpose have been described in the literature. One gap in these procedures has been the lack of any unrestricted method for realizing non-minimum phase transmission zeros in the form of simple unbalanced networks. This paper fills this gap with an R-C-transistor synthesis technique for realizing transmission zeros. The synthesis philosophy is in the tradition of Brune, Darlington and Dasher in that a driving-point-impedance is developed in ladder form by means of a cascade of canonical sections. Each section, consisting of a T structure of four passive elements in parallel with one transistor, realizes one pair of zeros and in the process, reduces the degree of the driving-point impedance by two. Alignment is thus considerably simplified because there is no interaction between sections with respect to their transmission zeros. Experimental examples are given and methods are described for making the transfer function so insensitive to the transistors, as to permit interchange of transistors of different manufacturers, with negligible effect on the network characteristics. NON-RECIPROCAL NETWORK THEORY APPLIED TO FERRITE MICROWAVE DEVICES (Abstract), by H. J. Carling. [1956] [1]p. (AF 18(603)105; continuation of AF 18(600)1505) Unclassified

Presented at meeting of the British Inst. of Electrical Engineering, London (England), Oct. 29, 1956.

The network expressions for the physical realizability of non-reciprocal structures are briefly examined. These are then applied to a discussion of the properties of linear ferrite microwave devices. Applications include properties and equivalent circuits for one-way lines, multiport circulators, multiport power dividers, variable directional couplers, phase shifters, and ferrite duplexers. Some discussion is also given to the use of non-reciprocal circuit concepts in the measurement of the terminal properties of linear ferrite devices by means of equivalent circuits, and by the application of a theorem which separates reciprocal and non-reciprocal effects in measurement techniques. Finally a brief introduction is given to the use of symmetry operators in analyzing the circuit properties of microwave junctions containing ferrites. (Contractor's abstract)

SENSITIVITY CONSIDERATIONS IN ACTIVE NETWORK SYNTHESIS, by J. G. Truxal and I. M. Horowitz. [1956] [11]p. incl. diagrs. (AF 18(603)105) Unclassified

Presented at Second Midwest Symposium on Circuit Theory, East Lansing, Mich., Dec. 3-4, 1956.

Published in Proc. Second Midwest Symposium on Circuit Theory, p. 6-1-6-11, 1956.

Attempt is made to indicate the increased flexibility attainable in feedback system realization if the input signals can be characterized as belonging to a restricted class — for example, pure sinusoids with only the network gain of interest, damped sinusoids or decaying exponentials, or typical transient test signals such as step functions. In the first case, the real part of the classical sensitivity function must be evaluated at real frequencies in the band of interest; in the second case, the value of the classical sensitivity function at a specified, complex value of frequency is pertinent; and in the third case, the root-locus method indicates the configuration and realization by which the loci can be made to move so as to preserve the desired characteristics of the transient response (e.g., radially expanding or contracting to leave the overshoot unaltered by changes in ζ). In each case, the active, feedback network can possess self-calibration properties (low sensitivity) without the high loop gain.

SUBMICROSCOPIC STRUCTURE DETERMINATION BY LONG WAVELENGTH X-RAY DIFFRACTION, by B. L. Henke and J. W. M. DuMond. [1955] [15]p. incl. illus. diagrs. refs. (Bound with its AFOSR-TN-57-436; AD 136426) [AF 18(600)1045] Unclassified

Also published in Jour. Appl. Phys., v. 26: 903-917, July 1955.

This paper reviews the theory of low angle x-ray diffraction as applied in the long wavelength region for the determination of particle sizes and shapes and other structural features in the submicroscopic size range and emphasizes the advantages to be gained by employing the longer x-ray wavelengths (8 to 25 A). It also is intended to serve as an introduction to a description of an entirely new instrumental technique developed for this long wavelength range utilizing a diffraction apparatus consisting of a special gas-filled x-ray tube and a total reflection camera in which the primary radiation is simultaneously monochromatized and made to converge to a point focus. The sample for study is placed in the converging part of the primary beam and the diffraction patterns are formed around the point focus on a photographic film. (Contractor's abstract)

DIFFRACTION MICROSCOPY — A LIGHT MICROSCOPE METHOD FOR THE MEASUREMENT OF SUBMICRON PARTICLES (Abstract), by B. L. Henke. [1956] [1]p. [AF 18(600)1045] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 34, Jan. 30, 1956.

Submicroscopic particles can be detected by using the conventional dark-field illumination which consists of an intense hollow cone of radiation that converges from the substage condenser to a point on the sample and then spreads out with sufficient angle to "miss" the objective. By reducing the size of the aperture stop of the objective and the angular "thickness" of the illuminating cone, the radiation which forms a point image is characteristic of a particular angle of scattering from a particle. A method has been developed for varying this half-angle of the illuminating cone and for measuring the light flux which forms an image point. Information is thus obtained as to the angular distribution in the forward direction of energy which is scattered from a single particle. The deduction of particle size becomes relatively straightforward for the important class of problems involving a small difference between the refractive index of the particle and that of the surrounding medium — a condition which usually obtains for biological materials in solution, for example. The diffraction theory as applied in low angle x-ray diffraction techniques can be used for the case of "soft" scatterers in the 0.1 μ to 1 μ range. (Contractor's abstract)

SEMIEMPIRICAL METHOD FOR THE COMPUTATION OF MASS ABSORPTION COEFFICIENTS FOR THE LONG WAVE-LENGTH X-RAY REGION (Abstract), by R. White and B. L. Henke. [1956] [2]p. [AF 18-(600)1045] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30–Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 34-35, Jan. 30, 1956.

The measurement of absorption coefficients in the x-ray wavelength region of 5 to 50 Å is usually very difficult because of the necessity for working in vacuum and for obtaining and measuring very small sample thicknesses. A considerable amount of work has been accomplished on the theoretical derivation of photoelectric absorption cross sections, but none of these seems to constitute a practical basis for an extensive computation of mass absorption coefficients. Nevertheless wave-mechanical theory does suggest that a "universal" absorption equation should exist for this long wavelength region of the form $(\mu/\rho)(A/\lambda) = f_K(\lambda/\lambda_1) + f_L(\lambda/\lambda_2)\ldots$ in which (μ/ρ) is the mass absorption coefficient, A is the atomic weight, λ_1 and λ_2 are characteristic wavelengths which "measure" the binding of electrons in the K and L shells and which consequently depend on the atomic number of the element, and f_K and f_L are universal functions. An empirical method has been developed which has permitted the determination of these universal functions and the characteristic wavelengths from available absorption data. The "universal" functions have been expressed in both tabulated and equation form and do permit a rapid and precise computation of mass absorption coefficients for wavelengths in the 5 to 50 Å region which lie below the critical L-absorption edge for the particular element. HYPERSONIC VISCOUS FLOW OVER A FLAT PLATE (Abstract), by L. Lees and R. F. Probstein. [1952] [1]p. [AF 33(038)250] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 31, Feb. 1-2, 1952.

Published in Phys. Rev., v. 86: 600, May 15, 1952.

The steady hypersonic flow of a viscous, heat conducting gas over a semi-infinite flat plate is examined in a region away from the leading edge. As a result of the curvature of the relatively thick boundary layer, variations in pressure are propagated into the main stream along Mach lines, with a subsequent interaction between the "inviscid" field and the boundary layer growth. Solution of this problem shows that the important generating parameter is $M^3/(Re_x)^{1/2}$, where, M is the free stream Mach number and Re_x the Reynolds number based on distance from the leading edge. By successive iterations between the "internal" and "external" fields, asymptotic expansions in terms of $M^3/(Re_x)^{1/2}$ are found for the flow quantities such as pressure, velocity, temperature, etc. The zero-pressure gradient flat-plate boundary layer solution is the first approximation in the expansions. It is shown that there is a wedge-like domain where the "higher order" viscous terms in the x-momentum equation can be neglected. In addition to the horizontal pressure gradient, the gradient normal to the plate is evaluated. From the results, the region of validity of the zero pressure gradient boundary layer solution, as well as the error made in the skin friction and heat transfer rate determined by this solution, can be found. When $M^3/(Re_x)^{1/2}$ is not small, compared to one, the error is considerable. (Contractor's abstract)

ON A SOLUTION OF THE ENERGY EQUATION FOR A ROTATING PLATE STARTED IMPULSIVELY FROM REST, by R. F. Probstein. Sept. 20, 1952, 10p. refs. (Rept. no. 213) (AF 33(038)250) ATI-169813 Unclassified

The problem of the steady, laminar incompressible flow of a fluid over an infinite plate rotating at a constant velocity was first solved by von Kármán. Recently the associated heat transfer problem for the von Kármán example was calculated by Millsaps and Pohlhausen. The purpose of this paper is to show that when heat conductivity is included a solution for the initial phase of the impulsive start may be obtained. Apart from an academic viewpoint, this solution offers an interesting mathematical analogy to the steady hypersonic laminar flow over a semiinfinite flat plate with a "self-induced" pressure gradient.

ON THE RECOVERY FACTOR FOR HYPERSONIC FLOW WITH A SELF-INDUCED PRESSURE GRADIENT, by R. F. Probstein and L. Lees. [1953] [2]p. (AF 33(038)250) Unclassified

Published in Jour. Aeronaut. Sciences, v. 20: 291-292, Apr. 1953.

This paper gives in closed form the first approximation for the wall temperature in hypersonic flow with a self-induced pressure gradient due to the laminar boundary layer. The equilibrium wall temperature has exactly the same value as for zero pressure gradient. Thus Busemann's conclusion that the recovery temperature is unaffected by pressure gradient for Pr = 1 is generalized to arbitrary Pr, at least for the case of weak interaction in hypersonic flow. STABILITY OF THE LAMINAR BOUNDARY LAYER WITH INJECTION OF COOL GAS AT THE WALL, by L. Lees. May 20, 1948, 24p. dtagrs. (Rept. no. 139) (Sponsored jotntly by [Offtce of Naval Research and Atr Force Office of Scientiftc Research] under N6ort-27006) Unclasstfied

The mtnimum critical Reynolds number, or "stabtlity limtt" for the laminar boundary flow of a hot gas over a porous-cooled flat plate ts calculated as a function of the rate of coolant tnjection from the computed velocity and temperature dtstrtbutions across the boundary layer. The result is found that for low rates of coolant injection, the stabtltzing effect of the heat transfer at the wall is dominant, and the laminar flow ts actually more stable than the tsothermal blastus flow over a non-porous flat plate. For large injection rates the mtnimum crttical Reynolds number declines extremely rapidly, and the flow ts almost certainly turbulent. (Contractor's summary, modified)

STABILITY OF THE SUPERSONIC LAMINAR BOUNDARY LAYER WITH A PRESSURE GRADIENT, by L. Lees. Nov. 20, 1950, 27p. diagrs. tables, refs. (Rept. no. 167) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N6ori-27006) U15373; ATI-93359 Unclassified

The effect of a negative pressure gradient on supersonic laminar boundary-layer stability was qualitatively considered. Approximate minimum critical Reynolds numbers (Re) were calculated for several insulated symmetrical circular-arc airfoils at Mach numbers (M) of 1.5, 2.0, and 3.0. Velocity and temperature distributions were obtained by the Dorodnitzyn-Pohlhausen method based on the von Karman momentum integral equation. The boundary layer was completely stabilized at low M's for parameters $\lambda \sim \frac{\delta^2}{\nu} \frac{d v}{dx} f(M)$ which exceeded a critical value dependent only on M and the gas properties, where δ is the boundary-layer thickness, v the gas velocity in adiabatic steady flow, x the surface distance, and f (M) a function of M. The aerodynamic-heating destabilizing effect was dominant at M= 2 and the minimum critical Re increase was small until $\Lambda - 11$. The negative pressure gradient was not influential at M= 3 for insulated surfaces. Comparisons between the stability-limit distribution over the airfoil at M=1.5 and the Re increase based on δ indicated (1) the existence of an unstable laminar-layer flow in the forward half of foil 6% thick at an angle of attack $\alpha = 0°$ with the complete stabilization at the 70% chord station for $Re > 7.5 \times 10^5$, (2) a small unstable region at $\alpha = 0°$ for foil 10% thick until $Re > 3 \times 10^6$ with stabilization at midchord, (3) a large unstable region on the upper surface of foil 6% thick at $\alpha = 4°$ and $Re = 7.5 \times 10^5$ and an insignificant region on the lower surface until $Re > 3 \times 10^6$, (4) complete stabilization below the given Re values, and (5) complete instability at M= 2 and $\alpha = 0°$ for both foils with $Re = 7.5 \times 10^5$. Transition on the airfoil was apparently delayed at low M's to a greater extent than insulated flat plates for $7.5 \times 10^5 \leq Re \leq 5.0 \times 10^6$. A stronger stabilizing effect α was postulated on the lower rather than the upper surface. The negative pressure-gradient effect is expected to increase with the thickness ratio.

REMARKS ON "INTERACTIONS BETWEEN WHOLLY LAMINAR OR WHOLLY TURBULENT BOUNDARY LAYERS AND SHOCK WAVES STRONG ENOUGH TO CAUSE SEPARATION" [BY G. E. GADD], by S. M. Bogdonoff. Nov. 17, 1953, 2p. incl. illus. (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N6onr-27006) AD 49151 Unclassified

Published in Jour. Aeronaut. Sciences, v. 21: 138-139, Feb. 1954.

Gadd's analysis of interactions between laminar or turbulent boundary layers and shock waves strong enough to cause separation (Jour. Aeronaut. Sciences, v. 20: 729, Nov. 1953) is discussed briefly by Bogdonoff of the Gas Dynamics Laboratory (GDL), James Forrestal Research Center. It is pointed out that data obtained at GDL differ considerably from the experimental results of Gadd. The GDL investigations, carried out at M~3, show separation occurring at a wall-static-pressure ratio between 2.0 and 2.1, as compared with Gadd's 2.5. A plot of the Gadd and GDL data concerning the effect of pressure ratio on the "influence regions" (those regions as defined by Gadd as the theoretical point of impingement of the incident shock to the beginning of the interaction divided by the displacement thickness of the boundary layer ahead of the interaction) reveals further disagreement. It is conjectured that this disagreement may have resulted from Gadd's use of generators that did not span the wind tunnel, and his assumption of the basic velocity profile at the reattachment point is questionable. Therefore, it is believed that the results of the Gadd analysis as applied to the prediction of the interaction of a turbulent boundary layer with a shock are not completely valid.

Also published in Jour. Aeronaut. Sciences, v. 22: 414-424, June 1955.

The separation of a supersonic turbulent boundary layer under the effect of a strong adverse gradient has been studied at M~3 by examining in detail the phenomena of flow over a step and shock wave-boundary layer interaction. Wall static pressures, total head surveys and optical techniques, including the use of color Schlieren, were used to provide a model of the separation phenomena. It was found that: (1) When the separated region is small, the phenomena appears to be quite different than when the separated region is large. For small regions the gradients are stronger and large changes can occur for small changes in the disturbance. (2) Separation at M~3 occurred at a pressure ratio of about 2, about two to three boundary layer thicknesses from the start of the interaction and was quite unaffected by the flow downstream. (3) A considerable pressure rise occurs after the separation point. The peak pressure ratio of about 2.6 occurs approximately six to eight boundary layer thicknesses downstream of the start of the interaction. (4) These results, combined with other investigations, indicate a very small change in separation pressure ratio with Mach number. (5) The effect of Reynolds number on the phenomena appears to be negligible. (6) The detailed model, showing considerable pressure rise after separation, appears to be susceptible only to the type of theoretical treatment proposed by Crocco and Lees. However, considerably more results on mixing rates are needed for its direct application.

Also published in Jour. Aeronaut. Sciences, v. 23: 208-224, 236, Mar. 1956.

The viscous transverse curvature effect in compressible axially symmetric laminar boundary layer flow was investigated. The effect was characterized by the parameter Δ/r_0 which is the ratio of the boundary-layer thickness to body radius. By a generalization of Mangler's transformation, the boundary layer equations are reducible to an almost 2-dimensional form. This simplifies the analysis for 2 asymptotic flow regions characterized by $\Delta/r_0 >> 1$ and Δ/r_0 less than or of the order of unity. For the latter case, the additional term in the momentum and energy equation, which differentiates it from the 2-dimensional form, behaves like an axial pressure gradient. The asymptotic solutions for the velocity and temperature can be found for zero pressure gradient when the body shapes go like $r_0 = ax^n$ and $r_0 = ae^{bx}$. The zeroth approximation is the Mangler result. The first order correction to the Mangler formulation Pr = 1 shows that in the case of the cone and cylinder the effect on both the skin friction coefficient and heat transfer rate can become appreciable in the range where Δ/r_0 is less than or of the order of unity. At a constant Δ/r_0, the effects are increased in magnitude when either the ratio of wall to free stream temperature, or Mach number, is increased. Also, all other conditions being equal, for the same value of Δ/r_0 the skin friction coefficient and heat transfer increase on the cylinder is greater than that on the cone. (ASTIA abstract)

THE TRANSVERSE CURVATURE EFFECT IN COMPRESSIBLE AXIALLY-SYMMETRIC LAMINAR BOUNDARY LAYER FLOW INCLUDING THE EFFECTS OF PRESSURE GRADIENT, by D. Elliott. July 1954 [106] p. incl. diagrs. tables, refs. (Rept. no. 269) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N6onr-27006) Unclassified

The viscous transverse curvature effect in compressible axially-symmetric laminar boundary layer flow has been investigated, and it is found that the effect is characterized by the parameter Δ/r_0 which is essentially the ratio of the boundary layer thickness to the body radius. It is shown that the Busemann and Crocco integrals of the two-dimensional energy equation for Pr = 1, are still valid for axially-symmetric flow in which the transverse curvature effects are considered. By a generalization of Mangler's transformation it is then shown that the boundary layer equations are reducible to an almost two-dimensional form, making the analysis simpler for two asymptotic flow regions characterized by $\Delta/r_0 >> 1$ and Δ/r_0 less than or of the order of unity. It is with the latter region that the present paper is primarily concerned, and for this case it is shown that the additional term in the momentum and energy equations which differentiates them from the two-dimensional form, behaves like an axial pressure gradient, on quantities such as the skin friction and heat transfer coefficients. On this basis, the results of previous authors are interpreted. Except for the cases of a "near paraboloid" with zero pressure gradient, and a cylinder with linear external velocity distribution, where similar profiles can be found for all values of Δ/r_0, it is necessary to obtain the "exact" solutions in the range where Δ/r_0 is less than or possibly of the order of unity, by means of asymptotic expansions in ascending powers of a parameter which is small compared to unity but proportional to Δ/r_0. It is shown how the asymptotic solutions can be found for, (1) the velocity and temperature distributions for the compressible zero pressure gradient case when the body shapes are given by $r_0 = ax^n$ and $r_0 = ae^{bx}$, and (2) the velocity distribution for incompressible flow with an external velocity of the form $u_e = bx^m$ past a body given by $r_0 = ax^n$. The zeroth approximation is the Mangler result. In the case of the cone and cylinder with zero pressure gradient where the equations have been numerically integrated for Pr = 1, the first order correction to the Mangler formulation shows that the effect on both the skin friction and heat transfer coefficients can become appreciable in the range where Δ/r_0 is less than, or of the order of unity. At a constant Δ/r_0, the effects are increased in magnitude when either the ratio of the wall to free stream temperature, or Mach number, is increased. Also, all other conditions being equal, for the same value of Δ/r_0 the skin friction coefficient and heat transfer increase on the cylinder, is greater than that on the cone. For flows with pressure gradient, the transverse curvature term behaves again like a favorable pressure gradient, and tends to delay both separation and transition when compared with axi-symmetric flows in which the transverse curvature effect is neglected. (Contractor's summary)

SOME ASPECTS OF UNSTEADY LAMINAR BOUNDARY LAYERS, by S.-I. Cheng. July 1, 1955 [64]p. tncl. diagrs. tables. (Rept. no. 311) ([AF]OSR-TN-55-172) (AF 18(600)498; conttnuation of N6onr-27006) AD 76587 Unclasstfted

Also published in Quart. Appl. Math., v. 14: 337-352, Jan. 1957.

The viscous flow over a semttnfinite flat plate started to move with velocity u = 0 for t ≤ 0 and u∼t^n for t ≥0 ts analyzed tn detatl with the boundary-layer equattons. Particular emphasts ts put on the jotntng of the solution at downstream tnfintty where the flow field is substantially x-tndependent and the solution in the upstream regton near the leading edge where the flow fteld is deftnitely x-dependent. The method of trying to perturb the downstream x-tndependent Rayletgh-type solution, including the possibility of stngular perturbations, fatls to introduce any nonvanishing x-dependent perturbations. This may be due to the parabolic nature of the boundary layer equattons, but it can also be conceived physically that such a process is invalid. A series solution is then constructed from the leading edge under the boundary-layer assumption that vortictty does not dtffuse in the longitudinal dtrection. Numerical results show that for practically all values of n, the skin friction approaches the value given by the x-dependent Rayleigh type solution to wtthin a % or 2 when the distance from the leadtng edge is about 4/10 of the distance travelled by the plate. Conttnuation of the solution into the downstream region for the flow field near the plate can be effected by regular perturbations. It is seen that such a continuation must eventually approach the Rayletgh-type solution in the far downstream regton; hence, the solution so determined posses the proper limiting behaviors at both small x and large x. The limiting bet aviors of the solution at small t and large t are also found to be proper. (Contractor's abstract)

A STUDY OF THE ANTICLASTIC DEFLECTIONS OF THIN PLATES IN BENDING, by J. J. Ginoux. Aug. 1955 [19 p. tncl. diagrs. (Rept. no. 320) ([AF]OSR-TN-55-198) (AF 18(600)498) AD 93809 Unclassified

A theory developed by Y. Yoler (The anticlastic bending of thin plates, Calif. Inst. of Tech. Thesis, 1952) is used to compute the maxtmum values of anticlastic deflections obtained in the bending of thin plates. Three separate regimes characterized by different types of deflections are obtained for the case of constant spanwise curvature and no support effects. The maximum positive and negative deflections are computed as a function of the width and thickness of the plate. The results, which are of tnterest tn supersonic nozzle construction, are presented in the form of eastly used charts.

INTERACTION OF A SHOCK WAVE WITH A TURBULENT BOUNDARY LAYER AT M = 3.85, by I. E. Vas and S. M. Bogdonoff. Apr. 1955, 9p. illus. dtagrs. refs. (Rept. no. 294) (AFOSR-TN-55-199) (AF 18-(600)498) AD 201644 Unclassified

The results of an experimental tnvestigation of the interaction between incident shock waves and a turbulent boundary layer at M = 3.85 are presented. The pressure ratio across the shock wave was varied from 1.5 to 3.0. Schlteren and shadowgraph pictures were taken, static pressures were measured along the wall, and the separation pressure ratio was determined. The phenomena observed were, in general, similar to those observed at M = 2.92. For low incident shock pressure ratios (on the order of 1.6), the pressure along the wall rose smoothly to a maximum value with no separation. For a shock pressure ratio greater than about 2.2, an inflection point occurred tn the static pressure dtstrtbution, and separation was observed. For incident shock pressure rattos ≥ 2.6, the over-all phenonenon remained similar, only the scale of the tnteractton changed. The measured pressure ratio at the separatton point was 2.4, as compared to a value of about 2.1 at M = 2.92. (Contractor's abstract)

INTERACTION OF A TURBULENT BOUNDARY LAYER WITH A STEP AT M = 3.85, by I. E. Vas and S. M. Bogdonoff. Apr. 1955 [57]p. incl. illus. diagrs. table. (Rept. no. 295) (AFOSR-TN-55-200) (AF 18-(600)498) AD 201645 Unclassified

This experimental investigatton of the flow of a turbulent boundary layer over a forward-facing step was carried out at a Mach number of 3.85. The effects of Mach number upon the phenomenon were determined, and a comparison was made with results obtained previously at M = 2.92. The separation and shock wave pattern were obtained for steps varying from .25 to about 2-boundary-layer thicknesses. Schlieren and shadowgraph pictures were taken, static pressures were measured ahead of the step, and the pressure ratio needed to separate the boundary layer was found. The measured peak pressure ratio agreed with the peak pressure value of Crocco-Probstein. A detailed total head study was made of the flow field ahead of one of the larger steps. The maximum reverse velocities measured in the separated region were in the order of 0.7 M. (Contractor's abstract, modified)

A DETAILED STUDY OF THE INTERACTION OF A 14° SHOCK WAVE WITH A TURBULENT BOUNDARY LAYER AT M = 2.9, by I. E. Vas. Apr. 1955 [50]p. incl. illus. diagrs. (Rept. no. 296) (AFOSR-TN-55-201) (AF 18(600)498) AD 210241 Unclassified

A detailed study has been made of the 2-dimensional interaction between a shock wave and a turbulent boundary layer. The shock was generated by a 14° wedge located in the free stream at a Mach number of 2.92. Total head profiles were taken of the entire interaction region. The separation region extended about 6-1/2 boundary layer thicknesses in length and 3/4 boundary layer thicknesses in height. The maximum reverse velocity measured was 0.39 M. The pressure at the separation point was about 2.1 times the free stream static pressure. The pressure at which separation occurred was also determined for wedges varying from 8° to 13°. No separation was evidenced for the 8° shock generating case. The pressure ratio at separation was found to be relatively independent of shock strength. (Contractor's abstract)

THE EFFECT OF SUPPORT INTERFERENCE ON THE BASE PRESSURE OF A BODY OF REVOLUTION AT HIGH REYNOLDS NUMBERS, by K. R. Sivier and S. M. Bogdonoff. Oct. 1955 [41]p. incl. illus. diagrs. refs. (Rept. no. 332) (AFOSR-TN-55-301) (Sponsored jointly by Office of Naval Research under N6onr-27006 and Air Force Office of Scientific Research under AF 18-(600)493) AD 79169 Unclassified

An experimental investigation has been made of the effect of a rear support sting on the base pressure of an ogive-cylinder body at a Mach number of 2.97 and at Reynolds numbers from 10×10^6 to 40×10^6. The body was mounted on wings to permit the measurement of a free base pressure. Stings having diameters from 0.6 to 0.0625 times the body's base diameter were employed to check the sting effect. Checks were made to assure that the present results were not affected by finite sting length. A second ogive-cylinder body, without mounting wings, was supported on a rear sting to check the effect of the wing on the base pressure. For the range of Reynolds numbers considered in this investigation, no critical sting diameter was found to exist. In fact, the variation of base pressure with sting diameter was greatest for the smallest diameters. The error in base pressure introduced by a sting of any given diameter was found to be a function of Reynolds number. Although the curves of base pressure vs sting size showed a tendency to level off at the lower sting diameters, the assumption by several investigators that this indicated a critical sting size was found to be in error. THE CRITICAL STUDY OF A BOUNDARY CONDITION ON PRANDTL'S BOUNDARY LAYER THEORY AND ITS APPLICATIONS, by S.-I. Cheng. Sept. 1955, 36p. (Rept. no. 329) ([AF]OSR-TN-55-340) (AF 18-(600)498) AD 74767 Unclassified

A method is presented whereby the physical argument of similitude or qualitative experimental information can be circumvented in constructing the boundary layer solutions. The necessity of additional assumptions or information is regarded as due to the incomplete mathematical formulation of Prandtl's boundary layer theory. The absence of longitudinal diffusion of vorticity according to the boundary layer theory does provide an x-wise boundary condition which leads to a unique determination of the x-wise expansion parameters for constructing the downstream boundary layer solution. The ordinary subsonic and supersonic steady boundary layer problems for a thin body in a uniform stream are discussed, and different types of series expansions are deduced for different types of inflow. The steady hypersonic boundary layer problems are treated, and proper series expansions are determined without making any assumption with regard to the matching procedure. The results of applying this method to unsteady problems are quoted from previous work by Cheng (Princeton U. Dept. of Aeronautical Engineering rept. no. 311, 1955) and by Cheng and Elliott (rept. no. 318, to be published). The generality of the principle, and the method involved suggests that this boundary condition be supplemented to the mathematical formulation of Prandtl's boundary layer theory. This supplement appears necessary, not only from the mathematical point of view, but also from the physical point of view that the boundary layer theory should suffice a solution without additional physical arguments. INTERACTION OF BOUNDARY LAYER AND COMPRESSIBLE FLOW, by L. Crocco. [1955] [38]p. incl. illus. diagrs. refs. (AF 18(600)498) Unclassified

Published in Proc. Conference on High Speed Aeronautics, Polytechnic Inst. of Brooklyn, N. Y. (Jan. 20-25, 1955), 1955, p. 75-112.

A number of facts are pointed out. (1) Both laminar and turbulent compressible boundary layer on insulated walls can be treated by a unified theory based only on the following assumption that: (a) the stagnation temperature is uniform in the whole field; (b) the incompressible laminar and turbulent boundary layers constitute two distinct one-parameter families; and (c) the velocity distribution of any compressible laminar

PRI. 04:009 - PRI. 04:011

or turbulent boundary layer can be obtained from that of a corresponding incompressible boundary layer through the Howarth y-transformation. (2) For arbitrarily high Mach numbers the laminar boundary layer on a flat plate has a subsonic behavior and is able to propagate upstream the effects of applied disturbances. (3) For high supersonic velocities the turbulent boundary layer on a flat plate exhibits a supersonic behavior and is unable to propagate disturbances in the upstream direction unless it first switches to subcritical conditions. (4) The switch of a turbulent boundary from supercritical to subcritical conditions can take place through a "jump," that is, a concentrated region where fast changes of pressure, velocity and distributions take place, and within which the boundary layer assumptions fail to be satisfied. (5) The jump is impossible (or only exceptionally possible) starting from subcritical (laminar) conditions. (6) A separated flow is always subcritical. (7) When a supersonic turbulent boundary layer becomes reattached to the wall, it must go from subcritical to supercritical conditions through a critical point, separating an upstream region where an additional disturbance can be propagated upstream, from a downstream region from which no such propagation is possible. SOME EXPERIMENTAL STUDIES OF THE SEPARATION OF SUPERSONIC TURBULENT BOUNDARY LAYERS, by S. M. Bogdonoff. June 1955 [18] p. incl. diagrs. refs. (Rept. no. 336) (AFOSR-TN-56-64) (AF 18(600)498) AD 81056 Unclassified

Also published in Heat Transfer and Fluid Mech. Inst. - Preprint of papers, Calif. U., Los Angeles, June 1955, preprint no. 5.

Studies were conducted of several simple geometries, i.e., fully developed turbulent boundary layers and gradients, impressed by shock waves, which are generated within the layers under investigation or impressed from external flows. Tests indicated that the wall static pressure ratio at which separation occurs is approximately a linear function of Mach number in the 1.35 to 3.85 range; it varies from a pressure ratio of about 1.4 at M = 1.35 to approximately 2.4 at M = 3.85. Strong changes occur in the interaction phenomenon when the separation region is small. The peak pressure ratios, which are a combination of the separation pressure ratio and an additional ratio resulting from mixing, indicate an increased effect of mixing with increasing Mach number. A study of the pressure ratios which can be obtained before separation occurs indicates a linear relation with Mach number which is higher than the separation pressure ratio or peak pressure ratio once the separation occurs. Results provide for the prediction of separation, the peak pressure ratios, and the pressure ratio before separation occurs for supersonic turbulent boundary layers in the range from M = 1 to 3.85. THE UNSTEADY LAMINAR BOUNDARY LAYER ON A FLAT PLATE, by S.-I. Cheng and D. Elliott. Sept. 1955 [95] p. incl. diagrs. tables, refs. (Rept. no. 318) (AFOSR-TN-56-115) (AF 18(600)498) AD 82511 Unclassified

Also published in Trans. Amer. Soc. Mech. Engineers, v. 79: 725-733, May 1957.

The unsteady laminar boundary layer on a flat plate moving with an arbitrary velocity $U_w(t)$ into an incompressible fluid at rest has been investigated. The motion is taken to start from rest at a time $t = 0$ with $U_w(t)$ continuous at $t = 0$ and infinitely differentiable for all $t > 0$. Under these conditions, a solution is constructed which is valid for all t and x, where x is the distance from the leading edge of the plate. The solution is also shown to be valid for the flow after a long time when $U_w(t)$ does not satisfy the above conditions. The effect of compressibility for small Mach numbers has been discussed briefly. (Contractor's abstract)

AN APPROXIMATE THEORY OF TURBULENT BOUNDARY LAYER SHOCK WAVE INTERACTION, by A. G. Hammitt. Apr. 1956 [44] p. incl. illus. diagrs. table, refs. (Rept. no. 340) ([AF]OSR-TN-56-160) (AF 18(600)498) AD 86320 Unclassified

The shock wave turbulent boundary layer problem was investigated in the absence of skin friction and momentum addition from the free stream. The analysis presented is based on 2 main assumptions: (1) momentum and mass are conserved in the boundary layer through the interaction and (2) the turbulent boundary layer is essentially a 1 parameter family. It is shown that, to a first approximation, most of the experimental observations for oblique shock wave boundary layer interactions, with the exception of the lengths of the interaction region, can be explained by flow models which do not include momentum changes caused by shear forces. The boundary layer contains enough momentum to overcome the pressure rises encountered. Methods which were developed make it possible to calculate the boundary layer conditions behind any particular interaction, and to consider the effects of a disturbed boundary layer before an interaction. The cases of flow through an incident reflected shock wave, in a corner, and over a forward facing step are treated. The differences between various shock wave configurations can be explained by using flow models which correspond to these configurations. The way in which

the pressure forces are applied to the boundary layer accounts for the different results obtained with the various configurations.

ON THE INTERACTION OF SUPERSONIC TURBULENT BOUNDARY LAYERS AND SHOCK WAVES, by S. M. Bogdonoff. [1956] [10]p. incl. illus. diagr. [AF 18(600)498] Unclassified

Published in Proc. Ninth International Congress of Appl. Mech., Brussels (Belgium), (Sept. 5-13, 1956), v. 4: 145-154, 1957.

As part of an overall study of viscous effects in supersonic flows, a combined experimental and theoretical program has been carried out in attempt to arrive at a better fundamental understanding of the interaction of supersonic turbulent boundary layers and shock waves. The pertinent results obtained to date are briefly reviewed. An experimental framework is developed which can be used to predict separation, pressure ratio, peak pressure ratio, and the pressure ratio for incipient separation for supersonic turbulent boundary layers at Mach numbers up to 4. The basis is provided for a theoretical investigation which neglects the skin friction and mixing from the external stream.

NONLINEAR CONTROL SYSTEMS RESEARCH PROJECT. Final interim progress rept. July 1, 1952 - June 30, 1953. July 1, 1953 [86]p. incl. illus. (AF 33(038)22614) AD 45751 Unclassified

The basic properties of certain classes of feed-back control systems using nonlinear components were investigated. Elements possessing nonlinear operating characteristics greatly complicate the problem of determining the stability of feed-back systems and may give rise to certain non-unique modes of response to an input signal. The investigation included: (1) the study of the philosophy underlying the design of nonlinear control systems in an attempt to develop logical and systematic methods of control network synthesis which will result in improved performance while also insuring stable operation of the system for all possible types of excitation; and (2) the study of the operation of certain special types of nonlinear servomechanisms which are of considerable practical importance and which can be used as tests of the theoretical design methods.

ON GENERALIZED STURM-LIOUVILLE OPERATORS, by W. Feller. [1955] [20] p. [AF 18(600)1379] Unclassified

Published in Proc. Conference on Differential Equations, Maryland U., College Park, (Mar. 17-19, 1955), 1956, p. 251-270.

The author continues his study of the generalized Sturm-Liouville operators (Ann. Math., v. 61: 90-105, 1955; Comm. Pure Appl. Math., v. 8: 203-216,

1955). He again considers the class of nontrivial linear operators Ω whose domain and range are in the space of continuous functions and which are of local character and have the minimum property. The work of the previous papers is greatly reduced by assuming Ω to be regular in the sense that there are two linearly independent solutions of $\Omega w = 0$ in the neighborhood of each point. It is shown that there exist strictly increasing functions $s(x)$ and $m(x)$, s being continuous such that if $w(x)$ is any non-vanishing (real or complex) solution of $\Omega w = 0$, the operator Ω has the representation

$$\Omega f = \frac{1}{w} D_m \left[w^2 D_s \left(\frac{f}{w} \right) \right].$$

Here D_m and D_s are generalized derivatives with respect to m and s respectively. Using this representation, the Weyl limit point limit-circle classification and related existence theorems are developed in a Hilbert space whose norm is $\int f(x)^2 dm(x)$ so that Ω is self-adjoint in this space. The following typographical errors were noted: (a) in (5.3) the inequality is reversed; (b) in (7.11) and (7.19) the lower limits of the first integrals should be s rather than s_0; (c) the inequality two lines below (9.3) should be $\Omega F(\xi) \geq 0$. STURM-LIOUVILLE AND HEAT EQUATIONS WHOSE EIGENFUNCTIONS ARE ULTRASPHERICAL POLYNOMIALS OR ASSOCIATED BESSEL FUNCTIONS, by S. Bochner. [1955] [26]p. incl. refs. (AF 18-(600)1379) Unclassified

Published in Proc. Conference on Differential Equations, Maryland U., College Park (Mar. 17-19, 1955), 1956, p. 23-48.

For fixed $\gamma \geq 0$ let $P_n(x) = P_n(\gamma)(x)$ $(n = 0, 1, \ldots)$, be the polynomial solution of $(1 - x^2)P'' - (2\gamma + 1)xP' = -\lambda_n P$ where $\lambda_n = n(n + 2\gamma)$, normalised by $P_n(1) = 1$, and write $\rho_n = 1/\int_{-1}^{1} \{P_n(x)\}^2 (1 - x^2)^{\gamma - \frac{1}{2}} dx$. For $f(x)$ $(-1 \leq x \leq 1)$ with absolutely convergent Fourier expansion $\sum \rho_n a_n P_n(x)$ consider the mapping $f(x) \to f(x;y)$ given by $f(x;y) \sim \sum \rho_n a_n P_n(x) P_n(y)$. The first part of the investigation centers round the fact that this mapping has "property P", namely that $f(x) \geq 0$ in $-1 \leq x \leq 1$ implies $f(x;y) \geq 0$ in $-1 \leq x, y \leq 1$. There is a continuous analogue of this result in terms of, in effect, Bessel functions. Apparently distinct examples of property P can be constructed from functions on a group in terms of group-representations. In the next section a study of the partial differential equations $(1 - x^2) f_{xx} - (2\gamma + 1)x f_x = f_t$ leads to the kernel $K(x, y;t) \sim \sum \rho_n \exp(-t\lambda_n) P_n(x) P_n(y)$.

The fact that $K(x, y;t) \geq 0$ is deduced in a rather striking way from a study of the semi-ring of bounded sequences $\{c_n\}$ such that $\sum \rho_n a_n P_n(x) \geq 0$ in $-1 \leq x \leq 1$ (postulating absolute convergence) implies $\sum \rho_n a_n P_n(x) \geq 0$ in $-1 \leq x \leq 1$. General expressions are found for such $\{c_n\}$, and also for a "homogeneous stochastic process" $\{c_n(t)\}$ (for definitions and formulae see the review of the author's previous note, Proc. Nat. Acad. Sci. U.S.A. 40 (1954), 1141-1147; MR 16, 834). Continuous analogues, corresponding to $f_{xx} + (2\gamma/x) f_x = f_t$, are also formulated. Finally, in connection with the probabilistic interpretation, the author outlines the role of "subordinators" in assessing the relative primacy of homogeneous processes, as explained more fully in his book, Harmonic analysis and the theory of probability (Univ. of California Press, 1955, Ch. 4; MR 17, 273). CURVATURE AND BETTI NUMBERS IN REAL AND COMPLEX VECTOR BUNDLES, by S. Bochner. [1956] [29]p. [AF 18(600)1379] Unclassified

Published in Univ. e Politec. Torino. Rend. Sem. Mat., v. 15: 225-253, 1955-56.

The theory of differential geometry for vector bundles based on tensor calculus as previously developed (Canad. Jour. Math., v. 3: 460-470, 1951) is reviewed and extended. An N-dimensional vector bundle over an n-dimensional space M_n was described by a so-called matrix structure, a system of transition matrices $a^B_A(y; x)$ between any two intersecting elements (x) and (y) in a fixed covering of M_n by a system of neighborhoods, the $a^B_A(y; x)$ being subjected to the consistency properties $a^A_B(z; y)a^B_C(y; x) = a^A_C(z; x)$ and $a^B_A(x; x) = \delta^A_B$. A generic point of the vector bundle is either a contravariant vectoroid u^A with the transition relations $u'^A(y) = a^A_B(y; x)u^B(x)$ or a covariant vectoroid t_A with the transition relations $t'_A(y) = a^B_A(x; y)t_B(x)$. More generally, matrix structures of the form $a^{A_r}_{B_r}(y; x)$ $(r = 1, 2, \ldots s)$ of various dimension N_r with no connection between them, likewise have a structure as their Kronecker product.

A general mixed tensoroid of the type $t^{A_1 A_2 \ldots A_p}_{B_1 B_2 \ldots B_q}$ can be defined, while ordinary tensors are defined with respect to the classical structure $\partial y^1 / \partial x^1$. The tensor algebra and tensor analysis in such metric and non-metric bundles are developed in the first two sections of the present paper. The following are proved in the third section. (1) On a compact metric M_n, if a vectoroid τ_A satisfies an equation of the form

$$g^{rs}\, \tau_{A,\,r,\,s} = S_{AB} P^{BC} \tau_C,$$

where the comma denotes covariant differentiation leaving the metric invariant, and if the tensoroid S_{AB} is positive definite, then τ_A is identically zero. If

PRI. 06:005 - PRI. 07:003

S_{AB} is only positive semi-definite, then $\xi_{A,r} = 0$ and $S^{C}_{A} \cdot \xi_{C} = 0$. (II) On a non-compact M_n, the entire conclusion holds if the vectoroid has "boundary value zero" in the following sense. To each $\varepsilon > 0$ there corresponds a compact subset M_n^{ξ} of M_n such that $g^{AB}\xi_A\xi_B < \varepsilon^2$ for all points outside M_n^{ξ}. A symmetric or skew-symmetric tensoroid is then considered of the type $\xi_{A_1A_2\ldots A_sB}$ in a compact M_n; the general theorem is then applied to the harmonic" tensoroid $\xi_{Ai_1i_2\ldots i_p}$ defined as a tensoroid satisfying

$$\xi Ai_1i_2\ldots i_p, j = \sum_{q=1}^{p} \xi Ai_1i_2\ldots j\ldots i_p, i_q \text{ and}$$

$$g^{ij}\,\xi_{Ai_1i_2\ldots i_{p-1}i,j} = 0.$$

The last section is devoted to complex vector bundles.

[SYSTEMS OF PARTIAL DIFFERENTIAL EQUATIONS RELATED TO GREEN'S FORMULAS] Systémes des équations aux dérivées partielles qui se rattachent aux formules de Green, by S. Bochner. [1956] [8]p. [AF 18(600)1379] Unclassified

Presented at a Colloqutum organized by the French Center of Scientific Research, Nancy (France), Apr. 9-14, 1956.

The solution is investigated of a system of partial differential equations in a bounded domain, in terms of the solution of a related system of equations in the neighborhood of the frontier, and of Green's integral and Green's formula. A consideration is included of the analytic continuation of the solution of such a system of equations. The paper is presented as an outgrowth of earlier and similar results which were given as terms of two special cases (analytic and meromorphic continuation by means of Green's formula. Ann. Math., v. 44: 652-673, 1943).

SHOCK LOADING OF RECTANGULAR STRUCTURES, by W. Bleakney. Jan. 10, 1952, 57p. illus. diagrs. tables, refs. (Technical repl. no. II-11) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordance Research under N6ort-10502) U21736; ATI-163038 Unclassified

The shock loading of two-dimensional rectangular blocks has been investigated as a function of length to height ratio, shock strength, and time after impact. A shock pressure ratio of about 1.95 was used for diffraction experiments on blocks having length: height - 1:8 (thin wall), 1:1, 3:1, and ∞:1 front and back (step up and step down). In addition, the 1:1 block was studied at shock strengths of 1.26, 1.48, 3.05, and 5.00. Pressure distributions are also given for these same strengths. A peaked shock having a pressure ratio of 1.48 has been obtained in the shock tube, and although the pressure drops only to about half of its maximum value, effects appear which are not predicted by straight-forward modification of flat-top shock data. These include the rapid decrease of the average pressure on the front face to a value below the free stream pressure and the persistence of average pressure on the back above that corresponding to free air pressure. A METHOD FOR MODIFICATION OF THE PRESSURE PROFILE IN A SHOCK TUBE, by D. R. White and D. K. Weimer. Apr. 1952, 9p. diagrs. (Technical repl. no. II-12) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10502) U22733; ATI-158692 Unclassified

A thin piece of sheeting suspended across a shock tube acts as a piston which may be accelerated by the incident shock and decelerated by a wire grid. The wide range of pressure profiles thus made possible should facilitate study of blast loading of structures, shock formation from a compression and effects due to conditions within the shock front. A wave form of 150 μsec. positive duration was produced in tests with a grid of 1/8-in. hardware cloth to catch the 0.0011-in. paper diaphragm and a shock of inverse pressure ratio of 0.8.

DIELECTRIC RELAXATION OF SOME SPHEROIDAL MOLECULES, by R. C. Miller and C. P. Smyth. [Oct. 18, 1955] [2.p. tncl. table. [AFOSIt-TN-55-376] [AF 18(600)1331] Unclassified

Presented at National Research Council Conference on Electrical Insulation, Pocono Manor, Pa., Oct. I9, 1955.

In this study, the effect of dtpole orientation on relaxation time tn nonspherical molecules was constdered. The crttical wavelengths and vtscosities of trtoxane (I), pyrtdtne (II), paraldehyde (III), and collidtne ($(CH_3)_3\ C_5H_2N$) (IV) were measured at a number of temperatures, the results obtained at 60°C betng presented tn a table. It is pointed out that I and II are nearly the same in molecular shape and stze; however, tn I the moment is normal to the ring, while tn II tt ts in the plane of the ring. Both the crttical wavelength and the viscostty of I are 1.7 times as large as those of II. Therefore, tf tt ts assumed that the critical wavelength is proportional to vtscostty, the data tndicate that direction of the moment has no effect on the critical wavelength. III and IV are nearer tn shape and stze than are I and II as tndtcated by thetr almost equal viscosities and molar volumes. Nevertheless the crttical wavelength of III, havtng tts moment normal to the rtng, is twtce as large as that of IV. This result and that for I ts explained by the fact that both I and III are disc-like tn shape, making tt necessary for them to turn over tn becoming ortented tn a field. This "turning over" dtsturbs neighbortng molecules much more than rotation about the axis of symmetry as tn the cases of II and IV; thus, the relaxation times of the dtsc-like molecules are expected to be longer. The effect is greater for the 2 trimethyl-substituted compounds which are more extended tn the plane of the disc.

The dielecirtc constants and losses of acetone, n-heptanone-2, n-heptanone-4, cyclohexanone, acetophenone, 2-acetonaphthone, benzophenone and phenyl ether have been measured at wavelengths of 1.24, 3.22 and 10.4 cm at temperatures between 1° and 90°. The low frequency dielectrtc constants, refractive indices, denstties, and viscosities have also been measured. Cole and Cole arc plots have been drawn and have been used to calculate the crttical wavelengths at which the loss is a maximum. The crttical wavelengths and the ratios of crttical wavelength to viscosity are examined in their relations to molecular size and shape. The crttical wavelength of 2-acetonaphthone is larger and that of phenyl ether is smaller than would be expected. As observed in

PRI. 08:004 - PRI. 08:007

previous work, marked changes in molecular shape may cause marked irregularities in the relations between molecular volume, critical wavelength and viscosity. (Contractor's abstract)

DIELECTRIC BEHAVIOR AND STRUCTURE. by C. P. Smyth. New York, McGraw-Hill, t955, 441p. incl. diagrs. tables, refs. [AF 18(600)t331] Unclassified

The theory of dielectric behavior as exemplified in dielectric constant and loss is presented in the first two chapters, the experimental information and interpretation in the next three, and the methods of measurement in Chapter VI. Information on the determination of dipole moments is given in Chapters Vt and VIt, a general account of their relations to molecular structure in Chapter VIti, and a detailed tabulation and interpretation of the moments of the principal types of compound in Chapters IX to XII. Amino acids, peptides, and proteins are treated tn Chapter XIIi, and induced polarization, particularly optical refraction, in the last Chapter.

MICROWAVE ABSORPTION AND MOLECULAR STRUCTURE IN LIQUIDS. XVI. DIPOLE DIRECTION AND RELAXATION TIME tN PYRIDINE, TRIOXANE, AND THEIR SYMMETRICAL TRIMETHYL DERIVATtVES, by R. C. Mtller and C. P. Smyth. Feb. 2, t956, 9p. tncl. tables, refs. (AFOSR-TN-56-51) (AF t8(600)1331) AD 81043 Unclasstfted

Also published in Jour. Phys. Chem., v. 60: 1354-1356, Oct. 1956.

Measurements of dtelectrtc constant and loss have been carried out at wavelengths of t. 24, 3. 22, and 10. 4 cm and 300 m and at temperatures from 20° to 80°C upon collidtne, or 2, 4, 6-trtmethylpyridtne (I), sym-trtoxane, and paraldehyde. The vtscostties and denstties have also been measured. The results are combined with those previously published for pyrtdtne to tnvestigate the effect of dipole ortentation tn the molecule upon dielectric relaxation. Paraldehyde and I, in spite of much larger molecular size, have virtually the same viscosity as pyridine; however, the critical wavelength, at which the dielectric loss is a maximum, has a value for I approximately 4 times that for pyridine, probably because of close-packing of the trtangular I molecules tn the liquid and, also, because of thetr larger stze. Paraldehyde, which has a molecule simtlar tn stze and shape to that of I, has a critical wavelength about twice as large, presumably, because the dipole is perpendicular to the molecular triangle instead of parallel to it as in I, thus requiring the triangular slabs to turn over instead of rotating in their plane when ortentatton occurs tn the applted fteld. MICROWAVE ABSORPTION AND MOLECULAR STRUCTURE tN LtQUIDS. XVII. DtELECTRIC RELAXATtON TIMES AND SHAPES OF RIGID MOLECtILES, by C. P. Smyth. Mar. 13, 1956 [6]p. incl. table, refs. (AFOSR-TN-56-119) (AF 18(600)1331) AD 82515 Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 42: 234-239, May 1956.

Abstract published in Science, v. t23: 675, 1956.

The relaxatton times and vtscostites of 5 homologous series of compounds with more or less flexible molecules were calculated from measured dielectric constants and losses. The results obtatned showed a tendency of the molecular relaxation time and the vtscosity to tncrease with tncreasing molecular stze in a pure ltqutd and of the relaxatton time to tncrease with viscosity, as required by the equatton $\tau_M = 4\pi\zeta a^3/kT$, where τ_M ts the molecular relaxatton ttme, a the sphere of radtus, and ζ the tnternal frtctton coeffictent. Many exceptions to thts tendency occur, and apparently the increase tn relaxatton ttme with viscosity may be the result of the increase tn molecular stze, whtch also tncreases the vtscosity. Although the attachment of a CH_3 group to a rtng may

not impede viscous flow, and may even facilitate it, apparently its protrusion impedes the molecular rotation necessary for orientation in an applied field, and thus lengthens the relaxation time.

DIELECTRIC RELAXATION AND MOLECULAR SHAPES OF SOME ALKYL-SUBSTITUTED BENZENES, PYRIDINES, AND NAPHTHALENES, by A. J. Peiro, R. W. Rampolla, and C. P. Smyth. [June 1956] 6p. incl. tables. (AFOSR-TN-56-255) [AF 18(600)1331] AD 88975 Unclassified

Also published in Proc. 130th meeting of the Amer. Chem. Soc., Atlantic City, N. J., Sept. 16-21, 1956.

In this study of the relationships between molecular size and shape and dielectric relaxation in liquids, a group of benzene-, pyridine-, and naphthalene derivatives are considered in order to determine the effect of substitution on the aromatic ring. As a result, the dielectric constants and losses of several alkyl-substituted benzenes, pyridines, and naphthalenes have been measured in the pure liquid state at wavelengths of 1.25 and 3.22 cm and at temperatures between 1° and 60°C. In addition, results have been obtained for dilute solutions of pyridine in benzene. The low-frequency dielectric constants, refractive indices, densities, and viscosities have also been obtained. From these data, Cole-and-Cole arc plots have been drawn, being used to determine the critical wavelengths at which the loss is a maximum. These results are collected in a table. For some of the compounds, molecular relaxation times, ratios of relaxation times, viscosity at 20°C, and activation energies for viscous flow and dielectric relaxation are presented.

MICROWAVE ABSORPTION AND MOLECULAR STRUCTURE IN LIQUIDS. XVIII. THE RELAXATION TIMES OF FOUR RIGID POLAR MOLECULES SURROUNDED BY NONPOLAR MOLECULES OF SIMILAR SIZES AND SHAPES, by R. C. Miller and C. P. Smyth. Sept. 1956, 10p. incl. tables. (AFOSR-TN-56-416) (AF 18(600)1331) AD 96225 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 308-310, Jan. 20, 1957.

In this study, the dielectric constant at 300-m wavelength and the dielectric constant and loss at 10.66-cm wavelength were measured for quinoline (I) and isoquinoline (II) over a range of temperatures. The results were combined with those of previous measurements to revise critical wavelength values. The corrected values agree well with the earlier values for I, but differ somewhat from those for II. Similar measurements were obtained for dilute solutions of pyridine (III) and s-trioxane in C_6H_6, and of I and II in naphthalene at 577 m and 3.22 and 1.244 cm. Comparison of the values of the molecular relaxation times calculated for the 4 substances in the pure liquid state with the relaxation times for the solutions indicates that, for these molecules, the method of calculating the molecular relaxation time and the assumption of its proportionality to liquid viscosity are not bad approximations. The closeness of the molecular relaxation times of III and trioxane to each other suggests that the III molecule may rotate with almost equal ease around axes in the plane of the ring, and perpendicular to this plane. The relaxation times of the C_6H_6 and naphthalene molecules are considered in the light of those of III and trioxane in C_6H_6 solution, and of I and II in naphthalene solution, respectively. The difference between the relaxation times of I and II shows a considerable amount of orientation of both molecules by rotation out of the plane of the rings. (C.A., 1957:6256d)

CONTRIBUTION TO THE THEORY OF FAST REACTION RATES, by R. De Vogelaere and M. Boudari. July 1953 [42]p. incl. diagrs. (Technical repi. no. 3) (AF 33(038)23976) AD 14057 Unclassified

Also published in Jour. Chem. Phys. v. 23: 1236-1244, July 1955.

Classical calculations were made of the motion of a mass poini on a poiential surface. The surface corresponds to a reaction of the type AB + A = A + BA and is characierized by a single saddle poini. For the mathematically similar problem of the allowed cone of cosmic radiation, a description is given of the possibility of a subsiantial decrease of the iransmission coefficieni above a critical energy of the sysiem. Unstable secondary periodic orbits appear above the critical energy; the region on the surface between 2 secondaries is designated the pseudobasin. The appearance of a pseudobasin may result in a substantial decrease of the reaction yield. The average distance of the boundaries of the pseudobasin from the ridge is 0.5 ai E = 1.5 E_s and 1 ai E = 2E_s, where E is the iotal energy and E_s is the saddle-point energy. The resuli is independeni of the analyiical expression of the surface. Consequences of the phenomenon are discussed.

THE OXIDATION OF CARBON MONOXIDE IN THE

PRESENCE OF OZONE, by D. Garvin. Sept. 1953 [34]p. incl. dtagrs. tables, refs. (Technical rept. no. 5) (AF 33(038)23976) AD 18439 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 76: 1523-1527, Mar. 20, 1954.

The rate and mechanism of CO oxidation was studied in mixtures of CO, O, N, and O_3 at atmospheric pressure and from 430° to 565°K. The slight production of CO_2 was explained by the reaction $CO + O + M \rightarrow CO_2 + M$ whtch has no activation energy and occurs every 10^3 3-body collision. The O aiom was supplied by the decomposition of O_3. The stmtlartties between the activation energies from the emplrical analysis and those of the Jahn mechanism (Zeitschr. anorganische Chem., v. 48: 260, 1906) for O_3 decomposition and the agreement of pre-exponential factors with photochemical work made this explanation more plausible than one based upon a dtrect $CO + O_3$ reaction. The results are tabulated and graphic relationships are presented.

EXPERtMENTAL STUDtES OF HYDROGEN SUPEROXIDE FORMATtON, by J. D. McKinley, Jr. Jan. 1954, 17p. illus. tables. (Technical rept. no. 9) [AFOSR-TN-54-34] (AF 33(039)23976) AD 27849 Unclassifted

Experiments were performed to verify the exisience of hydrogen superoxide (H_2O_4). Kruglyakova and Emanuel (Doklady Akad. Nauk SSSR, 83: 593, 1952) had reported the formation of H_2O_4 by the dimerization of HO_2 radtcals in the thermal decomposition of aqueous H_2O_2; vartous analyses which were destgned to detect H_2O_4 in tne presence of H_2O_2, however, failed to indicate the presence of the superoxide. An attempt was made to substantiale evtdence reported by Stadnik (Doklady Akad. Nauk SSSR, 87: 445, 1952) for the presence of H_2O_2 in water which absorbs active intermedlates from a hydrogen-oxygen dtffusion flame. Apparatus was built tn which the flame was formed tn close proximity to a moving siream of cold H_2O. The results showed that oxides of N were present tn the absorbing solution, but hydrogen peroxides were absent. Since HNO_2 would destroy any H_2O_2 in the solution, the expertment was inconclusive in determining the abtlty of the apparatus to trap active tntermediates from the hydrogen-oxygen flame. The increase in fluorescence yield of β-naphthylamine vapors in the presence of foreign gases provides a new powerful method for studying energy exchange. The effect, discovered by Neporent, is analyzed kinetically and the analogue of the Stern-Volmer equation for this effect is derived. Neporent's data are recalculated in the light of this analysis. Fluorescence stabilization by deuterium and sulfur hexafluoride is studied experimentally following the procedure of Neporent. It is concluded, in particular, that the vibrational and rotational modes of the hydrogen molecules are inactive in the excitation or deexcitation of vibrational energy of complex molecules. THE VIBRATIONAL SPECTRUM OF METHYL NITRATE, by J. C. D. Brand and T. M. Cawthon. Oct. 1954 [18]p. incl. diagrs. tables, refs. (Technical note no. 14) ([AF]OSR-TN-54-292) (AF 33(038)-23976) AD 50137 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 319-323, Jan. 25, 1955.

The infrared absorption of methyl nitrate in the vapor and liquid phase has been measured in the range 2-15μ and frequencies have been assigned to all the fundamental vibrations except the two torsional modes. The characteristic frequencies of the $-ONO_2$ group are at 1672 (vs), 1287 (s), 854 (s), 759 (m), 657 (m) and 578 (m) cm^{-1}. The heat capacity (C_p = 16.2 cal mol^{-1}) and entropy ($S^o_{298.2}$ = 75.97 e.u.) of methyl nitrate vapor have been calculated assuming free internal rotation. Comparison of the statistical and thermal entropies indicates that the barriers hindering internal rotation are small, and the infrared band contours and Raman depolarization factors are interpreted assuming free rotation about the O-N bond. KINETICS OF THE THERMAL DECOMPOSITION OF AMMONIUM NITRATE, by T. M. Cawthon and H. Taylor. Nov. 1954 [23] p. incl. diagrs. tables, refs. (Technical note no. 17) ([AF]OSR-TN-54-334) (AF 33(038)23976) AD 50205 Unclassified

The rate of thermal decomposition of ammonium nitrate has been determined as a function of temperature and the amount of ammonium nitrate decomposing. These data are expressed by the equation:

$$dN_2O/dt = k[NH_4NO_3] \text{ in which } k = 5.62 \times 10^{12} \exp$$

$(-39900/RT)\ sec^{-1}$. Kinetics of the decomposition reaction, determined by the dependence of the decomposition rate on the concentration of ammonium nitrate in mixed nitrate melts, are consistent with a mechanism which involves as the rate-controlling step, reaction of ammonia with hydrated nitronium ion to give nitramide. According to this mechanism, the energy of activation for the thermal decomposition of ammonium nitrate is due largely to the endothermicity of the reaction:

$$NH_4^+ + NO_3^- \rightarrow NH_3 + HNO_3.$$

THE THERMAL DECOMPOSITION OF ALIPHATIC AMINE NITRATES, by T. M. Cawthon and H. Taylor. Dec. 1954 [52] p. incl. diagrs. tables, refs. (Technical note no. 18) ([AF]OSR-TN-54-365) (AF 33(038)23976) AD 52430 Unclassified

The rate of methyl ammonium nitrate decomposition ts proporttonal to the amount of methyl ammonium nttrate decomposing, and initial first order rate constants for the formation of nitrogen are expressed by the Arrhenius equation:

$$k = 1.45 \times 10^9 \exp(-30,000/RT)\ sec^{-1}.$$

A mechanism for the decomposition of methyl ammonium nitrate is proposed. This mechanism involves as the slow step, reaction of methyl amine with hydrated nitronium ion to give methyl nitramine, and methyl nitramine is assumed to decompose rapidly to give either nitrous oxide or nitrite ion as one of the products. The rate of nitrogen formation in the thermal decomposition of tertiary butyl ammonium nitrate has been determined as a function of temperature and the amount of tertiary butyl ammonium nitrate decomposing and expressed by the equation:

$$\frac{dN_2}{dt} = 6.4 \times 10^{14} \exp\left(\frac{-43,600}{RT}\right) [C_4H_9NH_3NO_3] \text{ mole sec}^{-1}$$

A mechanism analogous to the methyl ammonium nitrate mechanism is proposed for the thermal decomposition of tertiary butyl ammonium nitrate. A general mechanism which is consistent with the decomposition kinetics and observed volatile products from methyl ammonium nitrate, tertiary butyl ammonium nitrate, iso butyl ammonium nitrate, trifluoro ethyl ammonium nitrate and dimethyl ammonium nitrate, is proposed for the thermal decomposition of primary aliphatic amine nitrates. VIBRATIONAL RELAXATION TIMES BY THE IMPACT TUBE METHOD. I. EXTENSION OF METHOD TO LONG RELAXATION TIME RANGE. II. INVESTIGATION OF THE OXYGEN-H_2O, OXYGEN-D_2O SYSTEM, by C. S. Tuesday and M. [J.] Boudart. Jan. 1955 [60] p. incl. diagrs. tables, refs. (Technical note no. 7) ([AF]OSR-TN-55-67) (AF 33(038)23976) AD 57918 Unclassified

The theory of the impact tube method is discussed and

the general equations derived. The compressible flow solution for expansion is derived and used to obtain a general solution of the equation. Special cases of the general solution are considered, and the invalidity of the assumption of incompressible nozzle flow is demonstrated. Numerical solutions of the equations are given, and are used in an investigation of the influence of H_2O and D_2O on the vibrational relaxation time of oxygen. The results for the H_2O-oxygen system are found to agree with the results obtained using sonic methods, thus establishing the validity of the treatment. H_2O is shown to be much more effective in transferring vibrational energy from oxygen than D_2O. This is attributed to the near resonance in vibrational levels of oxygen and H_2O which results in resonance vibrational energy exchange. This concept is utilized in a proposed mechanism which satisfactorily explains the experimental results. (Contractor's abstract)

THE HIGH TEMPERATURE HYDROGEN-BROMINE REACTION, by D. Garvin and M. Plooster. June 27, 1955 [78]p. incl. diagrs. tables, refs. (Technical note no. 16) ([AF]OSR-TN-55-163) (AF 33(038)23976) AD 65495 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 6003-6008, Dec. 5, 1956.

A survey was made of methods of rapid adiabatic compression of gas mixtures. The H-Br reactions at temperatures between 800° and 1000°K were studied by using a modified shock tube technique. A study of the strengths of the shock waves in the modified shock tube system shows that: (1) the shock waves generated produce temperatures higher than those calculated (assuming a reversible adiabatic process); and (2) the terminal pressure of the process was generally greater than 1 atmosphere. In addition, when a high-pressure reservoir has essentially an infinite diameter, the shock waves are stronger than those predicted for a shock tube of uniform cross section at a given ratio of pressures at the diaphragm. The reaction process was studied by measuring photometrically the changes in Br concentration in the compressed, heated gas. Reaction appeared to take place by a near-adiabatic thermal explosion mechanism. From the induction periods of the thermal explosions, it is shown that reaction was slower than would be predicted by the extrapolated rate of the low-temperature reaction, with an apparently lowered activation period. An approximate theoretical treatment of the behavior of the H-Br reaction under nonsteady-state reaction conditions is presented. Satisfactory agreement is found between the experimentally observed induction periods and those calculated on the basis of a nonsteady-state reaction. Exact agreement between theory and experiment is difficult to obtain because: (a) there is some scatter in the experimental data; and (b) the rates of dissociation of Br_2 molecules and the recombination of Br atoms are very uncertain. THE REACTIONS OF ATOMIC HYDROGEN WITH OZONE AND WITH OXYGEN, by J. D. McKinley, Jr. and D. Garvin. May 1955 [20]p. incl. diagrs. tables, refs. (Technical note no. 19) ([AF]OSR-TN-55-164) (Also bound with its AFOSR-TN-54-249; AD 50136) (AF 33(038)23976) AD 65496 Unclassified

Also published in Proc. Symposium on The Airflow and The Aurorae, Queen's U., Belfast (Ireland) (Sept. 6-7, 1955), N. Y., Pergamon Press, 1955, p. 264-269.

Also published in Jour. Amer. Chem. Soc., v. 77: 5802-5805, Nov. 20, 1955.

The reactions of oxygen and ozone with atomic hydrogen at room temperature have been studied in a low pressure flow system, and the products (trapped at liquid nitrogen temperature) have been determined. The yields of water, hydrogen peroxide and "evolved" oxygen under various operating conditions are compatible with the view that product formation occurs primarily by radical recombination reactions in the cold trap. Hydroxyl is the immediate precursor of all water formed (and of a small amount of peroxide) while the fate of perhydroxyl is the formation of hydrogen peroxide (in the cold trap) and either hydroxyl or molecular oxygen in the pretrap phase. FLAME PROPAGATION RATES ALONG A NICHROME SURFACE, by A. L. Thomas and R. H. Wilhelm. Sept. 1955, 1v. incl. illus. diagrs. tables, refs. (Technical note no. 22) ([AF]OSR-TN-55-361) (AF 33(038)23976) AD 75394 Unclassified

The rates of flame propagation, along a slot burner, of premixed methane-air flames at gas compositions in the range 10.2 - 14.6% methane have been determined

as a function of surface temperature in the temperature range 25°C - 300°C. The surface was Nichrome V. The slot spacing was 1/16 in. and the average contact time of the gas issuing from the burner with the heated walls of the burner was in the time interval 0.014 to 0.072 sec. The rate of flame propagation increased with surface temperature. The propagation velocity for a 12.4% gas mixture increased from 63 cm/sec at 25°C to 132 cm/sec at 300°C. Two statistical design experiments have indicated that tn the region of turbulent flame propagation, the average rate of propagation ts constant for a given surface temperature, gas flow rate and composition, independent of prepropagation surface conditiontng. No instabilities tn average flame propagation rates were detected. (Contractor's abstract)

THE FREE ELECTRON MODEL AND THE FLUORESCENCE OF CATACONDENSED HYDROCARBONS, by B. Stevens. Dec. 1955 [29]p. incl. diagrs. refs. (Technical note no. 25) (AFOSR-TN-56-39) (AF 33-(038)23976) AD 80551 Unclassifted

The effect of vibrattons of the conjugated perimeters of catacondensed hydrocarbons on their π orbital energies and π transition frequencies as given by the free-electron model is discussed. The free electron model gives the π orbital energies and hence π transition frequencies in terms of the length of the conjugated system. Owing to in-plane vibrations of the C-C bonds along the perimeter, this length varies so that the transition frequency depends upon the nuclear configuration at the instant of transition. The most probable configurattons are derived in terms of the vibrational properttes of the perimeter treated as a collection of independently vibrating C-C bonds with the imposition of certain restrictions. Insofar as electronic transitions are determined by the most probable nuclear configurations of the perimeter, term series are obtained for the vibrational structure of absorption and fluorescence spectra of this type of molecule. Following a tentative assignment of the strongest absorption and fluorescence bands of the benzene molecule, these term series are compared with those obtained previously and values obtained for the increase in C-C bond length upon excitation together with the zero-point amplitudes of the C-C bond are of the expected order. Qualitative aspects of the fluorescence phenomenon and associated spectra are discussed tn terms of a 2-dimensional energy diagram, and it ts suggested that the transfer of excess vibrational energy of the excited molecule may be accounted for by a collisionally induced intramolecular process. THE PHOTOLUMINESCENCE AND ASSOCIATED PROCESSES OF COMPLEX ORGANIC MOLECULES IN THE VAPOR PHASE, by B. Stevens. Feb. 1956, 61p. incl. diagrs. tables, refs. (Technical note no. 26) (AFOSR-TN-56-105) (AF 33(038)23976) AD 82019 Unclassifted

Also published in Chem. Rev., v. 57: 439-477, June 1957.

A general photokinetic scheme is constructed for a complex fluorescent molecule in the vapor phase. The 12 processes considered most probable following

PRI. 09:028 - PRI. 09:031

excitation by ultra-violet absorption are discussed with reference to the behavior of those molecules of this class which have been investigated photometrically. The relationship between the intensity of fluorescence emitted by a certain volume of vapor and the measured quantity is treated in some detail since variations in the latter may be caused by factors other than a change in fluorescence yield from which information concerning the rates of the various photokinetic processes is obtained. The rate of first-order fluorescence emission provides the yardstick with which the rate constants of competing processes may be measured, and for some time fluorescence quenching data have been used to determine the relative rates of very fast collisional deactivation processes. More recently similar measurements have been utilized to assess the rate constants of first-order radiationless deactivation of the excited molecule which are found to increase exponentially with the molecular vibrational energy reserve. The inhibition of this process by collisional transfer of excess vibrational energy to inert gas molecules results in fluorescence 'enhancement', the quantitative treatment of which provides an elegant method for obtaining vibrational energy transfer data which reflect the properties of inert gas as well as fluorescent molecules. RATE OF THE REACTION: $H + O_3 \rightarrow OH + O_2$. AN ANALYSIS OF A PRODUCT EMITTER FLAME, by D. Garvin and J. D. McKinley, Jr. June 1956, 4p. incl. table, refs. (Technical note no. 28) (AFOSR-TN-56-132) (AF 33(038)23976) AD 86008 Unclassified

Also published in Jour. Chem. Phys., v. 24: 1256, June 1956.

Reaction rate measurements of the reaction $H + O_3 \rightarrow OH + O_2$ was studied by the Polanyi diffusion flame method. Ozone was bled through a narrow nozzle (0.018 cm inside diam) into a low pressure atmosphere of H and H_2. The near IR emission of OH was photographed. The plate exposure was related to the reaction rate by means of an extension of diffusion flame theory to the case where the concentration of an intermediate is determined. Utilizing gas kinetic collision diameters of 2.5, 2.75, 4.5, and 5.0 Å for H, H_2, OH and O_3, respectively, kinetic theory formulas, and averaging procedures, the specific rates for 2 cases, which met the severe photographic and method limitations, were $2.4 \pm 0.3 \times 10^9$ and $2.5 \pm 0.9 \times 10^9$ 1/mol-sec or a collision efficiency of about 1/300. In the case of an alternative interpretation where there is reaction upon every collision, the average life for vibrationally OH* of 8×10^{-5} sec is obtained.

THE REACTIONS OF TRIFLUOROMETHYL RADICALS WITH HYDROGEN ISOTOPES, by J. C. Polanyi. Mar. 1956 [13]p. incl. diagrs. tables, refs. (Technical note no. 28) (AFOSR-TN-56-147) (AF 33(038)23976) AD 86306 Unclassified

At the present stage of development of the theory of reaction rates, reactions which differ only in the isotopic masses of the reagents are particulary suited to theoretical treatment. Recently measurements have been made of the absolute rates over a range of temperatures for the following rapid reactions: $CF_3 + H_2 \rightarrow CF_3H$, $E = 9.5 \pm 0.7$; $CF_3 + HD \rightarrow CF_3H$, $E = 10.5 \pm 1.5$; $CF_3 + HD \rightarrow CF_3D$, $E = 10.1 \pm 1.5$; and $CF_3 + D_2 \rightarrow CF_3D$, $E = 10.2 \pm 0.7$ kcal mole^{-1}. The experimental results are discussed in detail in terms of collision theory, and the absolute theory of reaction rates. The values for the pre-exponential factors, $A^{400°K}$, predicted by the absolute theory correspond to a 'steric factor' of $\sim 10^{-3}$, which is in agreement with observation. The calculated trend in $A^{400°K}$ values in the series of reactions is only in partial agreement with observation; it is not possible, on the basis of the present experimental data, to say whether this discrepancy arises from a shortcoming in the theoretical treatment or in the experimental method. Theoretical and experimental evidence is adduced for a progressive decline in pre-exponential factor in the series of reactions $H + H_2$, $CH_3 + H_2$, and $CF_3 + H_2$. (Contractor's abstract)

NEAR INFRARED EMISSION FROM THE H, O_3 REACTION. I. WAVELENGTH MEASUREMENTS OF HYDROXYL VIBRATION-ROTATION BANDS. II. OXYGEN EMISSION BANDS, by T. M. Cawthon and

J. D. McKinley, Jr. Mar. 1956 [12]p. incl. illus. tables, refs. (Technical note no. 30) (AFOSR-TN-56-148) (AF 33(038)23976) AD 86307 Unclassified

Also published in Jour. Chem. Phys., v. 25: 585-586, Sept. 1956.

Wavelength measurements are reported for several rotational lines of 8 vibration bands of OH ($^2\pi$) produced in the low pressure diffusion flame of O_3 in atomic H. Vibrational levels derived from these measurements are compared with the literature values. Attempts to photograph OD bands from the O_3, D atom flame were unsuccessful. Oxygen bands identified as due to the forbidden electronic transition, $^1\sum_g^+ \rightarrow {}^3\sum_g^-$, have been observed in the flames with atomic D and atomic H. (Contractor's abstract)

THE FLAME ATTACHMENT ZONE OF LAMINAR PREMIXED METHANE-AIR FLAMES, by A. L. Thomas and R. H. Wilhelm. Feb. 1956, 1v. incl. illus. diagrs. tables, refs. (Technical note no. 27) (AFOSR-TN-56-159) (AF 33(038)23976) AD 86319 Unclassified

Research was concerned with the attachment of flames to surfaces. Laminar flames were selected for study to give a frame of reference for work with turbulent flames. Studies were made of the effect on flame properties of the compositional control of the flame attachment zone. A flame model is proposed as a phenomenological interpretation of associated events in laminar flame stabilization at surfaces. Determinations were made of flame blowoff, flashback, and extinction characteristics for laminar CH_4-air systems stabilized in various inert and oxidant atmospheres and stabilized in air with oxidant (inert or combustible) issuing into the zone of flame attachment. Detailed results are presented for (1) premixed, laminar CH_4-air flames; and (2) premixed, turbulent CH_4-air flames. Results showed that small amounts of foreign gas, at less than 1 to 2% of the premixed gas flow, greatly affect and shape the pattern of blowoff stability. The introduction of an auxiliary mass of gas to enrich the local attachment zone was considered an alternate to stabilization with a pilot light which introduces heat into the critical flame base zone. The concept of critical boundary velocity gradient correlated well with blow-off and flashback data which were obtained on rectangular orifices for different orifice widths in atmospheres of air, O, and inert gases (CO_2, He, and N). Turbulent flames were stabilized both at the rim of a tubular burner and on a porous metallic tube which was placed at right angles to the premixed stream to serve as a bluff-object stabilizer.

THE FLAT FLAME BURNER AND ITS CHARACTERISTICS AS APPLIED TO THEORETICAL STUDIES, by J. W. Jenkins. Sept. 1955, 48p. incl. illus. diagrs. tables, refs. (Technical note no. 23) (AFOSR-TN-56-221) (AF 33(038)23976) AD 88028 Unclassified

The flat flame burner consists of a 1-in. burner tube packed with Cu gauze and closed at one end by a 1/4-in. stainless-steel porous plate with a mean pore size of 5 μ. The burner tube is surrounded by a water jacket with the water inlet at the bottom and the outlet at the top adjacent to the burner surface. A spiral within the jacket directs the water flow around and against the top of the burner tube. Thermistors which are coupled to an ac bridge circuit and calibrated against a Beckmann thermometer are used for measuring inlet and outlet water temperatures. Uniformity of the stream temperatures is obtained by jet mixers positioned upstream in the fluid flow. The water flow, which is measured by a capillary flowmeter, and the temperature rise indicate the heat removed from the flame front through the burner plate. Tests were conducted on 96% technical grade CH_4 and 99% CP propane. Gas flows were measured by rotameters before the gas passed to a mixing chamber; a traveling microscope measured the dead spaces from the base of the luminous flame to the burner surface; and an Eppley thermopile was used for comparative radiation measurements. Results indicated that the flat flame burner can be a useful and reliable tool for flame studies. The principal disadvantages of the burner are the difficulty of insuring a uniform flow and the influence of edge effects. A simple flame-lift method which is proposed for the rapid exploratory determination of the adiabatic flame velocities appears accurate to within 10%. (ASTIA abstract)

A RELATIONSHIP BETWEEN SOME BOND PROPERTIES OF DIATOMIC MOLECULES AND THE IONIZATION POTENTIALS OF THEIR CONSTITUENT ATOMS, by B. Stevens. [June 1956] [18]p. incl. diagrs. tables, refs. (Technical note no. 34) (AFOSR-TN-56-249) (AF 33(038)23976) AD 88369 Unclassified

In this study, an examination is made of (1) $kr_o^2 2 N(I_A + I_B)$, the empirical relationship between the force constant k, bond length r_o and bond order N of the diatomic molecule AB in its ground state, and the first ionization potentials $I_A + I_B$ of the atoms A and B. This relationship is satisfactory for the hydrogen halides and for stable diatomic molecules. For molecules having totals of 2, 12, and 14 electrons in their valence shells, the expression is modified by introducing 2 constants, a and b, becoming: (2) $k(a+br_o)^2/2 = N(I_A + I_B)$.

PRI. 09:035 - PRI. 10:001

where a = 0.52 and b = 1.2. Expression 1 ts compared with Gordy's expresston, (3) $k = aN(X_A X_B / r_o^2)^{0.75} + b$, where X_A and X_B are the electronegativtties of the bonded atoms, and in most cases $a = 1.07 = 2^{0.75}$. Expresston 1 has the theoretical advantage that the dimenstons on both stdes are equivatent, which ts not the case for Gordy's expresston if X has the dtmenston of energy. Expresston 3, however, has the advantage of much wider apptication, although tt is expected that expression 1 could be applted to any bond if the bonded radicals tonization potentials were known. The latter expression is satisfactory for covalent dtatomtc motecules tn the ground state.

HEAT TtRANSFER tN OSCILtATtNG FLOW, by J. P. Layton. Ftnal rept. July 1, 1953-Sept. 30, 1954. May 15, 1956, [v.] incl. tllus. dtagrs. tables, refs. (Aeronauttcal engineertng rept. no. 266a) (AF 33(038)23976) AD 115834
Unclasstfted

Exploratory research was conducted to determtne the effect of low-amplitude, AF oscillattons tn air, flowtng through a tube, upon the over-all heat transfer from the tube wall to the flowtng medtum. The results of the research tndicated an tncrease tn the rate of heat transfer of approximately 40% above that for steady flow under the conditions provided by the experimental apparatus. Air flowed through a heavy-wall stainless-steel tube located between 2 stagnation chambers. Tube tnlet stagnation-to-outtet static pressure ratios up to 8 and static pressures up to 2000 psta were tnvesttgated. Osctllattons were generated tn the air ftow by tocating a sharp-edged sonic orifice of several stzes at a section near the heat-transfer tube tnlet. Some experiments were conducted wtth an orifice at the tube exit section. An HF response pressure measuring system incorporating a special pressure transducer was emptoyed for recordtng the frequency and amptttude of the osctllations tn the atr flow. The tncrease tn the rate of heat transfer was evaluated from measurements of the stagnation temperatures of the air at the tntet and exit sections of the heat-transfer tube. A selective bibliography of 184 references on heat transfer in oscillating ftow ts appended.

THE REACTIONS OF IRON-NICKEL ALLOYS WITH OXYGEN, by M. J. Brabers, W. J. Heideger, and C. E. Birchenall. Feb. 29, t956, t6p. Incl. illus. tables, refs. (Metallurgy rept. no. 5) (AFOSR-TN-56-t02) (AF 18(600)967) AD 820t5 Unclassified

Also published in Jour. Chim. Phys., v. 53: 810-816 Oct. 1956.

In order to understand the kinetics of the oxidation of Fe-Ni alloys, it is desirable to know the nature of the Fe-Ni-O equtlbrta. Fe-Nt alloys of several compostttons have been partially oxidized and then equilibrated by maintaining them tn a closed system at 1050° or 1095°C for an extended pertod. The products have been examtned microscopically by x-ray diffraction and chemical analysts to determine thetr structure and compostttion. The 3-phase field for alloy-wustite-sptnel has been located approximately, and the sense of some of the 2-phase tie lines has been established. It is posstble to rationalize much of the earlier work on the kinettcs of oxidation of Fe-Ni alloys and to estimate the importance of some sources of error tn the determination of thermodynamic activities by the formation of thin oxtde ftlms in hydrogen-water vapor mtxtures. A summary of latttce constant determtnations are gtven.

THE GROWTH OF FERROUS SULFIDE ON IRON, by R. A. Meussner and C. E. Btrchenall. May 15, t956 [38]p. tncl. tllus. diagrs. tables, refs. (Metallurgy rept. no. 7) (AFOSR-TN-56-384) (AF 18(600)967) AD 96041 Unclassifted

Also publtshed tn Corrosion, v. t3: 677+, 689+, Oct. t957.

The rate of growth of FeS on Fe in S vapor has been studied between 650 and 900°C and between 10 and 500 mm pressure of S. When dtfferences in condttions are taken tnto account the rates seem to be substantially higher than those found by Hauffe and Rahmel (Zeitschr. Phys. Chem., v. 199: 152, t952). The behavior of inert markers and the sulftdation of eutectic mtxtures of Fe and FeS tndtcate that the Fe ton ts much more mobtle tn FeS than the sulftde ton. Self-dtffuston coefftctents for the Fe tons have been calculated approximately assumtng that Wagner's theory of scale growth (Atom Movements, Amer. Soc. for Metals, Cleveland, 1951) is applicable. It has been noted that markers are often found a considerable distance from their expected location at the metal-sulfide interface. This has attributed to cracking at the interface in some cases and to interference with growth by the markers in other cases. It has been shown that unoxidtzable inclusions slow down the rate of sulfidation. (Contractor's abstract)

Also published in Phys. Rev., v. 99: 657-658, July 15, 1955.

A study is made of the deep oxidation of Fe at high temperatures and in an O_2 atmosphere. Large cavities are always found in specimens whose total oxygen content has been brought to that of "FeO". The scale thickness of such specimens, along with other evidence, implies that "FeO" is plastic in the temperature range in which it is stable, while one or both of the higher oxides is relatively rigid. Evidence is presented which indicates that Fe is transported to its surrounding scale with little or no body diffusion path; the mechanism involved is not identified. An expression, analogous to the parabolic rate law of scaling of plane specimens, is developed for application to cylindrical geometry. (Contractor's abstract)

PLASTIC FLOW OF IRON OXIDES AND THE OXIDATION OF IRON, by J. D. Mackenzie and C. E. Birchenall. Aug. 31, 1956 [10]p. incl. illus. diagrs. (Metallurgy rept. no. 10) (AFOSR-TN-56-435) (AF 18-(600)967) AD 96518 Unclassified

Also published in Corrosion, v. 13: 783 , 786 , Dec. 1957.

In this study, it is shown that the oxidation of Fe in O_2 is accompanied by the formation of a central box-like cavity, the dimensions of which are identical to those of the original Fe specimen. The decrease in size of this cavity with increasing temperature and its disappearance when the formation of magnetite and hematite is excluded by a controlled oxidizing potential indicates that the plastic properties of the oxides may be an important factor. This is qualitatively confirmed by the measurement of the relative plasticity of the 3 oxides at 800° -1000°C in a specially designed apparatus, which is diagrammed. (Contractor's abstract)

A theory for propagation of turbulent flames is proposed which differs in many respects from previous concepts. Turbulence is assumed only to wrinkle and extend the flame area. The laminar flame velocity is thus assumed to remain constant and unaffected either by any increase in transport properties or by flame curvature. An initially flat flame surface of infinite extent propagating through a flowing combustible mixture agitated by isotropic turbulence of given scale and intensity is considered. For this system a relation is obtained which expresses the ratio of turbulent flame area to initial area of the flat flame in terms of the mean-square displacement of a flame element from the flame front, $\overline{y^2}$, and the scale. As time passes and the initially flat flame is wrinkled by turbulence, three effects are of importance in determining the area of the wrinkled flame: (a) eddy diffusion associated with turbulence in the unburned gases which tends to increase $\overline{y^2}$; (b) propagation of flame into the unburned gases which tends to reduce $\overline{y^2}$; and (c) shear and eddy diffusion gradients due to the density decrease of the gases upon passage through the flame front which tends to increase $\overline{y^2}$. Consideration is given to these three important effects acting independently and together on flames, and calculated results are compared with existing experimental data.

Presented at NATO-AGARD Combustion Colloquium, Cambridge U. (England), Dec. 7-11, 1953.

Published in Selected Combustion Problems, Cambridge U. (England) (Dec. 7-11, 1953), London, Butterworths Scientific Publications, 1954, p. 215-247.

Both turbulent diffusion flames and turbulent flames propagating in homogeneous mixtures are considered. For turbulent diffusion flames, typical experimental results are reviewed which establish that mixing, principally by eddy diffusion, controls the burning process. For both confined and unconfined turbulent flames propagating in homogeneous mixtures, the limited experimental results useful for comparison with theory are reviewed. Demonstrated are: the magnitude of the increase in flame velocity resulting from turbulence, the increase in flame distortion and in turbulent flame velocity with distance downstream from the stabilizer, the characteristic structure of the instantaneous flame front, and for confined flames, the presence of flame-generated turbulence. The experimental results are compared with a theory for the effect of large-scale turbulence, previously developed by the authors, which assumes that turbulence only wrinkles the flame front without changing S_L, and relates S_T/S_L to the dimensionless parameters v'/S_L, ρ_u/ρ_b, and $S_L t/l_2$. Three effects are taken into account in the theory: eddy diffusion, flame propagation, and flame-generated turbulence. Agreement of theory and experiment is acceptable in some instances, but in others the need for further refinement of the theory is evident. Indicated refinements include provision for effects of flame curvature and of flame front instability (when it exists) on S_T, provision for effect of "flame Reynolds number" on percentage conversion of available energy to turbulence, and provision for the effect on S_T of nonisotropy of the flame-generated turbulence. Additional experimental work is necessary to establish the exact nature of these effects. Experimental approaches which should yield useful data are suggested. Consideration of the effect of rate of increase of turbulent flame area in decreasing S_L indicates only a very small reduction even under extreme conditions. The possibility is discussed that at very high, but obtainable, volumetric heat release rates the combustion process may approach that of homogeneous chemical reaction and that under these conditions chemical reaction rate may become controlling. Presented at national fall meeting of the Amer. Rocket Soc., Buffalo, N. Y., Sept. 24-26, 1956.

Also published in Jet Propulsion, v. 27: 386-391, Apr. 1957.

Rotation of a cylindrical flame holder with its longitudinal axis normal to the flow of combustible gases about a transverse axis parallel to the flow resulted in the generation of flame front at higher rates than a stationary flame holder. The volumetric heat-release rates were increased, but the rotation tended to reduce the stability limits. For any one tailpipe length, the combustion efficiency increased with increasing rotation rate. This increase tended to be greater the lower the inlet-gas velocity. The power required to overcome the rotational drag was calculated to be usually less than the losses from wall-friction or from the axial drag of the flame holder.

The truncated-cone, Bunsen burner technique of measuring burning velocity is applied to flames of propane-air, methane-air, and ethylene-air mixtures from rectangular burner tubes (slot burners). Analysis of experimental results show the truncated cone method of calculation to give burning velocities for the plane combustion waves thus obtained, which probably correspond closely with true burning velocities. The values show agreement with those obtained by measurements in a spherical vessel with central ignition; they are somewhat lower than those obtained for the curved combustion waves of cylindrical burners due to removal of the effect of combustion-surface curvature of the cylindrical tube.

THE EXISTENCE AND STABILITY OF SIMPLE, ONE-DIMENSIONAL, STEADY-STATE COMBUSTION WAVES, by J. M. Richardson. [1953] [8]p. refs. [Proj. Squid technical rept. no. BUM-4-P] (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503] and NAonr-25-47) Unclassified

Published in Fourth Symposium (International) on Combustion, Mass. Inst. of Tech., Cambridge (Sept. 1-5, 1952), Baltimore, Williams & Wilkins, 1953, p. 182-189.

The existence and stability of one-dimensional, steady-state combustion waves are analyzed for the case of a simplified model of a combustion wave using only one state variable. A simple analytical approximation is devised for the determination of the steady-state solution and its limits of existence. The nonplanar transient problem linearized in deviations from the one-dimensional steady state can be treated by an exact method. It is found that the one-dimensional steady state, when it exists, is always stable.

A survey is made of theoretical and experimental studies concerning the formation of a combustion wave by a spark or other local source in an explosive medium. Ignition of an explosive gas mixture by an electric spark is considered, and development discussed of a thermal model which includes an observable quantity, the minimum flame diameter. Use of the concept of excess enthalpy h, accompanying a combustion wave when heat transport by conduction exceeds the opposing flow of enthalpy by interdiffusion of reactants and products, permits an equation for the minimum ignition energy, $H = \pi d^2 h$ where d is the critical flame diameter or quenching distance between electrodes. The excess enthalpy per unit area, h, can be computed from the heat conductivity μ of the mixture, the burning velocity Su, and the flame temperature Tb, by the equation $h \cong (\mu/Su)(Tb - Tu)$ where Tu is the temperature of the fresh gas. Comparison of theoretical and experimental data on minimum ignition energies and quenching distances indicates the theory to be basically correct. Discrepancies are analyzed indicating the value of h

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

calculated from the thermal model to be too great in mixtures where transport of enthalpy by diffusion is significant. Research concerning ignition by electrically heated wire, heated spherical pellets, and pilot flames is summarized.

Theoretical consideration of the heat flow from the reaction zone of a laminar flame into the unburned explosive mixture shows that in the presence of a velocity gradient the heat flow is spread out over a larger volume of gas, thus decreasing the laminar burning velocity. Exact limits where propagation of the flame would cease cannot be predicted, but the calculated laminar burning velocity is reduced several-fold by the effect of velocity gradient at the experimentally observed limit. Two ionization probe techniques are described for measuring turbulence in or near flames, and experimental results obtained by both methods are given. For regions where the flame front is not too strongly distorted, average flame front fluctuation velocity agrees with the velocity of turbulent fluctuations.

Presented at NATO-AGARD Combustion Colloquium, Cambridge U. (England), Dec. 7-11, 1953.

Published in Selected Combustion Problems, Cambridge U. (England) (Dec. 7-11, 1953), London, Butterworths Scientific Publications, 1954, p. 248-274.

The structure of turbulent flames burning in explosive mixtures is described and illustrated by examples. A theory of turbulent burning velocity is developed, based on this flame structure. The cardinal point of this theory is the calculation of the time interval, during which a small portion of the instantaneous combustion wave has statistical correlation with the random motion of a certain mass of gas. A comparison of measured values of the turbulent burning velocity with the predictions of this theory points to the possibility of turbulence generation by the turbulent flame. The mechanism is described by which the turbulent flame can generate additional turbulence and a theory of this process is developed, which permits the calculation of the intensity of flame-generated turbulence. Turbulence intensities calculated from measured turbulent burning velocity data are in good agreement with turbulence intensities calculated from this theory. For an independent experimental test of both theories the direct measurement of the turbulence intensity in the flame will be necessary. This appears feasible. A relationship is derived between the burning velocity, scale of turbulence, and the thickness of the turbulent flame brush. Measurement of the flame brush thickness by an electronic probe therefore

PRI. 11:012 - PRI. 11:014

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

gives information about the scale of turbulence in the flame. Further experimental work is required to complete the experimental test of the theory of turbulent flames, and to establish its range of validity. In the discussion of this and a previous paper (Experimental Studies in Turbulent Flames, by A. C. Scurlock and J. H. Grover, see item no. PRI. 11:002) G. H. Markstein considered the interaction of flame with upstream turbulence by means of linearized analysis, and K. Wohl presented supplementary experimental data on burning velocity of methane-air, butane-air, and propane-air mixtures. (Contractor's summary, modified)

THE SURFACE MIGRATION OF CARBON ON TUNGSTEN, by R. Klein. Jan. 20, 1954 [8] p. incl. diagr. (Proj. Squid technical rept. no. BUM-11-P; rept. no. 1147) ([AF]OSR-TN-54-12) ([Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ort-10503] and CSO-670-54-9) AD 89980 Unclassified

Also published in Jour. Chem. Phys., v. 22: 1406-1413, Aug. 1954.

The surface migration of carbon on tungsten was observed with the field-emission microscope technique. The carbon source was a carefully outgassed 5-mil diameter graphite filament. The vacuum attained in the system, exclusive of helium, was of the order of 10^{-12} mm Hg. The tungsten point was shadowed with carbon and heated to a given temperature; observations of the emission patterns were made at room temperature at various time intervals. The migration occurs at a measurable rate starting about 850°K. It is characterized by a sharp boundary of a form which clearly shows that the (011) and (121) planes are avoided. An activation energy of 55 ± 7 kcal/mole was calculated for the process by application of the theory of diffusion with a sharp moving boundary. (Contractor's abstract)

KINETICS OF THE GAS PHASE OXIDATION OF FORMALDEHYDE, by M. D. Scheer. June 1, 1954 [12] p. incl. diagrs. tables, refs. (Proj. Squid technical rept. no. BUM-11-P; rept. no. 1163) ([AF]OSR-TN-54-161) [Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ort-10503 and CSO-670-54-9] Unclassified

Published in Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y., Reinhold, 1955, p. 435-446.

In this study, at the end of each reaction or after any period of reaction, the pressure of the sample was determined rapidly, then mass-spectrometer scanned for CO, CO_2, O, H, HCHO, and peroxides. Evidence is presented for the peroxide-destroying property of Hg vapor. Therefore it is necessary to assume 2 types of stoichiometry, one in which peroxides rapidly are decomposed, forming no HCOOH, and the other in which peroxides decompose less rapidly, forming HCOOH in addition to other compounds. The following mechanism is proposed:

(I) for the main chain:
(1) $HCHO + O_2 \rightarrow HCO + HO_2$ (chain initiating)
(2) $HCO + O_2 \rightarrow HCO_3$ (chain continuing)
(3) $HCO_3 + HCHO \rightarrow HCOOOH + HCO$ (chain continuing)
(4') $HCO_3 + O_2 \rightarrow CO + HO_2 + O_2$ (chain terminating)
(4) $HCO_3 + M \rightarrow CO + HO_2 + M$ (chain terminating)
(5) $HO_2 +$ wall $\rightarrow$ destruction

(II) for the rapid decomposition of HCOOOH:
(6) 2HCOOOH + active surface or Hg vapor $\rightarrow$ $2CO + 2H_2O + O_2$
(7) $2HCOOOH +$ wall $\rightarrow 2CO_2 + 2H_2 + O_2$

(III) for an aged vessel:
(8) $HCOOOH + 2HCHO \rightarrow (CH_2OH)_2\,O_2 + CO$
(9) $(CH_2OH)_2\,O_2 +$ wall $\rightarrow HCOOH + CO_2 + 2H_2$
(6') 2HCOOOH + inactive surface $\rightarrow 2CO + 2H_2O + O_2$
(7') $2HCOOOH +$ wall $\rightarrow 2CO_2 + 2H_2 + 2H_2 + O_2$.

THE PYROLYSIS OF FORMALDEHYDE, by R. Klein, M. D. Scheer, and L. J. Schoen. Apr. 12, 1955 [3]p. incl. diagr. tables. (Proj. Squid technical rept. no. BUM-19-P; rept. no. 1177) ([AF]OSR-TN-55-456) ([Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research, under N6ori-10503] and CSO-670-54-9) Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 50-52, Jan. 5, 1956.

The pyrolysis of formaldehyde is shown to occur predominantly by a chain reaction. Carbon monoxide and hydrogen are formed in accordance with second-order rate laws. Methyl alcohol results from a homogeneous bimolecular reaction. An unspecified condensation product, amounting to a small fraction of the reacted formaldehyde, is also indicated. The thermal decomposition of mixtures of CH_2O and CD_2O gives H_2, D_2 and HD in proportions such that $P^2_{HD}/P_{H_2}P_{D_2}$ is a constant equal to about 3.6. The pyrolysis of CH_2O and D_2 mixtures shows that the hydrogen atom concentration, although small, exceeds that which would arise from the thermal decomposition of hydrogen atone. THE OXYGEN INDUCED HYDROGEN-DEUTERIUM EXCHANGE, by R. Klein, M. D. Scheer, and L. J. Schoen. Feb. 3, 1955, 15p. incl. tables. (Proj. Squid technical rept. no. BUM-20-P; rept. no. 1176) [AFOSR-TN-55-457] ([Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503] and CSO-670-54-9) Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 47-49, Jan. 5, 1956.

The H_2-D_2 exchange reaction, investigated in detail by A. Farkas and L. Farkas (Nature, v. 132: 894, 1933; Proc. Roy. Soc. (London), v. 152A: 124, 1935), was shown to be homogeneous, gas-phase, and to proceed by a mechanism involving atoms. It is shown in this study that trace amounts of O_2 can increase the velocity of the exchange reaction by several orders of magnitude. In a series of experiments, it was found that: (a) agreement with the Farkas-Farkas rate data could be obtained if O_2-free H_2-D_2 mixtures were reacted in outgassed quartz vessels; (b) the exchange velocities for 1:1 H_2-D_2 mixtures increased in the following order: (1) O_2-free mixture in baked-out quartz vessel; (2) O_2-free mixture in an unbaked quartz vessel; (3) O_2 (3 parts/1000) mixture in baked-out quartz vessel; and (4) O_2 (3 parts/1000) mixture in a quartz vessel previously exposed to H_2O vapor. From observations with different surface-to-volume ratios of the reaction vessel, it was concluded that the mechanism for the O_2-induced exchange involves chain initiation at the wall with chain termination in the gas phase. A burner of the Powling type (Fuel, v. 28: 25, 1949) was constructed and modified so that low-temperature flame could be stabilized. Preliminary studies were

PRI. 11:019 - PRI. 11:021

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

carrted out in which requirements for stabilization were observed, temperature measurements through the flame recorded, and several gas samples collected and analyzed. Stabilized cool flames were produced with diethyl ether, n-heptane-air mixtures, and n-hexane-air mixtures. The appearance of these three flames were all similar with a thin lower flame (cool flame) near the burner tip and hotter secondary flame above it. The ether flame could be stabilized without preheating but the hydrocarbon flames required preheating up to ~225°C. A table is given of gas composition at three positions relative to ether-air cool and secondary flames. The first position, just upstream of the cool flame shows little reaction; the second position, between cool and secondary flames, shows evidence of considerable reaction; the third position, above the secondary flame, indicates practically all the reactants consumed. Temperature profiles through the combustion region indicated a rapid rise in temperature through the visible cool flame, followed by a distance relatively constant temperature, then another rapid rise in temperature in the region of the visible secondary flame with a slope not so great as in the cool flame. As mixture becomes leaner the two flames move closer together and finally merge. The effect of preflame temperature increase is to increase the distance between the two flames without changing the temperatures of the cool and secondary flames.

Also published in Proc. Gas Dynamics Symposium, Northwestern U., Evanston, Ill. (Aug. 22-24, 1955), 1956, p. 151-157.

Burning-velocity measurements over the pressure range from 1.5 to 1/25 atm showed that pressure dependence is variable and apparently a function of burning velocity. Burning velocities below 50 cm/sec varied inversely with pressure. In the 50- to 100-cm/sec range, burning velocity was almost constant with pressure; from 100 cm/sec upward, burning velocity increased with pressure. Observations indicated that all burning velocities must approach a constant value at very low pressures.

SIGNIFICANCE OF QUENCHING BY PORTS IN BURNING-VELOCITY MEASUREMENTS BY BUNSEN-BURNER METHODS, by J. M. Singer, J. Grumer, and E. B. Cook. Mar. 1956, 3p. illus. (Proj. Squid technical rept. no. BUM-14-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503 and NAonr-25-47) AD 89152 Unclassified

Also published in Jet Propulsion, v. 26: 989, Nov. 1956.

An experiment was initiated pertaining to the role of flame port diameters in burning velocity measurements by burner methods. Two photographs are presented of a 0.8 stoichiometric CH_3-air flame stabilized by a 1.0-cm-diam coil of 1-mm-od stainless steel tubing, with and without water-cooling; the coil was hot in the latter instance. Both photographs are practically identical, showing the absence of major quenching by the port over most of the flame. A similar experiment with stoichiometric CH_3-air flames resulted in an increase in flame height of about 4 to 5% when the glowing hot coil was water-cooled. The small increment in burning velocity, indicated by the change in flame height, may be the result of preheating of unburned gas by the glowing hot coil. Another mechanism, possibly that of flame cooling by the ambient atmosphere, should be considered to explain low burning velocities obtained on small port burners.

Linear flame speeds at near-quenching limits were obtained for CH_4 air mixtures to test Lewis-von Elbe theory that the axial burning velocity and the linear flame speed at quenching are about equal to the standard burning velocity. Uniform flame movement in downward propagation was obtained within a few centimeters after ignition. Nonsymmetrical tilting of the flame front increased the instability and caused lower linear flame speeds and burning velocities. The dead-space distances increased sharply for lean and rich mixtures. The data confirmed the prediction of Lewis and von Elbe.

PRANDTL NUMBER DETERMINATION BY MEANS OF RECOVERY FACTOR MEASUREMENTS, by R. A. Seban, S. Scesa, and A. Levy. Sept. 1954, 35p. incl. illus. tables. (Proj. Squid technical rept. no. UCB-1-R) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 46387 Unclassified

A cylindrical probe was used to measure the difference between stagnation and wall temperatures. Recovery factors were obtained for the laminar boundary layer flow of air, N, He, and He-N mixtures in the 100° to 600°F range. The Prandtl number was inferred from the recovery factor results in which the square of the measured recovery factor was within 3% of the available values of the Prandtl number for air and N and within 1% when corrected for theoretically evaluated errors; these are magnitudes of uncertainty comparable to that on the individual properties for which the Prandtl number is evaluated. The less decisive results obtained with He and He-N mixtures indicated the available Prandtl number values for He may be too high.

SUPPLEMENTARY INFORMATION ON PRANDTL NUMBER DETERMINATION BY MEANS OF RECOVERY FACTOR MEASUREMENTS, by R. A. Seban and A. Levy. Nov. 1955, 4p. illus. (Proj. Squid technical rept. no. UCB-2-R) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 75713 Unclassified

Additional measurements made with air in the 500 to 700°F range indicate that magnitude of the square of the apparent recovery factor remains the same to 675°F. The source of the error in the platinum probes is unresolved, but it appears to be associated with the presence of oxygen in the gas, since the anomalous behavior was not experienced when operating with nitrogen at temperatures up to 625°F. Results of measurements with Bakelite probes were about the same as the results previously obtained with platinum probes for air and helium in the 100 to 200°F range.

DEVELOPMENT OF HIGH TEMPERATURE METALLOSCOPE, by E. H. Kinelski. Sept. 19, 1949, 22p. incl. illus. refs. (Proj. Squid technical memo. no. CAL-31-[M]) (Sponsored jointly by [Office of Naval Research and Office of Scientific Research] under N6ori-11901 and [N6ori-10503]) U13502; ATI-86539 Unclassified

A high-temperature metalloscope was designed and built which satisfactorily took photo and cinemicrographs of 24S-T Al microstructure up to 1000°F under a maximum vacuum of 4×10^{-5}mm of Hg. Ternary eutectic melting was photographed at 935°F in 24S-T Al. Preliminary attempts to secure photomicrographs of heat SAE-4130 steel and 70-30 cartridge brass were unsuccessful due to an oxide formation which obliterated the microstructure.

AN EVALUATION OF THE POTENTIAL MERITS OF DUCTED PULSEJETS, by G. Rudinger. Oct. 1949, 40p. incl. diagrs. (Proj. Squid technical memo. no. CAL-32-[M]; rept. no. DD-420-A-31) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-11901 and [N6ori-10503]) U11310; ATI-78578 Unclassified

A ducted pulsejet is a conventional pulsejet completely submerged in a surrounding duct, thus permitting operation at flight velocities which are so high that a pulsejet alone would not function. An analysis of such a power plant is presented in which the nonsteady phenomena are replaced by "effective" steady state conditions, and certain other simplifying assumptions are introduced. An analysis of the ramjet based on similar assumptions is also carried out. It is concluded that the ducted pulsejet should have a definite field of application in the subsonic range of flight velocities and possibly even up to low supersonic velocities, but any final decision on the best power plant for a specific application will also depend on additional considerations not treated here; i.e., drag or relative importance of engine size vs fuel consumption.

LINEARIZED SOLUTION OF NONSTEADY FLOWS THROUGH DUCTS, by W. Squire and T. R. Goodman. Mar. 1950, 38p. incl. illus. (Proj. Squid technical memo. no. CAL-33-[M]) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-11901 and [N6ori-10503]) U11181; AD 201062 Unclassified

Part I: An attempt was made to determine the wave phenomena resulting from a duct of slowly varying cross section by linearizing the Langrangian equation of motion. The duct was placed in a subsonic air stream; the velocity at the exit was controlled and given as a function of time. A solution for the first order equations was obtained for a straight duct. The solution of a numerical example was compared with those obtained by the method of characteristics and by the linearization of the Eulerian equations. Part II: A linear solution of the periodically pulsating flow inside a tube of constant cross-sectional area was attempted. The tube was submerged in a flowing gas so that its axis was parallel to the flow. Higher-order solutions were derived for the velocity- and pressure-forcing function of the differential equations and the boundary conditions. A general solution is given for the first-order terms.

FORCED SHOCK OSCILLATIONS IN DIFFUSERS, by J. G. Logan, Jr. Apr. 1950, 9p. illus. diagrs. (Proj. Squid technical memo. no. CAL-12-[M]; rept. no. DD-420-A-32) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-11901 and [N6ori-10503]) U16842; ATI-96025 Unclassified

An experimental technique for the study of shock motion in diffusers under the influence of downstream pressure oscillations is described. The results of preliminary experiments indicate that the maximum pressure amplitude of these disturbances that will permit the shock to be retained in a diffuser is approximately a linear function of diffuser length and frequency. These experimental results are compared with those predicted theoretically by Kantrowitz.

U13611, ATI-91033 Unclassified

A generalized method is presented analyzing the performance of existing or conceivable power plants of the single-flow type of jet engine. The method is based on the description of the modes of compression, heating, and expansion of the working fluid in terms of parameters that can be varied continuously over their respective ranges of practical significance. The thrust and specific impulse of single-flow jet engines are then derived as functions of such parameters. This method yields a direct comparison of the performance of existing engines, together with an indication of the extent to which they may be improved.

Also published in Jour. Aeronaut. Sciences, v. 18: 199-209, Mar. 1951.

The structure of flames burning in tubes has been studied. Slow-burning flames in rich mixtures of higher hydrocarbons, air and nitrogen were found to assume a cellular structure in the absence of turbulence in the approach stream. Lean mixtures gave smooth disc-shape flames, the transition from cellular to noncellular flames taking place at stoichiometric composition. Addition of hydrogen caused appearance of cell structure in lean mixtures of all hydrocarbons. For fuel concentrations between 1.2 and 1.4 times stoichiometric, the average cell diameter d of n-butane-air-nitrogen flames remained constant at atmospheric pressure. In the range of 1/3 to 1 atmosphere, it varied according to the expression $d \cdot p^{3/4} = \text{Const.}$ Within the same range of fuel concentrations and at atmospheric pressure, average cell size for various hydrocarbons and fuel molecular weight M were related by $d \cdot M^{1/3} = \text{Const.}$ Preliminary work on flame structure in fast-burning mixtures indicated a close connection between cellular flame structure and vibratory flame motion. Theoretical interpretations of the observed phenomena are discussed. (Contractor's abstract)

CYCLIC LOADING EFFECTS ON THE CREEP PROPERTIES OF SHEET MATERIALS, by F. J. Gillig and

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

G. J. Guarnieri. Sept. 28, 1951, 22p. illus. diagrs. refs. (Proj. Squid technical memo. no. CAL-38-[M]; rept. no. DD-420-A-38) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-11901 and [N6ori-10503]) U20707; ATI-128995 Unclassified

An investigation was made to determine the effects of cyclic loading on the high temperature creep deformation rate of metals, particularly as related to conditions encountered in jet propulsion engines. Armco iron and commercial high purity aluminum were used to establish generalizations concerning the following variables: (a) amplitude of cyclic load between 0 and 50% of the mean stress; (b) temperature (cold working and annealing ranges); and (c) frequency of load variation from 1.5 to 4,200 c/min. The data show that the superposition of a cycles load upon a static tensile load in a creep test on Armco iron will not necessarily cause deformation to proceed at an increased rate provided the frequency is high enough for the conditions of stress and temperature which prevail. Only a limited amount of data was obtained for the aluminum prior to termination of the project.

SPECTROSCOPIC STUDY OF COMBUSTION, by G. H. Rothgery and J. T. Grey. Summary rept. Sept. 28,

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

1951, 13p. diagrs. (Proj. Squid technical memo. no. CAL-34-[M]) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-11901 and [N6ori-10503]) U20729; ATI-130556 Unclassified

A study of combustion phenomena at low pressure has been made through a spectrographic examination of stable flames. A range of burner pressures and oxygen-fuel ratio has been investigated. The relative intensity of the OH, CH, and C_2 bands has been studied as a function of the combustion parameters, burner pressure, mass flow, oxygen-fuel ratio, and partial pressure of fuel. A correlation between the variations found for the relative intensity of these bands as a function of pressure and a previously suggested mechanism of formation of CH radicals has been noted.

ON THE PERFORMANCE ANALYSIS OF THE DUCTED PULSEJET, by G. Rudinger. Oct. 1951, 32p. diagrs. tables. (Proj. Squid technical memo. no. CAL-36-[M-P]; rept. no. DD-420-A-36) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-11901 and [N6ori-10503]) U20277; ATI-122295 Unclassified

Chapter III of this memorandum, The Magnitude of the Flow Pulsations in the Shroud of a Ducted Pulse Jet was presented at the First National Congress of Applied Mechanics, Chicago, Ill., June 1951.

Ducting of a pulsejet is a means to keep the engine operating at flight Mach numbers at which unducted conventional engines would not operate. It also allows the primary engine to take advantage of the possible ram precompression which is not utilized in the case of conventional pulsejets. Since no methods are available to analyze in detail the periodic flow phenomena that occur in engines of this type, some approximate method of performance calculation is required. Depending on the shroud configuration, mixing of the pulsejet exhaust with the remaining shroud flow may or may not take place. In the latter case, methods of analysis developed for single-flow engines may be applied; while in the former, only the equivalent steady flow approximation appears to be feasible at the present time. Estimates are derived for the magnitude of the flow pulsations in the shroud; and on the basis of this, a discussion of the equivalent steady flow approximation is presented. Unfortunately, it is found that only a rough estimate of the potential engine performance can be made. However, from the performance computed for various conditions, it is possible to draw conclusions about the merits of various configurations. (Contractor's abstract)

NONSTEADY FLOW IN STRAIGHT DUCTS, by C. Ferrari, tr. by R. H. Cramer. Nov. 1951, 40p. incl. diagrs. (Proj. Squid technical memo. no. CAL-43-[M]) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-11901 and [N6ori-10503]) U22417; ATI-152538 Unclassified

Presented at the International Union of Appl. and Theoretical Mech. Colloquium on Nonlinear Vibrations, Sept. 18-22, 1951 on the Ile de Porquerolles.

The nonsteady, isentropic flow of a liquid or gas in a straight duct with deformable sides is investigated by the method of characteristics. A closed-form solution in parametric form is derived by replacing the thermodynamic equation of state with a fictitious equation by applying a similarity principle which enables transfer between the unknown-real and the known-fictitious system. The result is applied to the analysis of the fuel inlet system of a diesel engine. A generalization of the equation of motion is included for the case where the changes of state are not isentropic.

Also published in Fourth Symposium (International) on Combustion, Mass. Inst. of Tech., Cambridge (Sept. 1-5, 1952), Baltimore, Williams & Witkins, 1953, p. 527-535.

Cellular structure and vibratory flame movement studies with mixtures of n-butane and methane showed a shift of the transition from smooth flames to fully developed cell structure to richer mixtures than for a single higher hydrocarbon. Only oscillations of the fundamental organ-pipe frequency occurred in a 2-ft tube, and the maximum amplitudes of these oscillations were significantly larger in mixtures that burned with cellular flame structure than others. In a 4-ft tube, excitation of the fundamental frequency was preceded by the first harmonic for mixture burning with cellular flame structure. The amplitudes of these oscillations showed no correlation with cell structure.

CAL-61-P) (Sponsored jointly by Office of Naval Research, [Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 52851 Unclassified

Presented in part at Second Canadian Symposium on Aerodynamics, Toronto, Ont., Feb. 25-26, 1954.

Also published in Jour. Appl. Phys., v. 26: 981-993, Aug. 1955.

The readjustment of the mean exit pressure to its steady-flow equilibrium level, following the arrival of a shock wave at an open end of a duct, has been investigated. For a cylindrical duct in which the gas is initially at rest, a solution based on acoustic theory was obtained in the form of a Fourier integral. The nature of this solution was established as a series of damped harmonic oscillations superposed on an exponential pressure decay. The actual pressure decay curve was obtained by numerical integrations. The same problem was attacked experimentally using a shock tube of 3.23 in i.d. From pressure records taken some distance from the open end, the "effective" exit pressure was derived. It was found that the exit pressure deviates appreciably from its steady-flow equilibrium value during a time in which a sound wave could travel about three duct diameters. Satisfactory agreement between theory and experiment was observed for shock pressure ratios up to about 1.9 (in air) although, near this limit, significant deviations due to wall friction were observed toward the end of the pressure decay region. For still stronger shocks, the influence of the decay time on the phenomena inside the duct becomes unimportant while friction effects

ON THE STABILITY OF A PLANE FLAME FRONT IN OSCILLATING FLOW, by G. H. Markstein and W. Squire. Nov. 5, 1954 [9]p. incl. illus. refs. [Proj. Squid technical rept. no. CAL-66-P] (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 83852 Unclassified

Also published in Jour. Acoust. Soc. Amer., v. 27: 416-424, May 1955.

Recent experimental studies revealed a close connection between spontaneous excitation of organ-pipe oscillations by flames propagating in tubes and flame front instability characterized by cellular structure. On the basis of these observations a dominant mechanism of vibratory flame movement is proposed, consisting of the following two steps: (1) as a consequence of acceleration instability, the oscillation of the gas column alternatingly distorts and flattens the flame front, thus creating the observed vibration-induced cell structure; and (2) the distortions of the flame front cause in turn periodic changes of flame surface area and therefore of burning rate. Spontaneous oscillations are excited if the phase relation between burning rate vibration and pressure oscillation is favorable. In this paper only the first step is analyzed. The linearized treatment yields stability limits in terms of dimensionless parameters representing amplitude and frequency of gas column oscillation and wavelength of flame front distortion. The properties of the flame front entering into the analysis are the ratio of densities of unburned and burned gases, the burning velocity of the plane flame front, and a characteristic length that determines its stability in the absence of oscillations. Results in qualitative agreement with experimental observations are derived. (Contractor's abstract)

A shock tube method was developed for studying the effects of pressure-wave disturbances on flame propagation. Preliminary results of the interaction phenomenon were obtained with oscillographic records of the pressure transients and schlieren high-speed motion pictures. A pressure record obtained with air in a combustion chamber was compared with a pressure record obtained while burning a stoichiometric butane-air mixture in the chamber. A sequence of frames are shown from a schlieren motion picture of flame front-pressure wave interactions in a stoichiometric butane-air mixture.

A NEW SHOCK TUBE TECHNIQUE FOR THE STUDY OF HIGH TEMPERATURE GAS PHASE REACTIONS, by H. S. Glick, W. Squire, and A. Hertzberg. Apr 1955, 33p. incl. illus. tables, refs. (Proj. Squid technical rept. no. CAL-63-P) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 58832 Unclassified

Also published in Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y., Reinhold, 1955, p. 393-402.

A large evacuated tank, separated from the high-pressure section by a second diaphragm, was added to a shock tube for the study of high-temperature chemical kinetics. A sample of reactant gas in the shock tube is subjected to a controlled high-temperature pulse with real gas temperatures up to several thousand degrees Kelvin and cooling rates in excess of 10^3 °K/msec. Quantitative data can be obtained on the equilibrium state of the reacted gas and the kinetics of the approach to equilibrium. The gas sample in the shock is heated and compressed by the incident and reacted shock waves. After the passage of the shock waves through the reacting gas, the gas remains heated and at rest until the rapid cooling by the tank generated expansion wave occurs. The amplitude of the temperature pulse is determined by the pressure and speed of the sound ratios of the high- and low-pressure gases. The pulse duration is controlled by the length of the shock tube and by the time delay between the breaking of the diaphragms. Helium was used as the driver gas. By using an auxiliary shock tube and variable length ducts to power diaphragm-piercing needles, a satisfactory method was devised for breaking the second diaphragm after the rupture of the first diaphragm within a delay accuracy of 100 μsec. Preliminary experiments were performed on the reaction $1/2\ N_2 + 1/2\ O_2 \rightleftarrows NO$. From 2500° to 3000°K, concentrations

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

of NO which approached equilibrium values were found. An estimate of the reaction rate was made by assuming a bimolecular mechanism from the data obtained below 2500°K. A least-square fit of the specific reaction-rate constant data gave an activation energy of 40 kcal/mol.

CELLULAR SLOT BURNER FLAMES, by G. H. Markstein and D. Schwartz. June 1955, 28p. illus. refs. (Proj. Squid technical rept. no. CAL-64-P) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 62883 Unclassified

Also published in Proc. Gas Dynamics Symposium, Northwestern U., Evanston, Ill. (Aug. 22-24, 1955), 1956, p. 83-94.

A slot burner method for investigating cellular flame structure was developed. Steady flames consisting of a single row of cells separated by straight and parallel ridges were obtained on the burner over fairly wide ranges of combustible mixtures composition and flow rate. Rich butane-air mixtures were employed in this study. Streak camera records of nonsteady cellular flames were obtained. Within the range of equivalence ratios between 1.25 and 1.45, minimum cell width remained almost constant, with an indication of a shallow minimum of 0.31 cm at an equivalence ratio of 1.36; for richer mixtures, the cell width increased up to 0.060 cm for an equivalence ratio of 1.75.

Also published in Jour. Appl. Phys., v. 27: 1339-1341, Nov. 1955.

The recently derived improved boundary conditions for the reflection of weak shock waves from an open end of a duct can be well approximated by a centered expansion wave if the center of the latter is located on the leading characteristic of the reflected wave and at some distance, e, outside the duct. An empirical formula,

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

$e/D = (0.90 + \frac{0.677}{(p_1/p_0)-1})(\gamma + 1.08) - 3.8$, was derived, where D is the duct diameter, p_1/p_0 the shock pressure ratio, and γ the specific heat ratio. This result allows application of the improved boundary conditions without losing the convenience of the customarily used wave-diagram procedure. (Contractor's abstract)

A FLOW INSTABILITY FOLLOWING SHOCK REFLECTION FROM A FLARED END OF A DUCT, by G. Rudinger and L. M. Somers. Sept. 1955, 10p. incl. illus. (Proj. Squid technical rept. no. CAL-67-M) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 70001 Unclassified

Also published in Jet Propulsion, v. 25: 541-544, Oct. 1955.

Studies indicated that violent pressure oscillations may occur in a duct following the reflection of a shock wave from a flared end. These oscillations could be qualitatively explained by alternate periods of separation and reattachment of the flow in the flare. This view is supported by high-speed schlieren motion pictures of the flow just outside the exit of the flare. The pictures show that a number of vortices are emitted from the duct when pressure oscillations appear. The instability occurs only when the flow becomes supersonic in part of the flare.

Presented at meeting of the Amer. Phys. Soc., New York, Jan 30-Feb. 3, 1956.

Published in Bull. Amer. Phys. Soc., Sertes II, v. 1: 15, Jan. 30, 1956.

When pressure waves in a duct reach an open end, a three-dimensional wave pattern is established in the vicinity of the exit. These waves tend to adjust the exit pressure to the level it would have if the flow

PRI. 11:062 - PRI. 11:065

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

remained steady but further arriving waves continually modify the adjusiment process. The instantaneous exit boundary conditons which determine the reflected waves depend therefore on the history of the flow. In the analysis of a nonsteady-flow problem by means of a wave diagram, this difficulty is customarily circumvented by the assumption that the exit pressure adjusts instantaneously to its steady-flow level. In the present investigation, the response of the exit pressure to an arbitrary incident wave was derived from the response to an incident shock wave by means of a Duhamel integral. A general wave diagram procedure is described which corrects the boundary conditions at any instant for the effects of the flow history. The correction is found to be small but may occasionally be significant. (Contractor's abstract)

Boundary conditions are surveyed which are encountered in a wave-diagram analysis of problems that involve quasi-one-dimensional nonsteady flow in a duct. Boundary conditions for open ends are presented which were derived by means of the acoustic theory discussed by Rudinger (Jour. Appl. Phys., v. 26: 981, 1955) to account for the effect of the flow history. The actuat flow conditions in the reflected wave lag behind those which are computed on the basis of the steady-flow boundary conditions. This lag is of the order of $3D/a_o$ after the reflection of a shock wave, where D represents the duct diameter and is the speed of sound of the initially quiet gas.

Also published in Sixth Symposium (International) on Combustion, Yale U., New Haven, Conn. (Aug. 19-24, 1956), N. Y., Reinhold, 1957, p. 387-398.

The interaction of initially laminar stoichiometric butane-air flames with shock waves of several pressure ratios was investigated. Schlieren spark photographs and streak records showed that reflection and transmission of the incident shock wave from the side of the unburned gas initially occurred according to theoretical expectation. Pressure transients near the bottom and top of the combustion chamber, and of flame radiation, were recorded. The radiation transients showed gradual increases during and after wave interaction and yielded maxima which depended on the shock-pressure ratio. The absence of abrupt changes of radiation during passage of the shock waves through the flame indicated that the radiation may be regarded as a rough measure of instantaneous burning rate.

The effects of shock waves on flame structure are analyzed in an attempt to determine the modifications required in the instability concept of Taylor (Proc. Roy. Soc. London A, v. 201: 192, 1950). The analysis is simplified by computing the effect of a constant acceleration of a very short duration τ and of such magnitude that the equation $\tau = U$ is satisfied. This simplification is equivalent to neglecting compressibility effects or regarding the speed of sound as infinite. The analysis shows that for a sufficiently large initial distortion, the disturbance velocities may be of the same order of magnitude as the velocity U.

The flame stability curves for a variety of liquid fuels burned in oxygen have been determined under varying conditions of stream temperature, flame tube diameter, and flame tube length-to-diameter ratio. Insufficient heat has been added to vaporize the fuel completely; thus, both the liquid and vapor states of the fuel are present in the mixtures. Results show a marked similarity between these flames and their gaseous fuel counterparts, except at low stream temperatures and high fuel concentrations, when a large portion of the fuel remains in the liquid phase. Benzene-oxygen flames appear to have favorable non-oxidizing qualities inherent in acetylene flames, and have the ability to produce strong fusion welds in steel. (Contractor's abstract)

Also published in Proc. Conference of the Inst. Mech. Engineers and the Amer. Soc. Mech. Engineers, London (England), Sept. 11-13, 1951.

Abstract published in Appl. Mech. Rev., v. 5: 138-139, Mar. 1952.

A 2-wavelength method is described in which the temperature is obtained from the ratio of 2 peak intensities of the near infrared H_2O-band system after the ratio of their emissivities has been established as a function of temperature. The method appears applicable to any combustion process where H_2O vapor is produced. The absolute accuracy of the temperatures obtained was approximately ± 20°C. A comparison of experimental and calculated temperatures indicated that the former did not exceed the adiabatic flame temperature; flame-point temperature of 3.33% butane was 86° below the adiabatic. The temperature of the burning zones of several lean and rich butane-air flames was measured as a function of distance from the zone. There was strong evidence of the thermal nature of infrared radiation; this was the case up to 0.2 mm from the burning zone where chemiluminiscent radiation was emitted in the visible and ultraviolet part of the spectrum.

Suggestions are made concerning the theory of turbulent flames by modification of the standard equations of turbulent burning velocity. The effect of approach stream turbulence involves amplification mechanisms, one of which may be called induction of flame created turbulence. Another effect is the tendency of the laminar flame front to become unstable with increasing fuel concentration for higher hydrocarbons. Experiments with flames burning from flameholders in ducts show that turbulent burning of this type of flame requires a high stream velocity, but not necessarily any approach stream turbulence.

Also published in Indus. Engineering Chem., v. 47: 825-834, Apr. 1955.

Theories of turbulent burning velocity are reviewed. The theory of Scurlock and Grover is discussed and tt is shown that the scale of turbulence affects the turbulent burning velocity only as long as the steady state ts not reached. An approximate verston of the ftnal differential equation for the turbulent burning velocity is given, which can be integrated tn closed form. The equations following from this theory are compared with the equation given by Karlovitz, Denniston, and Wells and a modified version of tt. The average turbulent burning velocity of butane-air and methane-air flames burning from tubes in air at ordinary pressure was measured from the area of maximum luminosity, which ts shown by chemical analysis to coincide with the one at which the oxygen concentration of the combustible mixture has dropped to 50%. Intensity of approach stream turbulence has been varied independently of velocity with the help of screens. The result for methane flames roughly agree with the predtctions of Karlovtiz, Denniston, and Wells for "passive" flame fronts. The burning velocity of rich butane flames ts much larger than predtcted; that of lean butane flames ts much smaller. These effects are explained on the basis of the difference between the diffusivities of butane and oxygen. With increasing tube diameter average turbulent burning velocity increases strongly because the flame front distortions traveling down the flame front have an increasing opportunity to grow. The peculiar shape of experimental curves confirms qualitatively Scurlock and Grover's theory of turbulence-generating flames. The measured average turbulent burning velocity and the average base diameter of flame front distortions are not affected by the scale of approach turbulence within the experimental range. ON THE STRUCTURE OF TURBULENT FLAMES, by K. Woht, H. von Rosenberg and others. June 1956, 15p. tllus. tables, refs. (Proj. Squid technical rept. no. DEL-6-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 95376 Unclasstfied

Also published in Stxth Sympostum (International) on Combustion, Yale U., New Haven, Conn. (Aug 19-24, 1956), N. Y., Reinhold, 1957, p. 333-340.

A comparative study was made between the progress of the chemical combustion process in several turbulent flames and the local luminosity of the flames as obtained by a densitometric evaluation of direct photographs. Studies of enclosed flames at atmospheric pressure involved the burning of various homogeneous propane-air mixtures in a horizontal duct. Analysis showed that, generally, slight combustion occurs in the schlieren front, most of the gas breaks through the front unburned or tncompletely burned. The quenchtng of the combustion reactton by cooling in the sampltng probe was independent of sampltng velocity. The relattonship between lumtnostty and progress of combustion was tested with open butane-air burning from a cooled tube through which N was flowing at 1 in./sec. The points of maximum luminosity in the flame axis were 5.3 mm below the points of 50% O consumption; the points of maximum luminosity in 2 flame cross sectlons at lower heights were 0.6 mm closer to the axis than the points of 50% O consumption. Results favored a model of flame front burning rather than a continuously distrtbuted reaction. An expertment was conducted wtth butane-air flames burning at 0.2 atm in a vertical cooled lube from a central stoichtometrtc H-O pilot flame. Data were used to make a comparison between the points of maxtmum luminostty and 50% consumption of reactable O in a hortzontal cross section, and between the outer points of 20% of maxtmum luminostty and those of 10% O consumption in a horizontal cross section. Results are presented for a stoichiometric flame at average cold stream velocities of 32 and 68 fps and turbulence levels of 0.6 and 7%.

SPARK IGNITION ENERGY, by I. R. Ktng and H. F. Calcote. May 1955 [6]p. tncl. tllus. table. (Proj. Squid technical rept. no. EXP-2-M) (Sponsored jotntly by Office of Naval Research, [Atr Force] Office of Sctentiftc Research, and Offtce of Ordnance Research under N6ori-10503) AD 62244 Unctassifted

Also published in Jour. Chem. Phys., v. 23: 2444-2445, Dec. 1955.

Data are presented concerntng the effect of the initial fuel-atr temperature on ignitton energy between -50° and 250°C for several hydrocarbons, propylene oxide, hydrogen, and carbon disulfide. Provision was made for controlling the temperature of the ignition bomb by circulating either cooling or heating liquids from a constant-temperature bath through cotls embedded tn the bomb watls. The graph of the mtnimum spark-ignition energy vs equtvalence ratio shows that the equivalence ratio at which the minimum in the ignition-energy curve occurs moves toward leaner mixture and extends over a broader range of equivalence ratios as the initial temperature is increased. An equivalent shift in the maximum burning-velocity curve with increasing initial temperature was also observed. The minimum spark-ignition energy for stoichiometric mixtures with air of a number of fuels is summarized at 0°, 25°, and 100°C. The logarithm of the ignition energy was inversely proportional to the temperature except in the range -30° to -50°C where for some fuels a rapid increase in energy was observed with a reduction in tnitial temperature.

STUDIES OF IONIZATION IN FLAMES BY MEANS OF LANGMUIR PROBES, by H. F. Calcote and I. R. Kttg. May 1955 [37]p. tncl. tllus. refs. (Proj. Squtd technical rept. no. EXP-1-P) (Sponsored jotntly by Offtce of Naval Research, [Air Force] Office of Scienttfic Research, and Office of Ordnance Research under N6ori-10503) AD 62243 Unclasstfied

Alsc published in Ftfth Sympostum (International) on Combustton, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), N. Y., Reinhold, 1955, p. 423-434.

The use of the Langmuir probe in studying ionization tn flames is described with typtcal results and an interpretation of some of the experimental evidence to prove that ionization in the combustion zone is not due to contaminants. The arguments for this conclusion are: (1) flames of some fuels do not contain ions. Were contaminants responsible, all flames would be expected to have ions present; (2) flames at low temperatures have high ion concentrations such tha. it would require one mole-percent sodium impurity in the input gas to account for the observed concentration;

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

(3) ionization is concentrated in a very thin region comparable in the thickness to the reaction zone; and (4) results at different pressures cannot be correlated by assuming thermal ionization of contaminants. (Contractor's abstract)

EFFECT OF PROBE SIZE ON ION CONCENTRATION MEASUREMENTS IN FLAMES, by I. R. King and H. F. Calcote. June 1955 [5]p. incl. tables. (Proj. Squid technical rept. no. EXP-3-M) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 64153 Unclassified

Also published in Jour. Chem. Phys., v. 23: 2203-2204, Nov. 1955.

It has been pointed out that when known concentrations of salts were introduced into a flame, the measured ion concentration was lower than the theoretical value by a factor of 200 to 400(H. F. Calcote and I. R. King, Fifth Symposium (International) on Combustion, Pittsburgh U., Pa. (Aug. 30-Sept. 3, 1954), 1955, p. 423-434). This lack of agreement was attributed to the cooling effect of the probe. A more detailed study of positive-ion concentration, N_+, has indicated, however, that the size of the measuring probe greatly influences ion-concentration values, the larger the probe, the lower the measured values of ion concentration. As a result, a correction, N_+ (corrected) = $(r/l)N_+$ (expertmental), where r = radius of the probe and l = mean flight path, has been introduced. The results of calculations seem to show that the discrepancy in ion-concentration values is caused by probe size and not by gas cooling, and that the correction r/l is reasonable.

INFLUENCE OF RESOLVING POWER ON MEASUREMENT OF CORRELATIONS AND SPECTRA OF RANDOM FIELDS, by M. S. Uberoi and L. S. G. Kovasznay. Jan. 1951. 34p. incl. illus. tables. (Proj. Squid technical rept. no. JHU-1-R.; technical rept. no. 30) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research, under N6onr-24320 and N6ori-10503]) AT1-130376 Unclassified

Functional relations are derived between the true correlations and spectra of a random field and those measured with a probe of finite resolving power. The case of a probe having zero resolving power in one direction (e.g., infinitely long hot wire) is examined; and it is shown that, in the case of homogeneous random fields, the true correlations and spectra can be recovered from the corresponding measured quantities. These relations are applied to turbulence measurements by hot wire anemometers and optical methods. Explicit calculations of hot wire length effect are made for some simple velocity and temperature spectra.

LAURENT SCHWARTZ'S THEORY OF "DISTRIBUTIONS" AND SOME OF ITS APPLICATIONS (FOURIER TRANSFORMATION), summarized by G. B. Mélèse. Sept. 1951, 106p. refs. ([Proj. Squid technical rept. no. JHU-2-R]; technical rept. no. 41) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6onr-24320 and [N6ori-10503]) AD 5903 Unclassified

This paper abstracts essentially the practical results of Laurent Schwartz's theory of "distribution" from his two books published in French (Théorie des Distributions, vol. 1-2, Hermann and Cie, Paris, 1950). It is written for applied mathematicians and theoretical physical scientists. The notion of "function" is first generalized to "measure" (Dirac delta function). With the new notion of distribution, justifications are given for many (previously heuristic) manipulations of discontinuities encountered in the solutions of partial differential equations.

EXPERIMENTAL INVESTIGATION OF OPTICAL METHODS FOR MEASURING TURBULENCE, by L. S. G. Kovasznay and P. C. Clarken. Jan. 1, 1952, 85p. incl. illus. refs. ([Proj. Squid technical rept. no. JHU-3-R]; technical rept. no. 42) (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N6ori-10503) AD 2352 Unclassified

Optical methods for measuring statistical properties of turbulent density fluctuations were explored. The analysis of shadow pictures of turbulent regions in the wake of special "grid projectiles" can yield the micro-scale of turbulent density fluctuations of the right order of magnitude. An experimental comparison between optical methods and hot-wire anemometer measurements was performed in a flow field in which both types of measurements were feasible. An electrically heated grid placed in a small jet provided a flow having sufficiently intense temperature, and therefore density fluctuations. The density fluctuations were measured by the shadow method and from the shadow correlation

PRI. 11:084 - PRI. 11:087

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

the microscale of density fluctuations was computed. From time record interferometer fringe fluctuations the power spectrum of the density fluctuations was determined. Hot-wire measurements of the power spectrum of the temperature fluctuations gave a comparison. The experiments proved that the optical methods are practicable in a certain domain of the variables but are not superior to the hot-wire anemometer where the latter is applicable. TURBULENCE IN SUPERSONIC FLOW, by L. S. G. Kovasznay. Jan. 1953 [19]p. incl. illus. refs. (Proj. Squid technical repl. no. JHU-4-P) (Sponsored jointly by [Office of Naval Research and Air Force Office of Scientific Research] under N6ori-10503) AD 26882 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 20: 657-675, Oct. 1953.

First-order perturbation theory indicates that the Navier-Stokes equations for a compressible, viscous, and heat-conductive gas can have three distinctly different types of disturbance fields, obeying three independent differential equations. These three "modes" of disturbance fields are: vorticity mode, entropy mode, and sound-wave mode. The modes are independent when the intensities of the fluctuations are small, but they interact at larger intensities when linearization is not permissible. The principal tool for measuring the fluctuating fields is the hot-wire anemometer adapted for supersonic flow. In a supersonic flow the hot-wire anemometer responds to two variables: mass flow fluctuations and stagnation temperature fluctuations. Each of the above three modes contributes to both of these variables. By taking fluctuation measurements at different wire temperatures, the relative sensitivity to the flow parameters varies and a "fluctuation diagram" can be obtained. The character of the fluctuation diagram differs for each mode, and even coexisting modes can be separately determined by analyzing the fluctuation diagram under certain restrictive conditions. Hot-wire measurements were obtained in various supersonic flows. Pure temperature spottiness (entropy mode) and pure sound-wave fields were explored. Detailed measurements were taken in a turbulent supersonic boundary layer. With the aid of the fluctuation diagram, the intensity of temperature spottiness (entropy mode) and of turbulent velocity fluctuations (vorticity mode) was measured across the layer. Energy spectrum and probability density measurements gave clues concerning the character of the fluctuations. (Contractor's summary)

ANALYSIS OF TURBULENT DENSITY FLUCTUATIONS BY THE SHADOW METHOD, by M. S. Uberoi and L. S. G. Kovasznay. Jan. 18, 1954 [6]p. incl. illus. refs. [Proj. Squid technical repl. no. JHU-7-P] (Sponsored jointly by [Office of Naval Research and Air Force Office of Scientific Research] under N6ori-10503) AD 103804 Unclassified

Also published in Jour. Appl. Phys., v. 26: 19-24, Jan. 1955.

Shadow pictures of turbulent flow regions give a particular kind of information about the three-dimensional density field. If homogeneity and isotropy of the fluctuation field can be assumed, the statistical properties of the picture uniquely determine the correlation function or power spectrum of the three dimensional turbulent density field. Shadow pictures obtained in the wake of a supersonic projectile were analyzed in this manner and encouraging results were obtained. In order to check the validity of the method, the density fluctuations in a heated jet were measured both by the shadow method and by the more conventional hot-wire technique.

The kinetic problem of axisymmetric turbulence is considered. Properties of directly measurable 2-point correlations caused by incompressibility, homogeneity, and axisymmetry are derived for first-, second-, and third-order correlation tensors. Equations are derived for correlation as a function of triple correlations in the dynamics of axisymmetric turbulence. A solution is given for double velocity correlations in the asymptotic state for small Reynolds numbers. Fourier transforms of the correlations are introduced, and the energy and the 1-dimensional spectrums are defined. Results are obtained for small and large wave numbers, and the spectrum is obtained in the case of small Reynolds numbers.

AN EXPERIMENTAL STUDY OF SHOCK WAVE TURBULENCE INTERACTION (Abstract), by L. S. G. Kovasznay. [1955] [2]p. [Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503] Unclassifted

Presented at meeting of the Amer. Phys. Soc., Old Point Comfort and Langley Aeronautical Lab., Va., Nov. 22-24, 1954.

Published in Phys. Rev., v. 98: 1141-1142, May 15, 1955.

Small perturbation theory indicates that fluctuations in a compressible, viscous, heat-conductive medium have three distinct "modes"; vorticity mode (turbulence); pressure mode (sound waves); entropy mode (temperature spottiness). As long as each of these fields is weak, there is no interaction between them within the fluid away from solid boundaries. When one or more of the three modes is intense, nonlinear interaction takes place and energy is converted from one mode into another. Weak turbulence passing through a stationary strong shock wave has been treated theoretically by Ribner. A simple experiment was carried out by the author in a supersonic wind tunnel. An axisymmetric turbulent wake was produced by a cylindrical body and a wedge created a strong oblique shock wave. The resulting flow field was explored by a hot-wire anemometer and the detailed fluctuation fields have been studied in the light of existing theories. (Contractor's abstract)

INTERACTION OF A SHOCK-WAVE AND TURBULENCE, by L. S. G. Kovasznay. June 1955 [16]p. incl. illus. (Proj. Squid technical rept. no. JHU-8-P) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 62882 Unclassified

Presented at meeting of the Heat Transfer and Fluid Mechanics Inst., Los Angeles, Calif., June 1955.

An attempt was made to demonstrate experimentally the interaction between the random fluctuation field and a strong shock wave. An axisymmetric wake is passed through an oblique shock produced by a wedge. Hot-wire anemometer survey of the turbulent fluctuations were made to explore the different modes. A comparison was made of the fluctuation in the wake before and after the passage through the shock, and sound waves emanating from the interaction zone were located.

ON AN INITIAL VALUE PROBLEM OF AN UNBOUNDED INCOMPRESSIBLE VISCOUS FLOW, by T.-S. Chow. Nov. 1955, 25p. illus. (Proj. Squid technical rept. no. JHU-9-T-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 75711 Unclassified

Also published in Jour. Rational Mech. and Analysis, v. 5: 263-276, 1956.

An attempt was made to analyze the interaction of the various Fourier components with each other which occur as a result of the nonlinearity of the Navier-Stokes equation when applied to the problem of unbounded incompressible viscous flow. An investigation is made of the subsequent development of the motion of an unbounded viscous incompressible fluid when initially its motion is described by 2 spatially periodic waves. The solution to this problem is carried out by successive approximation, and the existence of the solution is proved. The velocity and pressure fields are first expressed in a Fourier representation, and the Navier-Stokes and continuity equations are then transformed into equations for the Fourier components.

The tnftuence was studted of weak dtsturbances upstream of the shock on the flow field downstream of the shock. The basic flow pattern was taken as the one corresponding to a uniform supersonic stream past a 2-dimensional wedge. The unperturbed shock was considered to be a semi-inftnite ptane with ϵ as the upstream shock angle and β as the downstream shock angle. The upstream disturbance can be any one of 3 modes (entropy, vorticity, and sound) occurring separately or simultaneously. The dtscusston is confttned to an entropy disturbance of the step function type. The boundary equations and the governing equations which describe the flow fietd downstream of the shock are presented. The problem can be formulated conveniently in terms of the theory of conical flow. A governing equation for the perturbed pressure is derived which is shown to be hyperbolic or elliptic according to the range of one of tts variables. The method of characteristics ts used in considering the hyperbolic region. In the elliptic region, the governtng equation for the perturbed pressure is reduced to a Laptace equation by the Tschaplygin transformation; the problem is reformulated in a complex plane by using the method of conformat mapping.

ON THE INTERACTION OF WEAK UPSTREAM DISTURBANCE WITH AN INFINITELY-EXTENDED PLANE SHOCK OF ARBITRARY STRENGTH, by C.-T. Chang. May 1956, 26p. illus. (Proj. Squtd technical rept. no. JHU-13-P) (Sponsored jotntly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ort-10503) AD 95263 Unclassifted

The tnteraction between an upstream disturbance and a plane shock of inftnite extent were investigated. The interaction is analyzed by splitting the velocity field into (1) an irrotational part associated with a scalar potential and (2) a rotational part assoctated with a vector potential. The boundary conditions at the shock are formulated. The dependence on the original properties of the shock ts shown explicitly in terms of its strength and its inclination with respect to the downstream main flow. A boundary-value problem is formulated from the governing equation for the scalar potential. A parameter related to the inclination of the upstream disturbance is defined as an effective Mach number M_e of the problem; when $M_e > 1$, the governing equation for the scalar potential is reducible to a simple wave equation. When $M_e < 1$, the governing equation is reducible to a Laplace equation. An illustrative example is given of the interaction of a plane normal

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

shock with a sinusoidal entropy wave. The amplitudes of the shock displacement and of the downstream waves are plotted as functions of the inclination of the upstream disturbance at a given shock strength. The amplitudes are finite at the critical inclination of the upstream disturbance.

INTERACTION OF A PLANE SHOCK AND OBLIQUE PLANE DISTURBANCES WITH SPECIAL REFERENCE TO ENTROPY WAVES, by C. [-T.] Chang. [Oct. 26, 1956] [8]p. incl. diagrs. refs. (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 675-682, Sept. 1957.

The problem of the interaction between a plane entropy wave of arbitrary orientation and a plane oblique shock of infinite extent is investigated. As a result of the interaction, it is found that, in the perturbed flow field downstream of the shock, three kinds of disturbances are present — namely, an entropy mode, a vorticity mode, and a sound mode. The nature of the sound wave generated depends on the orienlation of the upstream disturbance. Within certain orientations of the upstream disturbance, the sound waves generated downstream attenuate. Beyond these orientations, the sound waves generated have constant amplitudes. When the downstream sound waves are not attenuated, there is no phase shift in the entropy disiurbance across the shock; when the downstream sound waves are attenuated, a phase shift occurs in the entropy disturbance across the shock. An illustrative example is given for the interaction between a plane normal shock and a sinusoidal entropy wave. At a given shock strength the amplitudes of the shock displacement and the downstream disturbances generated are plotted as functions of the orientation of the upstream disturbance. An attempt is made to estimate the limit of the amount

Princton U. James Forrestal Research Center, N. J. (Project SQUID)

of information carried by a photographic plate. Three cases of sampling are distinguished: poini sampling, sampling of a large area, and an intermediate sampling area. In the first case, the photodensitometer samples an area much smaller than the area of the average grain in the emulsion. The computations indicate that the total amount of information in this case is jusi proportional to the number of independent samples which in turn depend on the grain structure. For the case where the sampling is large compared to the grain area, the average transparency approaches closer and closer to the value of the ideal transparency. If the grain number is introduced as a parameter, the transparency is an exponential function of the number of grains. Computations show that the amount of information per sample increases as the logarithm of the area. For the case where the sampling area is neither very large nor very small compared to the grain area, both the grain shape and the statistical distribution of the grains is involved. Crude approximations are made for this case.

THERMAL CONDUCTIVITY OF GASES, by F. G. Keyes. July 1954 [8]p. incl. illus. tables, refs. (Proj. Squid technical rept. no. MIT-5-P) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 46155 Unclassified

Also published in Trans. Amer. Soc. Mech. Engineers, v. 76: 809-816, July 1954.

This paper is a continuation of earlier reported work in connection with two of the fundamental properties required for understanding and designing heat transfer equipment. New measurements of heat conductivity are presented along with values for viscosity obtained by correlation of all available data found in the literature. The simplest substance from the point of view of theory is the monatomic gas. The results of a study of the five rare gases are included. (Contractor's abstract)

Droplet burning was studied by projecting a stream of uniform droplets up into an electric furnace and allowing the droplets to follow their trajectories inside the furnace and out through the bottom of the furnace. The experiments showed that the combustion of pure hydrocarbon droplets takes place in two stages, preheat and vaporization. In the preheat region, heat is supplied by radiation for the furnace walls and by conduction from the hot ambtent gases. In the vaporization region, the major heat source in single-droplet burning is the flame envelope surrounding the droplet. Heat is transferred to the droplet surface by conduction against the vaporizing fuel.

EFFECT OF GAS TEMPERATURE GRADIENTS ON RADIANT HEAT TRANSFER, by E. S. Cohen. July 1955, 6p. illus. (Proj. Squid technical rept. no. MIT-7-T) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 67773 Unclassified

An tnvestigation to develop a technique for calculating radiant heat transmisston in enclosures is summarized which makes allowance for temperature nonuniformtties in the gas mass. The technique tnvolves the evaluation of the emission from either a gas zone or a surface zone and the radiant tnterchange between any 2 of these zones while taking into account the absorption along every beam from one zone to another and the partial diffuse reflection of every beam at every surface. The gas zones are taken as cubes or as shapes capable of being built of cubes, and the surface zones are taken as squares or shapes capable of betng built from squares. A numertcal example was worked out for the case of a highly idealtzed furnace to illustrate the salient points in the use of the method. The technique is considered capable of providing more detailed information on the radiant tnterchange within the enclosure than was previously possible. The chief weaknesses of the method are (1) the use of finite sized zones which are assumed to be tsothermal, (2) the assumption of uniform absorption and emission properties of the gas, and (3) the assumption that detailed knowledge of the combustion and mixing pattern is available.

Experimental work is summarized on a study of the effect of boundary layer thickness on (a) flame stability corresponding to vartous rates of boundary layer withdrawal, and (b) molecular diffusion and wake gas composition. The studies suggest that boundary layer removal produces the following effects in the wake of bluff-body flame stabilizers: (a) the combustion reaction propagating into the free vortex layer is chilled by the cold gases in a thinned vortex layer; (b) the recirculation rate of hot combustion products into the tmmediate wake is reduced because of the narrowing of the wake; and (c) the difference in compcsition between the tmmediate wake and the approach stream tncreases.

A paper presented before the Heat Transfer Dtv. at the 1953 Annual meeting (item no. PRI. 11:101) contains a description of the below-ice point temperature apparatus for measuring thermal conductivities of gases and liquids, and a few results for neon were reported. During the past year low-temperature measurements have been made on the remainder of the rare gases (argon, krypton, xenon, nitrogen, oxygen, carbon dtoxide and methane). Reliable results from thermal-conductivity measurements now appear to be forthcoming with the high-temperature apparatus to temperatures of 1380° F.

Atmospheric streams of propane vapor in air were studied to determine the effect of removal of the boundary layer from flame holders on the limits of stable operation and on the atomic composition of the burning gases in the immediate wake of the flame holder. A square-cross-section combustion chamber was used which was 3.17 in. wide and 10 in. long. The flameholders were located 2 in. from the inlet. A plenum chamber and nozzle just upstream from the combustion chamber were fed a homogeneous stream of propane and air; flow was directed into the combustion chamber at a low turbulence level with a flat velocity profile. Boundary-layer removal was effected by slots which were cut close to the isothermal-flow separation point on the stabilizers. Chemical analysis of gas samples from the immediate wake showed that the atomic composition of the gases was often significantly different from that of the approach stream; the difference decreased with increasing approach-stream velocity. Boundary-layer removal increased the difference in atomic composition the increase reached a maximum at intermediate Reynolds numbers. The effect of removal on the stability limits was a function of the feed mixture and velocity. Removal curtailed the fuel-lean limit in all cases; the effect decreased with increasing velocity of the approach stream. Removal extended the fuel-rich limits at low velocities, produced no change at intermediate velocities, and curtailed the limits at high velocities. Results are explained in terms of molecular diffusion across the laminar free vortex layers which bound the recirculation zone in the wake of the stabilizer.

Also published in Sixth Symposium (International) on Combustion, Yale U., New Haven, Conn. (Aug. 19-24, 1956), N. Y., Reinhold, 1957, p. 451-464.

Stability-limit measurements of 4 fuels showed that higher blowoff velocities were attainable with larger drops sizes, increased preparation time, and more volatile fuels. At low velocity, lean limits were reached when heat transferred to the rod exceeded requirements and when the rod became too hot (vapor bound) to collect fuel. At high velocity, lean limits with the less volatile fuels occurred with wet flameholders and were extended to leaner mixtures by increased fuel volatility. Rich limits with a dry stabilizer were made richer by a decreased drop size but were reached at lower fuel rates than when the rod was wet. Rich limits with a wetted stabilizer were extended by a decreased drop size, increased preparation time, and decreased fuel volatility.

MEASUREMENTS ON GASEOUS DETONATION WAVES, by J. A. Nicholls, R. B. Morrison, and R. E. Cullen. [1955] 15p. incl. illus. tables. [Proj. Squid technical rept. no. MICH-2-P] [Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503] AD 52144 Unclassified

Also published in Second ONR Symposium on Detonation, Washington, D. C., Feb. 9-11, 1955, p. 148-162.

An analysis of one-dimensional steady detonation waves is presented which emphasizes the dynamic properties of velocity and heat release. The analysis shows that two types of detonation are possible: the Chapman-Jouget type and the strong detonation. A comparison of heat release as a function of detonation Mach number is made between the simplified theory presented and the results of shock tube experiments. The experimental data correlate reasonably well with the theory, although the slope of the experimental curve differs from that of the theory. A number of spark schlieren photographs are presented which indicate the initiation of the steady detonation, the interaction of the wave with a wedge, and the possibility of a spinning detonation.

ON THE CLASSIFICATION OF NORMAL DETONATION WAVES, by T. C. Adamson, Jr. and R. B. Morrison. June 1955, 6p. (Proj. Squid technical rept. no. MICH-1-M) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 62881 Unclassified

Also published in Jet Propulsion, v. 25: 400, 403, Aug. 1955.

A classification of normal detonation waves is proposed which involves the definition of a heat-release function F that depends upon the incoming velocity and temperature and the heat release by the unburned mixture per unit mass. A Chapman-Jouguet detonation wave corresponds to $F = 1$; $1 < F < 2$ corresponds to a strong detonation wave; and $F = 2$ corresponds to a shock wave.

ON THE INTERACTION OF A CHAPMAN-JOUGUET DETONATION WAVE WITH A WEDGE, by R. S. B. Ong. June 1956, 73p. incl. illus. tables, refs. (Proj. Squid technical rept. no. MICH-3-T) [Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research and Office of Ordnance Research under N6ori-10503] AD 97587 Unclassified

A method is given for determining the critical angle which separates the region of Mach reflection from that of regular reflection for an impinging Chapman-Jouquet detonation wave of a certain known strength. This angle is determined by finding the limit of the real solutions of the equation for the deflection condition in the problem of regular reflection. The configuration of the reflected shock wave in the case of a Chapman-Jouquet detonation wave impinging on a wedge is approximated by assuming a cylindrical reflected shock wave as a zeroth-order solution. Schlieren photographs were made of both the regular and Mach reflection phenomenon, and numerical calculations were made to determine the zeroth-order circular reflected shock wave for an incident detonation wave of the same strength as that used in the experimental work. The configuration of the actual reflected shock wave is computed and constructed from the resulting theoretical analysis of the Mach reflection problem, and the theoretically constructed reflected wave is compared with that traced from the schlieren photographs.

Also published in Jour. Appl. Phys., v. 22: 940-951, July 1951.

The partial differential equation of heat conduction is a nonlinear equation when the temperature dependence of the thermal parameters (i.e., the thermal conductivity, K, the product of the density, and the specific heat constant pressure S) is taken into account. It is shown that a mathematical condition for the transformation to linear form of the one-dimensional, nonlinear, partial differential equation of heat conduction is the constancy of $1/(KS)\,[(d/dt)\log(S/K)]^{1/2}$. This discovery is the motivation for an investigation of the relations between the thermal parameters of simple metals on the basis of the theory of solids and available experimental data. It is found that KS is essentially constant, its variation with temperatures being much less than that of either K or S considered separately. It is also shown, as a result, that the condition for the afore-mentioned transformation is valid for simple metals. Application of the transformed equation to the solution of problems in heat conduction is considered. (Contractor's abstract)

THE EFFECT OF RAPID HEATING ON THE SPECIFIC HEAT CURVE OF LOW CARBON STEEL AT THE PHASE TRANSFORMATION POINTS, by A. M. Nathan. Mar. 13, 1951, 9p. illus. diagrs. (Proj. Squid technical memo. no. NYU-6-[M]-P) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-1102 and [N6ori-10503]) U20017; ATI-125305 Unclassified

Also published in Jour. Appl. Phys., v. 22: 234-235, Feb. 1951.

A dynamic method of measuring the specific heat curves of metals under conditions of rapidly increasing temperature (1000°C) is described and some results obtained with it are given. The method is used for a preliminary study of the specific heat curves of low carbon steel at the phase transformation points. The specimen employed is standard SAE-1040 steel containing 0.40% carbon, 0.60% manganese, annealed at 950°C. It is heated by high amperage DC currents from a storage battery source, while enclosed in an evacuated chamber. During the heating run, the temperature of the steel and the power input are continuously recorded. Temperature is measured by a fine wire (.002 inches) thermocouple, platinum-platinum 13% rhodium, spot welded to the specimen rod at its center. Power input is obtained by measuring the heating current and the voltage drop across the central 15 cm portion of the rod. These quantities are recorded

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

by photographing the face of a cathode ray tube which displays them. Results obtained indicate that the peak of specific heat which normally occurs at the A, allotropic phase transformation point under equilibrium conditions is greatly affected by rapid heating, while the specific heat anomaly at the Curie point is not affected by the rate of heating. SQUID CONFERENCE ON ATOMIZATION, SPRAYS, AND DROPLETS HELD AT NORTHWESTERN TECHNOLOGICAL INSTITUTE, SEPTEMBER 24-25, 1953. Dec. 1, 1954 [100]p. (Proj. Squid technical rept. no. NTI-1-C) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of [illegible]ance Research under N6ori-10503) AD 50186 Unclassified

A summary is presented of the proceedings of the conference. The following four papers are presented in

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

their entirety: Characteristics of Sprays and Droplets, by J. M. Pilcher, Battelle Memorial Inst.; Drop-Size Distributions and Their Averages, by R. E. Thomas, Battelle Memorial Inst.; Review of Mass Energy Transfer Between Liquid Droplets and Surrounding Gases, by C. C. Graves and D. W. Bahr, National Advisory Committee for Aeronautics; and Injection in Afterburning Turbojets, by D. G. Samaras, Wright Patterson Air Force Base. Abstracts are given, or references are made to, the following 13 papers: Review of Experiments and Empirical Correlations Relating to the Production of Sprays, by W. R. Marshall, Jr., Wisconsin U.; Review of Theoretical and Mathematical Analyses of the Performance of Atomizing Nozzles, by R. Lasier and M. Doumas, General Foods Corp.; Fuel Spray Spreading and Evaporation in a Flowing Air Stream, by D. W. Bahr, National Advisory Committee for Aeronautics; Review of Instrumentation and Methods of Experimental Study, by J. L. York, Michigan U.; An Apparatus for Suspending Small Droplets of Liquid in Space, by J. A. Boll, Michigan U.; Measurement of Dry Bulb Temperature in Mists, by E. W. Comings, Purdue U.; Gas Absorption and Aerosol Collection in a Venturi Atomizer, by H. F. Johnstone, R. B. Feild, and N. C. Tassler, Illinois U.; Fuel Injection Problems in Turbojets, by H. A. Fremont, General Electric Co.; Fuel Injection Problems in Ramjets, by J. P. Longwell, Standard Oil Development Corp.; Application of Spray Technology to Liquid Propellant Rockets, by C. C. Miesse, Aerojet-General Corp.; Vaporization of Fuel Droplets in a Diesel Engine, by P. S. Meyers, O. A. Uyehara and M. M. El Wakil, Wisconsin U.; Fuel Injection Problems in Otto Cycle Engines, by W. E. Meyers, Pennsylvania State Coll.; and Chemical Engineering Applications, by A. F. Johnstone, W. R. Marshall, J. L. York, E. W. Comings and G. G. Lamb.

A NEW TECHNIQUE FOR DROP-SIZE DISTRIBUTION DETERMINATIONS, by A. P. R. Choudbury and W. F. Stevens. Aug. 1955, 8p. illus. (Proj. Squid technical rept. no. NTI-2-M) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research and Office of Ordnance Research under N6ori-10503) AD 67774 Unclassified

Accurate knowledge of the drop-size distribution of liquid sprays is necessary in order to evaluate various atomization devices. This drop-size distribution is usually obtained by a procedure involving sampling of the spray, followed by actual counting of the various drop sizes in the spray sample. Such a procedure is extremely time-consuming and may be subject to sampling errors. This paper describes a new method which greatly simplifies the process of determining such a drop-size distribution. The new procedure involves the capture and instantaneous freezing of the entire spray in a bath of liquid nitrogen, followed by screening of the resulting solid spheres into sized fractions. The screening is carried on a set of standard test screens, inside a walk-in cold room kept at -60°F. After the individual fractions are obtained, each is transferred to a small beaker, placed in a desiccator, and allowed to warm up and melt. The weight of each fraction is accurately determined, on an analytical balance, after which the data are combined to give the complete drop-size distribution. The procedure is described in detail, and both advantages and disadvantages of the method are pointed out. Typical drop-size distribution curves obtained by the method are included. COMPOSITION CHANGE IN BINARY COMPONENT SPRAY VAPORIZATION AT ATMOSPHERIC PRESSURE, by J. F. Culverwell, P. W. Grounds, Jr. and others. Mar. 1956, 14p. illus. tables, refs. (Proj. Squid technical rept. no. NTI-3-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 90702 Unclassified

The behavior of the o-dichlorobenzene-tetrachloroethylene system was studied in air at 400° to 1000°F. Variables studied for their effect on the composition change-vaporization relationship were air temperature; feed composition, temperature and pressure; and distance from the nozzle. Measurements were made with a spray composed of drops with diameters in the 20- to 400-μ range. Equations are presented which describe mathematically the vaporization process, with the assumption of liquid diffusion control. Calculations agreed with the experimental data obtained for the first 5 in. of nozzle-to-tray travel. Beyond 5 in., the deviation was considerable. The behavior studies indicated that the change of residual spray composition with vaporization is a function of initial composition, chamber air temperature, and nozzle characteristics for a particular binary component spray. Feed pressure and temperature, and nozzle-to-tray distance locate the position on the vaporization-composition curve but do not affect its shape. Calculated results for the binary system which is based on the assumption of liquid diffusion control of mass transfer indicated that the smaller droplets slowed down, increased in temperature, changed in composition, and decreased in radius more rapidly than the larger drops.

CORE CENTRIFUGAL PRESSURE NOZZLES, by A. P. R. Choudbury, G. G. Lamb, and W. F. Stevens. May 1956 [24]p. incl. illus. tables. (Proj. Squid technical rept. no. NTI-4-P) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 93806 Unclassified

A successful correlation is presented for drop-size distribution data obtained by a unique technique (item no. PRI. 11:128) which appeared exceptionally reproducible. The drop size distribution data for 13 systems having a wide range of fluid properties best fit the square-root-normal distribution. For this distribution the square root of the random variable, the droplet diameter, plotted against the distribution function, cumulative mass percentage over the stated size, an arithmetic probability paper, results in a straight line.

The most probable size ($X_{50}^{1/2}$) and the selected second point ($X_{15.87}^{1/2}$), where standard deviation equals $X_{15.87}^{1/2} - X_{50}^{1/2}$, were determined for each run by graphical integration of a plot of cumulative fraction over the stated size as the square root of the average screen aperture on rectangular coordinates. Then, the values were correlated in terms of fluid properties and nozzle characteristics. The entire correlation may be expressed as $X_{50}^{1/2} = mN_{Re}^2 + I$, where $m = f(N_{Re}\ I/2) =$ the slope of plot $EX^{1/2}$ (or $X_{15.87}^{1/2}$) vs N_{Re}^2 and I = intercept of the plot of $EX^{1/2}$ (or $X_{15.87}^{1/2}$) vs N_{Re}^2. Limitations of the correlation are caused by deviations at the extreme values of Reynolds and Ohnesarge numbers and the necessity of using the hydraulic diameter which is sometimes difficult to evaluate because of a lack of knowledge of the air core dimensions.

HEAT TRANSFER IN A LAMINAR COMPRESSIBLE BOUNDARY LAYER ON A POROUS FLAT PLATE WITH VARIABLE FLUID INJECTION, by S. W. Yuan and N. Ness. Sept. 1, 1950, 9p. diagrs. ([Proj. Squid] technical memo. no. PIB-15-[M.]) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research, under N6ori-9802 and [N6ori-10503.]) U16034; ATI-96625 Unclassified

A theoretical investigation of the heat transfer in a laminar compressible boundary layer on a partially porous flat plate with variable fluid injection (trapezoidal and bilinear types) is made. The method of iteration and graphical integration is used to obtain the solution of the boundary layer equation. The relation between wall temperature and the rate of coolant injection is calculated for 3 different injection profiles (trapezoidal, bilinear, and uniform). The results indicate that for equal quantities of coolant injected, the variable injection cases are slightly more efficient than is the uniform injection case. (Contractor's abstract)

AN EXPERIMENTAL INVESTIGATION OF THE ISOTHERMAL LAMINAR BOUNDARY LAYER ON A POROUS FLAT PLATE, by P. A. Libby, L. Kaufman, and R. P. Harrington. Apr. 19, 1951 [8]p. incl. illus. diagrs. refs. ([Proj. Squid] technical memo. no. PIB-16-M-P) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-9802 and [N6ori-10503]) U23016 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 19: 127-134, Feb. 1952.

The transition Reynolds numbers and velocity profiles of the laminar isothermal boundary layer on a porous flat plate with suction or injection have been measured and compared with the laminar boundary layer analyses that have been carried out in the past several years. The results indicate that porous plates closely approximating the mathematical or ideal porous plates can be realized and that the theoretical velocity profiles are in good agreement with experiment.

ON HEAT TRANSFER OVER A SWEAT-COOLED SURFACE IN LAMINAR COMPRESSIBLE FLOW WITH A PRESSURE GRADIENT, by M. Morduchow. Nov. 15, 1951 [8]p. incl. illus. refs. [Proj. Squid technical rept. no. PIB-21-P; technical rept. no. 44.] (Sponsored jointly by [Office of Naval Research and Air Force Office of Scientific Research] under N6ori-10503) AD 9091 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 19: 705-712, Oct. 1952.

A simple expression is derived for the normal injection velocity distribution theoretically required to maintain a given uniform temperature along a porous surface in the laminar-boundary layer region of a compressible flow with a given velocity distribution outside of the boundary layer. This expression is valid for any given free-stream Mach number but is

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

valid based on a Prandtl number of unity and on the assumption that the viscosity coefficient varies linearly with the temperature. By using the Dorodnitsyn type of transformation the variation of fluid properties even in the case of zero Mach number is taken into account. This study is of practical interest in connection with the sweat cooling of turbine blades and of airfoil surfaces in high-speed flow. The method of analysis consists of applying the Kármán-Pohlhausen method to both the momentum and energy boundary-layer equations and of using an additional heat balance equation, involving the coolant temperature. A closed-form approximate solution of the equations is then derived. Numerical examples for flow in the immediate vicinity of a stagnation point and for a typical type of flow over a turbine blade are given. (Contractor's summary)

ON THE TEMPERATURE DISTRIBUTION ALONG A SEMI-INFINITE SWEAT-COOLED PLATE, by N. Ness. Nov. 15, 1951 [9] p. incl. illus. ([Proj. Squid technical rept. no. PIB-22-P]; technical rept. no. 45) (Sponsored jointly by [Office of Naval Research and Air Force Office of Scientific Research] under N6ori-10503) AD 9092 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 19: 760-768, Nov. 1952.

A theoretical investigation of the temperature distribution along a semi-infinite porous flat plate under the condition of uniform injection from the bottom of the plate is made. A heat-balance differential equation of the second order, including a term containing the physical parameters of the plate, is derived and is employed in conjunction with the well-known Prandtl boundary-layer equations of continuity, momentum, and energy for a solution of the problem. The temperature distribution along the plate is obtained for the respective cases of thermal conductivity not equal to, and equal to, zero. Results show that the inclusion of the thermal conductivity term in the heat-balance equation eliminates the infinite temperature gradient at the leading edge. Other results when thermal conductivity is considered are: (a) the boundary conditions at the leading edge — i.e., the ratio of wall to free-stream temperature and the axial temperature gradient there may be chosen arbitrarily but are related mathematically to each other; (b) the ratio of thermal to velocity boundary-layer thickness is less than unity at the leading edge for Prandtl numbers greater than 0.35 and is equal to unity at an infinite distance downstream; and (c) at an infinite distance downstream, the wall temperature approaches the coolant temperature.

A PROVISIONAL ANALYSIS OF TURBULENT BOUNDARY LAYERS WITH INJECTION, by J. H. Clarke, H. R. Menkes, and P. A. Libby. May 12, 1954 [6] p. incl. illus. tables. [Proj. Squid technical rept. no. PIB-26-P] (Sponsored jointly by [Office of Naval Research and Air Force Office of Scientific Research] under N6ori-10503) AD 82574 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 22: 255-260, Apr. 1955.

Prandtl's analysis of the incompressible turbulent boundary layer over a flat plate is extended in this report to include the effect of uniform, transverse fluid injection. The nondimensional parameters characterizing such a flow are deduced by dimensional reasoning. Velocity profile is generated by considering the flow over a plane wall; this distribution reduces to the universal log law when the mass transfer is zero. The expression also serves to relate the local skin friction to the boundary-layer thickness. When these relationships are used in conjunction with the von Kármán integral, the problem becomes mathematically specified. Since only a limited amount of experimental data is available, it is necessary to assign to certain parameters that arise in the velocity profile the constant values they have for no mass transfer. When more measurements are completed, it may be possible to adjust these parameters as or if required. The results give the variation skin-friction coefficient with the injection ratio and the Reynolds number based on streamwise coordinate. The agreement between these results and the experimental data available is found to be satisfactory. The significant reductions in skin friction, and therefore in heat transfer, to be realized with small rates of injection are indicated. (Contractor's abstract)

TRANSPIRATION COOLING IN THE TURBULENT FLOW THROUGH A POROUS-WALL PIPE, by S. W. Yuan and L. S. Galowin. July 1956 [17]p. incl. illus. (Proj. Squid technical rept. no. PIB-30-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 102725 Unclassified

Also published in Proc. Ninth International Congress of Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956), v. 2: 331-340, 1957.

Data show the effect of coolant injection on the velocity and temperature distributions of fully developed turbulent flow in a circular pipe. The data were obtained from a 5-in.-diameter 20-in.-long, porous-wall stainless steel pipe. The Reynolds numbers ranged from 10^5 to 3 x 10^5; the mass flow ratios were 0.0, 0.0058, and 0.0103. Comparison of the theoretical curve with the experimental velocity-distribution data showed close agreement. Agreement between theory and experiment for temperature-distribution data was better for low coolant injection rates. Based on the Prandtl mixing-length theory, the velocity and temperature distributions were obtained from the Reynolds equations and the eddy heat transfer equation, respectively. A significant reduction occurred in the heat transfer to the wall with low rates of coolant injection.

HEAT INSULATING PROPERTIES OF THE LAMINAR COMPRESSIBLE BOUNDARY LAYER (Abstract), by P. A. Libby. July 1952, tp. [Proj. Squid technical rept. no. PIB-23-P] (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N6ori-t0503) Unclassified

Presented at Eighth International Congress of Theoretical and Applied Mechanics, Istanbul (Turkey), Aug. 20-28, 1952.

Published in Jet Propulsion, v. 26: 663, Aug. t956.

Results of a theoretical investigation of the insulating properties of a laminar compressible boundary layer are given. The Kármán-Pohlhausen integral method extended to both the momentum and energy partial differential equations are then solved for two unknown functions of the distance along the wall. These two functions are related to the boundary layer thickness and to the wall temperature. Initial conditions corresponding to a given initial wall temperature and an initial boundary layer thickness are prescribed. Exact, closed-form solutions for the case of zero axial pressure gradient are obtained. For the case with axial pressure gradient, approximate numerical solutions for the interesting case of an accelerating pressure gradient have been obtained. Circumstances under which the laminar compressible boundary layer may insulate a surface from high energy gases are discussed.

A THEORY OF UNSTABLE COMBUSTION IN LIQUID PROPELLANT ROCKET SYSTEMS, by M. Summerfield. Apr. 1951, 16p. incl. illus. (Proj. Squid technical rept. no. [PR-43-R-P]; technical rept. no. 26) (Sponsored jointly by [Office of Naval Research and Air Force Office of Scientific Research] under N6ori-10503) ATI-114348 Unclassified

Also published in Jour. Amer. Rocket Soc., v. 21: 108-114, Sept. 1951.

On the basis of an hypothesis that low frequency oscillations ("Chugging") sometimes observed in liquid propellant rocket engines are the result of oscillatory propellant flow induced by a combustion time lag, conditions for the suppression of such oscillations are derived. It is found that stability can be achieved by increases in the length of feed line, the velocity of the propellant in the feed line, the ratio of feed pressure to chamber pressure, and the ratio of chamber volume to nozzle area. Equations are given for the frequencies of oscillations. Examination of the equation for stability indicates that self-igniting propellant combinations are likely to be more stable than non-self-igniting systems.

THERMODYNAMIC AND TRANSPORT PROPERTIES OF LIQUIDS, PROBLEM I. THERMAL CONDUCTIVITIES OF LIQUIDS, by E. F. Johnson, Jr. and W. J. Sheffy. Final rept. Oct. 1, 1951, 6p. (Proj. Squid technical memo. no. PR-17-M) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-10503) U21040; ATI-131270 Unclassified

The measurement of thermal conductivities and diffusivities in pure liquids and liquid mixtures over extensive pressure and temperature ranges is considered. On the basis of experimental work and a survey of the literature, a comparison is made between disk-type apparatus and a heterogeneous apparatus of concentric metal cylinders for measuring thermal diffusivities in steady- and unsteady-state operation.

THE DESIGN, CONSTRUCTION, AND OPERATION OF THE PRINCETON 4 BY 8 INCH VARIABLE-DENSITY SUPERSONIC TUNNEL, by S. M. Bogdonoff. Oct. 22, 1951, 39p. incl. illus. diagrs. ([Proj. Squid technical rept. no. PR-44-R]; technical rept. no. 34) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-10503) ATI-139932 Unclassified

The design, construction, and operation of the Princeton 4- by 8-in. variable density supersonic wind tunnel are described in some detail. The tunnel has been designed for a range of Mach numbers from 1.5 to 5.0 and has operated in a Reynolds number range from less than 1×10^3 up to 60×10^6. Model mounting and tunnel starting problems are discussed and the present research program now under way is outlined. (Contractor's abstract)

EXPERIMENTAL STUDIES OF ENERGY RELEASE RATES IN ROCKET MOTOR COMBUSTION CHAMBERS, by J. V. Charyk and G. B. Matthews. Final rept. Mar. 1952, 61p. incl. illus. tables. (Proj. Squid technical rept. no. PR-76-R) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-10503) AD 147698 Unclassified

By measuring axial pressure distributions in tubular rocket motors and applying this data to the one-dimensional equations of motion, heat release parameters were calculated for the combustion of gaseous methane and oxygen at pressures above atmospheric. The results were interpreted to give a minimum resistence time and hence a minimum L* (the ratio of combustion-chamber volume to throat area) for the process.

Also published in Jour. Amer. Chem. Soc., v. 76: 926-931, Mar. 20, 1954.

The thermal gas phase reaction between hydrazine and oxygen shows none of the chain characteristics of, e.g., the hydrocarbon series. It is predominantly surface reaction, the activation energy of which, below 100°C, was found to be 6430 cal/mole. On comparison with the absolute reaction rate expression for a bimolecular surface reaction, unrelated by the products, and in which neither reactant is strongly adsorbed, very good agreement is obtained between the experimental and the theoretical rate value. KINETICS OF THE NON-CATALYTIC OXIDATION OF AMMONIA: STATIC EXPERIMENTS IN AN EMPTY UNCOATED SILICA VESSEL, by E. R. Stephens and R. N. Pease. [1952] [3]p. illus. [Proj. Squid technical rept. no. PR-36-P] (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-10503) Unclassified

Published in Jour. Amer. Chem. Soc., v. 74: 3480-3482, July 20, 1952.

A study of the oxidation of ammonia in an uncoated silica reaction vessel indicates that the rate increases in passing from ammonia rich to ammonia lean mixtures. On the rich side, rates are roughly proportional to the product of ammonia and oxygen concentrations, whereas on the lean side the square of the oxygen concentration seems to be involved. The activation energy approximates 45,000 cal in both regions.

CURRENT THEORETICAL CONCEPTS OF STEADY STATE FLAME PROPAGATION, by M. W. Evans. [1952] 93p. incl. illus. tables, refs. ([Proj. Squid technical rept. no. PR-37-P-R]; technical rept. no. 27) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-10503) ATI-131269; AD 16728 Unclassified

Also published in Chem. Rev., v. 51: 363-429, Dec. 1952.

Current theoretical concepts of steady-state flame propagation are discussed. General notations used in all theories are given at the beginning of the report. The details of the discussion cover: the basic equations of fluid dynamics and the generalizations and simplifications required for their use in theories of one-dimensional, steady-state, nonviscous flame propagation; simplifying assumptions used to effect a solution of the equations for one-dimensional steady-state nonviscous flame propagation; the physical structure of the one-dimensional steady-state flame, flame velocity measurements; and classification of theories of steady-state flame propagation.

Also published in Fourth Symposium (International) on Combustion, Mass. Inst. of Tech., Cambridge (Sept. 1-5, 1952), Baltimore, Williams & Wilkins, 1953, p. 310-313.

Burning velocities at one atmosphere and 25°C have been determined for methane in nitrogen-oxygen, argon-oxygen, and helium-oxygen mixtures. Results are correlated with values calculated by means of the Tanford-Pease theory. Experimental burning velocity ratios for the nitrogen-argon-helium case at 10% methane are 0.43:1:1.417. Calculated values are 0.359:1:1.296. A modified Tanford-Pease theory gives 0.373:1:1.392.

Also published in Fourth Symposium (International) on Combustion, Mass. Inst. of Tech., Cambridge (Sept. 1-5, 1952), Baltimore, Williams & Wilkins, 1953, p. 886-893.

Report includes an experimental verification of the use of the one-dimensional equations of mixing and burning in the theoretical performance calculations for a liquid oxygen-gasoline-air ducted rocket. Methods are presented for predicting empirically the longitudinal static pressure distribution in the ducted rocket burner and thus the burner length as a function of R and R* for the liquid oxygen-gasoline system. These results are generalized, making it possible to predict empirically the static pressure distributions along the burner duct for a wide range of ram-rocket operating conditions, including other propellants and different flight conditions.

A THEORETICAL AND EXPERIMENTAL STUDY OF FINITE AMPLITUDE WAVE INTERACTIONS WITH CHANNELS OF VARYING AREA, by A. Kahane, W. R. Warren, [Jr.] and others. Nov. 23, 1953 [21]p. incl. illus. tables, refs. (Proj. Squid technical rept. no. PR-53-P) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 51469 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 21: 505-525, Aug. 1954.

A theoretical and experimental investigation has been made of the interaction of waves of finite amplitude in ducts of varying cross section. A new one-dimensional method is described by which the steady-state conditions after passage of an isentropic wave may be obtained from a chart without necessity of previously required iterative procedures. The chart has proved useful in the discussion of the spectrum of physical solutions which has been presented here. Experiments were carried out in a shock tube to indicate the nature of the actual two-dimensional interaction processes occurring, and to determine how accurately one-dimensional methods could be applied to such interactions. A two-dimensional channel of area ratio 0.504 was made in such a way that the normal shock wave could be incident on either end. Density fields were measured with the aid of a Mach-Zehnder interferometer. Comparison of the transient density distribution obtained in the center of the channel with results of a one-dimensional unsteady flow calculation for the converging channel indicates excellent agreement. The establishment of steady flow was observed for a variety of incident shock strengths using both the converging and the diverging models. The isentropic theory fits the measured densities well for weak shocks. Satisfactory agreement is obtained for strong shocks using real shock theory.

A COMPARISON OF THREE METHODS FOR THE ANALYSIS OF GASEOUS OZONE, by C. C. Schubert, S. J. Garvin, and D. Garvin. Mar. 1956, 7p. illus. (Proj. Squid technical rept. no. PR-63-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, Office of Ordnance Research under N6ori-10503) AD 86634 Unclassified

Ozone (O_3) at low concentrations in air or oxygen was analyzed by 3 methods: absorption in aqueous potassium iodide (KI) followed by titration with sodium thiosulfate ($Na_2S_2O_3$); IR absorption; and measurement of the gas volume increment upon thermal decomposition. Intercomparison of these methods indicates that the titration method as applied in a flow system is not precise for gas streams containing more than 1 mol-% of O_3. At higher concentrations, errors occur which tend to reduce the observed O_3 concentration below that actually present. The recommended method for the analysis of gases containing 2 to 100 mm Hg of O_3 is IR absorption based on a calibration curve obtained from absolute method analyses; the calibration curve is included.

A KINETIC STUDY OF THE DIBORANE-ETHYLENE REACTION, by A. T. Whatley and R. N. Pease. Aug. 10, 1953 [4]p. incl. illus. tables. (Proj. Squid technical rept. no. PR-50-P) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research and Office of Ordnance Research under N6ori-10503) AD 42986 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 76: 835-838, Feb. 5, 1954.

The combination of ethylene with diborane yielding boron triethyl as a final product proceeds in range 120-175° at a rate given by:

$$dp/dt = k[B_2H_6]^{3/2}(1-a[B_2H_6]/[C_2H_4]).$$

As the equation indicates, the reaction becomes mildly explosive when the B_2H_6/C_2H_4 ratio is sufficiently increased (beyond about 0.5); and the excess of diborane is consumed in the process. A mechanism of ethylene addition is proposed. (Contractor's abstract)

Also published in Jour. Amer. Chem. Soc., v. 77: 5806-5808, Nov. 20, 1955.

Burning velocities of hydrogen-air mixtures were measured by the Bunsen burner method. A modified angle technique applied to the dark outer edge of the shadow cone was used in calculating the burning velocities. An attempt was made to correlate the experimental result with approximate diffusion and thermal theories of flame propagation. Diffusion theory predicts a maximum in burning velocity at a leaner H composition than is observed experimentally, whereas thermal theory predicts a maximum at a richer composition (29 vs 42 vs 55% H_2).

A COMPARISON OF THE BURNING VELOCITIES OF METHANE AND HEAVY METHANE IN NITROGEN AND ARGON "AIRS" AT ATMOSPHERIC PRESSURE, by W. H. Clingman and R. N. Pease. Nov. 1955, 11p. illus. refs. (Proj. Squid technical rept. no. PR-60-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 80813 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 2695-2698, June 20, 1956.

The burning velocities of methane (CH) and heavy methane (CD_4) were measured at atmospheric pressure and in both nitrogen (N) and argon "airs" (A) to determine whether diffusion or heat conduction is more important in flame propagation. The CD_4 was prepared by the decomposition of Al_4C_3 with D_2O following the procedure of Wright and Taylor (Canad. Jour. Research, v. 27B: 303, 1949). The apparatus used for measuring

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

the burning velocity of CD_4 was essentially that used by Brokaw and Pease (Jour. Amer. Chem. Soc., v. 75: 1954, 1953). The ratio of the burning velocity of a mixture with CH_4 to that of a mixture with CD_4 of the same composition was always greater than 1 and increased with increasing concentration of fuel. A proposal was made that the burning velocities of CH_4 and CD_4 be compared at 1 atm and varying compositions. Measurements of the burning velocity were made over a range of compositions with N-air and A-air to study the effect of isotopic substitutions at 2 flame temperatures. The results of the study were considered to favor a diffusion mechanism.

CRITICAL CONSIDERATIONS IN THE MEASUREMENT OF BURNING VELOCITIES OF BUNSEN BURNER FLAMES AND INTERPRETATION OF THE PRESSURE EFFECT, by W. H. Clingman and R. N. Pease. Nov. 1955, 17p. illus. refs. (Proj. Squid technical rept. no. PR-59-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 81192 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 1775-1780, May 5, 1956.

An investigation was conducted of the burning velocity of CH_4 under various conditions. Experimental results were compared with the Semenov theory (Prog. Phys. Sci. (USSR), v. 24: no. 4, 1940) and a modified form of the Tanford-Pease theory of flame propagation (Jour. Chem. Phys., v. 15: 861, 1947). An improved Bunsen burner method of determining the burning velocity is presented in which it is determined for each flame observed whether there is a region of the flame cone over which the flame velocity is constant. This method yields burning-velocity values which are independent of flow rate and burner diameter. The Tanford-Pease theory qualitatively predicted the results.

THE VAPOR PHASE INFRA-RED SPECTRA OF OZONIDES OF ETHYLENE, PROPYLENE AND ISOBUTYLENE, by C. C. Schubert and D. Garvin. Nov. 1955, 4p. incl. illus. (Proj. Squid technical rept. no. PR-61-M) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 80812 Unclassified

Also published in Jour. Phys. Chem., v. 60: 807-808, June 1956.

The ozonides of ethylene, propylene, and isobutylene after ozonization at -78°C in an inert solvent showed no strong absorption in the carbonyl region (about 5.7μ). Vapor-phase IR spectra are presented which indicate that any absorption in the 5.7 region is weak compared with absorptions at other wavelengths. Pure isobutylene ozonide was very resistant to decomposition in the presence of water vapor, but showed rapid hydrolysis in concentrated HCl. The results suggest that ozonide identification should be based on characteristic bands in spectral regions other than the carbonyl region.

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

Reaction rates of ozonized oxygen (ca 3 mole % O_3) with methane, propane, n-butane, and isobutane were measured, in situ, in a temperature-controlled infrared absorption cell by observing the decrease of ozone concentration as measured by the absorption at 1055 cm^{-1}. The activation energies calculated on the basis of a reaction first-order with respect to ozone were 14.9, 12.1, 11.1 and 10.3 kcal, respectively. The pre-exponential term for the methane-ozone 3.1×10^9, for n-butane - ozone 8.2×10^8 and for isobutane-ozone 4.4×10^8 cc $mole^{-1}$ sec^{-1} estimated on the basis of a reaction $\alpha[O_3]\cdot[HCl]$. The isobutane-ozone reaction was predominantly homogeneous; n-butane-ozone showed some acceleration in rate due to increased Pyrex surface, little dependence on sodium chloride surface. The main gaseous product of the isobutane-ozone reaction was t-butanol with smaller amounts of acetone and 1-carbon products approximately equal to molar amounts of acetone. A mechanism based on the postulation of a low lying triplet state of ozone is presented. (Contractor's abstract)

THE OXIDATION OF LOWER PARAFFIN HYDROCARBONS. PART II. OBSERVATIONS ON THE ROLE OF OZONE IN THE SLOW COMBUSTION OF ISOBUTANE, by C. C. Schubert and R. N. Pease. Apr. 1956, 15p. incl. illus. tables, refs. (Proj. Squid technical rept. no. PR-65-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 90461 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 5553-5556, Nov. 5, 1956.

The reaction of ozonized oxygen (ca 3-6 mole % O_3) with isobutane in the temperature range 110° to 270°C was compared with the slow uncatalyzed reaction with oxygen alone. The ratio of gram atoms of oxygen fixed in liquid product to moles of ozone added increased from 3.4 at 125°C to 4.2 at 200° and 5.0 at 225°. The ozone-induced oxidation merges into the normal slow combustion reaction at ca 265°C. Approximately one third of the condensed products of isobutane-ozone reaction at 150°C was found to be t-butyl hydroxymethyl peroxide. The same peroxide was indicated to be a product of the isobutane-oxygen reaction at 270°C by a comparison of infrared spectra. It is proposed that ozone may be the active intermediate responsible for chain branching during the slow combustion of hydrocarbons in oxygen. Ozone might result from the reaction: $RO_2^{\cdot} + O_2 \rightarrow O_3 + RO$. Ozone probably has the stability requirements to account for the cool flame reaction and negative temperature coefficient region observed in the combustion of hydrocarbons. Preliminary attempts to detect ozone during the normal slow reaction by observing the ultraviolet absorption in a 3-meter tube were unsuccessful due to general absorption in the 2500 Å region. A PRELIMINARY STUDY OF THE PHOTOLYSIS OF PENTABORANE VAPOR, by H. Burwasser and R. N. Pease. June 1956, 5p. incl. table. (Proj. Squid technical rept. no. PR-66-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 95526 Unclassified

Also published in Jour. Phys. Chem., v. 60: 1589-1590, Nov. 1956.

A preliminary investigation was made of the results of exposing pentaborane vapor to an H arc through a thin SiO_2 window. Results demonstrated that increasing the exposure time beyond 1/2 hr only moderately increased the extent of the reaction; this is probably the result of solid deposition on the cell window upon rinsing with water, the solid product seemed to consist of small white crystals which went into solution slowly; the characteristically strong odor of B hydrides was detected. The freshly prepared solution reduced permanganate solution partially. The presence of borate ion was confirmed by fluorescence test of White, Weissler and Busker (Anal. Chem., v. 19: 802, 1947) involving an alcoholic benzoin solution complex with borate ion. Experiments with D were undertaken. A mixture of H, D, and HD was produced in approximately equilibrium concentrations when 11 mm each of D and pentaborane were irradiated for 1 hr.

A semi-emptrtcal theory ts presented for predtcting the boundartes, velocity decay on the axis, and the velocttty at any potnt in an air jet or vartable denstty exhausting tnto atr at rest. The tntegrated momentum equation ts employed as the basic equation tn the analysts and an approximate expression for density variation ts presented and analyzed. The shear stress is represented by a form suggested by Retchardt. This form is simpler than the ordinary Prandti expresston. Calculattons are made for range of denstty ratios and an analysis of the results ts attempted. A compartson with expertment ts made tndtcating that the mixtng parameter $\frac{k}{u}$, is dependent upon the denstty ratio. A method for solution of the mixing problem ustng a more exact density varlation ts tndicated tn Appendtx 1. (Contractor's abstract)

THE STATIC PRESSURE VARIATION IN COMPRESSIBLE FREE JETS, by W. R. Warren, Jr. July 16, 1954, 9p. illus. ([Proj. Squtd technical rept. no. PR-64-P]; AEL rept. no. 270) (Sponsored jotntly by Office of Naval Research, [Air Force Offtce of Sctenttftc Research] and Office of Ordnance Research under N6ort-10503) AD 57735; AD 97480 Unclasstfted

Also published in Jour. Aeronaut. Sciences, v. 22: 205-207, Mar. 1955.

Experimental static pressure profiles are presented for free axial symmetric jets of 0.97 and 2.60 tnitial Mach number. The accuracy of the constant pressure assumption in free jets is discussed, and it ts shown that this assumption becomes less valid with tncreasing initial jet Mach number. Conclusions are reached concernting the mechanisms governing the physical structure of a free jet. The shape of velocity profiles as a function of initial jet Mach number is discussed briefly. It is shown that turbulence corrections to test readings would only accentuate the conclusions drawn. (Contractor's abstract)

AN EVALUATION OF THE HEAT TRANSFER ENCOUNTERED IN A ROCKET MOTOR OPERATING AT HIGH CHAMBER PRESSURES, by C. F. Warner and M. J. Zucrow. July 20, t949, 24p. incl. diagrs. table, refs. ([Proj. Squid technical rept. no. PUR-2t-R]; technical rept. no. 18) (Sponsored jointly by Office of Naval Research and [Atr Force Office of Scientific Research] under N6ort-1040t and [N6ort-10503]) U11871; ATI-8t556 Unclassified

The theoretical rates of heat transfer between the walls of a 500-lb-thrust rocket motor and the combusiton gases resulting from the oxtdation of octane and aniline by white fuming nitric acid are obtained as a function of the rocket motor chamber pressure. The convective heat transfer coefficients, obtained by using the McAdams correlation, are compared with the rates obtained by Humble-Lowdermilk-Grele correlation. The radiant heat transfer rates are obtained by the Hottel-Egbert method. It was found that the chamber and nozzle heat transfer rates increase linearly with chamber pressure and that the nozzle heat transfer rates become extremely high at chamber pressures beyond 1500 psia.

PROGRESS REPORT ON THE STABILITY OF LIQUID FILMS FOR COOLING ROCKET MOTORS, by M. J. Zucrow, C. M. Betghley, and E. Knuth. Nov. 30, 1950, 33p. tncl. diagr. table, refs. ([Proj. Squtd technical rept. no. PUR-22-R]; technical rept. no. 23) (Sponsored jointty by Office of Naval Research and [Air Force Office of Sctentiftc Research] under N6ort-10401 and [N6ort-10503]) U15690; ATI-95562 Unclasstfted

Presented at annual meeting of the Amer. Rocket Soc., New York, Nov. 30, 1950.

A prelimtnary report ts made of an experimental study of coottng rocket motor walls by tnjecting ltquids through slots to form a liquid film along the wall while air is blown through the test station. Vtsual determtnation of the point at which the liquid separates and flows tnto the air stream rather than along the wall shows that as the velocity of the air increases, the velocity of liquid flow can be increased. The width of the injection slot, the angle of injection, and the viscosity and density of the liquid influence the maximum rate for nonseparating flow; the attitude of the injector, the surface tension of the ltquid, and the size of the gas duct do not affect it.

HEAT TRANSFER COEFFICIENTS FOR GASES: EFFECT OF TEMPERATURE LEVEL AND RADIATION, by H. J. Ramey, J. B. Henderson, and J. M. Smith. Dec. 1953, 11p. illus. refs. [Proj. Squid technical rept. no. PUR-24-P] (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under [N6ori-10503]) AD 42988
Unclassified

Presented at annual meeting of the Heat Transfer Symposium, St. Louis, Mo., Dec. 13-16, 1953.

Convection heat transfer coefficients for the cooling of steam and air flowing inside a 2-in. pipe were measured from 500° to 1200°F at gas-to-wall temperature differentials of 300° to 1000°F, and over a range of Reynolds numbers from 2000 to 20,000 for air and 5,000 to 60,000 for steam. The convection heat transfer coefficients for air increased slowly with temperature level. Similar measurements with steam indicated that published information on the emissivity of steam were satisfactory for predicting radiation contribution encountered within the above range of variables. Data taken with different entrance conditions indicated that the convection coefficients could be increased several hundred percent at constant Reynolds number by substituting a jet entry for the usual straight entrance section with well developed turbulence. LATTICE PARAMETERS OF THE $FeFe_{(2-x)}Cr_xO_4$ SPINEL SYSTEM, by H. J. Yearian, J. M. Kortright, and R. H. Langenheim. Feb. 9, 1954, 3p. incl. illus. table, refs. (Proj. Squid technical rept. no. PUR-26-P) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503, N6ori-10401, and N7onr-39419) AD 50674 Unclassified

Also published in Jour. Chem. Phys., v. 22: 1196-1198, July 1954.

Spinels of the $FeFe_{(2-x)}Cr_xO_4$, $0 < x < 2$, system have been made by reduction of the corresponding sesquioxide solid solution at 1180°, 1100°, and 950°C and the lattice parameters determined at room temperature. The solutions of approximately stoichiometric composition have lattice parameters which vary with x in a nonlinear manner from 8.396 ± 0.002A at $x = 0$ to 0.376 ± 0.002A at $x = 2$. The four essentially linear segments comprising the total curve are interpreted as follows: from $x = 0$ to $x = 0.3$ the structure is completely inversed; from $x = 1.28$ to $x = 2.0$ it is completely normal; between these regions reversion from the inversed to the normal form occurs in two successive stages. Oxygen rich spinels crystallized at 950°C show the same general variations of parameter but the region of complete inversion extends to approximately $x = 0.6$.

THE STRUCTURE OF OXIDE SCALES ON CHROMIUM STEELS, by H. J. Yeartan, E. C. Randell and T. A. Longo. July 18, 1955, 11p. incl. illus. tables, refs. (Proj. Squid technical rept. no. PUR-30-P) (Sponsored jotntly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503, [N6ori-10401, and N7onr-39419]) AD 123681 Unclassified

Also published in Corrosion, v. 12: 515-525, Oct. 1956.

The structure of the oxide scale which ts formed on commercial Cr steels containing from 5 to 26% Cr when oxidtzed in air or O from 700° to 1160°C for times up to 100 hr was determtned by x-ray dtffraction methods supplemented in some tnstances by chemical analysis. Two dtstinct scale types were observed: an A type scale occurs when the rate of metal loss ts less than approximately 10 mg/sq cm/day, and a B type occurs when the attack rate is tn the excesstve range. For exposures near the critical conditions, an tnitial A type scale transforms to B type durtng oxidation. The essential component of the A type scale is Cr_2O_3 which is usually accompanied by αFe_2O_3 in an amount which tncreases with the Fe conteni of the alloy. The B type scale, which ts more complex than A scale, may be considered as 2 layers. The duplex outer layers is similar to the Fe_3O_4 and Fe_2O_3 layer of the scale on pure Fe. The maior constituent of the inner layer, corresponding to the FeO layer on pure Fe ts a solid solution $FeFe_{(2-x)}Cr_xO_4$, of the spinel type. Experimental data are compared and contrasted with existing data and are qualttatively interpreted by use of a tentatively proposed Fe-Cr-O phase diagram and a special theory of alloy oxidation.

STRUCTURE OF OXIDE SCALES ON NICKEL-CHROMIUM STEELS, by H. J. Yearian, H. E. Boren, Jr., and R. E. Warr. July 18, 1955, 8p. incl. illus. tables, refs. (Proj. Squid technical rept. no. PUR-31-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503, [N6ori-10401], and N6onr-39419) AD 123682 Unclassified

Also published in Corrosion, v. 12: 561-564, Nov. 1956.

The structure of the scales formed on a series of typical Ni-Cr steels when oxidized for 100 hr in air at temperatures from 1600° to 2200°F were investigated by x-ray diffraction methods. The scales are of two distinct types. The principal and definitive constituent of the more protective type is Cr_2O_3. A solid solution of Fe_2O_3 - Cr_2O_3 also may be present; in such cases its Fe_2O_3 content tends to increase with attack rate at any given temperature. For very low attack rates considerable amounts of $MnCr_2O_4$ occur when the alloy contains a few tenths percent of Mn. As the attack rate increases this Mn-chromite spinel ts replaced by a Ni-Cr-Fe spinel, the amount and the alloying element content of which increase with temperature and wtth the Ni level of the alloy. For an 80 Nt-20 Cr alloy, NtO is also present. When the attack rate becomes excesstve the scale changes to a type containing no Cr_2O_3 phase but consisting of one or more Fe_2O_3-Cr_2O_3 solutions and Ni-Cr-Fe spinels. The ferrtc-chromic oxide solution tends to concentrate in the outer layer and tt then contains less than 10 mole per cent Cr_2O_3; the proportion may increase when tt occurs tn an tnner layer. Sptnels are present tn all layers but thetr content of the alloying elements tncreases tn the tnward direction. These results are compared with existing data and tnterpreted using a theory of selective oxidation and depletion. (Contractor's abstract)

A LITERATURE SURVEY ON SOME PHYSICAL ASPECTS OF THE COMBUSTION OF FALLING FUEL DROPS, by P. M. Blair. Nov. 1955, 79p. incl. illus. refs. (Proj. Squid technical rept. no. PUR-27-R) (Sponsored jotntly by Office of Naval Research, Atr Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 757t2 Unctassified

Dynamics of falling drops: A classtfication by size is proposed for small homogeneous solid and liquid gas dispersoid particles in order to provide a frame of reference for comparing the stzes of fuel drops in a turbojet combustor with other particles. Vartous methods for studytng the combustion of individual fuel droplets are discussed. The dynamics of rigid spheres are revtewed, and available terminal velocity and drag coefficient data are given for liquid drops falling in 70°F air. Factors determining the size and shape of stable falling drops are discussed. Heat transfer for drops and spheres: Summarles are given of theoretical analyses which have been reported on (t) heat transfer to a sphere immersed in flowing fluid in the absence of mass transfer, and (2) heat transfer to a hypothetical spherical fuel drop burning in still air and surrounded by a concentric flame front. Data are presented which show an increase in the Nusselt numbe: with increasing turbulence intensity for spheres in a turbulent air

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

stream. Mass transfer for drops and spheres: The laws for molecular and eddy diffusion are given for mass transfer in the absence of heat transfer, and experimental results showing the effect of relative air velocity on such mass transfer coefficients are summarized. A report is given of investigations which show the effect of instantaneous drop diameter on the mass transfer rate of drops in still air and drops in an air stream. The derivation of a general 3-dimensional heat-conduction equation is outlined.

INVESTIGATION OF THE FACTORS AFFECTING THE ATTACHMENT OF A LIQUID FILM TO A SOLID SURFACE, by C. F. Warner and B. A. Reese. June 1956 [30] p. incl. illus. tables, refs. (Proj. Squid technical rept. no. PUR-28-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 98478 Unclassified

Presented at fall meeting of the Amer. Rocket Soc., Buffalo, N. Y., Sept. 24-26, 1956.

Results are summarized for an experimental investigation of the film-attachment phase of the film-flow study and of an empirical equation based on momentum exchange which correlates the film-attachment results with 2- and 3-dimensional flow fields. The injection of liquid through slots resulted in the establishment of stable films on solid surfaces over a relatively large range of liquid flow rates with a variety of geometric configurations for air velocities ranging from 40 to 630 fps. The critical velocity of injection decreased with increases in slot width and increased with increases in air velocity and angle of injection; separation was not obtained with angles larger than 75°. The critical velocity of injection (V_i^*) is independent of liquid surface tension and viscosity but is a function of the liquid and air densities (momentum). Equations are presented for predicting V_i^*. Large velocities of injection, below but approaching V_i^*, resulted in the formation of surface disturbances on the film surface and the entrainment of a considerable portion of the injected liquid by the air stream.

THE FORMATION OF OXIDE FILMS ON CHROMIUM AND 18 Cr-8 Ni STEELS, by H. J. Yearian, W. D. Derbyshire, and J. F. Radavich. June 22, 1956 [11 p. incl. illus. tables, refs. (Proj. Squid technical rept. no. PUR-36-P) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under N6ori-10401, N7onr-39419, and [N6ori-10503]) AD 205692 Unclassified

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

Also published in Corrosion, v. 13: 597-607, Sept. 1957.

The formation of oxide films on simple chromium steels and 18-8 stainless steels oxidized in air at temperatures of 300° to 700°C has been studied by electron microscopy, electron diffraction and x-ray diffraction methods. A thin uniform film forms in the first few minutes of oxidation and grows very slowly thereafter. As oxidation proceeds the protectiveness of the base film fails at randomly distributed positions, permitting the rapid growth of localized polycrystalline nodules of oxide. These nodules continue to grow and new ones are formed until the base film is completely covered. The rate at which the process proceeds depends on alloy composition and temperature in the same way as does the scaling rate at higher temperatures. There is no evidence that the failure is due to cracking of the base film. There seems to be no deterimental effect produced by the usual amounts of minor constituents in the alloys. Local failure may be due to blistering or recrystallization. The principal component of the base film is a solid solution of ferric and chromic oxides preferentially oriented with the (111) plane parallel to the surface. The degree of the orientation and the chromic oxide content of the solution increase with time of oxidation. A small amount of spinel may be present also. In the case of the 18 Cr-8 Ni alloy the spinel contains some Ni. The nodules are principally Fe_2O_3 or a low chrome ferric-chromic oxide solution and contain somewhat more spinel than does the base film. (Contractor's abstract)

BEHAVIOR OF LIQUID HYDROCARBONS WITH WHITE FUMING NITRIC ACID, by C. H. Trent and M. J. Zucrow. Feb. 26, 1952 [7]p. incl. illus. tables. refs. [Proj. Squid technical rept. no. PUR-18-P; technical rept. no. 43] (Sponsored jointly by Office of Naval Research and [Air Force] Office of Scientific Research under N6ori-10503) AD 9093 Unclassified

Also published in Indus. Engineering Chem., v. 44: 2668-2673, Nov. 1952.

A problem often encountered in the development of liquid bipropellant rocket engines is that of reliably igniting propellants that are not spontaneously inflammable upon contact. One fuel currently specified for certain types of rocket engines is a hydrocarbon fuel endowed with physical properties common to both gasoline and kerosene. That fuel is not spontaneously inflammable with either liquid oxygen or white fuming nitric acid, and presents the problem of igniting these propellant combinations in the rocket motor. The lack of knowledge of the ignition behavior of hydrocarbon fuels when

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

oxidized by white fuming nitric acid provided the impetus behind an experimental study of the ignition behavior with white fuming nitric acid of a number of pure hydrocarbons reacted under conditions simulating those found in actual rocket motors. Twenty hydrocarbon compounds possessing different molecular structures were treated with anhydrous nitric acid and the relative rates of reaction (determined by measuring rates of temperature rise, during the liquid phase reaction), the maximum reaction temperatures produced, and the minimum ignition temperature were measured. The correlation among the time to reach maximum reaction temperature, the maximum reaction temperature produced, and the minimum ignition temperature indicates that the principal factors governing the minimum ignition temperature are the concentration and the thermal instability of the unstable intermediate products formed. The maximum reaction temperature produced is a factor in determining the quantity of additional energy necessary to initiate combustion. The present study indicates, that from the standpoint of ease of ignition, the presence of high concentrations of unsaturated hydrocarbons, especially diolefins, in hydrocarbon fuels is desirable, as these compounds react rapidly with white fuming nitric acid, produce high maximum temperatures, and require relatively low temperatures to initiate combustion. Highly aromatic hydrocarbon fuels may be undesirable. Despite their rapid reaction in the liquid phase, all the aromatic hydrocarbons tested exhibited high ignition temperatures. Also published in Jour. Amer. Rocket Soc., v. 22: 323-330, Nov.-Dec., 1952.

The performance and heat transfer rates for 500-lb thrust, L* = 100 in., rocket motors were determined experimentally as a function of mixture ratio at 300-, 500-, and 700-psia combustion pressures. In all cases the propellants used were white fuming nitric acid (WFNA) and jet engine fuel (JP-3). The maximum values of specific impulse were obtained at a mixture ratio of 4.5 and the values were 222, 235, and 246 for 300-, 500-, and 700-psia combustion pressure, respectively. Raising the combustion pressure from 300 psia to 700 psia increased the over-all heat transfer for the thrust cylinder from 1.3 to 2.3

EQUATIONS OF A SIMPLE FLAME SOLVED BY SUCESSIVE APPROXIMATIONS TO THE SOLUTION OF AN INTEGRAL EQUATION. PART I. FIRST ORDER REACTION, by G. Klein. June 9, 1954, 24p. incl. illus. tables. ([Proj. Squid technical rept. no. WIS-1-R, pt. 1]; WIS-ONR-8) (Also bound with its AD 64151, as part 1) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503 and N7onr-28511) AD 37302
Unclassified

The problem of idealized flame whose underlying chemical reaction is unimolecular, reversible, and of the first order, is reconsidered; the kinetic energy of the gas stream is neglected. The solution depends on the solution of an integral equation which contains an unknown parameter whose eigenvalue has to be determined. The equation is solved by a method of sucessive approximations.

WIS-1-R, pt. 2]; WIS-ONR-13) (Also bound with its AD 64151, as part 2) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503 and N7onr-28511) AD 46170
Unclassified

The problem of an idealized flame whose underlying chemical reaction is unimolecular and reversible (where the kinetic energy of the gas stream is neglected), which has been solved by integral equation method of successive approximations for a first reaction (Part I), is now extended to a second order reaction. The problem is very nearly equivalent to that of a simple chain reaction flame in which the catalyst reactions are assumed to be in equilibrium. In this case the behavior near the hot boundary of the functions involved is very different from that of the case of a first order reaction, and a careful choice of the integral equation and of the lowest approximation to be adopted has to be made. The diffusion coefficient is assumed constant: for a certain value of this constant

Princeton U. James Forrestal Research Center, N. J. (Project SQUID)

the problem simplifies considerably, and for other values an alternative perturbation and expansion method is proposed which involves only linear differential equations. It is verified that neglect of of the back reaction affects the method and results immaterially, and the effect of varying the hot boundary temperatures is briefly considered. A chain reaction flame of the type $A \rightleftharpoons B$, $AB \rightleftharpoons B + C$ is considered and its equations are solved by a generalization of the method employed in Parts I and II. The reaction rate of the second reaction is assumed of the form $R_c = \omega \left\{ x_A x_B F_{AB}^{(\tau)} - X_B X_C F_{BC}^{(\tau)} \right\}$ where ω is a parameter whose value is left open. It is assumed that the reaction rate of the first reaction, $R_B = X_A f_A^{(\tau)} - X_B f_B^{(\tau)}$ can be expanded in the form $R_B = \omega r(\tau;\omega) = \omega \left\{ r_0^{(\tau)} + \omega r_1^{(\tau)} + \omega^2 r_2^{(\tau)} + \dots \right\}$, a hypothesis which appears justified by the rapidity of the convergence obtained. For the standard value of the reduced diffusion constant ($\delta = 1$) the rate of production of B is negative near the cold boundary, showing that the component corresponding to a free radical of a real flame occurs in the low temperature region overwhelmingly by diffusion. The equations of a one-dimensional stationary flame $A \rightleftharpoons 2B$ and $A + B \rightleftharpoons B + C$ are solved by a perturbation method. The unperturbed equations are those of the reduced problem in which (1) the first reaction is in equilibrium, and (2) the diffusion constant, $\delta = \delta_{AB} = \delta_{AC} = \delta_{BC}$, has the special value unity; the reduced problem is solved by successive approximations to the solution of an integral equation. The results are qualitatively very similar to those of the $A \rightleftharpoons B$, $A + B \rightleftharpoons B + C$ problem already treated, (cf. Part III); in particular, one finds that the component B, corresponding to a free radical in a real flame, occurs in the cold temperature region overwhelmingly by diffusion, its rate of chemical production there being negative. DERIVATION OF THE FLAME EQUATIONS, THEIR TRANSFORMATION AND SUGGESTED METHOD OF THEIR SOLUTION, by G. Klein. Feb. 25, 1955, 92p. incl. illus. tables, refs. (Proj. Squid technical rept. no. WIS-2-R; rept. no. WIS-Squid-1) (Sponsored jointly by Office of Naval Research, [Air Force] Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 75715; AD 74926
Unclassified

The equations of a one-dimensional flame under stationary conditions are deduced from the general equations of a gas mixture, and their boundary conditions are discussed. These flame equations are transformed so as to make them amenable to solution by a perturbation method of successive approximations. They are divided into (a) two principal equations, formally analogous to the equations of a unimolecular reaction flame $A \rightleftharpoons B$, and (b) subsidiary equations containing the remaining physical relations. The core of the flame problem is then an ordinary, non-linear differential equation involving an eigenvalue parameter, and a method of its solution as an integral equation is given. It is suggested that the general flame equations should be solved by several stages of simplified problems (ideal flames). Earlier work on ideal flames, such as $A \rightleftharpoons 2B$, $A + B \rightleftharpoons B + C$, is reviewed, and the general formalism is illustrated by reference to the HBr flame.

Also published in Sixth Symposium (International) on Combustion, Yale U., New Haven, Conn. (Aug. 19-24, 1956), N. Y., Reinhold, 1957, p. 199-212.

Calculations are presented for the flame velocity and chemical profiles of a prototype chain-branching system with a second-order chain-breaking step: $2B \xrightarrow{k_1} A$ and $A + B \xrightarrow{k_2} 2B + C$. The constants which were used were chosen to reproduce some of the features of H-O combustion. The values of the assumed diffusion coefficients were varied greatly without appreciably affecting either the flame velocities or the chemical profiles. A criterion is presented for the deviation of the free-radical concentrations from their pseudo-steady-state values. Deviations from the pseudo steady state are explained in terms of a time lag in the formation and destruction of the free radicals with a diffusional effect which varies as the second derivative of the free-radical concentration with respect to the coordinate. The purely diffusional theories of flames are shown to be incorrect in 2 respects: (1) the free radicals actually diffuse away from the flame-holder in the hot part of the flame where most of the reactions occur, and (2) the flame velocity is almost independent of the coefficients of diffusion of the radicals. The ABC flame studied by Klein (rept. no. WIS-SQUID-1; item no. PRI. 11:202) was used as an example for the deviations from the pseudo steady state as a function of t_B/t_A. t_B and t_A are the relaxation times for free-radical formation and the over-all reaction, respectively.

A RELAXATION-TIME MODEL FOR FREE RADICAL CONCENTRATION, by J. C. Giddings. Aug. 1956, 18p. refs. (Proj. Squid technical rept. no. WIS-4-P) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 104499 Unclassified

A relaxation-time model was used for examining the accuracy of the quasi-equilibrium approximation in chemical kinetic studies. In the 2 general cases (time-lag and diffusion) which arise, the proposed model yields the same results as an approximate mathematical treatment. The kinetic processes in a flame front were examined and shown to involve the time-lag and diffusion cases. The model was justified by an independent approximate method. The model was examined in the region of the flame near the point of maximum reaction rate. A simple expression was found for the radical concentration at this point.

THE PROPERTIES OF FLAMES SUPPORTED BY CHAIN-BRANCHING REACTIONS, by J. C. Giddings and J. O. Hirschfelder. Nov. 1956, 14p. incl. illus. tables. (Proj. Squid technical rept. no. WIS-5-P; WIS-Squid-7) (Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research under N6ori-10503) AD 112175; AD 109592 Unclassified

Presented at Ninth International Congress of Appl. Mech., Brussels (Belgium), Sept. 5-13, 1956.

A Semenoff-type kinetic scheme in which the chain-breaking step is first order in radical concentration (FOB) is compared with a non-Semenoff scheme with second-order chain breaking (SOB). Both reaction schemes have 3 components: a reactant (A), an intermediate free radical (B), and a product (C). In contradiction to diffusion theories of flame-propagation, data showed that a large increase in radical diffusion coefficient resulted in a slight decrease in flame velocity. For the FOB Semenoff kinetic scheme, an explosion limit exists at the point at which the rate of branching, k_3AB, equals the chain-breaking rate k_2B. Beyond this point, the rate of production of radicals becomes greater than their rate of destruction. The radical increases until the A disappears. The rate of heat release is so large that it can be considered an explosion. Numerical calculations were made on flames supported by the FOB Semenoff type sequence. Attainment of the explosion point at which the radical concentration and reaction rate go to infinity depends for a particular flame on the assumed reaction rates. The Klein Method (item no. PRI. 11:023) was used for solving the flame equations for 5 cases. The deviation of the actual concentration of B from the pseudostationary concentration $(B)^*$ is measured by ϵ, where $B = (1 + \epsilon)(B)^*$. A procedure is given for making a preliminary estimation of ϵ in the reaction zone which is very accurate. The estimation of ϵ was useful in selecting the flame parameters, since the Klein method of integration does not converge if ϵ is greater than about 0.4.

HIGH SPEED AERODYNAMICS AND JET PROPULSION. VOLUME VI. GENERAL THEORY OF HIGH SPEED AERODYNAMICS, ed. by W. R. Sears. N. J., Princeton University Press, 1954, 758p. incl. illus. diagrs. tables, refs. ([Sponsored jointly by Office of Naval Research, Air Force Office of Scientific Research, and Office of Ordnance Research] under Nonr-03201) Unclassified

This volume summarizes present-day knowledge in the theory of high speed aerodynamics. It begins with an over-all sketch of the subject by T. von Kármán. Largely nonmathematical, this section touches on the major features of subsonic, transonic, and supersonic, and hypersonic flows and emphasizes both important recent developments and some problems still unsolved. K. O. Friedrichs presents a new study of the mathematical nature of hyperbolic flows, i.e. supersonic or unsteady compressible flows. Following these introductory sections, attention is directed especially toward the theories based on the small disturbance hypothesis. W. R. Sears presents and summarizes subsonic small perturbation theory, with emphasis on recent studies that unify and clarify this subject, and on rotational and unsteady flows. M. A. Heaslet and H. Lomax present in a unified manner the whole subject of linearized supersonic theory, especially with application to wings. Also included in this section are the transonic and hypersonic nonlinear approximations. M. J. Lighthill discusses the methods of higher approximation which are used to improve the first order theories and to explain and eliminate their shortcomings. Y. H. Kuo and W. R. Sears collaborate in a section presenting a review of the theory of potential subsonic and mixed supersonic-subsonic plane flows based on the hodograph method. Finally in two sections, A. Ferri writes on the method of characteristics applied to steady two- and three-dimensional flows and flow patterns characterized by the presence of shock waves, including Ferri's recent work on the linearized methods of characteristics.

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF A TWO-DIMENSIONAL ALL-SUPERSONIC DIFFUSING CASCADE AT MACH NUMBER 2.5, by E. Bedsr. June 1, 1955, 1v. tncl. tllus. dtagrs. tables, refs. (Rept. no. R-155) (AFOSR-TN-56-15) (AF 18(600)1143) AD 81780 Unclassifted

An all-supersonic 2-dimensional diffusing cascade was destgned for M = 2.5 and a slatic pressure ratio of 3.5:1. The tnlet flow angle from the cascade normal was 45°. Ths toial Mach number relative to ths blades remained supersonic, bui tts normal component was diffused from supersonic to subsonic (theoretically wtthoui the usual slrong transition shocks). Flow solutions were calcutated theoretically by the method of charactertstics. A 2-bladed model of the cascade, with an aspect ratio of 1.0 and a chord of t.625 tn., was tesied in a wind tunnel at M = 2.5 and Re/tn. ≈ 400,000. As an aid in investigating flow starting, breakdown, and changes in the slructure of slarted flows, (pressure gradients, throat location, etc.), the model design permitted adjustability (durtng running) of the following geometrical features: solidtty, inlet flow angle, back pressure, and discharge-flow passage angle. Blade surface slatic pressures, Schlieren photographs, and pitot-pressure surveys were taken. Qualitative effects of sidewall boundary-tayer bleed were investigated. Theoretical and experimental

results were compared for starting throat capture area ratios, and surface static pressures and waves of started flows.

THE STREAMSURFACE CHARACTERISTICS METHOD FOR SUPERSONIC FLOW, WITH APPLICATION TO SUPERSONIC COMPRESSORS, by H. G. Loos. May 1956, 93p. incl. diagrs. (Rept. no. R-207) (AFOSR-TN-56-367) (AF 18(600)1143) AD 95803 Unclassified

The characteristics method was developed for the analysis of supersonic flows along a curved surface S of general but given shape and with a given dtstance A to an inftnitesimally adjacent streamsurface. The resulting compatibility equations have a simple form and from them the equations for all possible applications of the 2-dimensional charactertstics method to the analysis of tsentropic supersonic flows can be derived. Application to the axisymmetric approximation of the supersonic flow through a compressor rotor is estimated to give a 30% labor saving, compared with an earlier method. A simple semigraphtcal method is suggested that can be used when S is developable tn a plane and no body forces are present. (Contractor's abstract)

B-SETS AND FINE CYCLIC ELEMENTS, by C. J. Neugebauer. July 1956, 38p. (Technical note no. 4) (AFOSR-TN-56-356) (AF 18(600)1484) AD 95442 Unclassified

A decomposition of proper cyclic elements for certain surfaces is reanalyzed by generalizing the concept of a set being cyclic. The analysis is with reference to Peano spaces P in which a proper cyclic element is a cyclic A-set, a closed set A of P with the property that each component of P-A has only a single frontier point. This concept is generalized to that of a continuum B of P such that the frontier of each component of P-B decomposes into a finite number of points. Such sets are called B-sets, and a fine cyclic element is defined as a B-set which remains connected after the removal of a finite set of points. Since a B-set need not be a Peano space, only Peano spaces are considered whose degree of multicoherence ts finite.

NON DEGENERATE SURFACES OF FINITE TOPOLOGICAL TYPE, by W. H. Fleming. July 1956, 6p. (Technical note no. 5) (AFOSR-TN-56-357) (AF 18(600)1484) AD 95443 Unclassified

A direct generalization is given of Morrey's theorem to surfaces of the topological type of any compact connected 2-manifold, orientable or not, with or without boundary. The main theorem states that every nondegenerate Fréchet surface of any finite topological type τ with finite Lebesque area has a quasi-conformal representation T(w). The domain of T(w) may be taken as a certain normalized parallel slit domain. T(w) ts defined as a continuous mapping from A (a compact, connected 2-manifold) tnto euclidean N-space E_N ($N \geq 3$). A surface S is called nondegenerate (of topological type τ) if S has a representation (T, A) such that for every $g \in \Gamma(T, A)$: (1) no boundary γ_t of A is contained tn g, or A ts not contained tn g when A ts closed; (2) $g \cap \gamma_t$ ts nonempty for at most one value of t; (3) g does not separate A; and (4) an open set $G \supset g$ exists such that any relatively closed curve ζ situated tn G separates A.

ON SURFACES OF THE TYPE ν, by L. Cesari. Apr.

PRF.01:006 - PRF.02:003

1956, 76p. incl. diagrs. refs. (Technical note no. 3) (AFOSR-TN-56-358) (AF 18(600)1484) AD 95444 Unclassified

The tools introduced by Cesari in his book (Surface Area, Princeton Univ. Press, 1956) are developed. The concept of retraction is discussed for continuous mappings S = (T, A) from a finitely connected Jordan region A = J, mappings, or surfaces of the ν-type with ν the connectivity of J, $0 \leq \nu < \infty$. For certain simple elements of a Jordan region of type $\nu \geq 1$, a concept of fine cyclic element σ of the surface S = (T, A) is introduced as a retraction. The concept and properties of these fine-cyclic elements are discussed in great detail

FINE-CYCLIC ELEMENTS OF SURFACES OF THE TYPE ν, by L. Cesari. [1956] 39p. incl. refs. [AF 18(600)1484] Unclassified

Published in Riv. Matem. Univ. Parma, v. 7: 149-185, 1956.

Let T be a single valued continuous mapping from a closed finitely connected Jordan region J in two-space into n-space. Denote by Γ the class of all the disjoint maximal continua of constancy for T in J. A continuum K in J is said to have property P_1 with respect to (T, J) if for every component ν of J−K the mapping T is constant on each component of the boundary of ν in J. A continuum K in J is said to have property P_2 with respect to (T, J) if for every component ν of J−K the common part of γ and its boundary is either empty or a subset of exactly one of the curves bounding J. A continuum K in J is said to have property P' with respect to (T, J) if every element of Γ which intersects K is a subset of K. A non-empty continuum K in J is defined to be a fine cyclic element of (T, J) if (1) K has both properties P_1 and P'; (2) T is not constant on K; (3) K is minimal with respect to properties (1) and (2). For each point w_0 in J let Ω denote the set of all points w in J for each of which there does not exist a finite subset of Γ whose union separates w_0 from w in J. It is shown that either Ω is the element of Γ containing w_0 or there are fine cyclic elements of (T, J) containing w_0 and Ω is the union of all such. It is proved that the class of fine cyclic elements of (T, J) is countable. Each fine cyclic element K_i of (T, J) is contained in a finitely connected closed Jordan region J_i contained in J and such that K_i has properties P_1, P_2, P' with respect to (T, J_i). The mapping T_i defined on J_i by the requirements that it agree with T on K_i, and map each component of $J_i - K_i$ onto the point onto which T maps the boundary of that component relative to J_i, is termed the retraction of (T, J) with respect to K_i in J_i. It is shown that the Lebesgue area $L(T_i, J_i)$ of the surface represented by (T_i, J_i) is independent of the choice of the region J_i subject to the conditions described above. If L(T, J) denotes the Lebesgue area of the surface represented by (T, J) it is proved that $L(T, J) = \sum L(T_i, J_i)$. (Math. Rev. abstract)

COMMUTATORS AND ABSOLUTELY CONTINUOUS OPERATORS, by C. R. Putnam. July 1957, 17p. refs. [Technical note no. 1] (AFOSR-TN-56-457) (AF 18(603)139) AD 97073 Unclassified

Also published in Trans. Amer. Math. Soc., v. 87: 513-525, Mar. 1958.

Two parts form the paper on commutators and absolutely continuous operators; Part I has five general theorems on commutators C and the associated sets W_C, while Part II will be devoted to applications of some of these results, in particular to Toeplitz, Hankel, and Jacobi, with three additional theorems. The methods of C. R. Putnam (Proc. Amer. Math. Soc., v. 7: 1026-1030, 1956) used with operators which are bounded linear transformations on a Hilbert space consisting of elements x, give the results.

ON SQUARE ROOTS OF NORMAL OPERATORS, by C. R. Putnam. July 1957 [3]p. (Technical note no. 2) (AFOSR-TN-56-479) (AF 18(603)139) AD 97363 Unclassified

Also published in Proc. Amer. Math. Soc., v. 8: 768-769, Aug. 1957.

The closed, convex set $W = W_A$ is investigated such that a criterion is found guaranteeing that the square root A of the normal operator N is normal due to the closure of the set of values (Ax, x) where $||x|| = 1$. It is proved that when N is a fixed normal operator and A an arbitrary solution of $A^2 = N$, if a line L exists in the complex plane passing through the origin and lying entirely on one side of (and all, or partly, in) the set W_A, then A is normal.

A NOTE ON FINITE MATRICES, by C. R. Putnam. [1956] 3p. (AFOSR-TN-56-480) (AF 18(603)139) AD 97364 Unclassified

It is shown that the number 0 is interior to the set W, a convex set consisting of values (Cx, x) where C = AB-BA from finite m x n matrices A and B and x, a complex-valued, n component vector of length 1, in the following senses. Either W consists of 0 alone or, if W is a segment or a two-dimensional set, 0 is in W, but is not a boundary point. The proof is independent of the trace arrangement and is valid in the case in which all the diagonal elements of C are zero

ON THE STRUCTURE OF THE RHENIDE ION, by J. W. Cobble. July 26, 1956, 10p. incl. diagr. refs. (AFOSR-TN-56-348) (AF 18(600)1525) AD 95434 Unclassified

Also published in Jour. Phys. Chem., v. 61: 727-729, June 1957.

In this study, the thermodynamic factors controlling the stability of the rhenide ion are examined. It is concluded that the structure of the aqueous ion is not simple, consisting rather of some type of an oxygenated complex such as $H_8ReO_4^-$. The instability of a hypothetical simple Re^- ion based essentially through analysis of the Born cycle, upon a high sublimation energy for Re metal which cannot be compensated by a reasonable electron affinity. The expectation is that solid rhenides must be "hydrated" to be stable. Other ions of this general type are also examined, and it is considered that, $W(H_2O)_4^=$ likely would not be stable while $Ta(H_2O)_8^-$ and $Tc(H_2O)_4^-$ might be. THERMODYNAMIC PROPERTIES OF TECHNETIUM AND RHENIUM COMPOUNDS. VI. THE POTENTIAL OF THE ReO_3/ReO_4^- ELECTRODE AND THE THERMODYNAMICS OF RHENIUM TRIOXIDE, by J. P. King and J. W. Cobble. July 20, 1956, 15p. incl. diagr. tables, refs. (AFOSR-TN-56-349) (AF 18(600)-1525) AD 95435 Unclassified

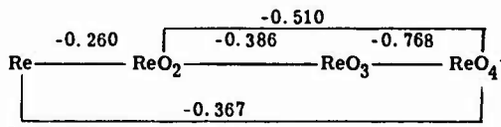
Also published in Jour. Amer. Chem. Soc., v. 79: 1559-1563, Apr. 5, 1957.

The potential of the ReO_3/ReO_4^- electrode was measured over a wide range of concentration and pH and the standard electrode potential for the half reaction $ReO_3 + H_2O = ReO_4^- + 2H^+ + e^-$ was found to be -0.768 ± 0.005 v. The cell was demonstrated to be satisfactorily reversible by close agreement of the standard potential calculated from measurements in both acidic and basic solutions, as well as from the reasonable entropy values obtained from a determination of the temperature coefficient. The thermodynamic functions for ReO_3 (c) were found to be -146.1 ± 0.8 kcal mol^{-1}, -128.1 ± 0.8 kcal mol^{-1} and 19.3 ± 2.5 cal mol^{-1} deg^{-1} for the heat of formation, free energy of formation, and the entropy, respectively. The revised potential diagram for Re in acid solutions becomes:



In speculation on the stability of the rhenate ion $ReO_4^=$ in aqueous media, it was considered feasible to prepare moderate concentrations of the rhenate ion and study the $ReO_4^=/ReO_4^-$ potential directly. The technitate ion $TcO_4^=$ was expected to be sufficiently stable in basic media and very dilute acids to allow cell measurements. (Contractor's abstract, modified)

VECTORIAL CHARGE DISPLACEMENT, by D. C. Peaslee. Oct. 5, 1956, 10p. (AFOSR-TN-56-212) (AF 18(600)1579) AD 87526 Unclassified

Also published in Nuovo Cimento, Series X, v. 4: 1583-1584, Dec. 1956.

The consequences are examined of recognizing an extreme symmetry between the nucleon and cascade (Ξ) particle. The simplest formalism for expressing this symmetry is to take the charge displacement number $a = q - 1_z$ for heavy particles as the z-component of a second, independent vector $\underline{A}$ in charge space. This scheme makes evident the possibility of 2 independent charge conjugation operators C and C' for heavy particles; it also has suggestive applications to the θ_1, θ_2 scheme and the π-e decay problem. Experimental tests for vectorial $\underline{A}$ appear remote. (Contractor's abstract)

COMPOUND MODEL FOR V-PARTICLES, by R. W. King and D. C. Peaslee. Oct. 24, 1956, 15p. refs. (AFOSR-TN-56-326) (AF 18(600)1579) AD 95202 Unclassified

Also published in Phys. Rev., v. 106: 360-363, Apr. 15, 1957.

A static model is considered in which all heavy particles are compounded out of 2 basic units, taken here to be the Λ and nucleon N (and/or the cascade particle Ξ). The model suggests the existence of some unstable particle states accessible to experiment: the ρ meson, a boson with I = 0; the Λ^{**}, a highly excited I = 0 state of the Λ; the Z hyperon unstable against rapid decay by $Z \rightarrow K + N$. Without artificial assumption the model directly indicates that in the present strangeness classification no metastable V-particles exist beyond those already known. The model is compatible with and somewhat favors the assumption of a high degree of symmetry between N and Ξ. Its general tenor is thus to emphasize the charge displacement $a = q - I_z$ as a physically significant parameter rather than the strangeness S. An inescapable implication of the model is that all heavy particles have comparable interaction strengths, apparent exceptions being possible over limited energy ranges. The model provides a vehicle for study of the parity doublet scheme, which introduces greater complication in return for an added flexibility at present unnecessary in the model. ANTISYMMETRIZATION AND E_1 SUM RULES, by D. C. Peaslee. Dec. 5, 1956 [8]p. (AFOSR-TN-56-587a) (AF 18(600)1579) AD 115012 Unclassified

A schematic method of taking nucleon correlations in the ground state into account is given E_1 sum rules without knowing fine features of nuclear matter. The phenomenological treatment is made with constants, fitted to experiment, which are consistent with the exchange term for Coulomb energies of light nuclei. Subunits are not introduced. The procedure is outlined for the harmonic sum σ_H and applied to the exchange terms in the direct E_1 sum $\sigma_D = \int \sigma dW$, which leads to the result.

ISOTOPIC SPIN IN E_1 SUM RULES, by D. C. Peaslee. Nov. 23, 1956 [5]p. (AFOSR-TN-56-588) (AF 18-(600)1579) AD 115013 Unclassified

The electric dipole (E_1) sum rules for the ground states of light nuclei isotopic spin $T = T_0$ and elevated $T = T_0 + 1$ are obtained separately by inserting a suitable projection operator. To the first order effect, all sum rules show: $\sigma(T_0)/\sigma(T_0 + 1) \approx T_0$, with T_0 the ground state isotopic spin. The experimental implications of this result are discussed.

QUESTION OF VECTORIAL STRANGENESS (Abstract), by D. C. Peaslee. [1956] [1]p. [AF 18(600)1579] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 209, Apr. 26, 1956.

It is not clear from present experiment or theory whether the V-particle strangeness number a should be viewed as a scalar or as the z-component of another vector like t. Direct observations bearing on this question appear difficult: e.g., the decay possibility $\Xi^- \rightarrow \beta^- + \nu + n$, reactions like $K^- + n \rightarrow \Xi^- + K^+$, proof of τ^0 nonexistence. The assumption of vectorial a, whether realistic or not, appears formally convenient in some cases.

ON ISOTROPIC SPIN OF ANTIPARTICLES (Abstract), by M. Sugawara. [1956] [1]p. [AF 18(600)1579] Unclassified

Presented at meeting of the Amer. Phys. Soc., New Haven, Conn., June 21-23, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 304, June 21, 1956.

J. V. Lepore has argued that protons and antiprotons (or neutrons and antineutrons) should be assigned the same eigenvalues of τ_3, isotropic spin operator describing nucleons, by requiring that a theory involving nucleons, mesons, and electromagnetic field should be invariant under charge conjugation. The present note states that, although his approach is quite correct, his interpretation is not entirely satisfactory, since it rests on one-particle Dirac theory. We should correctly base ourselves on field theory and calculate the eigenvalue of the total isotropic spin operator $\int \psi^* \tau_3 \psi dv$ of the nucleon field in a one-antinucleon state. Such considerations have already been given; they showed that protons and antineutrons have the same eigenvalue, which is opposite to that of neutrons and antiprotons, without arbitrariness in these assignments.

AN EXTENSION OF THE THEORY OF THE OPTIMUM BURNING PROGRAM FOR THE LEVEL FLIGHT OF A ROCKET-POWERED AIRCRAFT, by A. Miele. June 1956 [61] p. incl diagrs. (Rept. no. A-56-1) (AFOSR-TN-56-302) (AF 18(603)69) AD 90015 Unclassified

Also published tn Jour. Aeronaut. Sciences, v. 24: 874-884, Dec. 1957.

The burning program for the horizontal flight of a rocket-powdered aircrafi is analyzed matheinatically. The results of previous theories are extended to cover the general problem of minimizing an arbitrary function of the final values of time, mass, dtstance, and velocity. By using the indirect methods of the calculus of variations, ii is shown that the toiality of extremal arcs is composed of zero thrust subarcs, subarcs to be flown with maximum engine output and variable thrust subarcs. For the latter, a closed solution is obtained. Particular problems, such as maxtmum range, maximum endurance, minimum propellant consumption, and maximum velocity increase, are treated within the general frame of the present theory for various types of boundary conditions. Detailed attention is devoted to the thrust programming which maximizes the range for the case where the over-all flying time is prescribed. A method for constructing extremal paths is supplied under the assumption of a parabolic drag polar having either constant coefficients or coefficients depending on the Mach number. By a suitable choice of the burning technique, the over-all time can be considerably decreased with respect to the time associated with the solution of maximum absolute range. Numerical examples show that up to 25% savings in time can be achieved with a penalty of less than 5% in range. An important difficulty associated with the linear aspect of the present problem is constituted by the fact that the Legendre-Clebsch condition fails to yield any information on the minimum or maximum character of the Eulerian paths. Moreover, the Weierstrassian function is zero at all points of the variable thrust subarc. These difficulties are overcome with a generalization of a previous method of the same author, based on the use of Green's theorem. In appendixes, a method is presented for computing the distribution of the Lagrange multipliers λ_1 and λ_3 along the constant thrust subarcs of the Eulerian solution; and an application is demonstrated of the method in the analysis of the continuity conditions due to Erdmann and Weierstrass. NEW DEVELOPMENTS IN THE CHEMISTRY OF DIBORANE AND THE BOROHYDRIDES. I. GENERAL SUMMARY, by H. I. Schlesinger, H. C. Brown and others. [1953] [5] p. incl. refs. (Sponsored jointly by National Defense Research Committee, Signal Corps, Office of Naval Research, and [Air Force Office of Scientific Research under AF 18(600)310] Unclassified

Published in Jour. Amer. Chem. Soc., v. 75: 186-190, Jan. 5, 1953.

New developments are described regarding methods of preparation and the chemistry of diborane and the borohydrides. New and practical methods for the preparation of borohydrides (a) from diborane, and (b) without the use of diborane are discussed. As a result of the availability of borohydrides, prepared without the use of diborane, methods, far more satisfactory than those hitherto known for the preparation of the latter, have been developed. The investigation has led to the preparation of the hitherto unknown borohydrides of sodium, of potassium and of uranium, and some of their derivatives, as well as of a new type of substance, such as sodium trimethoxyborohydride, $NaBH(OCH_3)_3$, formed by the addition of compounds of trivalent boron to alkali metal hydrides. Sodium borohydride, as well as sodium trimethoxyborohydride, are of special interest because of their potential usefulness as reducing agents and sources for the generation of hydrogen; uranium (IV) borohydride and its derivatives are of interest because they are the most volatile compounds of uranium except the hexafluoride. A number of recent observations made are surveyed, and the subject matter is organized in the light of the application of the Lewis generalized acid-base concept to the reactions of diborane, of the salt-like hydrides and of the borohydrides. AD 50673 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 6269-6280, Dec. 5, 1955.

A study of the reaction of $AgNO_2$ with alkyl halides showed that it proceeds via a transition state which has S_N1 and S_N2 character in proportions that vary gradually with the structure of the halide. The reaction products reflect this variation in character; the greater the carbonium contribution to the transition state, the greater is the yield of nitrite ester and smaller is the yield of nitroparaffin. The reason for the divergent reactions of Ag and alkali metal salts with alkyl halides was established. The electrophilic attack of Ag on the halogen of the alkyl halide greatly enhanced the carbonium contribution to the transition state. This resulted in a preference for covalency formation to the most electronegative atom of the anion. The nature of the transition state was affected by changes in the reaction medium and in the structure of the alkylating agent. The generalization was made that the greater the S_N1 character of the transition state, the greater is the preference for covalency formation with the atom of the highest electronegativity, and conversely, the greater the S_N2 contribution, the greater the preference for bond formation to the atom of lowest electronegativity.

THE REACTION OF SILVER NITRITE WITH α-HALOESTERS, by N. Kornblum, M. E. Chalmers, and R. Daniels. Aug. 12, 1955 [1]p. incl. tables. (Paper no. 10) [AFOSR-TN-55-101] (AF 18(600)310)
AD 101760 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 6654-6655, Dec. 20, 1955.

A study has been made of the reaction of silver nitrite with α-haloesters to determine its usefulness for the preparation of α-nitroesters, and also to test the mechanism proposed for the reaction of silver nitrite with organic halides. It is pointed out that the reaction of α-bromoesters with silver nitrite is extremely slow, e.g., after 6.5 days at room temperature ethyl bromoacetate and ethyl-α-bromopropionate had only reacted to the extent of 12-15%. In contrast, the reaction of α-iodoesters proceeds to completion in several days, giving yields of the pure α-nitroesters of 75-84%. The theoretical implications of these facts are discussed briefly, the reaction of silver nitrite with organic halides being described as a "pull-push" process involving the development of an electron deficiency at the carbon atom undergoing substitution.

A NEW REACTION OF α-NITROESTERS, by N. Kornblum and J. H. Eicher. Apr. 1956 [4]p. incl. table, refs. ([AF]OSR-TN-55-240) (AF 18(600)310)
AD 101757 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 1494-1497, Apr. 5, 1956.

α-Nitroesters react with a solution of sodium nitrite in aqueous ethanol at room temperature, giving α-oximinoesters in 70-78% yields. Ethyl nitroacetate reacts vigorously to give a mixture of nitrous oxide, nitrogen, and carbon dioxide. If the α-nitroester does not have a hydrogen atom on the carbon holding the nitro group, it is quantitatively recovered. The mechanism of this new reaction is discussed. (Contractor's abstract)

ETHYL α-NITROBUTYRATE, by N. Kornblum and R. K. Blackwood. [1955] [3]p. [AFOSR-TN-55-379] (AF 18(600)310) Unclassified

Published in Org. Syntheses, v. 37: 44-46, 1957.

A procedure is described for preparing ethyl α-nitrobutyrate (I). Ethyl α-bromobutyrate is poured into a mixture of N, N-dimethylformamide (DMF), sodium nitrate, and anhydrous phloroglucinol, reacting as follows: $CH_3CH_2\underset{\underset{Br}{|}}{C}HCO_2C_2H_5 + NaNO_2 \xrightarrow[\text{Phloroglucinol}]{DMF}$

$CH_3CH_2\underset{\underset{NO_2}{|}}{C}HCO_2C_2H_5$(l) + NaBr. The reaction gives a 68-75% yield of colorless (I), having a bp of 71°C/1 mm and an n_D^{20} 1.4233. It is pointed out that (I) may also be prepared in 75% yield by the reaction of silver nitrite with ethyl α-iodobutyrate (Jour. Amer. Chem. Soc., v. 77: 6654, 1955). An 18% yield has been obtained by nitration and subsequent decarboxylation of diethyl ethylmalonate (Eicher, Thesis. Purdue U., 1950). The present method offers the advantage of a direct preparation using sodium nitrate.

THE REACTION OF ALIPHATIC NITRO COMPOUNDS WITH NITRITE ESTERS, by N. Kornblum, R. K. Blackwood, and D. D. Mooberry. Apr. 1956 [4]p. incl. tables, refs. ([AF]OSR-TN-55-446) (AF 18-(600)310) AD 101753 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 1501-1504, Apr. 5, 1956.

Although primary nitroparaffins, secondary nitroparaffins, and α-nitroesters are inert toward nitrite esters, the joint action of a nitrite ester and sodium destroys the nitro compound. Primary nitro compounds give the carboxylic acid, secondary nitroparaffins yield ketones and α-nitroesters are converted to α-oximinoesters. The course of these reactions is described. A NEW METHOD FOR THE SYNTHESIS OF ALIPHATIC NITRO COMPOUNDS, by N. Kornblum, H. O. Larson and others. [1955] [1]p. [AF 18(600)310] Unclassified

Published in Chem. and Indus. (London), v. 16: 443, Apr. 16, 1955.

The reactions employing 1- and 2-bromo-octane were found to be first order in halide and first order in nitrite ion. Clearly this is an S_N2 process. Consequently, it is not surprising that tertiary halides and cycloheryl halides, instead of giving nitro compounds, yield olefins.

Reaction of halides with sodium nitrite

Halide	Reaction time (hr)	Yield (%) Nitro compound	Alkyl nitrite
1-Bromo-octane	3	60	29
1-Iodoheptane	1	61	31
1-Iodo-3-phenylpropane	1	59	26
Benzyl bromide	5[a]	52	35
2-Bromo-octane	45[b]	58	c
2-Iodo-octane	4	60	28
cyclo Pentyl iodide	5[b]	55	–
Ethyl 2-bromopropionate	4[b,d]	63	–
Ethyl 2-bromocaproate	6[b,d]	64	–

([a]This experiment was carried out at −30° to −15°; all others at room temperature. [b] Anhydrous phloroglucinol, equimolar with the halide, is added initially. [c]Octan-2-ol isolated in 38% yield. [d]Urea not present.) The following preparation of 2-nitro-octane typifies the general procedure: 2-Iodo-octane (72 g) was added rapidly to dry sodium nitrite (36 g) and urea (40 g) in dry DMF (600 ml). After stirring for four hours at room temperature the mixture was poured into ice-water (1.5 l), extracted with light petroleum (b.p. 35–37°), dried and rectified. This gave 13.0 g (28% yield) of 2-octyl nitrite, b.p. 41-42°/6 mm, which, after a small interfraction, was followed by 28.4 g (60% yield) of pure 2-nitro-octane, b.p. 60°/1 mm, n_D^{20} 1.4280.

THE REACTION OF NITRIC OXIDE WITH 2-OCTANE, by N. Kornblum and E. P. Oliveto. [1955] [2]p. (AF 18(600)310) Unclassified

Published in Jour. Amer. Chem. Soc., v. 77: 5173-5175, Oct. 5, 1955.

After eight days at 100° 2-octanol did not react appreciably with nitric oxide. A mixture of 2-octanol and 2-octanone, heated together at 100° for a week (under nitrogen) also remained essentially unchanged. In contrast when 2-octanone was heated to 100° in the presence of nitric oxide (in the absence of light) 60% of the ketone reacted in eight days to give a number of products. Although acetic and heptanoic acids were isolated, neither formic acid nor caproic acid could be detected. And while capronitrile ($C_5H_{11}CN$) is present, acetonitrile could not be found. A substantial amount of a nitrogen-containing tar, not volatile with steam, was also obtained. The nitric oxide which reacted was converted to nitrous oxide and nitrogen; in addition, water and hydrogen cyanide were found.

PRODUCTS FORMED IN THE REACTION BETWEEN NITRIC OXIDE AND 2-OCTANONE

	grams	mmoles
original amounts of ketone	14.6	114
ketone reacting	8.6	67
heptanoic acid produced	1.0	7.7
acetic acid produced	1.2	19.6
capronitrile produced	ca 1.8	ca 18
nitrous oxide produced	1.5	33
nitrogen	3.1	110

THE INTERACTION OF ALKYL HALIDES WITH DIMETHYLFORMAMIDE, by N. Kornblum and R. K. Blackwood. [Oct. 21, 1955] 7p. incl. diagrs. tables. [AFOSR-TN-56-65] (AF 18(600)310) AD 81057 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 78: 4037-4039, Aug. 20, 1956.

Solutions of alkyl halides in dimethylformamide (DMF) undergo dehydrohalogenation and salt formation on standing at room temperature (25°-30°C). Results of the interaction of the following alkyl halides with DMF are presented:

Halide	Concentration (mol/l)	Reaction (% complete)
methyl iodide	0.2	10%, 12 days
1-iodobutane	0.100	41%, 17 days
2-iodobutane	0.100	69%, 19 days
benzyl bromide	0.2	10%, 19 days
1-bromooctane	0.200	64%, 324 days
2-methyl-1-bromo-propane	0.200	25%, 280 days
2-bromooctane	0.200	79%, 304 days
t-butyl bromide	0.100	75%, 7 days

The kinetics of the reaction of 3 of the above compounds in DMF solutions 1-iodobutane, 2-iodobutane, and t-butyl bromide, were studied, and the data obtained are presented in tables.

ULTRAVIOLET ABSORPTION SPECTRA OF NITROPARAFFINS, ALKYL NITRATES AND ALKYL NITRITES, by H. E. Ungnade and R. A. Smiley. [June 1956] 14p. incl. diagrs. tables, refs. [Technical note no. 18] (AFOSR-TN-56-252) (AF 18(600)310) AD 88972 Unclassified

Also published in Jour. Org. Chem., v. 21: 993-996, Sept. 1956.

In this study, UV absorption spectra have been determined for a series of nitroparaffins, alkyl nitrates, and alkyl nitrites. The spectra for the nitro compounds and alkyl nitrates were obtained in 95% ethanol, while those for the alkyl nitrites were obtained in anhydrous ether to avoid ester interchange reactions with alcohol. The measurements were made in 1-cm cells at 25°C with a Cary recording spectrophotometer, the data being presented in tables. The relationship between structure and absorption structure is discussed. It is concluded that since the UV spectra of the compounds studied differ sufficiently, they can be utilized in identifying these compounds.

PRECISION MEASURING METALLURGICAL MICROSCOPE, by A. G. Guy and A. S. Yue. Dec. 12, 1955 [3]p. incl. illus. (Rept. no. PRF-3) ([AF]-OSR-TN-56-34) (AF 18(600)1463; continuation of AF 18(600)310) AD 80545 Unclassified

Also published in Rev. Scient. Instruments, v. 27: 239-240, Apr. 1956.

A description and an illustration of this instrument are given. It incorporates the precision-measuring aspect of the Cooke nuclear research microscope no. M4005. The framework of the microscope is made up of a 1.5-by 2.5-in. brass post mounted on a 1-in. thick brass base plate, which is supported on 3 legs. The stage is a Cooke no. [M]4005 ball-bearing micrometer stage with hardened ways. It has a travel of 25 mm and a unit reading of 0.005 mm on the micrometers, allowing estimations to be made to the nearest 0.0005 mm. The microscope body is Baush and Lomb no. 31-29-03-01 with vertical illuminator no. 31-24-90-11. The eyepiece is fitted with a micrometer disc, ruled with 1 horizontal cross hair, and 2 vertical cross hairs between which the point to be measured is centered. A 20 x eyepiece and a 50 x, 0.85 N.A. objective were used in test readings made on a glass slide ruled with 2 lines separated by 0.2500 in. No blacklash was found in the micrometers. The separation distance was duplicated to ± 0.0005 mm.

APPROXIMATE METHOD FOR CALCULATIONS USING CONCENTRATION-DEPENDENT DIFFUSION COEFFICIENTS, by A. G. Guy, M. Golomb, and incl. diagrs. tables. (PRF rept. no. 4) (AFOSR-TN-56-194) (AF 18(600)1463) AD 87067 Unclassified

Presented at meeting of the National Metal Congress, Chicago, Ill., Nov. 1957.

Also published in Jour. Metals, v. 9: 1204-1206, Oct. 1957.

The diffusion equation is modified to account for variations in the value of the diffusion coefficient with concentration by the use of a special coordinate system x_0, such that for every elementary region dx there is a corresponding region dx_0 of such thickness that $dx/\sqrt{D} = dx_0/\sqrt{D_0}$, where D_0 is some constant reference value of the diffusion coefficient. Illustrative calculations are given for the semi-infinite and finite solid conditions for the diffusion of Zn into Cu. (ASTIA abstract)

DISCHARGE MECHANISM OF MERCURY POOL ARCS, by K. G. Hernqvist. Feb. 23, 1956, 16p. incl. tllus. diagrs. refs. (Rept. no. RB-34) (AFOSR-TN-56-18) [AF 18(600)1239] Unclassified

In this study, a model for the discharge mechantsm of Hg pool arcs ts proposed, and tt is shown to be in agreement with experiment. The following subjects are discussed in connection wtth the model: (1) schemattc dtagrams showing tube structure; (2) potential distrtbutions; (3) arc-energy balance; (4) current-denstty dtstrtbutton; (5) motton of arc cathode spot; (6) transtent behavtor of the Hg pool arc; (7) emission mechanism of Hg pool arcs; and (8) comparison between the Hg pool arc and thermtonic arcs (e. g., carbon arc). It is concluded that: (a) Hg pool arcs operate in the ball-of-ftre mode of dtscharge, and (b) the electron emission mechantsm is nonthermtonic. Emitted electrons from the cathode arrtve wtth only thermal energies in a plasma adjacent to the cathode. The potential of this plasma is equal to or slightly htgher than that of the Fermi level of the cathode. The emisston may result from etther a large electrtc field at the cathode (tunnel effect) or from an effecttve lowering of the cathode work functton. This lowering of the work functton may be caused by a vapor or plasma of high density adjacent to the cathode surface.

RESEARCH IN GASEOUS ELECTRONICS, by K. G. Hernqvist, R. W. Peter, and A. D. Sutherland. Final rept. Sept. 23, 1954-June 23, 1956, 48p. tllus. diagrs. refs. (AFOSR-TN-56-34) (AF 18(600)1239) AD 96229 Unclasstfied

A general classificatton of arcs based on the emission mechanism is made. A summary of characteristic properties of nonthermiontc arcs is presented based on a litterature survey. A study of retrograde motion done at these laboratories mainly before the activation of this contract is described. Based on the analogy between the ball-of-fire mode of hot cathode discharge and the Hg pool arc, a model for the discharge mechanism of the latter is proposed. Studies of discharge behavior after arc extinguishing indicate that the electron to ion current ratio of the arc is not less than about 50. A comparison between the power consumption for the Hg pool arc and that of thermionic arcs is made. Studies of the low current density mode of the Hg pool arc are described. These include the procedure to establish and maintain this mode of discharge and ultra-high-speed photographic studies of the cathode surface. These studies indicate that the time average of the emission current density is very low. Some previously proposed mechanisms of emission are discussed in view of the new experimental results obtained under this contract. It is indicated that a modified version of the field emisston mechantsm or a conttnuous cathode to plasma transition offers the most promising approach towards an understanding of the emisston mechanism. ON VARIATIONAL PRINCIPLES FOR REAL FLUIDS, by P. Lteber, O. Anderson, and K. S. Wan. Oct. 1955, 35p. incl. dtagrs. ([AF]OSR-TN-55-370) (AF 18(600)-499) AD 75078 Unclassifted

A theory of lift was developed for bodies, such as bodtes of revolutton, for whtch the Kutta condttions do not apply. The dissipation function was minimized mathematically and the assoctated Euler equations of condttion were developed based on the calculus of variation. In 2 dimensions the Euler condttions reduced to the biharmonic equattonfor the stream function. A principle to determine the real flow path under general conditions was formulated as a principle of virtual displacement for real fluids. According to this formulation, it is required that the virtual velocities associated with the actual flow path minimize the work done by traction applied at the surface enclosing the fluid. Using the energy conservation principle, the work done by these forces is then expressed in terms of the kinetic and dissipation energy of the flow enclosed by these surfaces. In performing the vartattons on the generating functions thus obtained, only the velocities were subjected to the vartation. The inertia and pressure forces corresponding to the real path were held constant with respect to the vartation. This yielded the Navier-Stokes equations as the Euler equations of the generating function. The minimum principle is applied to the calculation of a real flow between parallel plates and to the development of a boundary layer theory. (ASTIA abstract)

A LINEARIZED THEORY FOR THE NORMAL FORCE ON CLOSED BODIES OF REVOLUTION, by W. B. Brower [Jr.]. [1956] [10]p. incl. diagrs. (AF 18-(600)499) Unclassified

Published in Proc. Ninth International Congress Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956) v. 1: 439-448, 1957.

A theory is presented for the normal force on slender, closed bodies of revolution (i.e., bodies pointed at both ends) inclined slightly to the main flow. The theory embodies a mathematical model related to that employed by von Kármán in an unpublished work. In this model, a vortex sheet is assumed to emanate from the zero-meridian line aft of the section of maximum diameter. The strength and distribution of vorticity in the modified theory is determined by a boundary condition placed on the transverse flow. The theory is applied to the case of a paraboloid of revolution of fineness ratio 5. The actual computation is carried out by means of an electric-tank analogy. Comparison of results with theory are presented for the slope of the normal-force curve and the normal-force distribution. The theory with the new boundary condition yields results which are in close agreement with those of von Kármán. A few comparisons with wind-tunnel results are included. (Contractor's summary)

THE USE OF RHEOELECTRICAL ANALOGIES IN AERODYNAMICS, by L. C. Malavard. Aug. 1956, 173p. incl. illus. diagrs. refs. (NATO AGARDograph

rept. no. 18) [AF 18(600)499] Unclassified

The rheoelectric analogy method is based on the identity between the equations which govern certain fluid flows and those for the distribution of electric potential in a continuous conducting medium (electric tank, conducting paper, etc.). After a review of the principle of this method, the study describes the equipment and experimental techniques used in model construction, in the physical realization of the given problem data, in the exploration of the potential fields, and in carrying out the necessary adjustments and measurements. Next the different aerodynamic applications are examined: representations of plane flows, studies of airfoil sections and turbine blade lattices, practical accomplishment of conformal mappings, and studies of axially symmetric and three-dimensional flows. Detailed descriptions are given of the analog methods and set-ups used for the solution of lifting line, propeller, lifting surface, and compressible flow problems.

VORTEX STRUCTURES IN PIPE FLOW, by W. H. Webb and R. P. Harrington. Mar. 3, 1956, 3p. incl. illus. [AF 18(600)681] Unclassified

Published in Jour. Aeronaut. Sciences, v. 23: 792-794, Aug. 1956.

Apparatus is briefly described, and a method is presented for visualizing the dynamical properties of artificially produced vortex systems in order to shed light on the characteristics of vortices which may be observed in future studies of natural transition. The apparatus consists principally of two large steel water tanks connected by a long straight 1.25-in. id plastic pipe, flow being induced in the pipe by opening valves on the downstream tank. The maximum Reynolds number obtainable, based on pipe radius and mean velocity, was about 10,000. For visualization of the flow, dye was injected either through a rake inserted in the front of the entrance nozzle or through a thin slit in the pipe located some distance downstream of the inlet. Velocity profiles were measured by means of a micrometer pitot tube connected to a bifluid manometer, and mean flow measurements were made by use of a sight glass on the upstream tank. Many disturbance elements of widely varying shapes, e.g., 3/16 and 1/8-in. machine screws, and a 0.0038-in. diam wire, were utilized to produce a velocity perturbation normal to the mean parallel flow. Typical vortex sequences observed for all varieties of disturbances are shown. The vortices are of the horseshoe type as discussed by Theodorsen (Mechanism of Turbulence, Proceedings of the Second Midwestern Conference on Fluid Mechanics, 1952). An attempt was also made to measure the disturbance magnitude necessary to produce the last stage of flow for various Reynolds numbers. The results are presented on a graph. A sequence of slow-motion photographs (1000 frames/sec) is included showing the turbulent burst which occurred naturally, without an obstruction, in the pipe at a Reynolds number of 5000. The vortex-like motions which are seen at the wall are not clearly defined; it is felt, however, that photographic refinements will eventually allow detailed analyses to be made of the unique transition vortex configuration for pipe flow.

ON THE LAMINAR MIXING OF A TWO-DIMENSIONAL COMPRESSIBLE JET, by K.-T. Yen. Mar. 18, 1954 [17] p. incl. diagr. (Rept. no. TR-AE-5404) ([AF]OSR-TN-54-129) (AF 18(600)992) AD 40025 Unclassified

The 2-dimensional problem is considered of laminar mixing and induction by injection of a high-speed jet into a stationary fluid. By means of an asymptotic expansion and a change of independent variables, the usual boundary-layer-type differential equations are reduced to a single ordinary differential equation as a first approximation. The transformation of the independent variables is chosen such that it relates the compressible mixing problem to its associated incompressible one for which the solution is already known. The solution for the compressible case can then be readily obtained. The effect of compressibility on the divergence of the jet, the mass flow rate, and the velocity field is given. The method is equivalent to the technique suggested by Stewartson (Proc. Roy. Soc. London A., v. 200: 84, 1949), and is applicable to the turbulent case by suitable modification of the coefficient of viscosity.

AN INVESTIGATION OF THE COANDA EFFECT FOR SUPERSONIC FLOWS, by K.-T. Yen. Mar. 18, 1954 [30] p. incl. diagrs. (Rept. no. TR-AE-5405) ([AF]OSR-TN-54-130) (AF 18(600)992) AD 45023 Unclassified

The purpose of this work is to study the feasibility of utilizing the Coanda effect to improve the mixing and induction of supersonic flows. The problem studied here is the flow phenomenon of two supersonic streams as the result of inserting a curved surface into the primary stream. An approximate theory based on the Prandtl-Meyer flow is developed for the determination of the contact discontinuity between the two streams. The laminar mixing along the contact discontinuity is then studied. It is shown that the mixing of the two streams can be improved appreciably provided certain temperature and Mach number conditions for these two streams are satisfied. (Contractor's abstract)

AN INVERSE PROBLEM IN HYPERSONIC VISCOUS FLOW, by T.-Y. Li. July t3, t956, 35p. tncl. dtagrs. (Rept. no. TR-AE-5603) (AFOSR-TN-56-308) (AF 18-(600)159t) AD 94842 Unclasstfted

Also published in Proc. Ftfth Mtdwestern Conference on Flutd Mechantcs, Mtchtgan U., Ann Arbor (Apr. t-2, 1957), Ann Arbor, Untv. of Mtch. Press, 1957, p. 201-223.

This mathematical study deals wtth an "inverse" problem tn hypersontc vtscous flow, the problem of determtntng the body shape assoctated wtth a prescrtbed pressure fteld. Tangent-wedge approxtmatton is used to provtde an explctt relatton between the pressure inside the boundary layer and the local effective body tncltnatton. Moment integral method ts used in the analysis of the boundary layer growth. For a

prescribed pressure field, an iterative scheme is devised to compute the necessary body shape. Numerical examples are computed for a specific pressure field at $M_\infty = 10$ for a range of Reynolds numbers in 3 different cases: (1) a heated surface; (2) a cooled surface; and (3) a supercooled surface. Results show that the iterative scheme converges rapidly, at least in the present set of examples. Significance of the results and limitations of the method are discussed. (Contractor's abstract)

DETERMINATION OF A CONSTANT-PRESSURE SURFACE IN TWO-DIMENSIONAL HYPERSONIC VISCOUS FLOW, by R. A. Harris and T.-Y. Li. Aug. 24, 1956 [15]p. incl. diagrs. (Rept. no. TR-AE-5604) (AFOSR-TN-56-484) (AF 18(600)1591) AD 97368 Unclassified

A method is developed for determining that body shape which will maintain a constant pressure distribution on its surface in a 2-dimenstonal steady hypersonic flow. The tangent-wedge approximation is used inversely so that the pressure distribution is assumed and the body which will give this distribution is determined. Two numerical examples are computed: (1) $p/p_\infty = 1$ and (2) $p/p_\infty = 4$, in which p is the static pressure and ∞ denotes a free-stream condition. The calculations show a decrease in Reynolds number, based on an arbitrary reference length, and an increase in surface temperature; both of these tend to increase the viscous interaction effects. Boundary-layer thickness decreases as the pressure within the boundary layer increases. To maintain a constant pressure distribution on a body surface in hypersonic flow, the surface must be concave rather than plane. The degree of concavity is determined by the value of p/p_∞.

EFFECTS OF FREE STREAM VORTICITY ON THE BEHAVIOR OF A VISCOUS BOUNDARY LAYER, by T.-Y. Li. Aug. 2, 1956 [1]p. (AF 18(600)1591) AD 143926 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 23: 1128-1129, Dec. 1956.

The hypersonic boundary layer on a flat plate is associated with a region of inviscid rotational flow behind a curved shock wave from the plate leading edge. In earlier studies (Li, T.-Y., Jour. Aeronaut. Sciences, v. 22: 651-652, 1955; Li, T.-Y., Ibid., v. 22: 724-725, 1955), a simple example of a viscous boundary layer in a free stream of constant vorticity was treated, providing an understanding of the effects of free-stream vorticity on the behavior of a viscous boundary layer. The present study briefly gives a reformulation of the problem in which the pressure gradient induced by the displacement effect of the boundary layer is considered. The highlights of the analysis can be most simply presented in the case of steady, incompressible two-dimensional flow. It is demonstrated that neither the free-stream vorticity nor the boundary-layer displacement effect contributes any change on the viscous boundary layer; however, the free-stream vorticity effects may become significant as soon as the boundary-layer displacement effects become important, e.g., as in some hypersonic boundary-layer investigations. Generally, it can be stated that one of the effects of free-stream vorticity is the introduction of a modified pressure field. It follows that the skin friction, heat transfer, boundary-layer separation, and laminar stability characteristics are all affected, their effects becoming important as soon as the displacement effects become significant.

THE PREPARATION AND REPRODUCIBILITY OF THE THERMAL-ELECTROLYTIC TYPE SILVER-SILVER CHLORIDE ELECTRODES, by H. Tantguchi and G. J. Janz. Dec. 1955 [25] p. incl. diagrs. tables. (Technical note no. 3) ([AF]OSR-TN-55-476) (AF 18(600)-333) AD 80796 Unclassified

A procedure is described in detail for the preparation of the thermal-electrolytic Ag-AgCl electrodes for precision use. A reproducibility of the electrodes by this procedure of only ±0.1 mv can be expected unless the freshly prepared electrodes are evaluated relative to equilibrated Ag-AgCl electrodes selected as reference standards. With care, reference standards corresponding to an electrode in the ground energy state, and of constant potential (±0.005 mv) for periods of several months can be attained. It is suggested that the difference in the values of the standard potential of this electrode may be attributed in part to the limited reproducibility of these electrodes. The importance of the factors of porosity, amount of silver chloride, and color, relative to the attainment of stable electrodes that equilibrate rapidly are considered. (Contractor's abstract)

THE CONCEPT OF THE ABSOLUTE ELECTRODE POTENTIAL, by H. Mendelsohn and G. J. Janz. June 1956, 45p. incl. diagrs. tables, refs. (Technical note no. 4) (AFOSR-TN-56-253) (AF 18(600)333) AD 88973 Unclassified

Theoretical and experimental attempts were made to determine an absolute electrode potential. Theoretical attempts were based on the determination of partial molar free energy. Experimental determinations depend on the attainment of a null electrode to measure the absolute emf of a reference electrode. Thermodynamic reasoning indicated that attainment of an absolute emf is impossible. A nonthermodynamic arithmetical device was derived for splitting up molar quantities between the respective ions in order to evaluate partial molar ionic values in the application of the Born-Haber cycle to the problem. Theoretical values obtained by means of the Born-Haber cycle are actually approximations of the absolute emf resulting from numerous assumptions of the absolute emf of an electrode are achieved but the indisputable value of this measurement has not been obtained. The Lippman, Billiter, and Andauer potentials are included in a discussion of experimental attempts to prepare a null electrode.

COMPARISON OF THE ELECTROMOTIVE FORCE SERIES IN VARIOUS SOLVENTS, by H. Strehlow, tr. by G. J. Janz. Nov. 1953 [26] p. incl. diagrs. tables, refs. (Technical note no. 5) (AFOSR-TN-56-549) (AF 18(600)333) AD 110368 Unclassified

Also published in Zeitschr. Elektrochemie, v. 56: 827-833, 1952.

A critical discussion is made of the basis for the arrangement of the elements in the order of their normal potentials to form the electromotive force series. It is questioned whether the emf series in the various solvents form quite isolated systems or whether a relation exists between them. The desirability of another independent method from which the emf series can be studied by comparison is stated and two possible methods are discussed. Firstly, the difference in the free energy of solvation of the Rb ion can be calculated approximately in various solvents from theoretical molecular concept. Secondly, the order of the electromotive force series gained can be tested through the acidity measurements of solutions of strong acids in the specific solvents. Calculation results and experimental data are compared.

CONDUCTANCE OF HYDROGEN CHLORIDE IN ACETONITRILE, by S. S. Danyluk and G. J. Janz. Nov. 24, 1956, iv. incl. diagrs. tables, refs. (Technical note no. 6) (AFOSR-TN-56-600) (AF 18(600)333) AD 115029 Unclassified

The conductance of a freshly prepared solution is not constant, but increases with time to a maximum or "stabilized" value. In the light of the present investigations, the conductance-time effect may be attributed to a slow attainment of ionization equilibrium for hydrogen chloride, the effect being attributed in part to the weak proton-acceptor properties of acetonitrile. The equivalent conductance of "stabilized" solutions of hydrogen chloride has been studied as a function of concentration over the range 0.0009 to 0.6 equiv/litre. Interpretation of the results in the light of the Bjerrum ion-pair formation and Fuoss-Kraus triple-ion formation theories in solvents of low dielectric constant is discussed. The low values of the equivalent conductance are in accord with ionic association processes in

hydrogen chloride-acetonitrile solutions. A crystalline solid of analysis corresponding to $CH_3CN \cdot 2HCl$ can be separated by chilling a saturated solution of hydrogen chloride in acetonitrile. The infrared spectra of these solutions are in accord with such molecular type hydrogen chloride addition compounds being present. Both the formation of a mixture of electrolyte and nonelectrolyte species by the solute, i.e.: (1) $CH_3CN \cdot HCl \rightleftharpoons CH_3CN + HCl$, and (2) $CH_3CNH^+ \cdot Cl^- \rightleftharpoons CH_3CNH^+ + Cl^-$ must be considered in the ultimate interpretation of the properties of hydrogen chloride in anhydrous acetonitrile. ON THE EFFECTS OF THE ADDITION OF MASS TO VIBRATING SYSTEMS, by G. H. Handelman and H. Cohen. Sept. 1, 1956 [13]p. incl. diagrs. (Math. rept. no. 4) (AFOSR-TN-56-387) (AF 18(600)1586) AD 96045 Unclassified

Presented at Ninth International Congress of Applied Mechanics, Brussels (Belgium), Sept. 5-13, 1956.

The characteristic frequencies of a circular plate carrying a rigidly attached, rigid, concentric, circular mass of finite area and vibrating symmetrically are studied. The main problem is that of determining the ranges of the parameters for which the frequencies will always be above and always be below those of the unloaded case. The results obtained are compared with those previously found for longitudinal and transverse vibrations of bars and transverse vibrations of membranes. It is seen that critical values of the parameters depend on the specific system under study. The first term in the asymptotic expansion of the higher frequencies is obtained. It is found that the density ratios do not enter this term and the plate behaves like a beam. This is similar to the case of the membrane which behaves like a bar under longitudinal motion. (Contractor's abstract)

LIMITS OF RATIONAL FUNCTIONS, by G. R. MacLane. Aug. 9, 1954, 9p. (Technical note no. 1) ([AF]OSR-TN-54-206) (AF 18(600)1135) AD 54609 Unclassified

Also published in Pacific Jour. Math., v. 6: 111-116, 1956.

The principal results are given in 2 theorems. Theorem 1. Let D be a simply connected domain contained in $I(Z) > 0$ and let D^* be the reflection of D in $I(Z) = 0$. Let $f(Z)$ be an arbitrary holomorphic function in D, $f \neq 0$ in D. Let $f^*(Z) = f(Z)$; $f^*(Z)$ is holomorphic and nonzero in D^*. Then there exists a sequence of rational functions $R_n(Z)$ such that: (1) all zeros and poles of $R_n(Z)$ are real; (2) $R_n(Z) \rightarrow f(Z)$ uniformly in every compact subset of D and $R_n(Z)$ $c f^*(Z)$ uniformly in every compact subset of D^*, where c is a constant of modulus 1; and (3) the sequence $R_n(Z)$ is non-normal at every point of the complement of $D \cup D^*$. Theorem 2. Let D be a simply connected domain in the Z-plane, symmetric with respect to the real axis and containing no points of the interval $x \leq 0$ of the real axis. Let $f(Z)$ be holomorphic and nonzero in D, and let $f(x)$ be real on the single interval γ common to D and the real axis. Then there exists a sequence of rational functions $R_n(Z)$ such that (1) all zeros and poles of $R_n(Z)$ are real and negative; (2) $R_n(Z) \rightarrow f(Z)$ uniformly in every compact subset of D; and (3) the sequence $R_n(Z)$ is non-normal at every point of the complement of D.

ON THE ZEROS OF THE DERIVATIVES OF AN ENTIRE FUNCTION, PART I. MEROMORPHIC FUNCTIONS WITH SPECIFIED ASYMPTOTIC BEHAVIOR, PART II, by G. R. MacLane. July 19, 1955, 46p. (Technical note no. 2) ([AF]OSR-TN-55-223) (AF 18(600)1135) AD 73188 Unclassified

Also published in Proc. Amer. Math. Soc., v. 8: 702-706, Aug. 1957.

The following theorem is proved: if K is any compact subset of the z-sphere and $\omega \in K$, then there exists an entire function f(z) such that the set of all the zeros of all the functions $f^{(n)}(z)$ condenses exactly on K. An investigation is made of the existence of a meromorphic function asymptotic to several given meromorphic functions in disjoint domains stretching to ω. Emphasis is placed on the rapidity of approach in terms of $|z|$.

THE ACTION OF HEAT ON S-CROTYLTHIOSALICYLIC ACID AND RELATED COMPOUNDS, by J. C. Peiropoulos, M. A. McCall, and D. S. Tarbell. [1953] [5]p. [AF 18(600)482] Unclassified

Published in Jour. Amer. Chem. Soc., v. 75: 1130-1134, Mar. 5, 1953.

The behavior of allyl and crotyl aryl sulfides on heating is very different from that of the oxygen analogs. S-Allyl-3,5-dichlorothiosalicylic acid is converted in part to dichlorothiosalicylic acid and to bis-(carboxydichlorophenyl) sulfide by heating to 275°. S-crotylthiosalicylic acid yields 2-ethyl-2,3-dihydrobenzothiophene (I) and the 7-carboxy derivative of this compound (II) when heated at 260°. The structures were proved by degradation and synthesis. The decarboxylation involved is simultaneous with the rearrangement and the crotyl group must rearrange without inversion, followed by cyclization to form II and I. The following new compounds, isomeric with I, have been synthesized during the identification of I: 4-methylthiochroman; 3-ethyl-2,3-dihydrobenzothiophene-1,1-dioxide; 2-methylthiochroman; and 3-methylthiochroman. STUDIES ON MODEL COMPOUNDS FOR COENZYME A. A KINETIC STUDY OF AMINOLYSIS AND HYDROLYSIS OF ETHYL THIOACETATE AND β-ACETAMINOETHYL THIOACETATE IN AQUEOUS SOLUTION, by P. J. Hawkins and D. S. Tarbell. [1953] [4]p. incl. diagrs. tables, refs. [AF 18(600)482] Unclassified

Published in Jour. Amer. Chem. Soc., v. 75: 2982-2985, June 20, 1953.

A kinetic study of the reaction of n-butylamine with ethyl thioacetate and with β-acetamidoethyl thioacetate in aqueous solution showed the rate of hydrolysis of the thioesters in aqueous amine solution to be appreciable. The rate of disappearance of ester by aminolysis and hydrolysis was in agreement with the following rate equation: $-d([Ester]/dt) = k_4[Ester][RNH_2][OH^-] + k_5[Ester][OH^-]$. The rate of reaction of the ethyl thioacetate is similar to that of β-acetamidoethyl thioacetate, indicating little effect on the reaction rate of the amide group in the β-position. Bis-(β-acetaminoethyl) disulfide and N-n-butylacetamide have been isolated in high yield from the action of n-butylamine on β-acetaminoethyl thioacetate in aqueous solution. (Contractor's abstract)

CLEAVAGE OF THE CARBON-SULFUR BOND. KINETICS OF THE REACTION OF THIOBENZOIC ACID WITH ANILINE, by P. J. Hawkins, D. S. Tarbell, and P. Noble, Jr. [1953] [4]p. incl. tables, refs. [AF 18(600)482] Unclassified

Published in Jour. Amer. Chem. Soc., v. 75: 4462-4465, Sept. 20, 1953.

The kinetics of the reaction between thiobenzoic acid and aniline has been studied. In chlorobenzene solution, the rate is given by $k(C_6H_5COSH)(C_6H_5NH_2)$; variations in k between different samples of thiobenzoic acid are probably due to the presence of small amounts of benzoic acid as impurity. The effect of other substances on the rate has been measured. In aqueous acetic acid, the kinetics vary, depending on the composition of the solution, but most runs follow the above kinetics in the initial stage. In aniline solution, the kinetics follow the equation, rate = $k(C_6H_5COSH)^2$. The much greater rate of acylation of aniline by thiobenzoic acid, compared to benzoic acid, is discussed. A NEW METHOD OF PREPARING SUBSTITUTED THIOPHENOLS, by A. H. Herz and D. S. Tarbell. [1953] [4]p. [AF 18(600)482] Unclassified

Published in Jour. Amer. Chem. Soc., v. 75: 4657-4660, Oct. 5, 1953.

Attempts to carry out Friedel-Crafts acylations of diphenyl disulfide or formaldehyde diphenyl mercaptal were unsuccessful; however, it was shown that the readily formed addition product of a thiophenol and 3-nitrobenzalacetophenone is amenable to electrophilic substitution, and that this substituted addition product may be nearly quantitatively converted to the corresponding substituted thiophenol. It was demonstrated

by the preparation of acetylated, brominated and nitrated thiophenols that this scheme constitutes a general method for the preparation of electrophilically substituted thiophenols. (Contractor's abstract)

THE KINETICS OF BASIC HYDROLYSIS OF SOME γ-LACTONES AND γ-THIOLACTONES IN AQUEOUS ACETONE, by C. M. Stevens and D. S. Tarbell. Aug. 1, 1954 [8]p. incl. tables, refs. (Technical note no. 1) ([AF]OSR-TN-54-207) (AF 18(600)482) Unclassified

Also published in Jour. Org. Chem., v. 19: 1996-2003, Dec. 1954.

Rates of alkaline hydrolysis for 3 γ-lactones and 3 γ-thiolactones in 43% acetone - 57% H_2O have been measured conductometrically. The lactones and thiolactones show much smaller effects on the rates from increasing alkyl substitution around O_2 (or S) than do the open chain acetates and thioacetates. Methods of synthesizing γ-isocaprolactone and the corresponding thiolactone have been evaluated. The addition of thioacetic acid to 4-methyl-3-pentenoic acid is antiMarkownikoff, yielding 4-methyl-3-acetylmercaptopentanoic acid, which is also obtained from 4-methyl-2-pentenoic acid. AN INFRARED STUDY OF HYDROGEN BONDING INVOLVING THE THIOL GROUP, by D. S. Tarbell, D. Plant, and C. Whiteman. Aug. 1, 1954, 4p. incl. tables, refs. (Technical note no. 2) ([AF]OSR-TN-54-208) (AF 18(600)482) AD 89077 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 77: 1572-1575, Mar. 20, 1955.

A study of the infrared spectra of a series of aminothiols of the type $R_2N(CH_2)_nSH$ (n = 3 or 4) has given no indication of hydrogen bonding involving the -S-H group. Further studies on mixtures of sulfoxides and thiol compounds, and on thiobenzoic acid alone, indicate that hydrogen bonding through the -S-H group is negligible. The -S-D stretching frequency in thiophenol-d and n-hexanethiol-d has been found to occur at 1839 and 1870 cm^{-1}, respectively. The synthesis of several new aminothiols and aminoalcohols is reported. Thiol compounds are found to react with carbon tetrachloride in the presence of tertiary bases at room temperature to yield mainly the disulfide and the amine hydrochloride; the reaction presumably involves a displacement with the formation of $-SCCl_3$ compounds, which then react further. THE INFRARED SPECTRA OF SOME 1,4-THIAPYRONE DERIVATIVES, by D. S. Tarbell and P. Hoffman. [1954] [3]p. incl. table. [AF 18(600)-482] Unclassified

Published in Jour. Amer. Chem. Soc., v. 76: 2451-2453, May 5, 1954.

A study was made of the infrared spectra of 1,4-thiapyrone, its hydrochloride, 3-carboxy-1,4-thiapyrone, the corresponding ester and the amide. There was no evidence of normal carbonyl absorption. The spectrum of 1,4-thiapyrone hydrochloride was shifted toward lower frequencies compared to the thiapyrone itself. These results are in agreement with numerous other lines of evidence in indicating that the thiapyrone nucleus, and the thiapyrylium salts especially, are numerous hybrids with little or no contributions from forms with a carbon-oxygen double bond. The infrared spectrum of 1,4-thiapyrone sulfone, on the other hand, showed the absorption expected from a conjugated carbonyl group and carbon-carbon double bonds. The preparation of 3-carboxy-1,4-thiapyrone and its derivatives from 3-carbomethoxytetrahydro-1,4-thiapyrone is described. (Contractor's abstract)

THE ISOMERfZATION BY BASE OF ALKYL ALLYL SULFIDES TO ALKYL PROPENYL SULFIDES. THE MECHANISM OF THE REACTION, by D. S. Tarbell and W. E. Lovett. [1956] [6.p. incl. refs. [AF 18-(600)482] Unclassified

Published in Jour. Amer. Chem. Soc., v. 78: 2259-2264, May 20, 1956.

Allyl n-hexyl sulfide is isomerized to n-hexyl propenyl sulfide by refluxing with 3.7 M afcoholic sodium ethoxide; affyl-t-butyl sulfide behaves similarfy. Allyl n-hexyl eiher is recovered after similar treatment. Diallyl sulfide is isomerized to dipropenyl sulfide, and is also converted in part to an unsaturated mercaptan, 3-mercapto-1, 5-hexadiene, by a rearrangement of an allyl group. It has been found that N-sodiochloro-p-bromobenzenesulfonamide is superior to chloramine-T for characierization of sulfides by formation of sulfilimines. Isomerization of allyl n-hexyl sulfide by sodium ethoxide is deuteroethanol gives n-hexyfpropenyl sulfide containing (by mass spectrometric analysis) considerable quantities of mono- and dideuterated products, indicating that the isomerization proceeds through a carbanion which can exchange with the sofvent. The resufts of the siudy emphasize the ability of sulfide sulfur, not aitached io an aromatic ring, to stabilize a negaiive charge on the adjacent carbon, presumably through contributions from resonance forms with a decet of elecirons around sulfur. THE PfROTOLYSIS OF KETENE AT LOW PRESSURE, by G. B. Porter. [July 31, 1956] [2.p. incl. tables. (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under [AF 18(600) 1582.]) Unclassified

Published in Jour. Amer. Chem. Soc., v. 79: 827-828, Feb. 20, 1957.

Apparent quantum yields of carbon monoxide and of ethylene have been determined at wave length 3650 Å

as functions of temperature and of concentration of ketene. At the lowest concentrations studied the yield of ethylene decreases, probably because of heterogeneous disappearance of methylene radicals. Apparent quantum yields of carbon monoxide, based on a Beer's law extrapolation, are constant at concentrations below 5×10^{-5} mole/liter. The significance of this constancy is discussed in terms of a detailed mechanism including an internal conversion process. (Contractor's abstract)

THE RELATIVE INTENSITIES OF FLUORESCENCE AND PHOSPHORESCENCE IN BIACETYL VAPOR, by H. Okabe and W. A Noyes, Jr. Aug. 20, 1956 [6] p. incl. diagrs. table. refs. (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under [AF 18(600)1528]) Unclassified

Published in Jour. Amer. Chem. Soc., v. 79: 801-806, Feb. 20, 1957.

A technique is described for measuring the relative intensities of emission from biacetyl vapor in the blue (fluorescence) and in the green (phosphorescence) parts of the spectrum when exciting wave lengths are around 4358 and 3650 Å, respectively. In pure biacetyl at 26° and 42 mm pressure the integrated ratio of green to blue is 58 (±8):1. This ratio is unaffected by change in wave length and by the addition of acetone, benzene or methyl chloride. The ratio decreases as the temperature is raised and decreased rapidly to zero upon addition of oxygen. The state from which phosphorescence occurs by a step which parallels and is independent of fluorescence. Both rates must apparently be collision independent under the conditions studied. Dissociation must occur from upper vibration levels of the singlet state although the data do not provide conclusions about details of this process. Biacetyl emission in biacetylacetone mixtures irradiated at 3130 Å (absorbed mainly by the acetone) leads at room temperature to a preferential excitation of phosphorescence rather that fluorescence. The previously proposed mechanism can account for these facts.

PHOTOCHEMICAL STUDIES. LII. THE NITROUS OXIDE-ETHANE SYSTEM, by G. A. Castellion and W. A. Noyes, Jr. Aug. 27, 1956 [4] p. incl. tables, refs. (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under [AF 18(600)1528]) Unclassified

Published in Jour. Amer. Chem. Soc., v. 79: 290-293, Jan. 20, 1957.

The ratio of nitrogen formed photochemically at about 1900 Å in pure nitrous oxide to that formed under identical conditions in a nitrous oxide-ethane mixture is 1.4. This indicates that the primary photochemical process is probably $N_2O = N_2 + O$ and that oxygen atoms react much more rapidly with ethane than with nitrous oxide. Several products are formed including ethylene, butane, carbon monoxide, hydrogen, methane and probably ethanol and acetaldehyde. A complete elucidation of the mechanism is not possible, due to the fact that oxygen atoms seem to react more rapidly with one or more of the products than they do with ethane itself. More ethylene is formed than one would expect from the amount of butane. Due to secondary reactions which must involve the initially formed products it has not been possible to obtain precise information about the reactions of oxygen atoms and of hydroxyl radicals.

THE PHOTOOXIDATION OF DIETHYL KETONE, by J. E. Jolley. Oct. 4, 1956 [6] p. incl. tables, refs. (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under [AF 18(600)-1528]) Unclassified

Published in Jour. Amer. Chem. Soc., v. 79: 1537-1542, Apr. 5, 1957.

The photochemical reaction between diethyl ketone and oxygen has been studied at temperatures from 35 to 150° at several oxygen pressures and over a wide range of intensities. At all temperatures the carbon monoxide yield becomes small at high oxygen pressures, thus indicating that the propionyl radical reacts with oxygen without producing carbon monoxide. All yields pass through maxima (except possibly carbon monoxide at 35°), and oxygen acts as an inhibitor at high oxygen pressures. At room temperature quantum yields are independent of intensity, but at 150° they are in inverse linear function of the square root of the intensity. Oxygen at very low pressures strongly suppresses the formation of C_2 hydrocarbons so that the reaction between ethyl radicals and oxygen must be very rapid. A fairly complete mechanism for the reaction can be suggested and the relative values of several rate constants estimated. Chains must be propagated mainly by ethoxy and pentanonyl radicals. Since rates of formation of acetaldehyde and carbon dioxide are closely parallel to each other, possibly pentanonyl radicals react with oxygen to give acetaldehyde, carbon dioxide and ethyl radicals. ROC. 03:001 - ROC. 03:002

by Office of Naval Research and Air Force Office of Scientific Research under [AF 18(600)1528])
Unclassified

Published in Jour. Amer. Chem. Soc., v. 79: 1878-1880, Apr. 20, 1957.

The photolysis of ketene at 3650 A° was investigated in the presence of oxygen. Even at low concentrations, oxygen virtually eliminates the dissociation of ketene into carbon monoxide and methylene radicals at room temperature. There is a direct reaction of oxygen with excited ketene molecules which leads to carbon monoxide and carbon dioxide among the products, but which gives very little ethylene. Within experimental error, the quantum yield of formation of carbon monoxide is equal to that of oxygen consumption. All quantum yields are small and the principal reaction of oxygen is deactivation of excited ketene molecules. At low oxygen concentrations, the quantum yields, with exception of that of ethylene, show maxima at about 5×10^{-6} mole of oxygen/liter (about 0.1 mm pressure). At 160°, there is an intensity dependent chain reaction with oxygen. (Contractor's abstract)

HIGH ENERGY COSMIC-RAY INTERACTIONS IN PHOTOGRAPHIC EMULSION AND LEAD (Abstract), by D. M. Ritson, M. F. Kaplon, and W. D. Walker. Jan. 23, 1953 [2]p. [AF 18(600)380] Unclassified

Presented at meeting of the Amer. Phys. Soc., Cambridge, Mass., Jan. 22-24, 1953.

Published in Phys. Rev., v. 90: 360-361, Apr. 15, 1953.

In a flight at White Sands, N. M., in Apr. 1952, an arrangement consisting of a 750-cc "Block" of photographic emulsion on top of an "emulsion cloud chamber" was flown at 90,000 ft for several hr. The block consisted of ninety-two 400 μ G-5 stripped emulsions piled one above the other, and the emulsion cloud chamber contained twenty-five 3-mm lead plates separated by 250 μ photographic plates. Six proton induced interactions and one secondary interaction with energies of the $\sim 10^{13}$ ev have been observed in the emulsion with multiplicities of the ~ 15 and N_h values of 0, 0, 2, 4, 6 and 15 (secondary interaction had an N_h of 2). Thus, low N_h values are characteristic of high energy primary, as well as secondary, interactions in emulsion. The events found in lead ($\sim 310^{12}$ ev) show a strong increase in apparent multiplicity with increasing distance of the interaction back in the first lead plate setting a limit on the lifetime τ of the π^0 meson, $\tau \leq 10^{-14}$ sec. The multiplicity is similar to that observed previously for interactions in brass and for the interactions observed in emulsion, indicating a very weak dependence of multiplicity in a nucleus on the number of nucleons struck by the primary. (Contractor's abstract)

HIGH ENERGY NUCLEAR INTERACTIONS IN LEAD AND LIGHT ELEMENTS, by M. F. Kaplon, D. M. Ritson, and W. D. Walker. Mar. 31, 1953, 4p. incl. diagr. table, refs. (AF 18(600)380) AD 10875
Unclassified

Also published in Phys. Rev., v. 90: 716-717, May 15, 1953.

Previous measurements (Phys. Rev., v. 88: 386, 1952) were extended on nuclear interactions in the energy region 10^{12}-10^{14} ev, in a 6-hr flight at White Sands using an emulsion cloud chamber made up of a 6" x 4" x 2" "block" of 92 G-5 stripped emulsions, 6" x 4" x 400 μ, placed on top of an emulsion cloud chamber of 25 alternate 3 mm lead plates and 250 μ G-5 emulsion. The stripped emulsions of the "block" were separated after the flight and processed with emulsions attached to glass backing before development. Results are graphed and tabulated. The initial multiplicity of charged particles, observed on the plate directly below a lead absorber in which an interaction occurred, appeared to be about 20 in the majority of showers; the median energy of this group of interactions was estimated to be about 2×10^{12} ev. Seven primary interactions were found in emulsion; the average number of shower particles (N_s) about 16 appears to be independent of the number of evaporation prongs (N_h) which had a median energy of $\sim 10^{13}$ ev. If the interaction cross section for primaries of these energies is geometric, approximately half the collisions in emulsion would occur in Ag or Br and the rest in C, N, O, and H. Though the division of interactions on the basis of the number of star prongs is not certain, it seems likely that the cases with $N_h = 0$ occur in light elements, and the case with $N_h = 15$ must have arisen from an interaction in an Ag or Br nucleus. If the dividing line between the light and heavy elements is taken to be $N_h \approx 4$ or 5, then our data are consistent with half the interactions occurring in light elements and half in heavy elements. It is seen that the mean number of shower particles for interactions with $N_h < 4$ and $N_h > 4$ is 16 for both cases. Use of prior findings and corrections for the differences in median energies on the assumption that the multiplicity varies as $E^{1/4}$, permits the comparison of multiplicities of shower particles in various elements for primary energies of $\sim 5 \times 10^{12}$ ev. For lead the multiplicity is ~ 24, brass ~ 18, Ag and Br ~ 14, and light elements ~ 14. It would appear that the multiplicity in this energy region is almost independent of the target nucleus. There have been cases found in which the multiplicity of shower particles is much higher than those considered above. The possible multiple production of particles in initial interactions is briefly discussed as an explanation of experimental results. The occurrence of both high and low energy pairs of charged particles produced by neutral radiation, in observing the passage of the high energy showers through the block of stripped emulsions has

also been noted. The most reasonable assumption is that these pairs are electron-positron pairs produced by photons; though the present statistics are too low to draw any definite conclusion, the contribution of bremsstrahlung according to Schiff's theory seems to be too low to account for the low energy pairs.

THE ABSORPTION MEAN PATH OF THE HIGH-ENERGY NUCLEONIC COMPONENT OF COSMIC RADIATION, by M. F. Kaplon, J. Z. Klose and others. July 3, 1953, 4p. incl. diagr. (AF 18(600)380) Unclassified

Also published in Phys. Rev., v. 91: 1573, Sept. 15, 1953.

Two similar emulsion cloud chambers consisting of 24 alternate 3-mm lead plates and 250μ G-5 emulsions were exposed to cosmic radiation. One stack was exposed for 30 days at 10,700 ft with the planes of the emulsions and lead plates at an angle of 45° with the vertical. The other was exposed for 6 hr at 90,000 ft with the planes of the emulsions and lead plates horizontal. The two emulsion cloud chambers were used to obtain flux measurements of the nuclear interacting component of the cosmic radiation for energies $\gtrsim 10^{12}$ ev. The data obtained was used to determine the absorption mean path in the atmosphere (λ) for this energy region. Data is evaluated by means of a Gross transformation since the emulsion cloud chamber is not a unidirectional detector. Results show $\lambda = 129 \pm 15$ gm/cm^2 with a mean value not less than about 115 gm/cm^2, which is in agreement with the majority of previous results obtained at lower energies, and indicates it to be independent of energy from $\sim 10^9$ ev to $\sim 10^{12}$ ev. The calculated value of the primary nucleonic flux at the top of the atmosphere, $N_0 = 0.22 \pm 0.0075$/meter^2/sec/steradian, is in good agreement with a previous determination for a somewhat higher energy. For a distribution of nucleons $\alpha \cos^6 \theta$, the integral primary flux of nucleons at mountain altitude was found to be $N_0 = 0.0009 \pm 0.000$ 0.0004/meter^2/sec/steradian. For comparison the integral primary flux of nucleons determined at mountain altitude assuming an isotropic distribution of nucleons was $N_0 = 0.0004 \pm 0.0002$/meter^2/sec/steradian, representing a lower limit on N_0 at mountain altitude.

SOME K-PARTICLE MASS MEASUREMENTS, by D. M. Ritson. 1953. 1 p. (AF 18(600)380) Unclassified

Published in Phys. Rev., v. 91: 1572, Sept. 15, 1953.

Description is given of K-particle mass measurements determined with a new technique of measuring gap density as a function of residual range in electron-sensitive photographic emulsion. Mass values are obtained by assuming that singly charged particles of the same velocity, but different mass, produce emulsion tracks of identical gap density; then the ratio of the masses equals the ratio of the ranges where velocities are equal. Mass values ($\pm$ 100 m_e) of three K particles observed in balloon flight exposures were thus determined to be respectively 970, 1020, and 870. These results are consistent with assumption of a single mass value 950 $\pm$ 60 m_e and support the conclusions that masses of the majority of K particles observed in balloon flights are about 950 m_e and are within the accuracy of the experiments indistinguishable from the mass of the τ meson.

EMULSION CLOUD-CHAMBER STUDY OF HIGH ENERGY RADIATION AT MOUNTAIN ALTITUDE (Abstract), by J. Z. Klose, M. F. Kaplon and others. June 20, 1953 [1]p. [AF 18(600)380] Unclassified

Presented at meeting of the Amer. Phys. Soc., Rochester, N. Y., June 18-20, 1953.

Published in Phys. Rev., v. 92: 855, Nov. 1, 1953.

An emulsion cloud chamber consisting of 24 alternate 6 in. x 4 in. 3.13-mm Pb plates and 250 μ Ilford G-5 emulsions was exposed for one month at Echo Lake, Colo. High energy nuclear interactions and electronic showers were detected and studied. From the analysis of the nuclear showers (median energy $\sim 10^{12}$ ev) an absorption mean free path in atmosphere of the high energy interacting component is derived. The value obtained, $\lambda_A \sim 120$ g/cm^2, is appreciably longer than the geometric mean free path. The flux and zenith angle distribution of the electronic showers are discussed. INTERACTIONS OF HEAVY PRIMARIES OF THE COSMIC RADIATION (Abstract), by M. F. Kaplon, J. H. Noon, and D. M. Ritson. June 20, 1953. [1]p. [AF 18(600)380] Unclassified

Presented at meeting of the Amer. Phys. Soc., Rochester, N. Y., June 18-20, 1953.

Published in Phys. Rev., v. 92: 855, Nov. 1, 1953.

In tracing 300 heavy primaries, 90 interactions were found with nuclei of a photographic emulsion "block." The emulsion "block" was composed of ninety-two 400μ stripped emulsions (6 in. x 4 in.) piled above each other. The block was flown for 6 hr at White Sands (41° geomagnetic). Eight of the 90 interactions found

ROC. 03:007 - ROC. 03:010

appeared to be with the hydrogen of the emulsion. These can be used for charge calibration. Out of the 90 interactions 22 fragments with Z = 3, 4, or 5 were found to emerge, confirming previously published values. Thus it does not seem possible to account for an apparently observed primary flux of these nuclei in terms of secondaries produced in the atmosphere. A detailed discussion of mean free paths and mechanism of the interactions is presented. (Contractor's abstract, modified)

PRODUCTION OF FAST LITHIUM, BERYLLIUM, BORON FRAGMENTS FROM INTERACTIONS OF PRIMARY COSMIC-RAY NUCLEI, by J. H. Noon, M. F. Kaplon, and D. M. Ritson. [1953] 3p. incl. diagrs. (AF 18(600)380) Unclassified

Also published in Phys. Rev., v. 92: 1585-1586, Dec. 15, 1953.

Study was made of the interactions of heavy cosmic ray nuclei in a stack of ninety-two 400μ Ilford G-5 stripped emulsions flown at White Sands, N. M. (41° geomagnetic). Two hundred and seventy heavy primary nuclei were traced through the stack. Charge determination both for the primary and collision fragments was based on delta-ray counting. The primary nuclei were divided into two groups; medium nuclei (M)$6 \leq Z \leq 10$, and heavy nuclei (H)$Z > 10$. From a study of 87 interactions occurring in emulsion, the proportion of the light elements lithium, beryllium, and boron (L nuclei) produced as fast fragments in these interactions were determined.

OBSERVATION OF A NEW DECAY MODE OF A HEAVY MESON, by J. Crussard, M. F. Kaplon and others. [1954] [1]p. incl. diagrs. refs. [AF 18-(600)380] Unclassified

Published in Phys. Rev., v. 93: 253, Jan. 1, 1954.

The trajectories of stopping π mesons were traced back in a stack of stripped emulsions to detect unstable heavy particles giving rise to π mesons as decay products. The technique of microscopic examination is given of the stripped emulsions, which were flown vertically at an altitude of 102,000 ft for 9 hr at geomagnetic latitude $\lambda = 55°$. Of the 299 π mesons traced, 150 were positive and 149 negative (the sign being determined since either $\pi \to \mu$ decay or σ star were observed). Of these, 116 π^+ and 103 π^- originated outside the stack, of those originating in the stack, 32 π^+ and 44 π^- came from stars having 3 or more prongs while 2 π^+ and 2 π^- originated from 2-prong stars. One π^+ meson of 4.3-mm range originates from the end of a stopping tracks (diagrammed), there is no indication of any recoil. Since the π^+ undergoes a large angle scattering, its energy lies between 13.8 and 15 mev. The stopping track has been traced through 14 emulsions and leaves the stack at a residual range of 1.6 cm. A weighted mean value of $950 \neq 85\ m_e$ was obtained for all mass measurements made on the primary particle by scattering-range and ionization-range methods. Interpretations of the event favor the decay at rest of a positively-charged heavy particle into a slow π^+ meson and one or more neutral particles.

THE LIGHT ELEMENTS OF THE COSMIC RADIATION — EXPERIMENTAL (Abstract), by G. W. Racette, M. F. Kaplon, and D. M. Ritson. [1954] [1]p. [AF 18(600)380] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago Chicago, Ill., Nov. 27-28, 1953.

Published in Phys. Rev., v. 93: 914, Feb. 15, 1954.

A stack of 27 250μ Ilford emulsions on glass was flown with vertical orientation for 8 hr at White Sands, N. M. ($\lambda = 41°$) at a mean depth of 20 g; the 27 plates consisted of 9 triads of G-5, C-2, and D-1 emulsions. The G-5 emulsions were scanned for all tracks with $1 > 61$ min and with projected length $> 725\mu$. All tracks obtained were traced as far as possible through the stack, the variation of I with range being used to differentiate tracks with $Z \geq 3$ from nonrelativistic α particles, slow protons, and deuterons. Charge determination was made by gap density and grain count in the insensitive emulsions. In a survey of 15 cm^2 of emulsion, 21 particles were found with $3 \leq Z \leq 5$ (L nuclei), 26 with $6 \leq Z \leq 10$ (M nuclei), and 8 with $Z > 10$ (H nuclei). The primary flux values obtained for M and H nuclei are in accord with values previously reported. (Contractor's abstract)

THE LIGHT ELEMENTS OF THE PRIMARY COSMIC RADIATION—INTERPRETATION (Abstract), by M. F. Kaplon, G. W. Racette, and D. M. Ritson. [1954] [1]p. [AF 18(600)380] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill. Nov. 27-28, 1953.

Published in Phys. Rev., v. 93: 914-915, Feb. 15, 1954.

Also published in Bull. Amer. Phys. Soc., v. 28: 10-11, Nov. 27, 1953.

To analyze the preceding data we have considered the diffusion equation for the three charge groups (L, M, H). Besides the depth of observation, the solutions depend upon λ_I (interaction mean free path) and P_{I-J} (probability of J-type production when an I type interacts) which are not well known for atmosphere (particularly P_{I-J}). It is necessary in the experiment to sum over all zenith angles consistent with our scanning criteria. Letting α be the calculated ratio of observable L nuclei emerging from collisions in the residual atmosphere to observable M nuclei with our scanning criteria, it was found that $\alpha = 0.35; 0.61$ for $P_{ML} = 0.23; 0.40$, respectively; if, for $P_{ML} = 0.40$, λ_L is increased by 10 percent, $\alpha = 0.69$. Thus, the interpretation of the observed ratio L/M = 21/16 = 0.81 depends on the λ_I and P_I. Though the observations differ markedly with those of Bradt and Peters and tend to confirm those of the Bristol Group, it is believed that a primary flux value of L nuclei derived by extrapolation cannot yet be unequivocally given, though at present the evidence favors the existence of some primary flux of the light elements. ($0.10 \lesssim L_0/M_0 \lesssim 0.5$). (Contractor's abstract)

FRAGMENTATION OF HEAVY PRIMARY NUCLEI OF THE COSMIC RADIATION INTO LIGHT ELEMENTS (Abstract), by J. H. Noon and M. F. Kaplon. [1954] [1]p. (AF 18(600)380) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, May 1, 1954.

Published in Phys. Rev., v. 95: 647, July 15, 1954.

Interactions of heavy primary nuclei with carbon, oxygen, and hydrogen nuclei of plastic (cellulose acetate) have been studied to determine the proportion of light elements (Li, Be, B) produced as fast fragments. A vertical stack of stripped emulsions and plastic sheets was flown at Minnesota (55° geomagnetic) for 9 hr at 102,000 ft. Twelve 400 μ Ilford G-5 emulsions (6" x 4"), 11,200 μ G-5-200 μ G-0 emulsions and 11 plastic sheets were arranged in 11 sets of triads. In tracing 800 heavy primaries ($Z \geq 6$) through the stack, 15 interactions were found to occur in the plastic and in 8 cases light elements were produced as fast fragments. The probability for fragmentation into light elements thus obtained agrees with a previous calculation on the basis of a simple geometrical model using data from heavy primary interactions with nuclei of photographic emulsion. This information is important in estimating what proportion of the observed flux of light elements at a given depth in the atmosphere comes from interaction of heavy primaries with nitrogen and oxygen of the residual atmosphere. OBSERVATIONS ON THE HIGH-ENERGY SOFT CASCADE (Abstract), by M. Koshiba and M. F. Kaplon. [1954] [1]p. (AF 18(600)380) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, May 1, 1954.

Published in Phys. Rev., v. 95: 647, July 15, 1954.

The use of stripped emulsion stacks affords an excellent opportunity to study the soft cascade process in detail. In order to specify with some certainty the initial conditions of the cascade and to introduce no selection bias, it is appropriate to study the soft showers originating from the decay photons of neutral π mesons emitted in high energy nuclear interactions. Soft showers which appear to originate from a single electron or photon in the emulsion may be accompanied by one or more photons; further for these showers there may be a detection bias favoring those showers with the largest fluctuations. The soft cascades initiated by the decay π^0 photons of a very high energy nuclear interaction has been studied. For the showers of low initial energy the cascade seems

ROC. 03:015 - ROC. 03:018

to develop in accord with the predictions of shower theory; on the other hand for showers of very high initial energy (≳100 bev), the trident process seems to play an important role in the initial development. Detailed shower developments will be presented and the trident process discussed. (Contractor's abstract)

OBSERVATIONS ON UNSTABLE PARTICLES IN PHOTOGRAPHIC EMULSION (Abstract), by J. Crussard, M. F. Kaplon and others. [1954] [1]p. (AF 18(600)380) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 29-30, May 1, 1954.

Published in Phys. Rev., v. 95: 660, July 15, 1954.

Also published in Bull. Amer. Phys. Soc., v. 29: 72-73, Apr. 29, 1954.

Further evidence is presented for the existence of the alternate decay mode of the τ meson. A particle with a mass value of 1060 ± 100 m_e, originating from a star classified as either 2 + 1_0 or 2 + 0_p, is observed to decay into a π^+ meson of 15.2 mev energy. Two cases of normal 3 charged π decay of the τ meson are observed, one of which gives a precise Q value of 73.85 ± 1 mev; it is noted that the τ meson mass is identical within experimental errors to that of the θ° meson. A K meson is observed to be produced from a star with a total visible prong energy of 850 mev; this may suggest a low production threshold. Another K meson is observed to suffer large angle inelastic scattering at low energy (~40 mev) implying a direct nuclear interaction of this particle. Q values for 2 prong stars consisting of π^- mesons and protons will be reported; among these is a value of 37.8 ± .6 mev, corresponding to a Λ_0 decay. (Contractor's abstract)

ANOMALOUS EVENT OBSERVED IN PHOTOGRAPHIC EMULSION, by J. H. Noon, M. F. Kaplon, and J. Crussard. [1954] [2]p. incl. diagr. tables. (AF 18-(600)380) Unclassified

Published in Phys. Rev., v. 95: 1103-1104, Aug. 15, 1954.

In a stack of 400-μ G-5 stripped emulsions flown at high altitude an anomalous interaction of a fast heavy nucleus was observed. A fast Be nucleus (a) interacts producing a 6 + 1 $_{Be}$ star. Two of the prongs are relativistic particles of charge 3 and 2, each making an angle ~ 0.002 radian with the primary. The triply charged particle (b) interacts after 5.09 cm, giving a 0 + $6_{1.1}$ star. The doubly charged particle (c) travels 1.37 cm, then splits into 2 fast singly charged particles (d and e); there is no observational evidence of nuclear interaction and the event c→d + e is coplanar. Since it is resonable to assume in interaction of fast heavy nuclei that the fast heavy fragments observed originate from the incident nucleus, the charge of the fragments should not exceed that of the parent. The violation of this aspect of charge conservation provides the anomaly. Possible explanations are discussed. (C.A., 1954:11955e)

ABUNDANCE OF LITHIUM, BERYLLIUM, AND BORON IN THE PRIMARY COSMIC RADIATION, by M. F. Kaplon, J. H. Noon, and G. W. Racette. [1954] 29p. incl. diagrs. tables, refs. (AF 18(600)380) Unclassified

Also published in Phys. Rev., v. 96: 1408-1416, Dec. 1, 1954.

The flux of nuclei of charge greater than two of the primary cosmic radiation has been measured at 41° and 55° geomagnetic latitudes with photographic emulsions flown in "Sky Hook" balloons. The technique used at the lower latitude is similar in principle to that employed originally by Bradt and Peters, while that used at the higher latitude is the method of Dainton, Fowler, and Kent. The different experimental methods are discussed and the latter is found more satisfactory for the light element problem. Primary flux values are reported for the medium nuclei ($6 \leq Z \leq 10$) and the heavy nuclei ($Z > 10$) at the two latitudes. It is concluded that there exists a finite primary flux of the light nuclei ($3 \leq Z \leq 5$) and the most reliable value from these experiments of the ratio of the primary light-nuclei flux N_L° to the primary medium-nuclei flux N_M° at the top of the atmosphere is found to be 0.46 ± 0.15. β^--DECAY OF K-MESONS (Abstract), by G. Yekuttelt, M. F. Kaplon, and J. Klarmann. [t955] [1]p. [AF t8(600)380] Unclasstfted

Presented at meeting of the Amer. Phys. Soc., Washtngton, D. C., Apr. 28-30, 1955.

Published in Phys. Rev., v. 99: 64t, July t5, t955.

Two events in emulsion have been observed interpretable as the decay of the K-meson tnto an electron and two neutral partticles. In the first the decay track ts emitted at mtnimum tonization with E = 260 mev; identification rests upon the fact that it loses t10 mev in 4.6 cm with no change in tonization, an abnormal loss for a π or μ meson but not for an electron. In the second the secondary is emitted with 20 mev at mintmum tontzation; tn terms of known particles it must be an electron. For both particles the primary mass is ~ t000 M_e. In view of this and other recent observations on the K electron decay, it now seems conclusive that a K-meson exists and decays into an electron and two neutral massless partticles (this is implied by first event above). It is thus interesting to inquire as to whether the K decays giving a continuous electron and μ meson spectra may not be alternate modes via a Fermi tnteractton. The branching ratto is of order unity and the life time $\sim 10^{-9}$ seconds assuming a Universal Fermt Interaction. A survey of the observattons on K meson decay tn emulston shows the data does not contradtct this hypothesis. (Contractor's abstract)

"V"-PARTICLES IN NUCLEAR EMULSION, by J. Klarmann, M. F. Kaplon, and G. Yekutieit. [1955] [1]p. [AF t8(600)380] Unclassifted

Presented at meetting of the Amer. Phys. Soc., Washington, D. C., Apr. 28-30, t955.

Published in Phys. Rev., v. 99: 64t, July 15, 1955.

Emulston stacks are well sutted for precise energy determtnattons and tdentiftcattons of relattvely energetic charged particles (effective energy ltmtt determined by stack size) stnce they can be stopped and their energy limit determined by range measurement, whtle tdentiftcation ts assisted by the characteristics of the track termtnus. Emulsion stacks should thus afford the most precise Q-value determinations for unstable partticles if they can be detected and their decay fragments stop. We have searched for "V-particles" by tracing back trajectories of π-mesons; for those events in which the meson ortginates from a 2 prong star, the other prong being an endtng proton, a Q-value was calculated as sumtng decay of a neutral particle into a proton and

ROC. 03:023 - ROC. 03:027

π^-meson. Very precise Q-values are reported for the Λ° decay in this way. At present 12 "V-particles" selected this way in the laboratory give a spectrum of Q-values including 3 between 36.6 and 37 mev and two with 30.3 and 30.5 mev respectively. The latter two (having no counterpart in Cloud Chamber investigations) suggest a possible background of simulated V-particles in emulsion coincding with the Λ°. An attempt to assess this is made by studying stars of the type $(\pi^+)_o$, $(\pi^+)_p$, $(\pi^+ + p)_p$, $(\pi^- + 2p)_o$ and $(\pi^- + 2p)_p$ which, with the simulated V-particle stars $(\pi^- + p)_o$, represent the two possibilities of single $\pi^\pm$ meson production in photo-nucleon interaction and the four possibilities in nucleon-nucleon interactions. β-DECAY OF K-MESONS AND THE CLASSIFICATION OF K-MESON DECAYS, by M. F. Kaplon, J. Klarmann, and G. Yekutieli. May 5, 1955, 20p. incl. diagrs. tables, refs. [AF 18(600)380] Unclassified

Also published in Phys. Rev., v. 99: 1528-1533, Sept. 1, 1955.

Three well-identified cases of K-electron decay were observed. The secondary electrons have energies of 20-261 mev. This shows that the decay involves at least 3 particles. The available data on K-meson decays observed in nuclear emulsion is analyzed by determining how many of the secondaries are consistent with the assumption that they are μ-mesons from the $K_{\mu 3}$ decay or electrons from the Ke_3 decay. An appreciable fraction ($\sim$1/3 to 1/2) of the observed decays are consistent with this assignment. The observed branching ratio is consistent with that deduced from a Fermi interaction, but the lifetime predicted on the basis of a universal Fermi interaction is shorter than that suggested by the observations in emulsion. The existing data on K-mesons are consistent with the assumption that there are at least 5 separate decay schemes, and that in each case the parent K-meson has integral spin. (C. A., 1955:15532h)

HIGH-ENERGY ELECTROMAGNETIC PHENOMENA IN COSMIC RADIATION, by M. Koshiba and M. F. Kaplon. [1955] 1 v. incl. diagrs. tables, refs. [AF 18(600)-380] Unclassified

Also published in Phys. Rev., v. 100: 327-339, Oct. 1, 1955.

Isolated high-energy electron showers in photographic emulsion have been investigated and have yielded the following conclusions: (1) out of 16 cases of isolated electron showers observed to originate from single electron pairs of energy greater than 1 bev, 2 cases have been found to be anomalous in the sense that they seem to have been initiated by more than 2 photons; one of the two has been analyzed in detail. (2) The discrepancy between the experimental observations and theoretical predictions on the trident process found in a previous work has been obtained again with the additional experimental data of this experiment. NATURE OF THE NEUTRAL PARTICLES IN THE $K_{\mu 3}$ DECAY, by G. Yekutieli, M. F. Kaplon, and T. F. Hoang. [1956] [2]p. incl. diagr. (Sponsored jointly by Atomic Energy Commission and Air Force Office of Scientific Research under AF 18(600)380) Unclassified

Published in Phys. Rev., v. 101: 506-507, Jan. 1, 1956.

The reaction $K^+ \rightarrow e^+ + e^- + \mu^+$ was identified. The $e^- - e^+$ pair had p βc values of 21 ± 6 and 74 ± 9 mev. The μ^+ kinetic energy at emission was 17.93 mev. The K^+ mass was 1060 ± 200 m_e. A theoretical treatment of the $K_{\mu 3}{}^+$ decay is given.

FURTHER EVIDENCE ON THE NATURE OF THE NEUTRAL PARTICLES IN THE DECAY SCHEME OF $K_{\mu 3}$, by T. F. Hoang, M. F. Kaplon, and G. Yekutieli. [1956] [2]p. incl. diagr. (Sponsored jointly by Atomic Energy Commission and Air Force Office of Scientific Research under AF 18(600)380) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 3, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 15, Jan. 30, 1956.

Published in Phys. Rev., v. 101: 1834-1835, Mar. 15, 1956.

The decay $K_{\mu 3} \rightarrow \mu^+ + \pi^\circ + X^\circ$ (X° is a neutral particle with mass < 217 mev; it can be a π° meson, γ-ray, or a neutrino) was demonstrated previously. In a new $K_{\mu 3}$ decay, it was found that X° is massless, and that it is either a photon or a neutrino. (C. A., 1956:9903d)

METHODS FOR THE DETERMINATION OF GAP LENGTH DISTRIBUTION OF NUCLEAR EMULSION

TRACKS (Abstract), by J. Klarmann and R. A. Bryan. [1956] [1]p. (AF 18(600)380) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 230, Apr. 26, 1956.

Two different methods, using a multiple channel analyzer, have been employed to measure the gap length distribution for tracks of low Z components of the primary cosmic radiation. In previous methods the observer measured and recorded the length of each gap individually, but here the recording is automatic. At the end of a measurement the number of gaps longer than s microns for 8 adjustable values of s can be read off directly from the channel analyzer. In the first method the stage is driven at uniform speed along the track while in the second the observer moves at hairline along the track. In both methods the observer does not have to remove his eyes from the microscope for duration of the measurement. Thus these methods seem to be more expedient than others previously described. Data indicating the sensitivity and range of application of both methods are presented.

RATIOS OF DECAY MODES OF K^+ MESONS PRODUCED BY THE COSMOTRON, by T. F. Hoang, M. F. Kaplon, and G. Yekutieli. [1956] [3]p. incl. diagrs. tables. (Sponsored jointly by Atomic Energy Commission and Air Force Office of Scientific Research under AF 18(600)380) Unclassified

Published in Phys. Rev., v. 102: 1185-1187, May 15, 1956.

A beam of K^+ mesons, 270 ± 10 mev/c, was produced by 2.9 - bev protons on Cu. The occurrence of the modes of decay was: $K_{\mu 2}$, $59 \pm \frac{6}{5}\%$; $K_{\pi 2}$, 21 ± 3%; τ, 5.2%; $K_{\pi 3}$, 3.5%; $K_{\mu 3}$, $6 \pm \frac{3}{2}\%$; K_{e3}, $5 \pm \frac{6}{2.7}\%$. The results are compared with those of Ritson, et al. (Chem. Abstracts, v. 50: 6965i, 1956) and of Crussard, et al. (C.A., 1956:14404f)

CONTROLLED DEVELOPMENT FOR NUCLEAR EMULSIONS, by J. M. Blum. [May 28, 1956; rev. July 17, 1956] [2]p. incl. diagrs. [AF 18(600)380] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 26-28, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 1: 219, Apr. 26, 1956.

Published in Rev. Scient. Instruments, v. 27: 938-939, Nov. 1956.

A method consisting of separating the active phase of the development of nuclear emulsions into two or more stages is presented here. The purpose of this procedure is to obtain a reproducible degree of development of these emulsions at some prefixed level of sensitivity. The preliminary results reported indicate the feasibility of this procedure. (Contractor's abstract)

INVESTIGATION OF LEAD SULFIDE PHOTOCONDUCTIVITY BY OPTICAL SCANNING TECHNIQUE, by E. P. Woodruff and H. D. Polster. Technical rept. Nov. 1953, 7p. (AF 18(600)193) AD 28941 Unclassified

The photoconductive sensitivity of microscopic regions of PbS surfaces was investigated with a microbeam apparatus which produced a spot of light of a magnitude of 2 to 15μ on the photoconductor. PbS surfaces, chemically deposited onto glass with gold electrodes evaporated onto the ends, were examined. Electron photomicrographs indicated a crystallite size of 0.5 to 2.0 μ. All work was carried out at room temperature. In a number of parallel scans, it was found that few points varied by as much as a factor of 10 from the normal. Some of the localized spots of high sensitivity occurred near the ends of threadlike breaks. Several phenomena were found that involved changes in sensitivity over periods of hours. Ion migration is discussed with respect to these phenomena. Noise of an order of magnitude greater than normal followed a reversal of the polarity after continuous running in one polarity for days. The noise subsided to normal in about ½ hr. (ASTIA abstract)

FINE-SPOT SCANNING OF LEAD SULFIDE FILMS, by D. Dutton. Oct. 1954 [19]p. incl. diagrs. refs. ([AF]OSR-TN-54-288) (AF 18(600)193) AD 50329 Unclassified

High resolution optical scanning and potential probe measurements have been made on chemically deposited lead sulfide layers. Photoconductivity is localized to a high degree in regions at least as small as the optical resolution limit of 2 μ. These regions might be identified with potential barriers of the type proposed by Smith (Proceedings of the Reading Conference on Semiconducting Materials, 1951, p.198) and Gibson (Proc. Phys. Soc. London, v. 64B: 603, 1951) with the stipulations that: (a) diffusion of minority carriers is effectively limited by grain boundaries; and (b) those grain boundaries associated with important potential barriers are relatively infrequent. The films may show high optical sensitivity associated with large potential gradients near the electrodes. This is apparently a polarization effect absent in new cells. The high gradient develops near the cathode over a period of several hr, at room temperature, with an applied field of the order of 5v/mm. (Contractor's abstract)

LOCALIZATION OF PHOTOCONDUCTIVITY IN PbS FILMS, by D. Dutton. Aug. 1955 [11]p. incl. diagrs. (Technical note no. 3) ([AF]OSR-TN-55-279) (AF 18-(600)193) AD 77487 Unclassified

Presented at meeting of the Amer. Phys. Soc., Baltimore, Md., Mar. 17-19, 1955.

A test for the degree of localization of photoconductivity in thin films, first used by Müser (Zeitschr. physik. Chemie (Leipzig), v. 198: 52, 1951) and consisting of the comparison of the photocurrents produced by 2 orientations of a long narrow beam, parallel to and perpendicular to the applied field, has been applied to samples of lead sulfide photoconducting layers. The results are consistent with a localized-photoconductivity model. Because of inherent experimental difficulties, the method does not appear suitable for placing a small upper limit on the range of minority carriers. On the basis of the present measurements, the limit may be placed at from 0.1 to 0.3 mm. The limit suggested by fine-spot scanning observations is less than 2 x 10^{-3}mm. (Contractor's abstract)

LUMINESCENCE OF POTASSIUM IODIDE, by K. Teegarden. June 1956 [21]p. incl. diagrs. (Rept. no. 7) (AFOSR-TN-56-275) (AF 18(600)193) AD 89485 Unclassified

Also published in Phys. Rev., v. 105: 1222-1227, Feb. 15, 1957.

Single crystals of KI luminesced with a quantum yield between 0.5 and 1 when cooled to -160°C and illuminated with light absorbed in the first fundamental band. Emission occurred mainly in a single band with its peak at 3.3 ev. The results obtained indicated that lattice defects which broaden or add to the tail of the fundamental band also caused a shift of the emission band to longer wavelengths. With a single crystal containing a small amount of Th impurity, indirect excitation of Th luminescence apparently resulted from the absorption of light in the first fundamental band of the crystal at -160°C. It was indicated that a systematic study of the luminescence as a function of Th concentration may give a measurement of the so-called "exciton" diffusion length.

NEW DATA ON ALKALI HALIDE FILMS CONTAINING EXCESS HALOGEN, by K. Teegarden. June 1956 [9]p. incl. diagrs. (Rept. no. 6) (AFOSR-TN-56-276) (AF 18(600)193) AD 89486 Unclassified

The optical densities of thin films of KI and KBr containing Cl_2 and of KCl containing excess I_2, Br_2, and Cl_2 were measured at -183°C. The films were formed by simultaneously evaporating an alkali halide and the halogen onto a fused quartz substrate. The absorption spectrum of a large crystal of KBr and the optical density of single KCl crystals were obtained after x-irradiation at -140° and -80°, respectively. The optical absorption bands of films of KI or KBr formed by excess I_2, Br_2, or Cl_2 were the same as the V-absorption bands found in additively colored or x-rayed crystals. Different absorption bands were produced by the thin KCl films with excess I_2, Br_2 or Cl_2.

OPTICAL ABSORPTION BY SILVER HALIDES, by S. Tutthast. Oct. 1956 [13]p. incl. diagrs. refs. (AFOSR-TN-56-543) (Rept. no. 15 under AF 18(600)688 and rept. no. 8 under AF 18(600)193) AD 110362 Unclassified

Also published in Phys. Rev., v. 105: 882-884, Feb. 1957.

The absorption spectra of AgCl, AgBr and AgI films evaporated on quartz plates have been measured at room temperature and liquid nitrogen temperature. It has been found that the "exciton peaks," which have been believed to depend very little upon temperature, become sharper and shift toward the shorter wave-length side

as the films are cooled down to liquid nitrogen temperature. Attempts are made to combine the present data with some published data to give absorption curves for AgCl and AgBr over a large range of absorption spectrum at room and low temperatures. (Contractor's abstract)

F-CENTER WAVE FUNCTIONS IN ALKALI HALIDES, by D. L. Dexter. [1953] 5p. incl. refs. (Rept. no. R355-20-7) (AF 18(600)688) AD 42588
Unclassified

Also published in Phys. Rev., v. 93: 244-245, Jan. 1, 1954.

The discussion considers the conclusions of Kittel et al that the natural model for the F-center wave function is that corresponding to a linear combination of atomic orbitals (LCAO) centered on the 6 positive ions closest to the negative-ion vacancy. An attempt is made to show that previous experiments are consistent with the common alternative model of the F-center, based on a radial field directed at the negative-ion vacancy, when the model is properly applied. The LCAO model was capable of explaining the observed probability densities at the K nuclei, in agreement with previous conclusions, although in this simple form it predicts nothing about the density at the nearest Cl^- ions empirically found to be 0.12×10^{24} cm^{-3}. With the use of Tibbs' functions (Trans. Faraday Soc., v. 35: 1471, 1939), the probability density of the F-center electron at one of the 6 nearest Na nuclei was estimated to be 0.61×10^{24} cm^{-3}. The value for the density at one of the 12 nearest Cl nuclei was computed and found to be 0.45×10^{24} cm^{-3}. The relatively large value at the Cl nuclei is a result of the larger nuclear charge in Cl, which gives a large amplitude to the 4s-like function at the Cl nucleus. The width of the absorption peak for NaCl was measured as 162 oersteds, but with the estimated probability densities was calculated to be 265 oersteds. The next nearest shell of Na ions contributed only 1% to the mean square width. There is no obvious advantage to either type of wave function, except that the function $f(|r|)g(r)$ is simpler, and gives a more accurate description at larger r than does a LCAO containing only a few terms.
