LIQUID INJECTION THRUST VECTOR CONTROL

by
C. J. Green
and
F. McCullough, Jr.
Propulsion Development Department

CATALOGED IN ASTIA 268731
AS AD No. _____

ABSTRACT. The technique of obtaining thrust vector control by the injection of a liquid into the supersonic region of a rocket nozzle has been studied. This report presents the experimental results obtained with various liquid injectants together with the effects of some of the more critical physical parameters. Liquids studied were water, Freon-12, Perchloroethylene, nitrogen tetroxide and bromine. In addition, unsymmetrical dimethylhydrazine and inhibited red fuming nitric acid were injected simultaneously to explore the effect of energy release in the nozzle exit cone with bipropellant injection. Data on the relationships of side force to injectant flow rate, the effect of axial location of the injection port, the effect of injection pressure and the effects of injectant properties are presented and discussed.

Released to ASTIA for further dissemination with
out limitations beyond those imposed by security
regulations.

INTRODUCTION

As the performance of propulsion systems increases, accompanied in most cases by increased combustion temperatures, the problem of satisfactory materials for mechanical thrust vector control devices becomes increasingly critical. With this problem in mind a study of possible techniques of thrust vector control was initiated at the Naval Ordnance Test Station in 1958 (Ref. 1). The technique of injecting a fluid into the expansion cone of a supersonic nozzle (secondary injection) to produce a usable side force or thrust vector force appeared to be the most promising new technique (Fig. 1).

The initial study of the secondary injection technique, using cold-flow (air) equipment, was reported by the United Aircraft Corporation (Ref. 2). Following work was performed by the Naval Air Rocket Test Station (Ref. 3), by United Aircraft Corporation (Ref. 4), and the Naval Ordnance Test Station (Ref. 5 and 6), all with gases as the injected fluids. These studies, in general, indicated that for maximum effectiveness the injected gas should be near the combustion temperature of the main-stream gases. To avoid the high temperature material problems and to meet system requirements the use of liquids as injectants was proposed. The feasibility of using liquids was demonstrated early in 1959 (Ref. 7).

EXPERIMENTAL PROCEDURES

Both liquid and solid propellant motors were used in this experimental program. One injection test was conducted using a quarter-scale SUBROC motor loaded with B. F. Goodrich E-107 polyurethane propellant containing 17.7 percent aluminum by weight. The remainder of the tests were conducted with the liquid propellant applied research motor (LPARM).

LPARM TESTS

The LPARM, Fig. 2, consists of an injector, water-cooled combustion chamber, and the nozzle test section. For the work reported in

FIG. 1. Thrust Vectoring by Secondary Injection

FIG. 2. Liquid Propellant Applied Research Motor

this paper, the LPARM was operated with unsymmetrical dimethylhydrazine and inhibited red fuming nitric acid (UDMH and IRFNA) at the nominal conditions given in Table 1.

Measurements which were recorded during each test were:

1. Main thrust
2. Side thrust
3. Chamber pressure
4. Injection pressure
5. Oxidizer manifold pressure
6. Oxidizer line pressure
7. Fuel manifold pressure
8. Fuel line pressure
9. Oxidizer flow rate
10. Injectant flow rate
11. Fuel flow rate
12. Coolant water flow rate

Four types of secondary injection tests were conducted: single axial position (constant secondary fluid flow rate) (type C, Fig. 3), tests in which injection occurred at four different axial positions (type B, Fig. 4), variable secondary flow rate tests (type A, Fig. 5), and bipropellant injection tests (Fig. 6). Test type A was accomplished through the use of a hydraulically-operated, flow control valve which was opened and closed with water pressure. Opening and closing speed could be adjusted by metering the water to or from the piston-operated valve. Test type B utilized a series of four solenoid valves, which were opened and closed sequentially during the tests.

The test nozzles, Fig. 7 and 8, were uncooled and used graphite throat inserts. These nozzles were adequate for tests of three to four seconds duration. The 16 point nozzle, Fig. 7, was fabricated with four rows of four orifices 90 degrees apart. Each row of orifices was drilled a different diameter. This arrangement permitted the effect of orifice area and axial location of the injection port to be studied. All orifices were round and were drilled perpendicular to the nozzle axis.

For the bipropellant injection tests, the basic nozzle body was modified to permit the insertion of bipropellant injectors, Fig. 8.

Side-force measurements were accomplished through the use of a pivot mount, lever arm, and Wianko force transducer. The side-force assembly was in turn fastened to a flexure mount to permit the measurement of axial thrust, Fig. 9. All side-force measurements reported are resolved to a point on the nozzle 6.42 inches from the throat. Calibration of both side-force and axial thrust was accomplished "in place" through the use of Moorehouse proving rings.

FIG. 5. Schematic of Test Installation for Study of Secondary Injection--Test Type A

FIG. 6. Bi-propellant Injection Test Installation

FIG. 7. Sixteen Point Nozzle

FIG. 8. Bi-propellant Injection Nozzle

FIG. 9. Schematic of LPARM Motor Mount

In the tests of secondary injection, the motor was allowed to begin operating smoothly before injection was started. This permitted the measurement of side-force as a change in side-force, thus canceling the effects of any main thrust malalignments and other side-force effects caused by motor operation.

Typical LPARM tests may be seen in Fig. 10 and 11. Figure 10 shows the LPARM operating without secondary injection; Fig. 11 shows operation with secondary injection.

QUARTER-SCALE SUBROC TESTS

The test of secondary injection using a solid propellant motor was conducted primarily for purposes of data comparison. The effects of different motor performances and the aluminized propellant were of particular interest. In addition, three different injection geometries were investigated. Figure 12 depicts the quarter-scale SUBROC nozzle used in this test. The characteristics of the quarter-scale SUBROC motor are given in Table 2. The following measurements were recorded during this test:

1. Axial thrust
2. Chamber pressure
3. Injection pressure
4. Side thrust
5. Injection flow rate

Both Freon-12 and nitrogen tetroxide were used as injectants for this test. Nitrogen tetroxide was injected through a single orifice only, and Freon-12 was injected through both single and multiple orifice configurations.

The fluids were injected in a cyclic fashion during the first 26 seconds of the 35 second motor burning time. An attempt to vary the flow rate of each injectant by the "blow-down" technique was only partially successful due to faulty check valves. Figure 13 shows the test schematic, and Fig. 14 and 15 show the motor in position for firing.

Side-force was measured in two planes 90 degrees apart with Wianko force transducers as shown in Fig. 14. All side-forces are resolved to the nozzle exit plane.

RESULTS

Seven fluids, including UDMH and IRFNA, were used as injectants in this experimental program. The five fluids used individually were as follows: Freon-12, perchloroethylene, water, nitrogen tetroxide, and bromine. Tabulated data are presented in Tables 3 and 4 from the LPARM and quarter-scale SUBROC tests respectively.

LPARM DATA

Most data presented graphically in this report are in the form of the ratio of side-force to main thrust versus the ratio of secondary flow rate to main flow rate (F_s/F_m versus $\dot{w}_s/\dot{w}_c$). Consequently, the slope of the line describing the best fit to the data points represents the ratio of the specific impulse of the secondary fluid to the specific impulse of the main stream gases. This slope has been termed the performance ratio. The position number noted on each graph refers to axial location and size of the injection port, Fig. 7.

In some cases, fluids were injected through two orifices located in line axially. Consequently, the notation on the graphs, or in the data tabulation, calls out two position numbers.

The reproducibility of the LPARM side thrust measuring system may be seen in Fig. 16. This figure shows the actual data points obtained from eight different tests of Freon-12 injection.

FREON-12 INJECTION

The family of curves shown in Fig. 17 represents the results obtained by injecting Freon-12 at four different axial locations through orifices 0.152 inch in diameter. These data are shown again in a plot of performance ratio (F_s/F_m versus $\dot{w}_s/\dot{w}_m$) as a function of axial location at injectant flow rates of five, ten, and fifteen percent of the main propellant flow rate, Fig. 18. Both figures show the interdependence of injectant flow rate and axial location upon injectant performance.

Figure 19 shows the result obtained by injecting Freon-12 through 0.104-inch-diameter orifices at two different axial locations. The solid portions of the curve indicate the range in which data were obtained.

FIG. 16. Freon-12 Data Points

FIG. 17. Freon-12 Injection Data

FIG. 18. Effect of Axial Location

FIG. 19. Freon-12 Injection Data

PERCHLOROETHYLENE INJECTION

Figures 20 and 21 show the results obtained by injecting perchloroethylene through 0.152- and 0.104-inch-diameter orifices at various axial locations. Position 16 (0.152-inch-diameter) corresponds to position 14 (0.104-inch-diameter) in axial location, Fig. 7.

WATER INJECTION

Figure 22 shows the results obtained from water injection through one 0.152-inch-diameter orifice (position 12), and through two 0.152-inch-diameter orifices (position 16 and 12).

BIPROPELLANT INJECTION

Figure 23 shows the results obtained from the simultaneous injection of UDMH and IRFNA. These tests were intended to determine the effects of any exothermic reaction of the injectant within the expansion cone. Two injector designs were used for these tests (Fig. 8); both designs provided approximately the same results. Bipropellant injection provided the highest performance ratio obtained in this test series.

LPARM DATA SUMMARY

Figure 24 compares the results obtained from double orifice injection with Freon-12, perchloroethylene, and water. Figure 25 shows the relative performances obtained with bromine, UDMH and IRFNA, Freon-12, perchloroethylene, and water at similar axial locations.

SUBROC DATA SUMMARY

Figure 26 is a summary of data obtained from the injection tests with the quarter-scale SUBROC motor. Both Freon-12 and nitrogen tetroxide were used as injectants for this test. Nitrogen tetroxide was injected through a single orifice only, and Freon-12 was injected through both single and multiple orifice configurations (Fig. 12). In Fig. 26, "Freon-12 radial" and "Freon-12 parallel" refer to positions 2 and 4 respectively in Fig. 12. Main propellant flow rates were obtained by dividing the main thrust by the propellant specific impulse. The propellant specific impulse was assumed to remain constant over the test duration.

DISCUSSION

RELATION OF SIDE THRUST TO INJECTANT FLOW RATE

For a given orifice size and axial location, the variation in side thrust with secondary flow rate was found, in many cases, to be essentially linear; i.e., the injectant specific impulse was found to be constant over the flow range covered in these tests. The performance ratio, or slope of the plot of F_s/F_m versus $\dot{w}_s/\dot{w}_m$, is related to injectant specific impulse in that the performance ratio is equal to the injectant specific impulse divided by the motor specific impulse. The SUBROC data indicate a tendency for the performance ratio of an injectant to remain constant with changes in motor, or rather propellant, performance. Thus, injectant specific impulse may be increased if motor performance, via propellant performance, is increased. However, other factors affect the value of the performance ratio of a particular injectant, such as axial location, injectant momentum, and injection orifice configuration.

EFFECTS OF AXIAL LOCATION

The test data indicate an optimum axial location for maximum injectant performance, which is dependent upon injectant flow rate. The LPARM data indicate that injectant performance increases, for secondary flow rates of five to 15 percent through a 0.152-inch-diameter orifice, as the injection port is moved upstream to a point approximately 3.5 inches from the throat. As secondary flow rates exceed approximately 13 percent of main propellant flow rate at position 12, the performance ratio of Freon-12 appeared to decrease. It is believed that this reduction of the performance ratio of an injectant at high flow rates may be attributed to extreme radial dispersion of the pressure field causing side-force, or reflection of the shock wave off the wall opposite the injection port. In either case, the integration of the radial components of the pressure area forces can yield a decreased component of side-force. Data obtained from the three-port parallel orifice configuration, Fig. 12, indicate a reduction of the performance ratio of the injectant. This reduction was probably due to the radial spread of the pressure field. The three-port radial configuration, on the other hand, showed an increase in the performance ratio over the single-port configuration, indicating that some radial spread may be desired, probably due to the increase in mixing efficiency, and heat transfer.

EFFECT OF INJECTION PRESSURE

Variations in the performance ratio of a single injectant have been noted when the area of the injection port is changed. The data presented in this report indicate a relation between the rate of change of momentum of the injected fluid to the side thrust developed (Fig. 27, 28, and 29). In Fig. 28, the ratio F_s/F_m has been plotted as a function of $(\dot{w}_s/\dot{w}_c \div g/A)^{1/2}$. The square of the main propellant flow rate ($\dot{w}_c^2$) was included in the rate of change of injectant momentum term to take into consideration discrepancies in motor performance and thrust levels, Fig. 27. Thus, $(\dot{w}_s^2/\dot{w}_c^2 \div g/A)^{1/2}$ is essentially a rate of change of momentum ratio, as the rate of change of momentum of the exhaust gases is proportional to $\dot{w}_c^2$. Data on injection through two different sizes of orifices, and even for simultaneous injection through two orifices in line axially, appear to lie on essentially a single straight line when plotted on log paper. The data for these graphs were obtained from graphs of F_s/F_m versus $\dot{w}_s/\dot{w}_c$ for similar axial locations. Figure 29 shows points of equivalent secondary flow rates through various orifice diameters. From this arrangement of data it may be seen that injection pressure should be as high as possible for a given flow rate. Appreciable increases in the performance ratio of an injectant may be obtained by increasing the injection pressure. The increase in performance may be due to greater injectant penetration of the exhaust gases under these conditions.

From Fig. 29 the following approximate equation describing Freon-12 injection was obtained:

$$F_s/F_m = 0.223 (\dot{w}_s^2/\dot{w}_c^2 \div g/A)^{1/2}$$

Because the data from which this equation was derived covers only a relatively small range of conditions, it is highly approximate. Subsequent testing over a wider range has indicated a tendency of the injectant performance to approximate the curves of Fig. 30. This figure predicts the performance curves of Freon-12 when injected by a variable area, constant pressure technique. These curves were generated through the use of the approximate Freon-12 injection equation.

EFFECT OF INJECTANT CHARACTERISTICS

The total side-force resulting from the injection of a fluid into the expansion cone of a rocket nozzle may be considered to consist of two components: (1) a component of side-force due to the thrust of the fluid upon injection (product of mass flow rate and velocity plus

FIG. 27. Momentum of Injection Versus Force Ratio

FIG. 28. Momentum of Injection/(Chamber Flow Rate)²
Versus Force Ratio

FIG. 29. Momentum of Injection/(Chamber Flow Rate)²
Versus Force Ratio

FIG. 30. Effect of Orifice Size and Injection Pressure on Performance

a pressure area term for gas injection), and (2) a component due to the interaction of the injected fluid with the main-stream gases. The second component consists of a static pressure recovery of the main-stream gases acting over an asymmetrical area within the nozzle. The pressure area force resulting from this pressure recovery represents from 80 to 90 percent of the total developed side-force, in the case of liquid injection.

A one-dimensional model of this fluid interaction process has been analyzed (Ref. 8). The results of this analysis indicate that the injectant should provide as large an obstruction as possible to main-stream flow, and should react or decompose with a release of heat or, in the case of an inert fluid, vaporize and/or dissociate with a minimum amount of heat absorption. Consequently, the following, and in some cases conflicting, injectant characteristics are desired:

1. Low specific heat in liquid and vapor phases
2. Low boiling point
3. Low heat of vaporization
4. High heat of reaction or exothermic decomposition
5. Low molecular weights of products of combustion or decomposition
6. High density (from a packaging standpoint)

RECOMMENDATIONS

In view of the demonstrated performance of bipropellant injection, further effort should be directed toward the use of monopropellants and bipropellants as injectants. Various injection techniques which would enhance the occurrence of chemical reaction within the nozzle are required to take full advantage of the injectants' heat of reaction or decomposition. Some techniques which could be employed are as follows: (1) short L^* premix or decomposition chambers prior to injection, (2) multiport upstream injection to increase heat transfer and injectant residence time, (3) injecting the fluid upstream of an obstruction in the flow to trigger reaction when the fluid passes through the shock generated by the obstruction, and (4) premixing the injectant with some by-passed chamber gases.

Constant pressure injection by means of a variable area orifice may influence system design considerably if only small corrective forces are required for the major portion of the flight time. Figure 30 indicates that large savings in injectant weight could be realized due to the higher performance available during high-velocity, low-flow-rate injection.

Effort should also be directed toward the screening of various storable high density fluids which may perform well as injectants. Fluids should be chosen for testing which look promising in light of the one-dimensional analysis (Ref. 8) and in view of the desirability of high fluid density.

ABSTRACT CARD

U. S. Naval Ordnance Test Station <u>Liquid Injection Thrust Vector Control</u>, by C. J. Green and F. McCullough, Jr. China Lake, Calif., NOTS, 16 June 1961. 56 pp. (NAVWEPS Report 7744, NOTS TP 2711), UNCLASSIFIED. ABSTRACT. The technique of obtaining thrust vector control by the injection of a liquid into the supersonic region of a rocket nozzle has been studied. This report presents the experimental results obtained with various liquid injectants	U. S. Naval Ordnance Test Station <u>Liquid Injection Thrust Vector Control</u>, by C. J. Green and F. NAVWEPS Report 7744

together with the effects of some of the more critical physical parameters. Liquids studied were water, Freon-12, Perchloroethylene, nitrogen tetroxide and bromine. In addition, unsymmetrical dimethylhydrazine and inhibited red fuming nitric acid were injected simultaneously to explore the effect of energy release in the nozzle exit cone with bipropellant injection. Data on the relationship of side force to injectant flow rate, the effect of axial location of the injection port, the effect of injection pressure and the effects of injectant properties are presented and discussed.
