ABSTRACT

Performance tables are presented which were obtained by plotting data from machine calculations and interpolating to obtain vacuum specific impulses for integral values of the area ratio. The values are convenient reference points for the calculation of interpolated values of the specific impulse for any given area ratio. Tables of gas compositions and performances are also included in this handbook.

CONTENTS

A. Performance - Oxygen and N_2O_4 Systems (P_c = 150, 300, 500, 700, 1000)

Discussion

RP-1 - Oxygen A-1
Hydrazine-Oxygen A-6
UDMH-Oxygen A-11
Hydrazine-UDMH (50/50)-Oxygen A-16
Ammonia-Oxygen . . . . .
Hydrazine-N_2O_4 . . . . . A-26
UDMH-N_2O_4 . . . . . A-31
Hydrazine-UDMH (50/50)-N_2O_4 . . . . . A-36

B. Gas Composition - Oxygen and N_2O_4 Systems (P_c = 150, 300, 500, 700)

Discussion

RP-1 - Oxygen B-1
Hydrazine-Oxygen B-21
UDMH-Oxygen. B-41
Hydrazine-UDMH (50/50)-Oxygen B-61
Ammonia-Oxygen B-81
Hydrazine-N_2O_4 . . . . . B-101
UDMH-N_2O_4 . . . . . B-121
Hydrazine-UDMH (50/50)-N_2O_4 . . . . . B-141

C. Performance - Miscellaneous Systems

Hydrazine-Fluorine (P_c = 100, 150, 200, 500) C-1
Hydrazine-Chlorine Trifluoride (P_c = 150, 300, 500) C-5
Hydrazine-SFNA (P_c = 150, 300, 500) C-8
Hydrogen-Oxygen (P_c = 60, 100, 200, 300) C-11
Hydrogen-Fluorine (P_c = 100, 200) C-15
Methyl Hydrazine-SFNA (P_c = 150, 300, 500) C-17
Methyl Hydrazine-N_2O_4 (P_c = 150, 300, 500) C-21

INTRODUCTION

The performance tables in this manual were developed to meet the needs of engineers and systems analysts who frequently need to know the potential performance of a rocket engine with a specific area ratio and operating in a given ambient pressure.

The usual machine-calculated values for performance are obtained by fixing the pressure ratio and calculating the corresponding area ratio and specific impulse for expansion into a vacuum. The accompanying tables were obtained by carefully plotting data from machine calculations and interpolating to obtain vacuum specific impulses for integral values of the area ratio. These area ratio values thus become convenient reference points for the calculation of interpolated values of the specific impulse for any given area ratio.

As indicated in the theoretical discussion, the calculations involve simple arithmetic and can be made in a very short time.

It should be emphasized that I_v (vacuum specific impulse), as defined herein, is the theoretical impulse obtained for a motor with a given area ratio operating in a vacuum. The vacuum specific impulse is not the theoretical maximum specific impulse (corresponding to an infinite area ratio) for expansion into a vacuum.

All propellants are considered to be liquids at either ambient temperature or their boiling point, whichever is lower.

When interpolating for chamber pressures, it is useful to note that I_s is approximately proportional to $\log P_c$.

Linear interpolation for I_v is unsatisfactory for small values of ϵ since the curve is definitely nonlinear in this region, and calculated values will be from one to two seconds too low. If greater accuracy is required, a few points should be plotted and the appropriate value of I_v obtained from the curve.

NOMENCLATURE

A_e = area at exit (sq in.)

A_t = area at throat (sq in.)

c = effective exhaust velocity (ft/sec)

c^* = characteristic velocity (ft/sec)

C_f = nozzle coefficient

C_v = vacuum nozzle coefficient

ϵ = area ratio = A_e/A_t

F = thrust (lb)

g = acceleration of gravity (32.2 ft/sec^2)

ΔI = $I_v - I_s$

I_s = specific impulse (sec)

I_v = vacuum specific impulse (specific impulse for operation in a vacuum); i.e., when $P_a = 0$

P_a = ambient pressure (lb/sq in.)

P_c = chamber pressure (lb/sq in.)

P_e = pressure at exit (lb/sq in.)

r = mixture ratio = weight oxidizer/weight fuel

v_e = true velocity of efflux (ft/sec)

$\dot{w}$ = weight flow rate (lb/sec)

DIRECTIONS FOR THE USE OF PERFORMANCE TABLES

If ϵ and P_a are given, and I_s is desired;

1. Determine I_v and $\frac{\Delta I}{\epsilon P_a}$ from the table or by interpolation

2. Calculate $\Delta I = \epsilon P_a \times \frac{\Delta I}{\epsilon P_a}$

3. Then, $I_s = I_v - \Delta I$

4. For the optimum value of I_s at a given P_a, locate the value of P_e corresponding to the given P_a and also determine from the table the corresponding value of ϵ. Using the value of $P_e = P_a$ and the corresponding value of ϵ, determine the value of I_s as above. The value so obtained is a maximum for the given value of P_a.

   Values of P_e may be readily interpolated since log P_c/P_e is proportional to log ϵ.

5. The method of calculation of c*, c, C_f, C_v, and v_e is shown in the sample calculation which follows the discussion of the theory.

THEORY

The basic equation for rocket thrust is

$$F = \frac{\dot{w} v_e}{g} + (P_e - P_a) A_e \tag{1}$$

Newton's second law requires that

$$F = \frac{\dot{w} c}{g} \tag{2}$$

Specific impulse is defined as pounds of thrust per pound per second of propellant consumption. Therefore,

$$I_s = \frac{F}{\dot{w}} \tag{3}$$

Combining (1), (2), and (3) we obtain

$$I_s = \frac{c}{g} = \frac{F}{\dot{w}} = \frac{v_e}{g} + \frac{(P_e - P_a) A_e}{\dot{w}} \tag{4}$$

Letting $P_a = 0$, we obtain

$$I_v = \frac{v_e}{g} + \frac{P_e A_e}{\dot{w}} \tag{5}$$

NOTE: Maximum I_s for a given value of P_a is obtained when $P_e = P_a$

Subtracting (5) from (4)

$$I_s = I_v - \frac{P_a A_e}{\dot{w}} \tag{6}$$

By definition,

$$c^* = \frac{P_c A_t g}{\dot{w}} \tag{7}$$

Solving (7) for $\dot{w}$ and substituting in (6), we obtain

$$I_s = I_v - \frac{A_e}{A_t} \cdot \frac{P_a}{P_c} \cdot \frac{c^*}{g} \tag{8}$$

But

$$\epsilon = \frac{A_e}{A_t} \text{ (definition)} \tag{9}$$

Substituting (9) in (8)

$$I_s = I_v - \frac{\epsilon P_a c^*}{P_c g} \tag{10}$$

Let

$$\Delta I = I_v - I_s = \frac{\epsilon P_a c^*}{P_c g} \tag{11}$$

or

$$\frac{\Delta I}{\epsilon P_a} = \frac{c^*}{P_c g} \tag{12}$$

Equation (12) is used to calculate the values of $\frac{\Delta I}{\epsilon P_a}$ shown in the tables.

Then

$$I_s = I_v - \Delta I$$

or

$$I_s = I_v - \epsilon P_a \left(\frac{\Delta I}{\epsilon P_a}\right) \tag{13}$$

Since ϵ and P_a are known and $\frac{\Delta I}{\epsilon P_a}$ is given in the table, the calculation of I_s is simple.

To Find c*, c, C_f, and C_v

Solving (11) for c* we obtain

$$c^* = \left(\frac{\Delta I}{\epsilon P_a}\right) P_c g \tag{14}$$

Since the value of $\frac{\Delta I}{\epsilon P_a}$ is given in the table, c* is readily obtained by the use of Equation (14).

From Equation (4),

$$c = I_s \cdot g \tag{15}$$

By definition,

$$C_f = \frac{F}{P_c A_t} \tag{16}$$

Combining Equations (3), (7), and (16) we obtain

$$C_f = \frac{c}{c^*} = \frac{I_s g}{c^*} \tag{17}$$

Therefore,

$$C_v = \frac{I_v g}{c^*} \tag{18}$$

Combining (17) and (18)

$$C_v = C_f \cdot \frac{I_v}{I_s} \tag{19}$$

From Equation (6)

$$I_v - I_s = \frac{P_a A_e}{\dot{w}} = \Delta I \tag{20}$$

From Equations (5) and (6)

$$\frac{v_e}{g} = I_s - \frac{A_e}{\dot{w}} (P_e - P_a) \tag{21}$$

From Equation (20)

$$\frac{A_e}{\dot{w}} = \frac{\Delta I}{P_a} \tag{22}$$

Substituting (22) in (21)

$$v_e = g \left[I_s - \frac{\Delta I}{P_a} \cdot (P_e - P_a) \right] \tag{23}$$

Since $\frac{\Delta I}{\epsilon P_a}$ is given in the tables, it is more convenient to rearrange Equation (23) as follows:

$$v_e = g \left[I_s - \epsilon \left(\frac{\Delta I}{\epsilon P_a} \right) (P_e - P_a) \right] \tag{24}$$

Using Equation (24) and the data obtained in the example, we obtain

$$v_e = 32.2 \left[395.7 - 20 \times 2.189 \, (0.52 - 0.20) \right]$$

$$v_e = \underline{12,291} \text{ ft/sec}$$

Note that the value of c, the effective exhaust velocity, was 12,742 ft/sec.

EXAMPLE

Given $\epsilon = 20$ and $r = 2.00$

$$P_a = 0.20 \text{ and } P_c = 100$$

From table,

$$I_v = 404.5 \text{ sec}$$

From table,

$$\frac{\Delta I}{\epsilon P_a} = 2.189$$

By Equation (13),

$$I_s = 404.5 - 20 \times 0.20 \times 2.189$$

$$= \underline{395.7 \text{ sec}}$$

Also

By Equation (14),

$$c^* = 2.189 \times 100 \times 32.2 = 7049 \text{ ft/sec}$$

By Equation (15),

$$c = 395.7 \times 32.2 = 12,742 \text{ ft/sec}$$

By Equation (17),

$$C_f = \frac{12,742}{7049} = 1.808$$

By Equation (19),

$$C_v = 1.808 \times \frac{404.5}{395.7}$$

$$= 1.848$$

To Obtain Maximum I_s for $P_a = 0.20$

Set $P_e = P_a = 0.20$

From table, corresponding value of ϵ is 40

Calculate I_s as above; i.e.,

$$I_v = 418.0 \text{ sec}$$

$$I_s = 418 - 40 \times 0.20 \times 2.189$$

$$= \underline{400.5 \text{ sec}}$$

This value might also have been obtained by plotting calculated values of I_s (for $P_a = 0.20$) as a function of ϵ. At the maximum value of I_s, the corresponding ϵ is optimum and P_e must equal P_a.

For example, for $P_a = 0.20$ psia and $r = 2.00$

ϵ	ΔI	I_v	I_s
10	4.4	386.7	382.3
15	6.6	397.4	390.8
20	8.8	404.5	395.7
25	10.9	409.2	398.3
30	13.1	412.8	399.7
40	17.5	418.0	400.5 (max)
50	21.9	421.5	399.6

As determined previously, the value of I_s is optimum at $\epsilon = 40$ and is 400.5 sec.

It is of theoretical interest to calculate the value of v_e in order to compare v_e with c, which is the <u>effective</u> exhaust velocity.

GAS COMPOSITION - OXYGEN AND N_2O_4 SYSTEMS

CALCULATION OF SPECTRAL EMISSIVITIES OF GASES

For the purpose of designing detection systems capable of identifying and tracking missiles during the launch phase by means of infrared radiation, it is essential to be able to make reasonable estimates of the energy radiated by the missile exhaust in the sensitive wavelength region of the detector. One of the most important factors in a theoretical calculation of this quantity is the spectral emissivity of the chemical components present in the exhaust. Experimental determination of the spectral emissivity is quite difficult because of the elevated temperatures of the gases comprising the exhaust, slit width corrections, and the problem of making absolute intensity measurements. Theoretical calculations of the type performed by Stull and Plass (Ref. 1) for diatomic molecules are extremely complex and require extensive machine calculations for a complete treatment. In addition, these quantum mechanical calculations require a knowledge of the shapes of individual rotational lines, parameters which can be determined only by experiments of the same type used to measure spectral emissivities (Ref. 2).

A method of calculation proposed by Golden is based on a calculation by Penner, Sulzmann, and Ludwig and gives good estimates of radiation more simply than by the Plass method.

Golden has treated only the HF and HCl molecules in his paper, which leaves the task of applying a suitable and simple approximate calculation to other molecules that are present in the combustion equilibrium of typical propellants. This is particularly important for H_2O and CO_2 which are formed from many propellant combinations.

The detailed compositions which follow in this report can be used in final radiation calculations for a given system and also provide a survey of important combustion species to be considered in future calculations.

Aerospace Corporation, El Segundo, California. PROPELLANT PERFORMANCE AND GAS COMPOSITION HANDBOOK, prepared by S.A. Johnston, E.A. Mathias, P.C. Hanzel, and L. Schieler. 3 January 1962. [280] p. (Report TDR-930(2210-07)TN-1; DCAS-TDR-62-2) (Contract AF 04(647)-930) Unclassified report

Performance tables are presented which were obtained by plotting data from machine calculations and interpolating to obtain vacuum specific impulses for integral values of the area ratio. The values are convenient reference points for the calculation of interpolated values of the specific impulse for any given area ratio. Tables of gas compositions and performances are also included in this handbook.
