A

DESCRIPTION & DEFINITIONS

This supplement presents in tabular form the results of digital computer calculations for the solution of planetary thermal radiation and planetary albedo incident to space vehicle surfaces. Although the data was displayed graphically in Supplement A, it was felt that the tabulation of the data would be beneficial as direct tabular input for digital computer vehicle heating programs. The geometries and results are discussed briefly and the terms defined.

I PLANETARY THERMAL RADIATION

The planetary thermal radiation incident to a vehicle surface may be computed by the general equation

$$q = PAI_t \quad (1)$$

where q = thermal radiation rate incident to the vehicle surface, BTU/hr.

A = characteristic area defining the surface, ft^2 .

I_t = total energy rate emitted per planet unit area, BTU/hr- ft^2 .

P = geometric factor for radiation from the planet to the vehicle surface, dimensionless

The value of I_t is tabulated for the planets in Table I. The geometric factors have been computed for standard vehicle surface geometries with respect to the earth and tabulated as a function of altitude from the earth. These geometric factors may also be used for vehicles in the vicinity of other planets or moons if the geometric factor is used which corresponds to the adjusted equivalent altitude determined by multiplying the altitude of the vehicle from the planet by the ratio of the radius of the earth to the radius of the planet. These radius ratios are tabulated for the planets in Table I.

(1) SPHERE:

Figure 1 describes the configuration for planetary thermal radiation to a sphere. The geometric factor is defined on the basis of the characteristic area $A = \pi r^2$,

where r is the radius of the sphere. Then

$$F = q / \pi r^2 I_t \quad (2)$$

The geometric factor for a sphere with respect to the earth is tabulated in Table 2 as a function of altitude.

(2) CYLINDER

Figure 2 describes the configuration for planetary thermal radiation to the convex surface of a cylinder. Because of lack of three dimensional symmetry an attitude parameter, δ , is required and is the angle between the cylinder axis and the vertical to the vehicle. The geometric factor is defined on the basis of the characteristic area, $A = DL$, where D and L are the diameter and length, respectively, in feet for the cylinder. Then

$$F = q / DLI_t \quad (3)$$

The geometric factor for a cylinder with respect to the earth is tabulated in table 3 as a function of altitude with the attitude angle, δ , as the parameter.

(3) HEMISPHERE

Figure 3 describes the configuration for planetary thermal radiation to the convex surface of a hemisphere. The geometric factor is defined on the basis of the characteristic area, $A = \pi r^2$, where r is the radius of the hemisphere. Then

$$F = q / \pi r^2 I_t \quad (4)$$

The geometric factor for a hemisphere with respect to the earth is tabulated in Table 4 as a function of altitude with the attitude angle, δ , as parameter.

(4) FLAT PLATE

Figure 4 describes the configuration for planetary thermal radiation to one side of a flat plate. The angle, γ , between the normal to the plate and the vertical to the vehicle defines the attitude of the plate with respect to the planet. The geometric factor is defined on the basis of the characteristic area, $A = P$, the area of one side of the plate. Then

$$F = q / PI_t \quad (5)$$

The geometric factor for a flat plate with respect to the earth is tabulated in Table 5 as a function of altitude with the attitude angle, γ , as parameter.

It should be noted that the flat plate thermal radiation solution may be used to approximate the thermal radiation incident to any generally convex vehicle surface by dividing the surface into a series of flat plate elements and summing the thermal radiation incident to each of these flat plates.

II PLANETARY ALBEDO

The planetary albedo incident to a vehicle surface may be computed from the general equation:

$$q = FASa \quad (6)$$

where q = albedo heat flux rate incident to the vehicle surface, BTU/hr.

A = characteristic area defining the surface, ft^2

S = solar heat flux or "constant", BTU/hr.- ft^2

a = average reflectivity of the planet's surface, dimensionless

F = geometric factor which accounts for reflected energy distribution on the planetary surface and the geometry, dimensionless

The geometric factor for a sphere is independent of attitude due to

three dimensional symmetry. In the case of all surfaces the location of the vehicle with respect to the sun is defined by the zenith distance between the surface and sun, θ_s . The zenith distance is the angle between the earth-vehicle vector and the earth-sun vector. In the case of surfaces lacking spherical symmetry, the attitude of the surface is defined by two angles. One is the angle, δ , between the axis of the cylinder or hemisphere or normal to the flat plate and the vertical to the vehicle. The other is the angle, ϕ_c , of rotation of the axis or normal about the vertical to the vehicle from the planet. The datum $\phi_c = 0$ occurs when the axis or normal lies in the plane defined by the earth-vehicle vector and the earth-sun vector.

The value of S and a are tabulated for the planets in Table I. The geometric factors for albedo have been computed for standard vehicle surface geometries with respect to the earth and tabulated as a function of altitude from the earth. Again, as described for thermal radiation, these geometric factors may be applied to other planets by using the ratio of the radius of the earth to the radius of the planet tabulated in Table I.

(1) SPHERE

Figure 5 shows the configuration for albedo incident to a sphere. The geometric factor is defined on the basis of the characteristic area, $A = \pi r^2$, where r is the radius of the sphere, then

$$F = q / \pi r^2 S a \quad (7)$$

The geometric factor for albedo incident to a sphere from the earth is shown in Table 6 as a function of altitude in nautical miles with zenith distance, θ_s , as parameter.

(2) CYLINDER

Figure 6 shows the configuration for albedo to the convex surface of a cylinder. For a cylinder the geometric factor is defined on the basis

of the characteristic area, $A = DL$. Then

$$F = q / DLSa \quad (8)$$

where D = diameter of cylinder, ft.

L = length of cylinder, ft.

The geometric factor for albedo incident to a cylinder from the earth is tabulated in Tables 7 through 28 as a function of altitude in nautical miles with θ_s , γ , and ϕ_c as parameters. Each table is for a constant γ and ϕ_c , i.e. particular attitude with respect to the earth.

(3) HEMISPHERE

Figure 7 shows the configuration for albedo to the convex surface of a hemisphere. For a hemisphere the geometric factor is computed on the basis of the characteristic area, $A = \pi r^2$. Then

$$F = q / \pi r^2 Sa \quad (9)$$

where r = radius of hemisphere, ft.

The geometric factor for albedo incident to a hemisphere from the earth is tabulated in Tables 29 through 65, as a function of altitude in nautical miles with θ_s , γ , and ϕ_c as parameters. Each table is for a constant γ and ϕ_c , i.e., particular attitude.

(4) FLAT PLATE

Figure 8 shows the geometry for albedo to one side of a flat plate. For a flat plate the geometric factor is computed on the basis of the characteristic area; $A = P$. Then

$$F = q / PSa \quad (10)$$

where P = area of one side of the flat plate, ft.²

The geometric factor for albedo incident to one side of a flat plate from the earth is tabulated in Tables 66 through 101 as a function of altitude in nautical miles with θ_3 , δ , and ϕ_c as parameters. Each table is for a constant δ and ϕ_c , i.e., particular attitude.

The flat plate albedo solution may also be used to approximate albedo heating of any generally convex satellite or satellite surface by dividing this surface into a series of flat plates and summing the albedo heating for each of these flat plates.

* To use the albedo and thermal radiation curves and tabular data for a planet other than the earth, an equivalent earth altitude for the planet must be found. This may be done by multiplying the planetary altitude under consideration by the altitude correction factor given in the above table. The abscissa of the curves should then be entered with this corrected altitude.

Example: Thermal radiation to a sphere 200n.mi. above the surface of Mars.

$$200 \times 1.916 = 383.2 \text{ n.mi.}$$

$$\text{from Fig. 3, } q/\sqrt{r^2 I_t} = 1.12$$

$$\text{Using } I_t \text{ for Mars gives } q/\sqrt{r^2} = 45.3 \text{ Btu/hr-ft}^2$$
