NO OTS

FOREWORD

This report was prepared by the Avco Research and Advanced Development Division under USAF Contract No. AF33(616)-7327. This contract was initiated under Project No. 7350, "Ceramic and Cermet Materials", Task No. 73500, "Ceramic and Cermet Materials Development"; and Project No. 7381, "Materials Application", Task No. 73812, "Data Collection and Correlation". The work was administered under the direction of the Directorate of Materials and Processes Deputy for Technology, Aeronautical Systems Division, with Mr. P. W. Dimiduk acting as project engineer.

This report covers work conducted from 1 May 1960 to 30 April 1961.

Assistance from a number of sources has given vital support to the work on this project. The authors wish to acknowledge contributions from Prof. W. Klemperer in giving advice on spectroscopic experiments, Dr. D. R. Stull of the Dow Chemical Co. for many valuable discussions, the loan of microfilms, etc., Mr. T. R. Munson for providing the program for the machine computations on diatomic molecules, Dr. G. T. Furukawa for counsel on methods of smoothing C_p data, the staff of the Avco RAD Mathematics Section in programming and computing machine assistance, Dr. Joan B. Berkowitz-Mattuck and Mr. S. N. Goldstein at the A. D. Little Company in providing translations of Russian articles, Dr. S. Ruby for interest in the work and supervisory assistance, Mr. T. Licht in making chemical analyses, Mr. P. F. Jahn in sample preparation, and Mr. R. E. Walters and Mrs. Ann Wise in the literature search. Other contributors at Avco RAD have been Messrs. J. K. Hill and P. Demenkow (assistance in X-ray diffraction studies), J. Achramowicz (sample preparation), V. H. Early (spectroscopic studies), E. J. Kay and D. V. LaRosa (coding and other assistance in the work with IBM cards and computations), D. A. Dreselly (manuscript preparation), L. Fitzpatrick (chemical analyses), and W. S. Bennett (glass-blowing). Reprints, reports, and other sources of data were contributed by Mr. P. W. Dimiduk (ASD), Dr. K. K. Kelley (U. S. Bureau of Mines), Dr. G. M. Rosenblatt (Univ. of California), Dr. G. R. Somayajulu (Univ. of California), Dr. D. L. Hildenbrand (Aeronutronics), Dr. R. H. Crist (Union Carbide Corp.), Dr. J. L. Margrave (Univ. of Wisconsin), and Dr. C. W. Beckett and others at the National Bureau of Standards (Heat Division).

ABSTRACT

Theoretical and experimental studies were undertaken of the thermodynamics of certain refractory compounds from 298.15° to 6000°K. The list of compounds included the oxides, borides, carbides, and nitrides of the metals in groups IVB, VB, VIB, and VIIB of the periodic chart in addition to those of silicon, scandium, beryllium, magnesium, calcium, strontium, and osmium.

Tables of ideal gas thermodynamic functions of all the above elements were either prepared or brought up to date. Reviews and critical analyses of the available data were completed on the oxide systems of Be, Ca, Cr, Mg, Mo, Sr, Ti, and W, the borides of Ti, and the monocarbide of Ti. Sixty-one tables of thermodynamic functions, in various degrees of completion, were prepared on the important chemical species of the above systems.

A comprehensive review of the literature was made for the existing theoretical background needed in the interpretation of high-temperature C_p° data and for the improvement of methods of estimating missing data.

In the experimental studies, careful checks were made of the purity of all samples. A Bunsen ice calorimeter apparatus was developed for specific heat measurements up to 1500°C. An apparatus employing the pulse method of specific heat measurements was used to make determinations in the temperature range from 1500° to 2500°C on borides of Mo, Ti, W, and Zr, on carbides of Nb, Ta, Ti, and Zr, and on a nitride of Ti. Spectroscopic studies were carried out on the Si-C, Mo-C, W-O, and the B-O system vapor species to determine their molecular structures and spectroscopic constants.

PUBLICATION REVIEW

This report has been reviewed and is approved.

FOR THE COMMANDER:

J. I. Wittebort

I. INTRODUCTION

Contract AF33(616)-7327 has for its purpose the determination of the thermodynamic functions of a limited number of highly refractory compounds up to 6000°K. The scope of the contract encompasses the oxides, carbides, nitrides, and borides of elements in groups IIA, IVB, VB, VIB, VIIB, plus scandium, osmium, and silicon. This is summarized in figure 1 wherein the elements in the solid boxes are to be combined with those in the broken box to form the subject compounds. The metals Ir, Pt, and Rh were added to the list at the request of the project engineer.

The state of knowledge on these highly refractory compounds is such that much preliminary work was necessary to search for and to adapt required basic material property data before reliable computations could be made. Moreover, much of the existing data were inadequate, inaccurate, and in many cases even contradictory. Thus, only a limited number of the compounds could be completely characterized thermodynamically without a program of experimental measurements to provide additional basic data and to verify the existing data that are uncertain. Accordingly, the scientific effort on this project was distributed among three major phases as follows:

Phase I -- Review of the literature and compilation of all available data.

Phase II -- Calculation and tabulation of thermodynamic properties from available data.

Phase III -- Experimental studies to provide missing data, to prove the adequacy of computational techniques, and to verify any assumptions made throughout the program.

The list of basic data sought in Phase I includes not only those directly useful in the computations of Phase II, but also some that may find use in later applications of the thermodynamic functions. The list is as follows:

1. Phase diagrams
2. Heat capacity versus temperature
3. Enthalpy versus temperature
4. Entropy versus temperature
5. Heats of phase transformations
6. Heats of formation or reaction
7. Thermal expansion coefficients and compressibilities
8. Melting and triple points
9. Free energies of formation
10. Vapor pressures
11. Composition of gaseous species in vapor
12. Spectroscopic constants

Manuscript released by the authors (September 1961) for publication as an ASD Technical Report.

13. Ionization or appearance potentials
14. Emf's of electrolytic cells
15. Heats of solution or dilution
16. Other thermodynamic functions.

The experimental studies of Phase III can be grouped into the following three categories:

- a. Preparation of compounds and specimens. This includes analyses to verify purity and crystal structure, or the existence of special conditions such as extent of solid solution, etc.
- b. Heat capacity and total heat content determinations with a pulse-method apparatus and a Bunsen ice calorimeter.
- c. Spectroscopic studies of vapor species.

II. REVIEW OF THE LITERATURE AND COMPILATION OF AVAILABLE DATA

A. SCOPE OF THE LITERATURE SEARCH

The literature search has been very comprehensive, the intention being to cover all the literature of at least the last ten years. The following is a list of the literature sources searched:

1. Nat. Bur. Stds. Circular 500, Selected Values of Chemical Thermodynamic Properties (1952-1956).
2. Kubaschewski, O. and E. Evans, Metallurgical Thermochemistry, Pergamon Press, N. Y. (1958).
3. Quill, L. L., The Chemistry and Metallurgy of Miscellaneous Materials -- Thermodynamics, McGraw-Hill, N. Y. (1950).
4. Brewer, L., Chem. Revs. 52, 1-75 (1953).
5. Coughlin, J., Bur. Mines Bull. 542 (1954), p. 1-80.
6. Ehl, R. G., R. J. Sime, and J. L. Margrave, Binary Nitrogen Compounds of the Elements: A Literature Survey, WADC Tech. Note 59-115 (1959).
7. Kelley, K. K., Bur. Mines Bull. 407 (1937).
8. Kelley, K. K., Bur. Mines Bull. 584 (1960).
9. Elliott, J. F. and M. Gleiser, Thermochemistry for Steelmaking, Vol. I., Addison-Wesley, Reading, Mass. (1960).
10. Hansen, M. and K. Anderko, Constitution of Binary Alloys, McGraw-Hill, N. Y. (1958).
11. White, D. W. and J. E. Burke, The Metal Beryllium, Am. Soc. Metals (1959).
12. Thomas, D. E. and E. T. Hayes, The Metallurgy of Hafnium, Naval Reactor Handbook, Supt. Doc., GPO (1960).
13. Lustman, B. and F. Kerze, Jr., Metallurgy of Zirconium, McGraw-Hill, N. Y. (1955).

14. Richardson, F. D., Thermodynamics of metallurgical carbides and of carbon in iron, J. Iron Steel Inst. 175, 33 (1953).

(U.S.) Rept. 6645 (Supplement to Repts. 6297 and 6484), (1 January 1960, amended 1 April 1960). Also Rept. 6928 (Supplement to NBS Repts. 6297, 6484, and 6645), (1 July 1960).

29. Chem. Abstracts (1950-1961).

30. Nuclear Sci. Abstracts (1950-1961).

31. Eng. Index (1953-1958).

32. Phys. Abstracts (1950-1961).

33. Ceram. Abstracts (Recent Years).

34. Dissertation Abstracts (Recent Years).

35. IUPAC Bibliography (April 1960-1961).

36. Battelle Tech. Rev.

37. Monthly Index of Russian Accessions (Library of Congress), (1960).

The scope of the entire primary literature uncovered is best indicated by the list of references in the reference code file in section VII-B.

B. ACCUMULATED FILES

Four files have been accumulated as products of the literature search. The primary ASM card file contains all the information obtained and handwritten by the searchers and abstractors. All references were coded and punched into IBM cards for the second file. An author index file could have been made from duplicate IBM cards of the "L" type (described in section C). However, it was found more convenient to use printouts from the IBM cards (one for each

abstractor) in place of the author index, whose purpose has been to expedite the elimination of duplicate references at the source and avoid needless repetition of effort. The IBM card file was intended to store all the information in a form that could be handled by sorting, collating, and computing machines. The fourth file is a subject index made up from the IBM card file.

C. DATA CODING AND IBM CARD FILE SYSTEM

1. Introduction

a. General Remarks

In the work on Phase I of this project, it has been necessary to store in readily accessible form large amounts of bibliographic information and numerical data on thermodynamic properties of certain chemical elements and compounds. In Phase II, it has been necessary to calculate thermodynamic properties by routine and often repeated procedures. The problems of information storage, retrieval, and modification, and calculation of related thermodynamic properties were expedited and simplified by the use of electronic calculators and sorting equipment available at Avco RAD. For this, a system for handling both bibliographic information and numerical data had to be developed.

The system was designed to treat one phase of the problem, that of storing the data in relatively accessible form when coded on standard IBM cards in a fixed format. By means of the IBM Sorter, information of any category could be easily culled out of the master file.

The following paragraphs describe the part of this system which was used extensively in the literature search and bibliographic work.

b. Mnemonic Symbols

Limited storage space, the unwieldiness of large files, and minimization of machine running time require symbols of minimum number of characters to describe categories of information, units, values, etc. On the other hand, this minimum length symbol might not easily be remembered and coding time would be lost in continual reference to a glossary and codes. A compromise has been reached in allowing the symbol to correspond as much as possible to the commonly accepted abbreviation. When shorter codes were required, the attempt was to make them correspond to the sound of the quantity being coded.

c. Structure of IBM Cards

For purposes of reference, the IBM card is divided into rows and columns. Columns are numbered consecutively 1 to 80 from left to right. Rows are numbered from top to bottom 12, 11, zero and 1 to 9. To record information in the card, a given character (i.e., number, letter, or special symbol such as *) is punched as a characteristic hole or series of holes, all in the same column. Any character can be punched into any column, but two or more characters cannot occupy the same column. The character can be simultaneously printed at the head of the column it occupies, allowing ready reading of information on the card. A number is represented by a single hole (or punch) in the given column. Thus, for example, the number 9 in column 73 would be represented by a punch in column 73 row 9. A letter is represented by two characteristic holes in the same column and a special character by three.

For more compact storage of information, one allows a punch in the 12, 11, or zero row of a column where numeric information is stored. Sometimes row 12 is called + and row 11 -. This is called an over-punch (O/p).

d. Fixed Field Format

Since a character occupies a column, a multicharacter symbol occupies a series of contiguous columns called a field. For ease in sorting, it is convenient to have all symbols of the same general type occupy the same columns on different cards. Thus, for example, suppose one denotes molar heat capacity at constant pressure by the symbol CP (all letters must be capitals and no subscripts or superscripts are allowed). The convention is made that, for a given series of cards, each card with a symbol for a thermodynamic property will have the property in columns 2-5. Then to distinguish cards with C_p data from those of other thermodynamic properties, sorts for C in column 2, P in column 3, and blanks in 4 and 5 are made. The cards selected in this way will have the desired information.

2. Types of Cards

In general, widely different types of information to be handled and sorted will result in different types of formats. For compatibility with other machines, which will eventually handle and use the data, the format of the rest of the card is denoted in column 1. The various types of cards are as follows:

<u>Column 1</u>	<u>Meaning</u>
D	Definition Card
L	Library Card
C	Comment Card
Other	Type A Card.

In all these cards, column 1 describes the type of card, 2 to 72 describe the information, and 73 to 80 are reserved for card identification.

3. Card Identification Format

To have absolute, sequential numbering of cards and reference to the person who took the abstract and the approximate date, the following format was used in columns 73 to 80 of cards of all types.

<u>Column</u>	<u>Character</u>	<u>Meaning</u>
73	α	One character symbol for month A = May 1960, B = June 1960, etc.
74	$\overset{\circ}{\nu}$	Abstractor. O/p indicates finder card
75 to 79	ν	Serial number
80	α'	Not used.

The explanation of character symbols is as follows:

- μ Numeric character
- $\overset{\circ}{\nu}$ Overpunched (O/p) numeric character
- α Alphabetic character
- α' Alphabetic or numeric character
- σ Special character
- b Blank.

4. Library Cards

It was supposed that several pieces of data would often be taken from the same reference. Each piece of data needs to be punched on a card which will also have coded the reference by journal, volume, page, and year. It would also be convenient to give further information about a given reference. For example, one might want to know the names of the authors or a reference to an abstract, if any. This information was recorded on the library cards, whose format is summarized below.

a. The symbols used in library card coding were as follows:

Column	Character	Meaning
1	L	Identifies library card.
2-11	10 a	Last name of first author. (The "10" means that the 10 columns (2-11) contain letters (alphabetic symbols).)
12	, or a	A comma is the usual character, it is used to separate last name from the first initial. For last names of eleven or more letters however, the comma is replaced by the eleventh letter.
13	a	First initial of author's name. If the last name is eleven letters long however, this column is blank. If last name is twelve or more letters long, the twelfth letter of the author's name occupies this column.
14-22	9 a	Second author's name.
23	, or a	Follow the procedure indicated for column 12, unless last name contains ten or more letters, in which case comma is replaced by the tenth letter.

Column	Character	Meaning
24	a	First initial of second author's name. However if the last name is ten letters long, this column is blank. If last name is eleven or more letters long, the eleventh letter occupies this column.
25-29	5a	Five-letter symbol for the original reference. Column 25 must be a. Occasionally, numerical information is put in columns 27, 28, and 29. For example, a report with a designation AD-101-773 would have the AD-101 located in columns 25-29, while the 773 would be in columns 30-32.
30-32 (usual case)	3v (see exceptions below)	Volume number of original reference. Several variations are possible for 30-32, 33, and 34-39.
30 (alternative 30-1)	R	Report number will be given in the following columns (31-39), using a fixed-field format (31, 32), (33, 34), (35, 36), (37, 38, 39). Dashes will be assumed but not written between columns 32 and 33, etc.
30 (alternative 30-2)	F	Report number will follow in (31-39), using a free field. Report numbers are given with no regard for field. Any combination of numbers and dashes can be used, but the dashes must be written explicitly.
30 (alternative 30-3)	P	Paper number will follow, using same type of fixed field as for alternative 30-1 above.
32 (alternative 32-1)	*	Asterisk means no volume number is given.
32 (alternative 32-2)	+	Plus means volume number is the same as the year.

Column	Character	Meaning
33 (usual)	.	Comma is the usual symbol used to indicate that the page number of the original reference follows in columns 34-38.
33 (alternative 33-1)	or *	Means an abstract number follows in columns 34-38, rather than a page number.
33 (alternative 33-2)	or /	Means next two columns (34 and 35) contain issue number, while column 36 <u>must</u> contain another virgule, and page numbers are in columns 37-39.
33 (alternative 33-3)	or S	Means a supplement number will follow in column 34. Page numbers will be placed in columns (35-38).
33 (alternative 33-4)	or P	Means a part number of a report follows in column 34.
34-38 (usual case)	5 v	Page number or abstract number of original reference. The smallest number is placed in column 38. This system is used if comma, or asterisk, is located in column 33.
39 (usual case)	a '	A letter or a number is used with the preceding page number to locate the column or row on the page where the reference is found. If this information is not available, this column is blank.
34-39 (alternative)		
Alternatives are available as described by 30-1, 30-2, 30-3, 32-1, 32-2, 33-1, 33-2, and 33-3.		
40	(or *	Beginning parenthesis means that original reference was consulted; asterisk means that data were taken from a source other than the original reference.

Column	Character	Meaning
41-42	° ° ν ν	Last two figures of the year. A minus (-) overpunch in column 41 means nineteenth century. In column 42 a plus (+) overpunch means in Russian; a minus (-) overpunch means in German.
43-44	2 a	Symbol for abstracting journal. If the symbol has four characters, the last two characters are coded in columns 57-58.
45-46	2 ν	Volume number of abstract.
47	, or *	Comma denotes page number to follow; asterisk denotes abstract number to follow.
48-53	5 ν a'	Page, column, or abstract number.
54	(or *	Same as column 40. Usually, the beginning parenthesis will be used here.
55-56	2 ν	Last two figures of the year of abstract publication.
57-58	2 a	Last two symbols for the abstracting journal.
59	a'	Character to denote availability of original reference (see paragraph b of this section).
60-69	10 a	Third author's last name.
70	,	Follow procedure for column 12.
71	a	First initial of third author's name (see procedure for column 13).
72	E or M	If more than 3 authors, use "E" (<u>et al</u>). If any of the author's names could not be completely coded; i. e., if any first initials are missing, use "M".

Column	Character	Meaning
73	a	A letter to designate month in which original ASM card was taken. Thus, May (1960) = "A"; June (1960) = "B" ...
74-79	6v	Serial number for original ASM card.
80	v	This column is not used with "L" cards. However, "T" cards may have numbers starting with 1 in column 80. These indicate the order in which "T" cards should follow "L" cards in a bibliography.

b. A glossary of availability characters for column 59 of library cards follows:

Character	Meaning
L	Avco RAD Research Library.
E	Avco-Everett Technical Library.
M	MIT Library.
H	Harvard Libraries.
G	AFCRL* Library.
C	Avco Crosley.
N	Other nearby libraries (Boston area).
φ	Original on order.
v	Abstractor with number.
P	Personnel at Avco RAD.
Z	Abstract not available at Avco RAD.
X	Original practically unavailable.

* Now, the Air Force Cambridge Research Laboratories, Bedford, Massachusetts; formerly AFCRC (the Air Force Cambridge Research Center).

5. Title Cards

Since title cards have a relatively free field, they were quite simple to prepare. The coding scheme has been as follows:

Column	Character	Meaning
1	T	Title card.
2	b	Must be blank.
3-72	70 a'	<u>Case (1)</u> (Author elaboration card). If an "E" or "M" were located in column 72 of "L" card, then a title card is prepared wherein all authors' names are given in order.
4-72	69a'	<u>Case (2)</u> . Both columns 2 and 3 must be blank. The exact title is placed in columns 4-72 in first and any succeeding title cards if necessary.
73-79	a, 6 v	Same code is used as for "L" cards.
80	v	Denotes sequence of title cards. If an author elaboration card (Case 1) is used, a figure 1 is placed in column 80, and all succeeding title cards are numbered in sequence. If no author elaboration card is used (Case 2), the first title card is numbered 1, and the rest numbered in sequence.

6. Comment Cards

For verbal comment storage, column 1 of the card is a C, columns 2 to 8 are a symbol for the comment, column 9 is blank, and columns 10 to 72 are reserved for the comment. This type of card has been used sparingly.

7. Subject File

To avoid disruption of the file of ASM cards, a file arranged according to subjects was developed through the use of a special set of IBM cards. Only selected fields of these cards were coded as follows:

Column	Symbol	Meaning
1	P or M	"P" = pure compound, "M" = mixture.
2-5	4a	Property which was investigated. (A list is shown in property codes below.)
22-34	13 a'	Name of compound or material studied.
73-80	8 a'	Usual serial number.

Property codes for the subject file are as follows:

DEBTA	PRO	COMPRESSIBILITY COEFF BETA 1/V DV/DP T
DBIB	PRO	BIBLIOGRAPHY
DCEMP	PRO	CONDENSED PHASE, ELEC OR MAGNETIC PROP, EG WORK FUNC
DCOPT	PRO	CONDENSED PHASE, OPTICAL PROP
DCP	PRO	HEAT CAPACITY
DCRYS	PRO	CRYSTAL STRUCTURE
DCTEX	PRO	COEFF OF THERMAL EXPANSION
DDF	PRO	FREE ENERGY OF FORMATION, REACTION, ETC.
DDH	PRO	HEAT OF FORMATION, REACTION, ETC.
DE	PRO	INTERNAL ENERGY
DELCH	PRO	ELECTROCHEMICAL
DEMF	PRO	ELECTROMOTIVE FORCE

DERES	PRO	ELECTRICAL RESISTIVITY
DF	PRO	FREE ENERGY FUNCTION
DH	PRO	HEAT CONTENT
DKIN	PRO	KINETICS
DMISC	PRO	MISCELLANEOUS
DMSP	PRO	MASS SPECTROMETRIC DATA
DPHAS	PRO	PHASE DATA, MELTING, TRANSITION, BOILING TEMPS
DPMCH	PRO	MECHANICAL PROPERTIES
DREAC	PRO	CHEMICAL REACTIONS
DREV	PRO	REVIEW
DRHO	PRO	DENSITY
DS	PRO	ENTROPY
DSPK	PRO	SPECTROSCOPIC DATA
DTCON	PRO	THERMAL CONDUCTIVITY
DTHEO	PRO	THEORY
DTHER	PRO	THERMODYNAMIC DATA
DVAP	PRO	VAPORIZATION DATA
DZKP	PRO	EQ CONST

8. Definition Cards

a. The usual format for definition cards has been as follows:

Column	Symbol	Meaning
1	D	Definition.
2-6	2 a, 3 a'	Symbol for the reference.
2-11	REF	Stands for reference.
12	A	An abstracting journal is being coded.
	B	A book is being coded.
	S	A symposium is being coded.
	X	A journal or report number is being coded, and a portion of this number is to be included in the five-character symbol for the reference.
20-72	53 a'	Definition of journal using abbreviations of Chemical Abstracts and a free field except for books or symposia (see below).

b. For books (designated "B" in column 12), the following pertains:

Column	Symbol	Meaning
21-31	9 a, a	First author, first initial.
32-41	8 a, a	Second author, first initial.
42-63	22 a	Title of book.
64-70	(5a)	Publisher (abbreviated).
71-72	2 v	Year of publication.

c. For symposia (designated "S" in column 12), the following were used:

Column	Symbol	Meaning
21-31	11 a	Name of town.
32-41	10 a	Name of country.
42-70	29 a	Name of symposium.
71-72	2 v	Year of meeting.

d. Code-Field Entries

Columns 72-80 of the L-type and certain other cards are called the "code" field. For other fields, symbolic entries have to be defined by definition cards. The interpretation of the code field is too simple to require this, and thus, no "D" cards have been made for code-field entries.

e. Additional Functions of "D" Cards

It is useful to have the "D" cards not only to give the verbal definition of a symbol, but to show relationships between symbols. Thus, the "D" cards become a "thesaurus" as well as a "dictionary." Provision has been made for this in the "D" cards by including an associated symbol field and a control character.

One of the main purposes of the definition cards will be to find duplicate references. Thus, if two ASM cards have been prepared inadvertently from the same original reference, the "code" card will show that this similarity exists. Codes for other methods of using these cards are shown immediately below.

Column	Symbol	Meaning
1	D	Definition.
2-8	a, 6 v	Symbol for the ASM card to be defined.
9-11	CØD	Code.
12 (usual)	S	Identical (synonymous).
12 (Alternative 12-1)	L	Similar. If a publication had appeared as a journal publication, the contents might be quite similar but not identical.
12 (Alternative 12-2)	T	A translation of basic reference is available.
13-19	a, 6 v	Symbol for the ASM card in terms of which the entry in columns 2-8 is defined.

- f. The following symbol types have become established:

Symbol Type	Meaning
PRØ	Property
UNT	Units
SAG	State of aggregation
WAY	Method of determination
REF	Reference
TBL	Table
MIX	Mixture
CØM	Comment
CND	Condition.

Certain of these symbol types require specification of the A field.

Symbol Type	A Field
UNT	Property measured in these units
WAY	Quantity calculated by this method
CND	Property given by standard state value.

At present, there is only one use for the control character in column 12. S in column 12 means that the symbols in the D and A fields are synonymous. Other control characters can denote other relationships between the D and A fields.

III. CALCULATION AND TABULATION OF THERMODYNAMIC FUNCTIONS FROM AVAILABLE DATA

A. FORMAT AND SCOPE OF TABULATIONS

An important aspect of any project of this type, where thermodynamic functions are to be tabulated, is the format of the tables and the summaries of basic data used in their computation. The standard state reference temperature and the units of numerical data also require careful choice. Standardization in these matters has evolved from a number of such compilations of recent years from the National Bureau of Standards, the Bureau of Mines, etc. A particularly good model for the type of compilation undertaken in this project is that of the JANAF-Thermochemical Panel which is issued under the direction of Dr. D. R. Stull. Except for the introduction of a few innovations, the example of the Thermochemical Panel has been followed in the work on this project so that the results of the two compilations will be compatible. The innovations referred to are the addition of uncertainty estimates and extra entries to define property discontinuities at transition points.

B. STANDARDIZATION OF PHYSICAL AND CHEMICAL CONSTANTS

Another important aspect of data computation and tabulation work is the choice of a consistent set of physical constants such as the atomic weights, gas constants, temperature scales, etc., because more than one atomic weight scale is in general use, and the accepted best value of most constants changes from time to time.

The source of constants (other than atomic weights) selected for this study is the data tabulation by Cohen, Crowe, and Dumond.¹ However, their data have been obtained by reference to the physical atomic scale; whereas for the present work, the chemical atomic scale has been used. The factor for conversion of atomic weights from the physical to the chemical scales was taken as 1.000275 from Birge.² Constants converted in this way are given in Table I.

¹Cohen, E.R., K.M. Crowe, and J.W.M. Dumond, Fundamental Constants of Physics, Interscience, N.Y. (1957), 287 p.

²Birge, R.T., Repts. Progr. Phys. 8, 90 (1942).

TABLE I
VALUES OF USEFUL CONSTANTS ON THE
PHYSICAL AND CHEMICAL SCALES

Quantity	Physical Scale Value	Chemical Scale Value
Avogadro's number, N	$(6.02486 \pm 0.00016) \times 10^{23}$	$(6.02320 \pm 0.00016) \times 10^{23}$
Gas constant, R_0	1.98780 cal/°K mole	1.98726 cal/°K mole

Wichers³ has reported the latest status of the atomic weights on the chemical scale, and the table from his paper was used in this work. The authors are unaware of any further changes resulting from the proposed unification of physical and chemical scales by the International Commission on Atomic Weights discussed in Wichers paper.³

Some additional constants used in the computations of the project are as follows:

1 Thermochemical calorie (designated "cal" in the tables)	= 4.1840 absolute joules
e	= 2.7182818284
$\log_e 10$	= 2.3025850929
$\log_{10} e$	= 0.4342944819
$e \times R_0$	= 4.575835 cal/°K mole (chem)
1 cm^{-1}	= 2.8592696 cal/mole (chem)
1 erg/molecule	= 1.439584×10^{16} cal/mole (chem)
1 ev	= 23,062.999 cal/mole (chem)
Ice Point	= 273.150° K
hc/k	= $1.43880 \pm 0.00007 \text{ cm}^\circ \text{K}$.

³Wichers, E., J. Am. Chem. Soc. 80, 4121 (1958).

C. THEORETICAL RELATIONS FOR HEAT CAPACITY VERSUS TEMPERATURE

One of the most important steps in the computation of thermodynamic functions of solids is smoothing and curvefitting of C_p^0 -versus-temperature data. One looks to the existing theories for mathematical functions to use in this kind of analysis. The theory provides mathematical functions for C_v . C_v and C_p^0 are almost equal at low temperatures, and these theories are applicable to the data under these conditions. In fact, it may be only at low or moderate temperatures that there is any hope at present for finding suitable mathematical functions for these purposes. This is in no way an attempt at a comprehensive review of the theory but merely at a summary of the best available theories that have direct bearing on the problems of this project. Some comprehensive reviews are available on this subject.⁴⁻⁸

1. The Law of Dulong and Petit

An empirical rule that has been often used and quoted is the law of Dulong and Petit,⁹ which states that "All solid elements have the same heat capacity per gram atom." At moderate temperatures, the atomic heat capacities are almost constant at $6.2 \pm 0.4 \text{ cal deg}^{-1}$ in spite of the increase in atomic weight from 7 to 238.⁹ In time, it became evident that there were many notable exceptions to this rule, and recent theories have provided a basis for the rule and explanations for the exceptions.

2. Kopp's Law

Kopp's law⁹ states that "The molar heat capacity of a solid compound is approximately equal to the sum of the atomic heat capacities of its constituents." This rule has been very useful; for example, it has been used to estimate molecular weights in doubtful cases. Winkelmann's^{4, 10} expression for the specific heats of glasses is of the same form.

3. Vibrational Contributions at Low Temperatures

a. Einstein's Theory

The Einstein^{5, 11} theory was not completely successful in fitting experimental heat capacities, but the function derived from it is often used in other ways as shall be seen later.

The Einstein model for a crystal system of N identical particles is that each atom vibrates harmonically in the isotropic potential field of all the other atoms. The energy of the particles can be written in terms of three linear harmonic oscillators, one for each dimension in space. The mean energy of a quantum mechanical linear harmonic oscillator with a frequency ν is

$$\bar{\epsilon} = \frac{h\nu}{\exp(h\nu/kT) - 1} \quad (1)$$

The total energy of the system at equilibrium is therefore $3N\bar{\epsilon}$; and its constant volume heat capacity, obtained by differentiation with respect to temperature, is

$$C_v = 3NkE(x), \quad (2)$$

where

$$x = h\nu/kT, \quad (3)$$

and $E(x)$ is the Einstein function,¹²

$$E(x) = \frac{(x/2)^2}{\sinh^2(x/2)} \quad (4)$$

The limit approached by equation (2) as the temperature increases is $3R$ per gram atom as it should be, but the limiting form at low temperatures is

$$C_v \approx 3Rx^2 e^{-x}, \quad (5)$$

and this does not fit the low-temperature data of solids very well.

¹¹Einstein, A., Ann. Physik, **22**, 180 (1907).

¹²Sherman, J. and R.B. Ewell, A six-place table of the Einstein functions, J. Phys. Chem. **46**, 641 (1942).

b. Debye's Elastic-Continuum Theory

Debye^{4, 13} was the first to derive a theoretical expression that fitted experimental heat capacities well over the entire range of temperatures for which data existed at that time. It is widely used by itself and in combination with Einstein functions.

Any system of N harmonically coupled point masses has $3N$ independent, normal modes of vibration with frequencies $\nu_1, \nu_2, \dots, \nu_{3N}$. The total energy of such a system is

$$E = kT \sum_{j=1}^{3N} x_j \left(\frac{1}{2} + \frac{1}{1 - \exp x_j} \right), \quad (6)$$

where

$$x_j = h\nu_j/kT. \quad (7)$$

C_v is therefore given by

$$C_v = k \sum_{j=1}^{3N} \frac{(x_j/2)^2}{\sinh^2(x_j/2)}. \quad (8)$$

For very large values of N , the sum can be approximated by an integral and C_v is given by

$$C_v = k \int_0^{\nu_L} g(\nu) \frac{(h\nu/2kT)^2}{\sinh^2(h\nu/2kT)} d\nu, \quad (9)$$

wherein $g(\nu)$ is the frequency distribution function or frequency spectrum, and ν_L is the limiting (largest) or cutoff frequency resulting from the fact that there is a finite number of normal mode frequencies.

¹³Debye, P., Ann. Physik, 39, 789 (1912).

Equation (9) is obviously just an integration of the Einstein function over the distribution function $g(\nu)$.

Debye¹³ derived expressions for $g(\nu)$ and ν_L from the theory of vibrations of an elastic continuum.

$$g(\nu) = 4\pi V \nu^2 (2 c_t^{-3} + c_l^{-3}), \quad (10)$$

$$\nu_L = \left[\frac{9N}{4\pi V (2 c_t^{-3} + c_l^{-3})} \right]^{1/3}. \quad (11)$$

Therefore, the correct distribution function that allows for the cutoff is

$$g(\nu) = \begin{cases} \frac{9N}{\nu_L} \left(\frac{\nu}{\nu_L} \right)^2 & \text{if } \nu < \nu_L. \\ 0 & \text{if } \nu > \nu_L. \end{cases} \quad (12)$$

The final expression for C_v is then

$$C_v = 3Nk \left[4D^*(x) - \frac{3x}{\exp(x)-1} \right] = 3NkD(x), \quad (13)$$

where the entire function in the brackets is called the Debye specific heat function, $D(x)$,

$$x = \theta_D/T, \quad (14)$$

$$\theta_D = h\nu_L/k, \quad (15)$$

and

$$D^*(x) = \frac{3}{x^3} \int_0^x \frac{\eta^3 d\eta}{e^\eta - 1} \quad (16)$$

In equation (16), η is a dummy variable, and x is defined by equations (14) and (15). θ_D and $D^*(x)$ are called the Debye temperature and the Debye energy function, respectively. Beattie¹⁴ has tabulated values of the $D(x)$ and $D^*(x)$ functions.

The limiting form of equation (13) at low temperatures; i. e., $x \gg 1$, is

$$C_V = 3Nk \left[(4/5)\pi^4 x^{-3} + \dots \right] \quad (17)$$

The T^3 function has been extensively used to fit low-temperature heat-capacity data.

The high-temperature limiting form is

$$C_V = 3Nk \left[1 - \left(\frac{1}{20}\right)x^2 + \left(\frac{1}{560}\right)x^4 + \dots \right] \quad (18)$$

The limit approached by C_V as the temperature increases is therefore $3R$.

Closer examinations of the fit of the Debye theory expression to experimental data have shown that it is not perfect.⁵ According to the theory, C_V is a universal function of the temperature with only one adjustable parameter, θ_D . Yet the value of θ_D is found to be a function of the temperature for all substances.⁵ Improvement of the theory has been sought in sophisticated studies of the discrete lattice.⁸

c. Conclusions from Discrete Lattice Theory

It is only natural that attempts would be made to improve the fitting of experimental data by employing combinations of Einstein and Debye functions. The Nernst-Lindemann¹⁵ formula,

¹⁴Beattie, J.A., J. Math. Phys. 16, 1 (1926).

¹⁵Nernst, W. and F.A. Lindemann, Z. Elektrochem; 17, 817 (1911).

$$C_v = \left(\frac{3Nk}{2} \right) \left[E(x) + E(x/2) \right] , \quad (19)$$

is an example which fitted some data well because the vibrational spectra happened to contain two peaks, one at roughly one half of the frequency of the other.^{5, 16} Wise et al¹⁷ have recently employed the formula,

$$C_p^0/R = D(\theta_D/T) + 2E_1(\theta_1/T) + E_2(\theta_2/T) , \quad (20)$$

to represent their boron data where the significance of the subscripts 1 and 2 on E_1 and E_2 was not explained. This must be regarded as an arbitrary curve-fitting procedure since it is not applied to C_v , it leads to a high temperature limit of $4R$ for C_p^0 , and it neglects contributions from anharmonicity corrections as well as the $9\beta^2 VT/\kappa$ term to be discussed later.

Sophisticated theories of the discrete lattice^{8, 18} have provided a rational basis for this type of approach. For a lattice containing s atoms per unit cell, it has been deduced that there are $3s$ solutions to the secular equations for the angular frequency. Three solutions (acoustic branches) tend to $\omega = 0$ as the wavelength approaches infinity; $3s - 3$ solutions (optic branches) tend to $\omega = \text{constant}$ as the wavelength approaches infinity.

An important approximation has been obtained by application of the following assumptions:

- 1) The optical branches are considered to contain a narrow range of frequencies, and the specific heat contribution of each is approximated by an Einstein function ("i" summation index).
- 2) The acoustic branches are each represented by a Debye spectrum with a suitable Debye temperature. ("j" summation index).

¹⁶Blackman, M., Proc. Roy. Soc. (London), A148, 384 (1935).

¹⁷Wise, S., J.L. Margrave, and R.L. Altman, The heat content of boron at high temperatures, J. Phys. Chem. 64, 915 (1960).

¹⁸Born, M., Atomtheorie des festen Zustandes (1923).

Therefore, the heat capacity for a gram formula weight of the s atoms is

$$C_v^s = R \sum_{j=1}^3 D(\bar{\theta}_j/T) + R \sum_{i=4}^{3s} E(\bar{\theta}_i/T) . \quad (21)$$

$D(\bar{\theta}_j/T)$ is the Debye specific heat function (in Eq. (13)), and $E(\bar{\theta}_i/T)$ is the Einstein function (Eq. 4).

The $\bar{\theta}_j$ must be chosen so that C_v fits the data well at low temperatures (where the acoustic branches are important), and the corresponding average velocities satisfy the relation,

$$\frac{1}{\bar{c}_j^3} = \int \frac{1}{c_j^3} \frac{d\Omega}{4\pi} , \quad (22)$$

for each acoustic branch where Ω is the solid angle. This is necessary since the velocities can be orientation-dependent and the frequency spectrum, in the limit of low frequencies, is $3VF\nu^2$, where

$$F = (4\pi/3) \int \sum_{j=1}^3 \left(\frac{1}{c_j^3} \right) \frac{d\Omega}{4\pi} . \quad (23)$$

The quantity F corresponds to $(2c_t^{-3} + c_l^{-3})$ in the Debye theory. Values of $\bar{\theta}_j$ for the acoustic branches can be estimated from the elastic constants of the solid since

$$\bar{\theta}_j = \left(\frac{h}{k} \right) \bar{\nu}_j = \left(\frac{h}{k} \right) \bar{c}_j \left(\frac{3}{4\pi V_a} \right)^{1/3} , \quad (24)$$

where $\bar{c}_j$ is the average sonic velocity for each branch, and V_a is the volume of the unit cell. The average velocity can be calculated directly using the determinant for the velocity of propagation of elastic waves from the standard theory of elasticity of solids. This determinant

provides an equation relating c_j to the lattice parameters and the direction of propagation which makes it possible to evaluate the integral in equation (22) and obtain the average velocity $\bar{c}_j = \sqrt[3]{\bar{c}_j^3}$. The optical frequencies ν_4 to ν_{3s} can be taken as the frequencies where the solid shows minimum transmission in the infrared.

The limit approached by equation (21) as the temperature increases is $3R$ s for a gram formula weight of the s atoms. The average limiting heat capacity per gram atom is therefore the classical value $3R$.

Equation (21) applies best where the acoustic and optical branches are well separated. When they are not well separated, it may give a worse fit than a single Debye spectrum.⁵

In trying to obtain a fit to low-temperature data by simultaneous solution with $3s$ points, one should remember that the points must be "smoothed" since the raw data contain statistical variations within their accuracy limits. This method should be used in combination with a least-squares regression analysis to obtain the most probable values of the θ_j 's and θ_i 's.

Detailed calculations of frequency spectra have been made for several systems such as a body-centered cubic lattice (fitted to the tungsten elastic constants¹⁹), ionic crystals of the alkali halide type²⁰ (characterized by long-range coulombic forces between ions), diamond,²¹ face-centered (close-packed) cubic crystals,²² and alkali metals.²³ In general, these frequency spectra have a form not in good agreement with the assumptions in equation (21). Debye spectra do not generally represent the acoustic branches well. In the case of ionic crystals, there is a pronounced, high-frequency tail to the optic branches that makes the use of Einstein functions dubious. However, one must bear in mind that the heat capacity is rather insensitive to the form of the frequency spectrum, especially at very high temperatures, and crude approximations in $g(\nu)$ can give surprisingly useful representations of the harmonic vibration contributions to C_v .

²³Fuchs, K., Proc. Roy. Soc. (London) 157A, 444 (1936).

A number of methods have been worked out for obtaining Debye temperatures from other physical properties,⁵ such as the temperature dependence of the intensity of X-ray diffraction spots, infrared absorption or reflection peaks, compressibilities, melting points, electrical resistance, and expansion coefficients. Such methods provide only crude estimates of C_v at low or moderate temperatures because of the inadequacy of a single Debye temperature in fitting actual data. Moreover, the Debye temperatures so obtained do not exactly equal those obtained directly from C_v data at any temperature. The "thermal spot" theory appears to offer some promise since it can be used to obtain detailed frequency spectra indirectly from lattice constants derived from studies of X-ray scattering.⁵

4. Electron Gas Contributions at Very Low Temperatures

The free electron gas in electrical conductors is responsible for most of their heat capacity at very low temperatures.⁴ The free electrons obey Fermi-Dirac statistics, and this results in a low-temperature heat capacity contribution proportional to the absolute temperature. When combined with equation (17), this results in the expression often used with metals at very low temperatures

$$C_p^o = 464.4 (T/\theta_D)^3 + aT. \quad (25)$$

The electron gas contribution is negligible at the intermediate temperature level.

5. High-Temperature Specific Heat of Solids

Some progress has been made in the development of the theory of specific heats of solids at high temperatures^{5, 24, 25} but more progress needs to be made in calculations for individual systems before our understanding of this property is complete.

Experimental measurements provide C_p^o data, but the theory is usually concerned with C_v . These two quantities are related by means of the well-known equation derived from rigorous thermodynamic relations i.e.,

$$C_p^o = C_v + 9\beta^2 VT/\kappa. \quad (26)$$

where β is the linear thermal expansion coefficient, v is the volume, and κ is the bulk compressibility.* The first term on the right takes care of the vibrational energy contributions and approaches a high-temperature limit of $3R$ per gram atom for a harmonically vibrating lattice. The second term on the right accounts for the energy absorbed due to expansion against the cohesive forces of the solid.

In many actual cases, as one can see from Table II, the $3R$ limit per average gram atom is exceeded at high temperatures, and one must look for large contributions from the expansion term and other possible terms due to anharmonicity, conduction electrons, gradual transitions, and higher electronic energy levels. The extensive heat capacity data for tungsten³³ plotted in figure 2 show how these additional contributions and the expansion term vary with temperature for that substance.

a. Constant Volume (Vibrational) Heat Capacity Contribution

Born and Brody²⁴ and Schroedinger²⁵ investigated the specific heat of an anharmonically vibrating lattice. Born and Brody approached the problem by studying the contributions of terms higher than quadratic in the displacement coordinates of the potential energy to the Helmholtz free energy of a system of quantum mechanical oscillators at large amplitudes. From this, they calculated corresponding contributions to the entropy and internal energy and obtained those for C_v by differentiation of the latter with respect to temperature. They found the limiting form of C_v at high temperatures to be

$$C_v = 3R(1 - 6\sigma RT) \quad (27)$$

From equation (27), it can be seen that the anharmonicity correction over the classical limiting value is $-18\sigma R^2 T$. σ is a characteristic constant of the crystal whose sign is thought by some to be not determined so that it could presumably be either positive or negative.^{5, 7} Born and Brody²⁴ state that σ is negative and that C_v values above $3R$ are to be expected.

The case of rocksalt has been analyzed by two methods,^{34, 35} and there appears to be a maximum in C_v versus temperature of uncertain validity. There is no evidence for such a maximum in the tungsten³³ data in figure 2. It is also obvious from the figure that harmonic vibration contributions do not account for the value of C_v at high temperatures. The difference between C_v and $3R$ at high temperatures is large and not quite linear with temperature.

³⁵ Siegel, S. and L. Hunter, *Phys. Rev.* 61, 84 (1942).

* $\beta = (1/\bar{L}) (\partial \bar{L} / \partial T)_p$ and $\kappa = -(1/V) (\partial V / \partial p)_T$ where $\bar{L}$ is length and p is pressure.

It is possible in principle to calculate C_v for ionic crystals, using the free energy, by a method developed by Born.³⁶

b. The Expansion Term

Eucken and Dannohl³⁴ have made an analysis of $C_p^\circ - C_v$ for a number of substances relying upon the assumption that the Gruneisen constant γ is independent of temperature to obtain the compressibility from the thermal expansion coefficient. In the case of rocksalt, the results of their analysis differ enough from those of Siegel and Hunter,³⁵ who used a complete set of available data, that the method must be considered with some reservations. Siegel and Hunter found that the $9V\beta^2T/\kappa$ term is large at high temperatures.

Gruneisen's^{4, 37, 38} theory for the equation of state of a solid neglects anharmonicities. This theory assumes that the normal mode frequencies are volume- or lattice-spacing-dependent. This dependence is represented by a parameter γ , the Gruneisen constant. The equation of state and expansion coefficients are therefore functions of γ . For the well-known Debye continuum model of a crystalline solid, γ is defined as

$$\gamma = - \frac{\partial \log \theta_D}{\partial \log V} \quad (28)$$

where θ_D is the Debye temperature, and V is the volume. From the equation of state of a Debye crystal, one finds that

$$(\partial p / \partial T)_V = \gamma C_v / V \quad (29)$$

and

$$\beta = \kappa \gamma C_v / 3V \quad (30)$$

since

$$\beta = (1/3) \kappa (\partial p / \partial T)_V \quad (31)$$

³⁶Born, M., *J. Chem. Phys.*, **7**, 591 (1939).

³⁷Gruneisen, E., *Handbuch der Physik*, vol. 10, p. 22, Springer-Verlag, Berlin (1953).

³⁸Slater, J.C., *Introduction to Chemical Physics*, McGraw-Hill, N.Y. (1939), p. 215-220.

This provides a useful approximation for evaluating the expansion term $9V\beta^2T/\kappa$ in equation(26). γ for many metals remains constant over a wide range of temperatures and densities.

Lindemann and Magnus⁹ proposed the empirical equation,

$$C_p^\circ - C_v = aT^{3/2}, \quad (32)$$

wherein a is a different constant for each substance. Since this formula, with a equal to 7×10^{-6} cal $^\circ K^{-5/2}/g$ atom, fits the tungsten data in figure 2 within a few tenths of a cal/g atom $^\circ K$, it appears to be a useful approximation for use in extrapolating rough data. A more exacting test of this approximation is presented in figure 3 which shows more precisely the extent of accuracy that can be expected.

c. Conduction Electron Contributions

For the heat capacity of electrical conductors such as metals, there is a contribution proportional to the temperature for the conduction electrons at low temperatures as discussed in section III-C4.⁴ This contribution is negligibly small for most metals at room temperature except for the transition elements such as platinum and palladium.⁵ Since this contribution is an increasing function of the temperature, it could well contribute outside the experimental error at very high temperatures for many refractory metals. Many of the compounds within the scope of this project become conductors at high temperature, but the importance of this contribution to their heat capacity is unknown.

The large contribution in the case of ferroelectric metals has been discussed in some detail.^{39, 40, 41}

d. Transitions

The occurrence of thermal transitions complicates the analysis of high-temperature specific heat data even further. These can be of several types which in principle can be clearly classified but in practice are less definite. A brief but penetrating review of this subject has been provided by Smoluchowski.⁴²

Figure 2 ATOMIC HEAT CAPACITY OF TUNGSTEN VERSUS TEMPERATURE

Figure 3 TEST OF LINDEMANN-MAGNUS FORMULA WITH TUNGSTEN DATA

Ehrenfest suggested a classification of transitions into orders according to which a transition is of the n^{th} order when temperature derivatives of F , the free energy, lower than the n^{th} are continuous at the transition temperature while the n^{th} derivative is discontinuous. Strictly speaking, only first-order transitions are phase transformations, but this designation has been commonly used for all transitions.

The usefulness of Ehrenfest's classification has been limited because of various intermediate kinds of anomalies that make it difficult to determine whether or not continuity of thermodynamic functions exists. Figure 4, due to Mayer and Streeter,⁴³ illustrates various common types of transformations.

First-order transformations are in principle simple to treat. They are the most common type where two phases can coexist in equilibrium and there is a definite heat of transformation. Integrations for thermodynamic functions can be performed smoothly over the two separate phases on either side of the transition point, and a heat and an entropy of transition can be added above the transition temperature, the free energy of transition being zero. Often in practice however, each phase anticipates the onset of the other so that the transition is not perfectly sharp. Large rises in C_p^o just below the melting point, called pre-melting, have been observed.

Second-order transformations are usually of the "lambda" type. In such cases, some continuous change is evident, and a definite heat of transformation cannot be assigned.

Diffuse transformations are spread out over a large range of temperature. Here again a definite heat of transformation cannot be assigned to them.

Certain crystals such as ammonium and hydrogen halides undergo a transformation as the temperature is increased that was first thought to be due to the onset of free rotation.⁴⁴ A better interpretation appears to be that of Frenkel,⁴⁵ who proposes that it corresponds to a progressive decrease in orientation of oscillation axes of the ions up to a critical temperature and then random orientation above the critical temperature.^{46, 47, 48} How generally this type of transformation

Figure 4 TYPES OF TRANSFORMATIONS IN SOLIDS

occurs is not known, but a similar type has been reported to occur in many organic compounds and even polymers.⁴⁹

Another phenomenon which appears in many metals and compounds at very high temperatures is thermionic emission. This also cannot strictly speaking be considered a transformation since it develops gradually as the temperature is increased. Its importance to the thermodynamic properties of the solid depends upon the extent to which it occurs which in turn depends upon the work function. Since it provides an electron gas species in the vapor at equilibrium with the solid, it is related to the ionic equilibria in the vapor.

⁴⁹Glasstone, S., op. cit., p. 428.

D. THE MONATOMIC GAS COMPUTER PROGRAM

1. Method of Calculation

The methods of calculation for the thermodynamic properties of monatomic gases are well known and have been described in many standard texts, articles, reports, etc.^{50, 51} The general procedure followed in the present project has been that of Kolsky, Gilmer, and Gilles.⁵¹ Their equations were modified in some cases to give the following formulas adopted for use in the present work:

$$Q = \sum_i (2J_i + 1) e^{-\frac{a \nu_i}{T}}, \quad (33)$$

$$Q_1 = \sum_i (2J_i + 1) \nu_i e^{-\frac{a \nu_i}{T}}, \quad (34)$$

$$Q_2 = \sum_i (2J_i + 1) \nu_i^2 e^{-\frac{a \nu_i}{T}}, \quad (35)$$

$$H_{298}^{\circ} - H_0^{\circ} = K_1 \left(\frac{Q_1}{Q} \right)_{298} + 298.15 K_2, \quad (36)$$

$$H_T^{\circ} - H_{298}^{\circ} = K_1 \left[\left(\frac{Q_1}{Q} \right) - \left(\frac{Q_1}{Q} \right)_{298} \right] + K_2 \frac{(T - 298.15)}{1000}, \quad (37)$$

$$C_P^{\circ} = \frac{K_3}{T^2} \left[\left(\frac{Q_2}{Q} \right) - \left(\frac{Q_1}{Q} \right)^2 \right] + K_2, \quad (38)$$

$$S_T^{\circ} = \frac{K_1}{T} \left(\frac{Q_1}{Q} \right) + R \ln Q + K_4 \ln M + K_2 \ln T + K_5, \quad (39)$$

⁵⁰Mayer, J. E. and M. G. Mayer, *Statistical Mechanics*, Wiley, N.Y. (1940), p. 109.

⁵¹Kolsky, H. G., R. M. Gilmer, and P. W. Gilles, *The Thermodynamic Properties of 54 Elements Considered As Ideal Monatomic Gases*, Los Alamos Scientific Laboratory, Rept. LA-2110 (15 March 1957).

$$\begin{aligned}
-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right) &= R \ln Q + K_4 \ln M + K_2 \ln T + K_6 + \frac{K_1}{T} \left(\frac{Q_1}{Q}\right)_{298} \\
&\quad + K_2 \left(\frac{298.15}{T}\right), \quad (40)
\end{aligned}$$

$$\begin{aligned}
-\left(\frac{F_T^\circ - H_O^\circ}{T}\right) &= R \ln Q + K_4 \ln M + K_2 \ln T + K_6, \\
-\left(\frac{F_T^\circ - H_O^\circ}{T}\right) + \left(\frac{H_{298}^\circ - H_O^\circ}{T}\right) &= -\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right), \quad (41)
\end{aligned}$$

$$\Delta H_f^\circ = \Delta H_{f298}^\circ + (H_T^\circ - H_{298}^\circ)_{\text{monatomic gas}} - (H_T^\circ - H_{298}^\circ)_{\text{ref. state}}, \quad (42)$$

$$\begin{aligned}
\Delta F_f^\circ &= \Delta H_{f298}^\circ - \frac{T}{1000} \left[-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right)_{\text{monatomic gas}} \right. \\
&\quad \left. + \left(\frac{F_T^\circ - H_{298}^\circ}{T}\right)_{\text{ref. state}} \right], \quad (43)
\end{aligned}$$

$$\text{Log}_{10} K_P = \frac{-1000 \Delta F_f^\circ}{4.575835 T} \quad (44)$$

Definitions of some of the symbols used above can be found in Table III. The remainder are defined as follows:

- Q = partition function,
- J_i = inner quantum number of the ith state,
- ν_i = wave number for a given energy level in cm^{-1} ,
- T = absolute temperature in degrees Kelvin,
- $H_{298}^\circ - H_O^\circ$ = enthalpy of an ideal gas at 298.15°K relative to the ideal gas at absolute zero,

$H_T^\circ - H_{298}^\circ$ = enthalpy of an ideal gas at temperature T , relative to the ideal gas at 298.15°K.

C_p° = heat capacity of ideal gas in cal/°K, g mol,

S_T° = entropy of ideal gas in cal/°K, g mol,

$-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right)$ = free-energy function, in cal/°K, g mol,

M = molecular weight,

R = gas constant, cal/°K g mol,

ΔH_f° = standard heat of formation at temperature T , in Kcal/g mole,

ΔH_{f298}° = standard heat of formation at 298.15°K, in Kcal/g mole,

ΔF_f° = standard free energy of formation at temperature T , in Kcal/g mole,

K_p = equilibrium constant for sublimation or vaporization to a monatomic gas from the condensed phase of the pure element.

The values of the constants used in these equations were based on the work of Cohen, Crowe, and Dumond.¹ The derived constants for the above equations are listed in Table III. For the sake of comparison, the constants used by Kolsky et al.⁵¹ were also included. It should be noted that their value of the gas constant was based on the physical atomic weight scale, whereas the value based on the chemical atomic weight scale has been adopted in the fifth column of the table. All derived quantities were therefore correspondingly adjusted. The uncertainties in the fifth column were derived from the values of Cohen, Crowe, and Dumond.¹

The machine program used for preparing ideal monatomic gas tables con-

taining C_p° , S_T° , $-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right)$, $H_T^\circ - H_{298}^\circ$, ΔH_f° , ΔF_f° , and $\text{Log}_{10} K_p$ was

based on the equations summarized above. The required input data for its use are:

- a. J_i versus ν_i (cm^{-1}),
- b. The eight constants in the last two columns of Table III,
- c. The molecular weight on the chemical scale,
- d. $\Delta H_{f,298}^\circ$ in Kcal/mole,
- e. Enthalpy of the reference state as a function of temperature,
- f. Free energy of the reference state as a function of temperature,
- g. The temperature for each entry of the table.

2. Uncertainty-Range Calculations

The uncertainty limits were obtained by repeating the calculation described immediately above with the "perturbed" values in the last column of Table III and individually chosen values of the other input data. The difference between the results of the two calculations was taken as the uncertainty range.

Considerable thought had to be given to the choice of the other input data for the uncertainty analysis. This is worthwhile to discuss in more detail.

- a. J_i versus ν_i

The ν_i values were obtained by a "perturbation" of the last significant figure given in Moore's tables;⁵² i. e., the ones used in the normal calculation above. For example, if $\nu_i = 16 \text{ cm}^{-1}$ as reported by Moore, then the perturbation was -1, giving $\nu_{i(\text{perturbed})} = 15 \text{ cm}^{-1}$. A negative "perturbation" was used since this should lead to an increased occupation of excited levels at a given temperature, as compared with the "unperturbed" states.

This means that the partition function (and consequently, the free-energy function) was maximized. Since the free-energy function is basically the most important single thermochemical quantity with the exception of the heat of formation, it is seen that this procedure is the optimum one. However, if desired, a positive perturbation could also be used, and the calculations repeated.

⁵² Moore, C. E., Atomic Energy Levels, NBS Circular 467, vol. 1 (15 June 1949).

b. The Eight Constants of Table III

The constants in Table III were "perturbed" from the "best" values in the fifth column, again in such a manner as to maximize the errors in the free-energy function.

c. The Molecular Weight on the Chemical Scale

Normally, no perturbation was included for the molecular weight, but this could be included if the uncertainties in molecular weight became appreciable. For example, if the uncertainty in molecular weight became 1 part in 2500, an error of about 0.001 e.u. could be assigned to S_T° or the free-energy function.

d. ΔH_{f298}° in Kcal/mole

Errors in ΔH_{f298}° are ordinarily the largest and most significant in thermodynamic calculations. These errors will lead to errors in ΔH_f° , ΔF_f° , and $\text{Log}_{10} K_p$. The input to the calculation routine described above consisted of the absolute value of the uncertainty, designated a_{298} . This is equivalent to considering the true value of ΔH_{f298}° to lie in the range of $\Delta H_{f298}^\circ \pm a_{298}$.

e. Uncertainties in Enthalpy Functions

Uncertainties in the enthalpy functions of the monatomic gas were labeled b_T (Kcal/gram atom of gas). Thus, $(H_T^\circ - H_{298}^\circ)$ was considered to be within the range of values of $(H_T^\circ - H_{298}^\circ) \pm b_T$. Values of b_T were taken from results of the calculation based on the data in steps (a) through (c) above.

Uncertainties in the enthalpy functions of the reference state were labeled c_T and fed into the program as input data.

f. Uncertainties in Free-Energy Functions

Uncertainties in the free-energy functions of the monatomic gas and reference state were designated as d_T and e_T , respectively. They were obtained in the same manner as b_T and c_T described just above.

g. Uncertainties in ΔH_f° , ΔF_f° , and $\text{Log}_{10} K_p$

The uncertainties in ΔH_f° , ΔF_f° , and $\text{Log}_{10} K_p$ were obtained as the sum of the component uncertainties since each term in the summation is independent of any other. For example, since

$$\Delta H_f^\circ \pm \delta \Delta H_f^\circ = (\Delta H_{f298}^\circ \pm a_{298}) + \left[(H_T^\circ - H_{298}^\circ)_{\text{gas}} \pm b_T \right] - \left[(H_T^\circ - H_{298}^\circ)_{\text{ref}} \pm c_T \right] \quad , \quad (45)$$

then,

$$\delta (\Delta H_f^\circ) = a_{298} + b_T + c_T \quad . \quad (46)$$

Likewise, the other uncertainties are

$$\delta (\Delta F_f^\circ) = a_{298} + \frac{T}{1000} (d_T + e_T) \quad , \quad (47)$$

and

$$\delta (\text{Log}_{10} K_p) = [\delta (\Delta F_f^\circ)] \left[\frac{1000}{4.575835 T} \right] \quad . \quad (48)$$

E. DIATOMIC MOLECULE CALCULATIONS

The computer program used in the calculations of the thermodynamic functions of diatomic molecules was based on a treatment of the diatomic molecule developed by Mr. T. Munson of Avco RAD over a period of time. A program for a single electronic state using this treatment has been in use on other projects at Avco RAD. The present program was designed to be applied to the general case of the diatomic molecule with multiple electronic states. The following discussion of the calculation is based on the standard equations and symbols of the spectroscopists, except where duplications of symbol usage might result in confusion.

The treatment of a given electronic state is an elaboration of the method of Mayer and Mayer⁵⁰ but takes into account spectroscopic constants of higher order than the latter.

The input data for the program are the electronic energy (defined later) and the standard spectroscopic constants ω_e , $\omega_e x_e$, $\omega_e y_e$, B_e , a_e , γ_e , and D_e . Although values of γ_e are not commonly tabulated, they may be estimated from Dunham's equations.⁵³ Spectroscopic constants which are sometimes determined but which are not included in the present calculation are $\omega_e z_e$, β_e , and coefficients of powers of v ($v + 1$) greater than the second.

It is assumed that the internal energy, exclusive of the electronic energy, may be expressed as a function of the quantum numbers v and j for a given electronic state by the expression

$$\begin{aligned} \epsilon_i = & \omega_e \left(v + \frac{1}{2} \right) - \omega_e x_e \left(v + \frac{1}{2} \right)^2 + \omega_e y_e \left(v + \frac{1}{2} \right)^3 \\ & + j(j+1) \left[B_e - a_e \left(v + \frac{1}{2} \right) + \gamma_e \left(v + \frac{1}{2} \right)^2 \right] - D_e j^2 (j+1)^2, \end{aligned} \quad (49)$$

where the energy is expressed in wave numbers.

If the energy of the lowest level ($v = 0$, $j = 0$) is taken as zero, equation (49) may be re-arranged and put in the form

$$\begin{aligned} (\epsilon - \epsilon_0)_i = & \omega v - \omega x v(v-1) + \omega y v(v-1)(v-2) \\ & + j(j+1) \left[1 - \rho j(j+1) - (\delta - \phi)v - \phi v^2 \right] B_e (1 - \delta/2), \end{aligned} \quad (50)$$

⁵³Dunham, J.L., Phys. Rev. 41, 721 (1932).

where

$$\omega = \omega_e - 2\omega_e x_e + (13/4)\omega_e y_e,$$

$$\omega x = \omega_e x_e - (9/2)\omega_e y_e,$$

$$\omega y = \omega_e y_e,$$

$$x = \omega x / \omega,$$

$$y = \omega y / \omega,$$

$$\rho \approx D_e / B_e, \quad (51)$$

and the following definitions are added

$$\delta = a_e / B_e + (a_e / B_e)^2 - 2\gamma_e / B_e,$$

$$\phi = -\gamma_e / B_e + \frac{1}{2}(a_e / B_e)^2. \quad (52)$$

In arriving at the above definitions, it is convenient to use the approximation

$$\gamma_e \approx (2/3)a_e^2 / B_e, \quad (53)$$

which follows from Dunham's equations.⁵³

The internal partition function, exclusive of a term for the electronic energy, may be written as

$$Q(v, j) = \sum_{v, j} (2j+1) \exp \left\{ -u \left[v - xv(v-1) + yv(v-1)(v-2) \right] \right. \\ \left. - \sigma j(j+1) \left[1 - \rho j(j+1) - (\delta - \phi)v - \phi v^2 \right] \right\} = \frac{Q_e}{\sigma(1-e^{-u})}, \quad (54)$$

where $1/\sigma$ is the partition function for the rigid rotator, $1/(1 - e^{-u})$ is the partition function for the harmonic oscillator, and Q_c contains the terms for anharmonicity and rotation-vibration interactions. Further definitions for these terms are

$$\sigma = B_e(1 - \delta/2)hc/kT, \quad (55)$$

and

$$u = hc\omega/kT. \quad (56)$$

A procedure analogous to that of Mayer and Mayer⁵⁰ was used to expand the exponential and approximate the summation in equation (54). The contributions to the thermodynamic functions from internal degrees of freedom (designated by subscript i) then become

$$\begin{aligned} - \left(\frac{F_T^\circ - H_O^\circ}{RT} \right)_i &= \ln Q(v, i) = -\ln \sigma - \ln \psi + \sigma/3 + \sigma^2/90 + 2\rho/\sigma \\ &+ \delta e^{-u}/\psi + 2xu e^{-2u}/\psi^2 \\ &+ 2x^2 e^{-2u} u^2 (1 + 4e^{-u})/\psi^4 + \delta^2 e^{-u}/2\psi^2 \\ &+ 4\delta xu e^{-2u}/\psi^3 - 6yu e^{-3u}/\psi^3 + 2\phi e^{-2u}/\psi^2 \end{aligned} \quad (57)$$

$$\begin{aligned} \left(\frac{H_T^\circ - H_O^\circ}{RT} \right)_i &= 1 + u e^{-u}/\psi - \sigma/3 - \sigma^2/45 + 2\rho/\sigma + \delta e^{-u}u/\psi^2 \\ &+ 4xu^2 e^{-2u}/\psi^3 - 2xu e^{-2u}/\psi^2 + 6yu e^{-3u}/\psi^3 \\ &- 18yu^2 e^{-3u}/\psi^4 + 4x^2 u^3 e^{-2u}(1 + 7e^{-u} + 2e^{-2u})/\psi^5 \\ &- 4x^2 u^2 e^{-2u}(1 + 4e^{-u})/\psi^4 + 4\delta xu^2 e^{-2u}(2 + e^{-u})/\psi^4, \\ &- 4\delta xu e^{-2u}/\psi^3 + \delta^2 u e^{-u}(1 + e^{-u})/2\psi^3 + 4\phi e^{-2u}u/\psi^3, \end{aligned} \quad (58)$$

and

$$\begin{aligned} \left(\frac{C_P^\circ}{R} \right)_i &= 1 + u^2 e^{-u}/\psi^2 + 4\rho/\sigma + \sigma^2/45 + \delta e^{-u}u^2(1 + e^{-u})/\psi^3 \\ &- 8xu^2 e^{-2u}/\psi^3 + 4xu^3 e^{-2u}(2 + e^{-u})/\psi^4 \\ &+ 36yu^2 e^{-3u}/\psi^4 - 18yu^3(3 + e^{-u})e^{-3u}/\psi^5 \end{aligned}$$

$$\begin{aligned}
& + 4x^2u^2e^{-2u}(1 + 4e^{-u})/\psi^4 - 8x\delta u^2e^{-2u}(2 + e^{-u})/\psi^4 \\
& - 16x^2u^3e^{-2u}(1 + 7e^{-u} + 2e^{-2u})/\psi^5 \\
& + \delta^2u^2e^{-u}(1 + 4e^{-u} + e^{-2u})/2\psi^4 \\
& + 8x^2u^4e^{-2u}(1 + 12e^{-u} + 11e^{-2u} + e^{-3u})/\psi^6 \\
& + 4\phi u^2e^{-2u}(2 + e^{-u})/\psi^4 + 4x\delta u^3e^{-2u}(4 + 7e^{-u} + e^{-2u})/\psi^5, \quad (59)
\end{aligned}$$

where

$$\psi = (1 - e^{-u}). \quad (60)$$

The total internal energy, ϵ_n , of the n^{th} electronic state is

$$\epsilon_n = E'_e + \omega v - \omega x v(v-1) + \dots, \quad (61)$$

where E'_e is the electronic energy of the state expressed in wave numbers. Since, for a given electronic state, the energy of the lowest level ($v = 0, j = 0$) is taken as the reference point of the energy scale, E'_e becomes T_e (the electronic energy as defined by Herzberg⁵⁴) less the difference between the zero point energies of the n^{th} state and the ground state; i. e.,

$$\begin{aligned}
E'_e = T_e - & \left[(1/2)\omega_e - (1/4)\omega_e x_e + (1/8)\omega_e y_e + \dots \right] \\
& + \left[(1/2)\omega'_e - (1/4)\omega'_e x'_e + (1/8)\omega'_e y'_e + \dots \right], \quad (62)
\end{aligned}$$

where the unprimed terms are for the ground state, and the primed terms are for the upper state.

The total internal partition function for all electronic states is given by

$$\begin{aligned}
Q = & \sum_n g_n (2j+1) e^{-hc\epsilon_n/kT} = \sum_n g_n e^{-E_e/kT} \left\{ \sum_{v,j} (2j+1) \exp[-uv + uxv(v-1) + \dots] \right\} \\
= & \sum_n g_n e^{-E_e/kT} Q_n = \sum_n \frac{g_n e^{-E_e/kT} \ln(Q_c)_n}{\sigma \psi}, \quad (63)
\end{aligned}$$

⁵⁴Herzberg, G., Molecular Spectra and Molecular Structure, I. Spectra of Diatomic Molecules, Van Nostrand, N.Y. (1950).

where g_n is the multiplicity of the n^{th} electronic state, E_e is hcE'_e , Q_n and $(Q_c)_n$ are $Q(v, j)$ and Q_c , respectively, from equation (54).

The temperature derivatives of Q are therefore

$$\frac{dQ}{dT} = \sum_n g_n Q_n e^{-E_e/kT} (E_e/kT^2) + \sum_n g_n e^{-E_e/kT} (dQ_n/dT), \quad (64)$$

$$\begin{aligned} \frac{d^2Q}{dT^2} = & \sum_n g_n e^{-E_e/kT} (d^2Q_n/dT^2) + 2 \sum_n g_n e^{-E_e/kT} (dQ_n/dT) (E_e/kT^2) \\ & + \sum_n g_n e^{-E_e/kT} Q_n (E_e/kT^2)^2 - 2 \sum_n g_n e^{-E_e/kT} Q_n (E_e/kT^3). \end{aligned} \quad (65)$$

Values for Q_n and its derivatives are obtained from equations (66), (67), and (68).

$$Q_n = \frac{e^{\ln(Q_c)_n}}{\sigma \psi}, \quad (66)$$

$$dQ_n/dT = \frac{Q_n}{T} \left(\frac{H_T^\circ - H_O^\circ}{RT} \right)_{i,n}, \quad (67)$$

and

$$d^2Q_n/dT^2 = \frac{Q_n}{T^2} \left(\frac{C_p^\circ}{R} \right)_{i,n} + \frac{Q_n}{T^2} \left(\frac{H_T^\circ - H_O^\circ}{RT} \right)_{i,n}^2 - \frac{2}{T} (dQ_n/dT), \quad (68)$$

where

$$\ln(Q_c)_n = \sigma/3 + \sigma^2/90 + 2\rho/\sigma + \delta e^{-u}/\psi + \dots \quad (69)$$

From the above expressions, the contribution of the internal energies of all electronic states to the thermodynamic functions (designated by the subscript Σ_i) may be derived.

$$-\left(\frac{F_T^\circ - H_O^\circ}{RT}\right)_{\Sigma_i} = \ln Q, \quad (70)$$

$$\left(\frac{H_T^\circ - H_O^\circ}{RT}\right)_{\Sigma_i} = (T/Q)(dQ/dT), \quad (71)$$

$$\begin{aligned} \left(\frac{C_P^\circ}{R}\right)_{\Sigma_i} &= (2T/Q)(dQ/dT) - (T/Q)^2(dQ/dT)^2 + (T^2/Q)(d^2Q/dT^2) \\ &= 2\left(\frac{H_T^\circ - H_O^\circ}{RT}\right)_{\Sigma_i} - \left(\frac{H_T^\circ - H_O^\circ}{RT}\right)_{\Sigma_i}^2 + (T^2/Q)(d^2Q/dT^2), \end{aligned} \quad (72)$$

and

$$\left(\frac{S_T^\circ}{R}\right)_{\Sigma_i} = \left(\frac{H_T^\circ - H_O^\circ}{RT}\right)_{\Sigma_i} - \left(\frac{F_T^\circ - H_O^\circ}{RT}\right)_{\Sigma_i}. \quad (73)$$

After addition of the contribution of translational degrees of freedom, changing of the reference temperature from 0° to 298.15°K , and substitution of the values of the fundamental constants adopted here, the total thermodynamic functions (in units of cal, $^\circ\text{K}$, and moles) become

$$C_P^\circ = 1.98726 \left(\frac{C_P^\circ}{R}\right)_{\Sigma_i} + 4.96815, \quad (74)$$

$$\begin{aligned} S_T^\circ &= 1.98726 \left(\frac{S_T^\circ}{R}\right)_{\Sigma_i} + 6.863753 \log M + 11.439588 \log T \\ &\quad - 4.575835 \log \theta - 2.31538, \end{aligned} \quad (75)$$

$$\begin{aligned}
-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right) = & -1.98726 \left(\frac{F_T^\circ - H_O^\circ}{RT}\right)_{\Sigma i} + \frac{(H_{298}^\circ - H_O^\circ)_{\Sigma i}}{T} \\
& + 6.863753 \log M + 11.439588 \log T \\
& - 4.575835 \log \theta + \frac{1481.2539}{T} - 7.28353, \quad (76)
\end{aligned}$$

$$\begin{aligned}
(H_T^\circ - H_{298}^\circ) = & 1.98726T \left(\frac{H_T^\circ - H_O^\circ}{RT}\right)_{\Sigma i} - (H_{298}^\circ - H_O^\circ)_{\Sigma i} \\
& + 4.96815 (T - 298.15), \quad (77)
\end{aligned}$$

and

$$(H_{298}^\circ - H_O^\circ) = 592.5016 \left(\frac{H_T^\circ - H_O^\circ}{RT}\right)_{\Sigma i, 298} + 1481.25392, \quad (78)$$

where M is the molecular weight of the diatomic gas, and θ is the symmetry number of the molecule (1 for a heteronuclear and 2 for a homonuclear diatomic molecule).

The program for machine computation of the thermodynamic functions of diatomic gases was based on the above formulas. Calculations for the natural isotopic mixture of molecular oxygen are in excellent agreement with those of Woolley⁵⁵ when the spectroscopic constants he selected are used for the $^3\Sigma_g^-$, $^1\Delta_g$, $^1\Sigma_g^+$, $^3\Sigma_u^+$, and $^3\Sigma_u^-$ states. The results after minor adjustments are compared in Table IV.

Woolley's values were corrected for a change in the gas constant R and the Sackur-Tetrode constant and converted to a reference temperature of 298.15°K. Woolley used a different summation procedure and included some higher-order spectroscopic constants for the ground state which the present calculation does not include. He also broke off rotational sums at the dissociation limit, whereas they are extended here to infinite energy. The additional contribution to the enthalpy would be about 15 cal/gfw at 5000°K and negligible at 4000°K had he extended his rotational summation to infinite energy.

⁵⁵Woolley, H.W., J. Research Nat. Bur. Stds. 40, 163 (1948); Nat. Bur. Stds. (U.S.) Circ. 564 (1955).

F. POLYATOMIC MOLECULE CALCULATIONS

The program for the calculation of thermodynamic functions for ideal gases of polyatomic molecules was based upon the standard relations of molecular dynamics employed by spectroscopists.

One of these basic relations is that the total energy of an ideal polyatomic molecule is the sum of its translational and internal energies.

$$\epsilon = \epsilon_t + \epsilon_{int} \quad (79)$$

The internal energy is composed of electronic, vibrational, rotational, and interaction or coupling contributions. The interaction terms are rarely, if ever, accurately known and are usually ignored. The internal energy was therefore considered to be the sum of the electronic, vibrational, and rotational contributions.

$$\epsilon_{int} = \epsilon_r + \epsilon_v + \epsilon_{el} \quad (80)$$

The partition function (Q) can then be written as the product of the individual partition functions

$$Q = Q_t Q_r Q_v Q_{el} \quad (81)$$

and the thermodynamic functions can be separated into sums of translational, rotational, vibrational, and electronic contributions.

$$C_p^\circ = C_p^\circ(t) + C_p^\circ(r) + C_p^\circ(v) + C_p^\circ(el) \quad (82)$$

$$H_T^\circ - H_O^\circ = (H_T^\circ - H_O^\circ)_t + (H_T^\circ - H_O^\circ)_r + (H_T^\circ - H_O^\circ)_v + (H_T^\circ - H_O^\circ)_{el} \quad (82A)$$

$$- \left(\frac{F_T^\circ - H_O^\circ}{T} \right) = - \left(\frac{F_T^\circ - H_O^\circ}{T} \right)_t - \left(\frac{F_T^\circ - H_O^\circ}{T} \right)_r - \left(\frac{F_T^\circ - H_O^\circ}{T} \right)_v - \left(\frac{F_T^\circ - H_O^\circ}{T} \right)_{el} \quad (82B)$$

and

$$S_T^\circ = S_t^\circ + S_r^\circ + S_v^\circ + S_{el}^\circ \quad (82C)$$

Evaluation of the Q's in the usual manner,⁵⁰ combination of the translational and rotational contributions, and substitution of required physical constants¹ then leads to the following equations which were employed in the computer program:

1. Linear Polyatomic Molecules

a. Heat Capacity in cal/° K mole

$$C_p^\circ = C_{p(t,r)}^\circ + C_{p(v)}^\circ + C_{p(el)}^\circ, \quad (83)$$

$$C_{p(t,r)}^\circ = 6.95541 + 0.091420 \left(\frac{E}{T} \right)^2, \quad (84)$$

$$B = 2.79889 \times 10^{-39}/I, \quad (85)$$

$$C_{p(v)}^\circ = \sum_i \frac{1.98726 \left(\frac{1.43880 \omega_i}{T} \right)^2 \left(e^{-\frac{1.43880 \omega_i}{T}} \right)}{\left(1 - e^{-\frac{1.43880 \omega_i}{T}} \right)^2}, \quad (86)$$

$$C_{p(el)}^\circ = \frac{4.113917}{T^2} \left[\frac{Q_2}{Q} - \left(\frac{Q_1}{Q} \right)^2 \right], \quad (87)$$

$$Q = \sum_i g_i e^{-\frac{1.43880 \epsilon_i}{T}}, \quad (88)$$

$$Q_1 = \sum_i \epsilon_i g_i e^{-\frac{1.43880 \epsilon_i}{T}}, \quad (89)$$

$$Q_2 = \sum_i \epsilon_i^2 g_i e^{-\frac{1.43880 \epsilon_i}{T}}, \quad (90)$$

ω_i is a fundamental frequency in units of cm^{-1} , I is the principal moment of inertia, ϵ_i is an electronic energy level in units of cm^{-1} , and g_i is the degeneracy of the corresponding electronic energy level.

b. Enthalpy in cal/mole

$$H_T^\circ - H_{298}^\circ = (H_T^\circ - H_O^\circ)_{t,r} + (H_T^\circ - H_O^\circ)_v + (H_T^\circ - H_O^\circ)_{el} - (H_{298}^\circ - H_O^\circ)_{t,r,v,el} \quad (91)$$

$$(H_T^\circ - H_O^\circ)_{t,r} = T \left[6.95541 - 0.953090 \left(\frac{B}{T} \right) - 0.091420 \left(\frac{B}{T} \right)^2 \right] \quad (92)$$

$$(H_T^\circ - H_O^\circ)_v = \sum_i \frac{1.98726T \left(\frac{1.43880\omega_i}{T} \right) \left(e^{-\frac{1.43880\omega_i}{T}} \right)}{1 - e^{-\frac{1.43880\omega_i}{T}}} \quad (93)$$

$$(H_T^\circ - H_O^\circ)_{el} = 2.859270 \left[\frac{Q_1}{Q} \right] \quad (94)$$

$$\begin{aligned} (H_{298}^\circ - H_O^\circ)_{t,r,v,el} = & 298.15 \left[6.95541 - 0.953090 \left(\frac{B}{298.15} \right) - 0.091420 \left(\frac{B}{298.15} \right)^2 \right] \\ & + \left[\sum_i \frac{1.98726(298.15) \left(\frac{1.43880\omega_i}{298.15} \right) \left(e^{-\frac{1.43880\omega_i}{298.15}} \right)}{\left(1 - e^{-\frac{1.43880\omega_i}{298.15}} \right)} \right] \\ & + \left[\frac{\sum_i e_i \cdot e^{-\frac{1.43880\epsilon_i}{298.15}}}{\sum_i e_i \cdot e^{-\frac{1.43880\epsilon_i}{298.15}}} \right] \quad (95) \end{aligned}$$

c. Free-Energy Function in cal/° K mole

$$-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right) = -\left(\frac{F_T^\circ - H_O^\circ}{T}\right)_{t,r} - \left(\frac{F_T^\circ - H_O^\circ}{T}\right)_v \\ - \left(\frac{F_T^\circ - H_O^\circ}{T}\right)_{el} + \left(\frac{H_{298}^\circ - H_O^\circ}{T}\right)_{t,r,v,el} \quad (96)$$

$$-\left(\frac{F_T^\circ - H_O^\circ}{T}\right)_{t,r} = 6.863753 \log M + 11.439588 \log T \\ - 4.575835 \log \left(\frac{B\theta}{T}\right) + 0.953090 \left(\frac{B}{T}\right) \\ + 0.045710 \left(\frac{B}{T}\right)^2 - 8.00651 \quad (97)$$

$$-\left(\frac{F_T^\circ - H_O^\circ}{T}\right)_v = - \sum_i 4.575835 \log \left(1 - e^{-\frac{1.43880\omega_i}{T}}\right) \quad (98)$$

$$-\left(\frac{F_T^\circ - H_O^\circ}{T}\right)_{el} = 4.575835 \log \sum_i g_i e^{-\frac{1.43880\epsilon_i}{T}} \quad (99)$$

B , ω_i and ϵ_i were defined earlier. M is the molecular weight, and θ is the symmetry number.

d. Entropy in cal/° K mole

$$s_T^\circ = \left(\frac{H_T^\circ - H_{298}^\circ}{T}\right) - \left(\frac{F_T^\circ - H_{298}^\circ}{T}\right) \quad (100)$$

2. Nonlinear Polyatomic Molecules

a. Heat Capacity in cal/° K mole

Equations (83), (86), and (87) through (90) were used with

$$C_p^{\circ}(t,r) = 7.949040 \quad (101)$$

b. Enthalpy in cal/mole

$$\begin{aligned} H_T^{\circ} - H_{298}^{\circ} = & \left(H_T^{\circ} - H_O^{\circ} \right)_{t,r} + \left(H_T^{\circ} - H_O^{\circ} \right)_{\nu} \\ & + \left(H_T^{\circ} - H_O^{\circ} \right)_{el} - \left(H_{298}^{\circ} - H_O^{\circ} \right)_{t,r,\nu,el} \end{aligned} \quad (102)$$

$$\left(H_T^{\circ} - H_O^{\circ} \right)_{t,r} = 7.949040 T \quad (103)$$

$$\left(H_{298}^{\circ} - H_O^{\circ} \right)_{t,r,\nu,el} = [7.949040(298.15)]$$

$$\begin{aligned} & + \left[\sum_i \frac{1.98726(298.15) \left(\frac{1.43880\omega_i}{298.15} \right) \left(e^{-\frac{1.43880\omega_i}{298.15}} \right)}{1 - e^{-\frac{1.43880\omega_i}{298.15}}} \right] \\ & + \left[2.859270 \frac{\sum_i \epsilon_i g_i e^{-\frac{1.43880\epsilon_i}{298.15}}}{\sum_i g_i e^{-\frac{1.43880\epsilon_i}{298.15}}} \right] \end{aligned} \quad (104)$$

$(H_T^\circ - H_0^\circ)_v$ and $(H_T^\circ - H_0^\circ)_{el}$ are given by equations (93) and (94). All other parameters are as previously defined.

c. Free-Energy Function in cal/°K mole

$$\begin{aligned}
 - \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right) = & - \left(\frac{F_T^\circ - H_0^\circ}{T} \right)_{t,r} - \left(\frac{F_T^\circ - H_0^\circ}{T} \right)_v \\
 & - \left(\frac{F_T^\circ - H_0^\circ}{T} \right)_{el} + \left(\frac{H_{298}^\circ - H_0^\circ}{T} \right)_{t,r,v,el}
 \end{aligned} \tag{105}$$

$$\begin{aligned}
 - \left(\frac{F_T^\circ - H_0^\circ}{T} \right)_{t,r} = & 6.863753 \log M + 18.303341 \log T \\
 & - 4.575835 \log \theta + 2.287918 \log I_A I_B I_C \times 10^{120} \\
 & - 17.16242.
 \end{aligned} \tag{106}$$

$$- \left(\frac{F_T^\circ - H_0^\circ}{T} \right)_v \text{ and } - \left(\frac{F_T^\circ - H_0^\circ}{T} \right)_{el} \text{ are given by equations (98) and (99).}$$

$I_A I_B I_C$ is the product of the three principal moments of inertia. All other parameters are as previously defined.

d. Entropy in cal/°K mol (given by Eq. 100).

G. CONDENSED-PHASE CALCULATIONS

Solid and liquid-phase thermodynamic functions are calculated in essentially the same way. Calculations for both phases can therefore be discussed together.

1. Solid Phases

a. Basic Equations

In a reference state table, only C_p° , S_T° , $-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right)$, and $(H_T^\circ - H_{298}^\circ)$

are included. For the solid phase, the last three functions can be calculated if C_p° and solid-state transition data are available. The formulas for a solid with n first order transitions below the temperature T and above the reference temperature are

$$S_T^\circ = \int_0^{T_1} \left(\frac{C_p^\circ}{T}\right) dT + \sum_{i=1}^n \lambda_i/T_i + \sum_{i=2}^n \int_{T_{i-1}}^{T_i} \left(\frac{C_p^\circ}{T}\right) dT + \int_{T_n}^T \left(\frac{C_p^\circ}{T}\right) dT \quad (107)$$

$$-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right) = S_T^\circ - \left(\frac{H_T^\circ - H_{298}^\circ}{T}\right), \quad (108)$$

$$\begin{aligned} H_T^\circ - H_{298}^\circ &= \int_{298.15}^{T_1} C_p^\circ dT + \sum_{i=1}^n \lambda_i + \sum_{i=2}^n \int_{T_{i-1}}^{T_i} C_p^\circ dT \\ &+ \int_{T_n}^T C_p^\circ dT, \end{aligned} \quad (109)$$

$$H_T^\circ - H_{298}^\circ = (H_T^\circ - H_0^\circ) - (H_{298}^\circ - H_0^\circ), \quad (110)$$

where λ_i is the heat of the i^{th} transition at T_i . The solid-liquid transition can be included as the n^{th} one in which case, the C_p° of the liquid is used in the last term of eqs. (107) and (109).

b. Method of Choosing Basic Data

Since experimental C_p° data are often reported directly in the literature and since empirical equations are often presented for the temperature dependence of this quantity, there appear to be several advantages for conducting calculations with this quantity, rather than doing so with other quantities such as $(H_T^\circ - H_{298}^\circ)$. Therefore, in the work of this project, first priority was given to locating C_p° data for each solid as it came under consideration. The second step was to plot graphs and compare the data from various sources. After a choice of the "best" data was made, several alternatives presented themselves for proceeding with the calculations, depending upon the state of the available C_p° data.

- 1) The "best" data for C_p° and the other functions may already have been tabulated at the desired temperatures throughout the entire temperature range of the tables.
- 2) Data may have been tabulated only for portions of the desired temperature range.
- 3) The C_p° data may have been in the form of data points given at various temperature intervals.
- 4) The C_p° data may have been presented in the form of an analytical expression. A variety of possible analytical expressions have been used. These include Debye or Einstein functions, polynomials, etc.

c. Machine Computation

The computer program used on this project for condensed phases was designed to accept numerical values of C_p° at the 100°K intervals required in the final tables and carry out a numerical integration of these input data to give the other thermodynamic quantities. This eliminated the need for first reducing the original data to an analytical expression.

d. Uncertainty Analysis

The standard procedure adopted in the computation of error estimates has been to assign uncertainties to the primary C_p° and heat-of-transition data and to calculate the uncertainties in the derived functions S_T° ,

$$-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right), \text{ and } (H_T^\circ - H_{298}^\circ) \text{ from them. An assigned uncertainty could}$$

be made at each of the tabular temperatures. Since highly precise calculations were not expected in these cases, an average value for the uncertainty in a given temperature interval was used.

1) Heat capacity

Heat capacities are usually obtained experimentally, and the original experimenter is the one best able to set the uncertainty limits. However, this is often neglected and must be done instead by the reviewer. If data from several sources are available, the spread in the data can give some indication of their reliability. Questions of purity of samples, the method of, and the care taken in the measurements, etc., should all be considered.

2) Entropy

The range of heat capacity values is defined as

$$C_p^\circ = C_{po}^\circ \pm \delta C_p^\circ \quad , \quad (111)$$

where

$$\delta C_p^\circ = (C_{pU}^\circ - C_{pL}^\circ)/2 \quad , \quad (112)$$

C_{po}° = best value for heat capacity available,

C_{pU}° = upper limit of uncertainty range,

and

C_{pL}° = lower limit of uncertainty range.

The true value C_{pt}° is expected to lie somewhere between the limits given by equation (111).

From the thermodynamic definition of entropy, one can write

$$S_T^\circ = S_{298,o}^\circ \pm s_{298} + \int_{298}^T \frac{C_{po}^\circ}{T} dT \pm \int_{298}^T (\delta C_p^\circ / T) dT \quad , \quad (113)$$

where

$S_{298,o}^\circ$ = the best available value of S_{298}° , and

s_{298} = the uncertainty in S_{298}° .

The uncertainty in S_T° is therefore,

$$s_T = s_{298} + \int_{298}^T (\delta C_p^\circ / T) dT. \quad (114)$$

Or assuming that $\delta C_p^\circ \neq f(T)$,

$$s_T = s_{298} + \delta C_p^\circ \ln(T/298.15) \quad (115)$$

is obtained.

3) Enthalpy

Since

$$H_T^\circ - H_{298}^\circ = \int_{298.15}^T C_p^\circ dT, \quad (116)$$

one obtains, for an actual point with its associated uncertainties,

$$H_T^\circ - H_{298}^\circ + \delta(H_T^\circ - H_{298}^\circ) = \int_{298.15}^T C_{p0}^\circ dT + \int_{298.15}^T \delta C_p^\circ dT \quad (117)$$

from equation (111). The uncertainty in $H_T^\circ - H_{298}^\circ$ is therefore,

$$h_T = \int_{298.15}^T \delta C_p^\circ dT = \delta(H_T^\circ - H_{298}^\circ) \quad (118)$$

4) Free energy Function

The uncertainty in the free-energy function defined as

$$f_T = \delta \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right) \quad (119)$$

can be obtained from those of the entropy and enthalpy functions just discussed because of equation (100). Due to this equation, one can simply write the uncertainty in the free-energy function as

$$f_T = s_T - h_T/T \quad (120)$$

This is contrary to the usual practice in summing errors because in this particular case, the uncertainties s_T and h_T are due to a common uncertainty in C° and are matched. The independent error in S_{298}° is simply added on.

From equations (114) and (118), it can be seen that $s_T > h_T/T$.

2. Liquid Phases

The calculation of thermodynamic functions for liquid phases was done in essentially the same manner as described above for solid phases. Primary heat capacity data were scantier and less precise for liquid phases and more ingenuity in making estimates was required.

H. EVALUATION OF STANDARD HEAT OF FORMATION OF ELEMENTS AT 298.15°K [ΔH_f°]

Heats of vaporization or sublimation may be derived from vapor pressure measurements in two different ways.

The first technique, based on the Clausius-Clapeyron equation, is called the "Second Law Method." When applied to the vaporization of an element it will give a single value of ΔH_{f298}° equal to ΔH_{v298}° or ΔH_{s298}° from each set of vapor pressure measurements.

If it is assumed that the vapor of the element is ideal, the Clausius-Clapeyron equation may be written as a form of Van't Hoff's equation,

$$\frac{d(-R \ln K_p)}{dT} = - \frac{\Delta H_f^\circ}{T^2} \quad (121)$$

where K_p is the equilibrium constant for the vaporization process. For the special case of liquid or solid vaporization without polymerization, K_p equals the vapor pressure.

The heat of formation, ΔH_f° , may be obtained as a function of the temperature from the equation

$$\Delta H_f^\circ = \Delta H_{f298}^\circ + \int_{298}^T \Delta C_p^\circ dT \quad (122)$$

where ΔC_p° is the difference between the heat capacity of the gas and that of the condensed phase. The exact analytical expression used for ΔC_p° will depend on the precision of available heat capacity data and on the form of the functions used to express the temperature dependence of the heat capacities of both phases concerned. If the form of the expression for ΔC_p° is that favored by Kelley⁵⁶ for the heat capacity of solids; namely,

$$\Delta C_p^\circ = \Delta A + \Delta B T - \Delta C T^{-2} \quad (123)$$

where the coefficients are related to those of the enthalpy expression by $\Delta A = \Delta a$, $\Delta B = 2\Delta b$ and $\Delta C = \Delta c$, equation (122) then becomes

$$\Delta H_f^\circ = (\Delta H_{f298}^\circ + \Delta A(T - 298.15) + \frac{\Delta B}{2} [T^2 - (298.15)^2] + \Delta C(1/T - 1/298.15)). \quad (124)$$

⁵⁶Kelley, K. K., Bureau of Mines Bull. 584 (1960).

If equation (124) is substituted into equation (121), the result may be integrated and re-arranged to give

$$- R \ln K + \Delta A \ln T + \frac{\Delta B T}{2} - \frac{\Delta C T^{-2}}{2} + \Delta D T^{-1} = \frac{\Delta H_{f298}^{\circ}}{T} + I, \quad (125)$$

where

$$\Delta D = 298.15 \Delta A + \frac{(298.15)^2 \Delta B}{2} + \frac{\Delta C}{298.15}, \quad (126)$$

and I is an integration constant. If terms on the left-hand side of equation (125) are designated by Σ , the equation becomes

$$\Sigma = \frac{\Delta H_{f298}^{\circ}}{T} + I. \quad (127)$$

Therefore, one may calculate ΔH_{f298}° , by the Second Law Method, by computing Σ for each experimental vapor pressure measurement, and plotting it against the reciprocal of the temperature. The resulting plot should be a straight line, and the slope of that line is the value of ΔH_{f298}° . The constant of integration, I , is related to the entropy of formation at 298.15° K by the equation

$$\Delta S_{f298}^{\circ} = \Delta A + \Delta A \ln(298.15) + \Delta B(298.15) + \frac{\Delta C(298.15)^{-2}}{2} - I \quad (128)$$

When free-energy functions are available for the condensed and gas phases, these functions may be used in combination with experimental vapor pressure data to calculate a value of ΔH_{f298}° for each vapor pressure measurement. This technique is known as the "Third Law Method." Thus, the difference between the free-energy functions of the gas and condensed phases, $\Delta(f.e.f.)$ is

$$\Delta(f.e.f.) = \left[\frac{F_T^{\circ} - H_{298}^{\circ}}{T} \right]_g - \left[\frac{F_T^{\circ} - H_{298}^{\circ}}{T} \right]_c = \frac{\Delta F_T^{\circ}}{T} - \frac{\Delta H_{f298}^{\circ}}{T}. \quad (129)$$

However,

$$\frac{\Delta F^\circ}{T} = -R \ln K_p \quad (130)$$

Therefore,

$$\Delta H^\circ_{f298} = T [-R \ln K_p - \Delta(f.e.f.)] \quad (131)$$

Ideally, the two methods should give the same results. In practice, they seldom do because of errors in the experimental results or approximations made in analytical expressions for the temperature dependence of heat capacities in the Second Law treatment. The Third Law treatment is to be preferred for the present work, and was the one adopted. Because the latter method permits a calculation of ΔH°_f corresponding to each vapor pressure measurement, a sensitive check for a possible drift with temperature is available. Calculations are possible for situations in which the temperature dependence of heat capacities may not have been reduced to an analytical expression. Most important however, the thermodynamic compilations are thereby made internally consistent. In this way, experimental vapor pressures are more closely reproduced from the compilations than they would be if the Second Law treatment were used. In that sense, the values of ΔH°_{f298} listed will be legitimately used only with the free-energy functions for gas and condensed phases with which they are tabulated.

The two techniques just described have general applicability to the vaporization of systems other than those of the elements. When applied to the vaporization of compounds, however, they simply yield heats of the vaporization or decomposition process which yields the vapor species.

IV. REVIEWS OF DATA AND COMPUTATION SUMMARIES FOR INDIVIDUAL ELEMENTS AND COMPOUNDS

With the exception of Th and Ce for which there were insufficient data, ideal monatomic gas tables were prepared for all the elements within the scope of the contract plus several other metals which were included at the request of Materials Central, WADD. Emphasis was placed initially on the preparation of tables for the elements because they were needed for the preparation of tables on compounds. In some cases, it was only necessary to add uncertainty estimates to existing tables for the elements. A number of existing tables were re-computed because better energy level data had become available. Oxide compounds were also given high priority in the work because more data were available on them than on the other classes of compounds such as the carbides, borides, and nitrides.

A. ELEMENTS

1. Beryllium

a. Crystal Structure and Melting Point

At room temperature, elemental beryllium has a hexagonal, close-packed structure.⁵⁷ The possible allotropy of beryllium has been a subject of dispute for over thirty years. In general, two allotropic transformations have been discussed; one occurring in the temperature range from 400° to 800°C, and the other around 20° to 30°C below the melting point. Most of the evidence in support of allotropy in the lower-temperature range can probably be discounted as originating from impure beryllium. The most likely impurity, BeO, will not be revealed by the usual spectroscopic analysis.

Lewis⁵⁸ inferred the existence of allotropic transformations at -45 and 450°C by thermal emf and electrical resistivity measurements. Jaeger and Rosenbohm⁵⁹ found evidence for a second beryllium phase from specific heat measurements. From X-ray measurements, Jaeger and Zanstra⁶⁰ proposed that, β -Be is hexagonal close-packed with a relatively large unit cell and is metastable at room temperature. They also reported that the high-temperature phase was most successfully produced by heating to 630°C. Kosolapov and Trapoznikov⁶¹ obtained

evidence for allotropy from extra reflections in X-ray measurements on beryllium samples. Noyce and Daane⁶² reported an allotropic transformation at 730°C from thermal and dilatometric effects. However, Gordon and Kaufmann⁶³ were unable to confirm the latter results. Gordon⁶⁴ measured the thermal coefficients of expansion of beryllium up to 1000°C by X-ray methods, and found no evidence for allotropy. However, Chatterjee and Sidhu⁶⁵ reported allotropy by X-ray measurements on 99.9 percent pure beryllium. Sidhu and Henry⁶⁶ examined spectroscopically pure beryllium and very dilute gold-beryllium alloys, and from the position and intensity variations of extra lines, concluded that a β -Be phase was present which had a complex hexagonal structure. Seybolt et al⁶⁷ criticized these conclusions and stated that the extra reflections were probably due to BeO or AuBe₅. Kaufmann et al⁶⁸ found no evidence for allotropy by thermal analysis studies and microstructure examination of beryllium that had been cooled down from temperatures up to the melting point. The last investigators further stated that the fact that single crystals of beryllium could be successfully grown from the melt was evidence for the nonexistence of the disputed phase.

In addition to the questionable allotropic transformation below 1000°C, a double thermal arrest has been reported in the temperature range from 1250° to 1260°C (20 or 30 degrees below the melting point).⁶⁹⁻⁷² This observation has been variously interpreted as due to an allotropic transformation or the presence of a eutectic with a contaminant. Losano⁷³ reported finding only a single thermal arrest in 99.96 percent pure beryllium. However, Martin and Moore⁷⁴ later found no evidence, with thermal analysis techniques, for the existence of a solid-state change between 25° and 1000°C, but they detected a double thermal arrest in the vicinity of the melting point. On cooling, the second arrest started on the average 20°C below the melting point arrest; on heating, the average was 17°C below the melting point. The latter measurements

were made on beryllium samples of varying purity and included zone-refined beryllium containing 0.056 weight percent of metallic impurities, 0.4 cc/g of H₂, and 0.008 weight percent of O₂. They also reported lattice spacings for 99.4 percent pure beryllium containing 0.3 weight percent of BeO from -193° to 1265°C. They found deviations from linearity for the temperature dependence of the lattice spacings at about 200° and 800°C. These deviations were attributed to the effects of solutes. A discontinuity in lattice spacings at about 1250°C was stated to coincide with the transformation of hexagonal close-packed β -beryllium to body-centered cubic α -beryllium.

It was concluded, in summary, that beryllium is hexagonal, close-packed from room temperature to about 20 degrees below its melting point. A transformation to a body-centered cubic phase is quite possible at the latter temperature, but was ignored in the present compilation.

The melting point of beryllium was taken as 1556° $\pm$ 3°K on the basis of the available information.^{56, 75-78}

b. Thermodynamic Properties

1) Heat of fusion

The heat of fusion of beryllium was taken as 2.800 $\pm$ 0.500 Kcal/gfw from the review of Kubaschewski *et al.*⁷⁹ This value was derived from Oosterheld's⁸⁰ thermal analysis studies (2.40 Kcal/gfw), Losano's⁷³ measurements on the pressure dependence of the melting point (1.98, 2.23, 2.56 Kcal/gfw), Sloman's⁸¹ measurements on the melting-point depression of beryllium by silver (3.4 Kcal/gfw), and regularities among the entropies of transformation of the alkali and alkaline earth metals (3.0 Kcal/gfw). It should be noted that the value for the heat of fusion of magnesium accepted here destroys some of the regularity of Kubaschewski's comparison. However, the limits of error assigned to the value are probably adequate to cover any shift in the estimated value. The heat of fusion of beryllium adopted here was the one in general acceptance.^{56, 75-78}

2) Entropy and heat content at 298.15°K

Values of the entropy and heat content of elemental beryllium at 298.15°K were based on the measurements of Hill and Smith⁸² (4° to 300°K). These data have been joined with the high-temperature data of Ginnings, Douglas, and Ball⁸³ (367° to 1169°K) by the Bureau of Standards.⁷⁸ S_{298}° was calculated to be 2.282 ± 0.02 e. u., and $(H_{298}^{\circ} - H_0^{\circ})$ was computed to be 467 cal/gfw by the Bureau of Standards. The latter values were accepted for the present work. These same low-temperature data have been used elsewhere^{75, 76} to calculate the value of $S_{298}^{\circ} = 2.280$ e. u.

Other low-temperature heat capacity measurements on beryllium included those of Simon and Ruhemann⁸⁴ (71° to 79°K), Lewis⁵⁸ (97° to 463°K), and Cristescu and Simon⁸⁵ (10° to 300°K).

3) High-temperature heat content

The measurements of Ginnings, Douglas, and Ball⁸³ (367° to 1169°K) were used to calculate the high-temperature heat capacity and heat content of beryllium. These authors gave results for two samples, each of which contained 99.5 percent beryllium, but differed in the composition of their impurities. An average of the results for the two samples, which differed a maximum of 0.5 percent, was adopted. The heat contents to 1000°K were considered to be good to ± 1 percent. The uncertainty of an extrapolation from the highest temperature of measurement (1169°K) to the melting point is larger. Derived values of the heat capacity, which increase essentially at a uniform rate with temperature from 700° to 1000°K, show an inflection around 1000°K to a more rapid increase with temperature. The extrapolation made herein assumed that the heat capacity above 1100°K increases at the same rate as it does between 1000° and 1100°K; namely, 2.5×10^{-3} cal/°K² gfw. Between 1000°K and the melting point, the heat capacities were considered to be good to ± 3 percent. It should be noted that the temperature of the observed inflection lies in the region of one of the disputed allotropic transformations discussed above.

⁸⁵Cristescu, S. and F. Simon, *Z. physik. Chem.* 25B, 273 (1934).

Other available data for the high-temperature heat capacity or heat content of solid beryllium included those of Fieldhouse *et al*⁸⁶ (434° to 1328°K), Jaeger and Rosenbohm⁵⁹ (273° to 1338°K), Lewis⁵⁸ (282° to 463°K), Magnus and Holzmann⁸⁷ (295° to 1173°K), and Nilson and Pettersson⁸⁸ (273° to 573°K).

In the absence of experimental data for the heat capacity of liquid beryllium, the value of 7.50 cal/°K gfw recommended by Kelley⁵⁶ was used.

4) Heat of formation of monatomic gas

The Third Law Method was used with the free-energy functions for beryllium tabulated herein and the vapor pressure data from the following sources to give the indicated values for the heat of formation of beryllium at 298.15°K:

Source	Temperature (°K)	ΔH_f° at 298.15°K (Kcal/gfw)
Gulbransen and Andrew ⁸⁹	1103 - 1229	78.170 ± 0.600
Holden <i>et al</i> ⁹⁰	1172 - 1552	77.840 ± 0.700
Schuman and Garrett ⁹¹	1174 - 1336	80.590 ± 1.300
Baur and Brunner ⁹²	1850 - 2331	79.540 ± 2.500

Original data points were used for the calculations.

The value for ΔH_{f298}° adopted herein was an average of the results of the first two authors listed; namely, 78.00 ± 0.500 Kcal/gfw. The uncertainty given was based on the scatter of experimental vapor pressures, and did not include uncertainties due to estimated heat capacities for liquid beryllium.

⁸⁶Fieldhouse, I.B., J.C. Hedge, J.I. Lang, and T.E. Waterman, Wright Air Development Center, Tech. Rept. WADC-TR-57-487, AD-1550954 (1958).

⁹²Baur, E. and R. Brunner, Helv. Chim. Acta 17, 958 (1934).

An extrapolation of ΔF_f° to zero gave a normal boiling point for beryllium of 2754°K . An uncertainty of 50 degrees was estimated for the boiling point from uncertainties in ΔH_{298}° and liquid heat capacities. At the boiling point, ΔH_f° was calculated to be 70.498 Kcal/gfw.

5) Thermodynamic functions

The beryllium reference state thermodynamic functions are given in Table V.

The thermodynamic functions for beryllium as an ideal monatomic gas in Table VI were calculated using all the levels listed by Moore.⁵² $H_{298}^\circ - H_0^\circ$ was found to be 1,481 cal/mole. Uncertainty estimates are given on the backs of the tables.

2. Boron

Existing tabulations on boron were found to be inadequate for three reasons. First, they were not based upon the most up-to-date data; second, they did not extend up to 6000°K; and third, estimates of uncertainty in the data were not included. Therefore, the re-computation of the boron data was undertaken.

a. Crystal Structure

Elemental boron exists in several modifications. However, the stable modifications and their temperature ranges of stability are still in doubt.

It is generally accepted that β -rhombohedral boron is the stable form above 1500°C,⁹³⁻⁹⁵ and also that it may be stable down to as low as 1100°C.⁹³ α -rhombohedral boron is also fairly well documented,^{96, 97} being stable at lower temperatures than the β -rhombohedral form.⁹⁴ Other common forms include the tetragonal,^{98, 99} and amorphous borons.⁹⁴ Several other polymorphs have been reported, but it appears likely that many of them are formed as a result of kinetic considerations and the presence of a foreign substrate and have no real thermodynamic range of stability.⁹³

In view of the uncertainties regarding the stable phases of boron, it is impossible to specify solid transition-point temperatures. Such transitions usually have low but generally unknown heats of transition (commonly a few hundred calories). Hence, the thermodynamic tabulations will contain these added uncertainties.

b. Melting Point

For the melting point of boron, there were also many reported values. These are summarized in Table VII.

In evaluating these various melting-point data, the most important consideration is probably sample purity. Usually, small amounts of impurities are expected to lower the melting point, and cause an increase in the melting-point range. The highest values in Table VII (from 2200° to 2400°C) are based on very old work, and were not given serious consideration. The values of Cueilleron^{100, 107} appear to be too low in the light of the more recent work. The values from references 104-106 and 108 in Table VII should be considered in more detail.

TABLE VIII

SUMMARY OF RECENT BORON MELTING-POINT DATA

Reference	Type of Boron	Purity (percent)	Melting Point (°K)
Searcy and Myers ¹⁰⁴	{ Fairmount amorphous, sublimed.	{ 98.9 } { 99.95 }	> 2420
Cline ¹⁰⁵	Pacific Coast Borax, "fused!"	95-97	2403
Cooper ¹⁰⁶	Briquette.	---	2373-2473
Piper ¹⁰⁸	Pacific Coast Borax, powder.	98.9	2403 ± 10

The work of Searcy and Myers¹⁰⁴ seems to be the most reliable since some of their samples had purities up to 99.95 percent. Since they could still not obtain fusion at 2420°K, it is necessary to estimate the melting point. In view of the lower, recent values given in references 105 and 108, it would seem that the melting point could not be much higher than 2420°K. Accordingly, the melting point was taken to be 2450° ± 50°K, which would encompass these recent values.

c. Thermodynamic Data

For crystalline boron as the reference state, the data of Wise, Margrave, and Altman¹⁷ to 2400°K have been used in the present report. Their values were based on the low-temperature data of Johnston et al,¹¹⁴ and their own measurements to 1200°K. They have extrapolated these data to 2400°K. Their data have been extrapolated here to the estimated melting point of 2450°K. For the heat of fusion, the

¹¹⁴ Johnston, H.L., H.N. Herah, and E.C. Kerr, J. Am. Chem. Soc. 73, 1112 (1951).

Sinke et al³² procedure has been followed to obtain an entropy of melting of 2.3 e.u., or a heat of fusion of 5635 cal/g atom. Similarly, the liquid heat capacity has been estimated as 7.5 cal/°K g atom.

d. Sublimation Data

The available data for the sublimation of boron showed considerable uncertainty also (see Table IX).

e. Calculations

1) Condensed phases

Wise, Margrave, and Altman¹⁷ have tabulated values of C_p° , $H_T^\circ - H_0^\circ$, $-\left(\frac{F_T^\circ - H_0^\circ}{T}\right)$, and S_T° from 100° to 2400°K. These values were converted to the standard reference temperature of 298°K according to equations (107) through (110). $H_{298}^\circ - H_0^\circ = 290.4$ cal/gfw was taken from that reference.¹⁷

The formula given by Wise, Margrave, and Altman,¹⁷ (see eq. (20) and its discussion)

$$C_p^\circ/R = D(\theta_D/T) + 2 E_1(\theta_1/T) + E_2(\theta_2/T), \quad (132)$$

was used to obtain the C_p° value at 2450°K by extrapolation. It was used as in equation (133) with available tabulations of $D(\theta_D/T)$ and $E(\theta/T)$ with the reported values of θ_D , θ_1 and θ_2 .

$$C_p^\circ/R = D(\theta_D/T) + 2 E(\theta_1/T) + E(\theta_2/T). \quad (133)$$

The Einstein functions $E(\theta_1/T)$ and $E(\theta_2/T)$ were evaluated from the tables of Sherman and Ewell,¹² and the Debye function $D(\theta_D/T)$ was evaluated from the tables of Taylor and Glasstone which give $3RD(\theta_D/T)$.¹²² The C_p° and other values in Table X, calculated from this formula at 2450°K, were in good agreement with those obtained by extrapolation of Wise, Margrave, and Altman's¹⁷ table by a difference method.

At the chosen melting point, 2450°K, the value of $C_p^\circ = 7.50$ was taken for the reasons discussed in section c. above. Similarly, the heat of fusion was taken to be 5635 cal/g atom, and the entropy of melting was taken to be 2.3 e. u. Hence, the quantities $H_T^\circ - H_{298}^\circ$ and S_T° had the respective increments of 5635 and 2.3 for the liquid phase at 2450°K.

For temperatures above 2450°K, the heat capacity was assumed to be constant at 7.50 cal/°K g atom. Therefore, $H_T^\circ - H_{298}^\circ$ became

$$H_T^\circ - H_{298}^\circ = [H_{2450}^\circ(\text{liq}) - H_{298}^\circ] + 7.5(T - 2450). \quad (134)$$

6000	±.001	±.001	±.001	±.006	±8.720	±8.980	±.320

The entropy was calculated according to equation (107) which reduced to equation (135),

$$S_T^\circ = S_{2450}^\circ(\text{liq}) + 17.2693 \log_{10} \frac{T}{2450} \quad (135)$$

The free-energy function was calculated according to equation (108). The reference state functions are summarized in Table X.

2) Gas phase

Wilkins and Altman¹²³ tabulated C_p° , $H_T^\circ - H_0^\circ$, and S_T° in the range from 0° to 6000°K at 100°K intervals. All these values were used as tabulated. The enthalpy (heat content) and free-energy functions were calculated from equations (108) and (110). The remaining functions were calculated from equations (42), (43), and (44). The ideal gas functions are summarized in Table XI.

3) Error analyses

a) Uncertainty estimates in condensed phase functions are given on the back of Table X.

1 Heat capacity

In the case of boron, C_p° data from more than one source have been available for comparison. They are summarized in Table XII.

TABLE XII
BORON HEAT CAPACITY DATA FROM VARIOUS SOURCES

Source	C_p° (cal/°K g atom)	
	298.15°K	2000°K
Wise et al ¹⁷	2.823	7.288
Sinke and Stull ³²	2.63	7.20
Evans et al ¹¹⁷	2.650	---

¹²³Wilkins, R.L. and R.L. Altman, J. Chem. Phys. 31, 337 (1959).

It can be immediately seen from Table XII that there is a spread of about $0.20 \text{ cal/}^{\circ}\text{K g atom}$ in the values of heat capacity at room temperature. Although the measurements of Wise *et al*¹⁷ were made on crystalline samples, whereas the others apparently used "amorphous" boron, the results of the former measurements could not be simply accepted since it would appear that their samples were not from a pure, single phase. For example, they made the statement that "some of the high temperature β - rhombohedral form" was present in all samples. A conservative evaluation therefore would require assuming that their samples contained a mixture of phases and adopting an uncertainty of $0.2 \text{ cal/g atom } ^{\circ}\text{K}$ for the room-temperature heat capacity of boron. In the absence of any better information, the same uncertainty was assigned to the heat capacity at 2000°K even though the agreement between values from the two sources was better at that temperature.

For the liquid, a value of $C_p^{\circ} = 7.50 \text{ cal/}^{\circ}\text{K g atom}$ and an uncertainty in this value (as well as ΔC_p°) equal to $1.0 \text{ cal/}^{\circ}\text{K g atom}$ was simply assumed.

2 Entropy

Uncertainty ranges were calculated from equation (115) with δC_p° equal to $0.2 \text{ cal/}^{\circ}\text{K gfw}$ in the temperature range from 298.15° to 2450°K .

An uncertainty of 0.3 e.u. was assumed for the entropy of fusion of boron.

In the melt ($2450^{\circ} < T < 6000^{\circ}\text{K}$), the uncertainty in heat capacity was assumed to be $1.0 \text{ cal/}^{\circ}\text{K gfw}$.

3 Enthalpy

Uncertainty range calculations were made with equation (118).

4 Free Energy function

Free energy function uncertainty range calculations were made with equation (120).

5 Uncertainty in gas phase functions

The effect of energy assignments on ideal gas function accuracy has been briefly considered by Kolsky, Gilmer, and Gilles.⁵¹

On the basis of their analysis, it appears that the energy levels of B(g) are well-established and that their small uncertainty causes an error of only ± 0.0002 cal/°K g atom in C_p° for the ideal gas. It is also reassuring to compare the available C_p° data from two separate tabulations.

Temperature (°K)	Values* of Wilkins <u>et al</u> ¹²³	Values* of Kolsky <u>et al</u> ⁵¹	Difference*
298.15	4.971	4.9709**	0.0001
6000	5.168	5.1683**	0.0003

Thus, one can conclude conservatively that these C_p° data are accurate at least to ± 0.001 cal/°K g atom.

A similar analysis of those authors^{123, 51} entropy data shows that S_T° is also accurate to ± 0.001 cal/°K g atom.

Temperature (°K)	Values* of Wilkins <u>et al</u> ¹²³	Values* of Kolsky <u>et al</u> ⁵¹	Difference*
298.15	36.649	36.648**	0.001
6000	51.597	51.5959**	0.0011

Free-energy and entropy functions calculated from these data have insignificant uncertainties for most practical purposes.

The uncertainties in ΔH_f° , ΔF_f° , and $\log_{10} K_p$ are much greater. These uncertainties are obtained from equations (42), (43), and (44).

*Cal/°K g atom.

** Converted to chemical atomic-weight scale.

The uncertainty estimates on the back of Table XI are slightly conservative in that the uncertainty in the heat of sublimation at 298°K has been used for all other temperatures. Since heats of sublimation of boron have been obtained from high-temperature (near 2000°K) experiments, it is reasonable to expect the values in the neighborhood of 2000°K to be more precise than the value at 298°K. Actually, the difference in uncertainties at these two temperatures is less than 0.5 kcal/g atom. This is small compared to the total error in the heat of sublimation.

3. Calcium

a. Crystal Structure, Transition Point, and Melting Point

Elemental calcium was shown by Smith, Carlson, and Vest¹²⁴ to have a face-centered, cubic structure from room temperature to 737°K and to transform at the latter temperature to a body-centered form stable up to the melting point.

These results are in contrast with those of earlier work from which the existence of additional allotropic modifications of calcium was inferred. Both a "low symmetry" or "complex" phase¹²⁵ and a hexagonal, close-packed phase had been previously reported.¹²⁵⁻¹²⁸

The transition temperatures and phase stabilities had been found to depend on the thermal history of the calcium samples. Smith, Carlson, and Vest¹²⁴ concluded that the additional phases were due to impurities. Schottmiller, King, and Kanda¹²⁹ later also reported the two additional phases and suggested that small amounts of impurities (presumably metallic) could nucleate a transformation that occurred only very slowly in highly pure calcium. However, Smith and Bernstein¹³⁰ subsequently concluded that nitrogen or carbon induced the formation of the "low symmetry" phase and that hydrogen was responsible for the formation of the hexagonal close-packed phase. The matter has probably not been unambiguously resolved to everyone's satisfaction because the impurities responsible are difficult to control and are relatively difficult to determine quantitatively.

The results of Smith, Carlson, and Vest¹²⁴ have been accepted, and 737° ± 10°K has been adopted as the transition temperature for the present project. Stull and Sinke⁷⁷ and Kelley⁵⁶ adopted a transition temperature of 713°K from the earlier review of Kubaschewski et al.⁷⁹

¹³⁰Smith, J. and B. Bernstein, *J. Electrochem. Soc.* 106, 448 (1959).

The melting point of calcium used here, $1123^{\circ} \pm 10^{\circ}\text{K}$, was listed by Kubaschewski et al,⁷⁹ and was also used in other recent compilations.^{56, 76, 77} The more reliable values reported range from 1116° to 1124°K .^{125, 129, 131-133}

b. Thermodynamic Properties

1) Heat of transition

The heat of transition of face-centered cubic calcium to body-centered cubic calcium was taken as 240 ± 60 cal/gfw. This value was recommended by Kubaschewski et al⁷⁹ from the heat content measurements of Moser and Schulze¹²⁷ (212 cal/gfw), Jauch¹³⁴ (240 ± 60 cal/gfw), and the thermal analysis results of Rinck¹³⁵ (275 cal/gfw). Eastman, Williams, and Young¹³⁶ reported the heat of transition to be 100 ± 25 cal/gfw from their heat content measurements. It was assumed that a change of the transition temperature from the previously accepted 713° to 737°K alters the heat of transition within the uncertainty given above.

2) Heat of fusion

Kubaschewski et al⁷⁹ list the heat of fusion of calcium as 2070 ± 100 cal/gfw. This value is based on Jauch's¹³⁴ heat content measurements and was adopted here. Kelley¹³⁷ arrived at a value of 2230 ± 300 cal/gfw from a review of phase diagrams of calcium alloys. Other determinations of the heat of fusion of calcium have been made by Zalesinski and Zulinski¹³⁸ (3150 cal/gfw, 3000 cal/gfw) and by Rinck¹³⁵ (1640 cal/gfw).

¹³⁸Zalesinski, E. and R. Zulinski, Bull. Int. Polon. Sci. Lettres (A), p. 479 (1928).

3) Entropy and heat content at 298.15°K

Kelley¹³⁹ gave the entropy of elemental calcium at 298.16°K as 9.95 ± 0.10 cal/°K gfw, based almost entirely on the low-temperature heat capacity data of Clusius and Vaughen¹⁴⁰ (10° to 201°K). Hultgren⁷⁶ arrived at the same value from these data plus the heat capacity measurements of Griffel, Vest, and Smith¹⁴¹ (1.8° to 4.2°K), and Roberts¹⁴² (1.5° to 20°K). $H_{298}^0 - H_0^0$ was calculated by the present authors to be 1375 cal/gfw for the solid.

Other low temperature heat capacity measurements on calcium include those of Gunther¹⁴³ (22° to 62°K), and of Eastman and Rodebush¹⁴⁴ (68° to 294°K).

4) High-temperature heat content

The heat capacity and heat content of elemental calcium are not very well-known. The only available low-temperature heat capacity data, those of Clusius and Vaughen,¹⁴⁰ terminate at 201°K and have been extrapolated to a value of 6.28 cal/°K gfw at 298.15°K. Above room temperature, data were derived from the heat content measurements of Eastman, Williams, and Young¹³⁶ (373° to 878°K), and of Jauch¹³⁴ (298° to 1223°K). For the face-centered cubic phase, heat capacities derived from the first source are 0.25 to 0.35 cal/°K gfw higher than those from the second source over the entire range of stability from room temperature to 737°K. Extrapolation of an algebraic expression for the data of Eastman, Williams, and Young¹³⁶ to 298.15°K gave a heat capacity of 6.20 cal/°K gfw.

For purposes of the present compilation, the following algebraic expression for the heat capacity of α -Ca in cal/°K gfw was used over the temperature range from 298.15 to 737°K.

$$C_p^0 = 5.205 + 3.605 \times 10^{-3}T. \quad (136)$$

¹³⁹Kelley, K.K., Bureau of Mines Bull. 477 (1950).

¹⁴⁰Clusius, K. and J. V. Vaughen, J. Am. Chem. Soc. 52, 4684 (1930).

¹⁴¹Griffel, M., R.W. Vest, and J.F. Smith, J. Chem. Phys. 27, 1267 (1957).

¹⁴²Roberts, L.M., Proc. Roy. Soc. (London) 70B, 738 (1957).

¹⁴³Gunther, P., Ann. Physik 51, 828 (1916).

¹⁴⁴Eastman, E.D. and W.H. Rodebush, J. Am. Chem. Soc. 40, 489 (1918).

This expression gives a heat capacity of 6.28 cal/°K gfw at 298.15°K and an average value of the results of Eastman, Williams and Young,¹³⁶ and Jauch¹³⁴ extrapolated to 737°K. This expression is slightly different from others which have been used elsewhere.^{56, 76, 77}

An algebraic representation of the heat content measurements of Jauch in cal/°K gfw over the temperature range from 737° to 1123°K was the basis for the calculation of thermodynamic functions of body-centered cubic β -Ca.

$$C_p^\circ = 1.50 + 7.74 \times 10^{-3}T + 2.5 \times 10^{-5} T^{-2}. \quad (137)$$

These data have also been accepted elsewhere^{56, 76, 77} with slight modification. The heat capacities of β -Ca derived from the data of Eastman, Williams, and Young¹³⁶ (to 878°K) are considerably lower than the accepted values. Zalesinski and Zulinski¹³⁸ are in better agreement with Jauch¹³⁴ than with Eastman, Williams, and Young.¹³⁶

Other sources for high-temperature heat capacity or heat content data for solid calcium are Bernini¹⁴⁵ (273° to 430°K), Bunsen¹⁴⁶ (273° to 373°K), and Schulze¹²⁷ (723° to 803°K).

Jauch's¹³⁴ value for the heat capacity of liquid calcium, 7.40 cal/°K gfw, was adopted on the basis of measurements of heat content from the melting point to 950°K. This value has been used to the boiling point with increasing assigned uncertainty. Zalesinski and Zulinski¹³⁸ reported the heat capacity of liquid calcium to be 10.7 cal/°K gfw. Jauch's¹³⁴ value was preferred because it was more consistent with the heat capacity of liquid magnesium, 7.8 cal/°K gfw (See section IV-A8).

5) Heat of formation of the monatomic gas

Free-energy functions tabulated herein were used with vapor pressure data from the following sources to calculate the indicated heats of formation at 298.15°K using the Third Law Method:

¹⁴⁵Bernini, A., *Physik Z.* 7, 168 (1906).

¹⁴⁶Bunsen, R., *Poggendorf's Ann.* 141, 1 (1879).

Source	Temperature Range (°K)	ΔH_{f298}° (Kcal/gfw)
Priselkov and Nesmeyanov ¹⁴⁷	748 - 943	42.200 $\pm$ 0.200
Hartmann and Schneider ¹⁴⁸	1254 - 1546	42.140 $\pm$ 0.400
Douglas ¹⁴⁹	807 - 918	42.310 $\pm$ 0.350
Tomlin ¹⁵⁰	801 - 877	42.230 $\pm$ 0.200
Pilling ¹⁵¹	775 - 973	42.220 $\pm$ 0.650
Smith and Smythe ¹⁵²	730 - 965	43.010 $\pm$ 0.350
Ruff and Hartmann ¹⁵³	1233 - 1380	41.060 $\pm$ 3.000
Rudberg ¹⁵⁴	774 - 897	46.060 $\pm$ 0.350
Pidgeon and Atkinson ¹⁵⁵	1401 - 1477	54.520 $\pm$ 0.700

The data of Smith and Smythe¹⁵² were derived from an algebraic representation of their results. The heat of formation tabulated from the results of Pidgeon and Atkinson¹⁵⁵ has been taken from Hultgren.⁷⁶ Original data points were used from the remaining sources. The results of Rudberg¹⁵⁴ and Pidgeon and Atkinson¹⁵⁵ were excluded in arriving at an average value of 42.220 Kcal/gfw to which an uncertainty of 0.250 Kcal/gfw was assigned.

¹⁵⁵Pidgeon, L.M. and J.T.N. Atkinson, Can. Mining Met. Bull. 249, 14 (1949).

The normal boiling point of calcium was calculated to be $1765^{\circ} + 45^{\circ}\text{K}$, and ΔH_f° at the boiling point was taken to be 35.871 ± 0.870 Kcal/gfw.

6) Thermodynamic functions

The reference state thermodynamic functions of calcium are given in Table XIII. The ideal monatomic gas thermodynamic functions of calcium given in Table XIV were calculated using all the energy levels listed by Moore.⁵² Uncertainty estimates are summarized on the back of the tables. $H_{298}^{\circ} - H_0^{\circ}$ was found to be 1,481 cal/mole for the ideal gas.

TABLE XIII

CALCIUM

REFERENCE STATE

Ca

Reference State for Calculating ΔH_f° , ΔF_f° , and $\log K_p$: Solid from 298.15° to 1123° K,
Liquid from 1123° to 1765° K, Gas from 1765° to 6000° K.

gfw = 40.08

4. Carbon

a. Graphite

The thermodynamic data for graphite have required extended critical review. The most recent compilations have been those of Evans¹⁵⁶ (up to 4000°K) and of Stull and co-workers⁷⁵ (an extension of the work of Evans up to 6000°K). The only experimental heat capacity values above 3000°K appear to be those of Rasor and McClelland.^{27, 157} This work leads to values of C_p° versus T that show a very sharp rise above 3600°K and would therefore bring about marked alterations in existing thermodynamic tables for graphite if taken into account.

The rise in C_p° versus T in question is extremely rapid and its theoretical explanation appears to be uncertain. It occurs at such a high temperature that one is led to suspect insipient sublimation.

With only the available information on hand, the preparation of a reference table would be impossible at temperatures above 3600°K because $C_p^\circ(T)$ appears to have no finite limit.

For the above reasons, condensed phase calculations on graphite were postponed until further measurements could be made and the problem given more thought. Recent studies on this project are presented in section V-B with a detailed discussion of other available data.

b. Monatomic Gas (C)

Thermodynamic functions for the ideal monatomic gas in Table XV were calculated using the spectroscopic energy levels listed by Moore.⁵² Energy levels and J values not definitely established in these tables were estimated. The calculation was carried out using the monatomic gas machine program discussed earlier in this report. Uncertainty estimates are summarized on the back of the table.

c. Diatomic Gas (C₂)

The thermodynamic properties of C₂ gas have been the subject of some disagreement for several years.^{77, 158, 159} The dispute has centered about the location and number of electronic states and in particular the

¹⁵⁶National Bureau of Standards Report 6928 (1960).

¹⁵⁹Altman, R.L., J. Chem. Phys. 32, 615 (1960).

characterization of the ground state. The work of Ballik and Ramsay^{160, 161} is now accepted, thus firmly establishing the $^1\Sigma$ state as the ground state for the C_2 molecule. Altman¹⁵⁹ has recently calculated the thermodynamic functions of C_2 gas up to 5000°K based on the observed spectroscopic constants of Ballik and Ramsay.^{160, 161} More recently, Clementi¹⁶² has predicted the existence, location, and spectroscopic constants for several additional electronic states and has re-calculated the thermodynamic functions for C_2 gas from 2000° to 6000°K taking into account all experimentally observed and estimated electronic states. The thermodynamic functions of C_2 gas will be calculated using the diatomic computer program described earlier in this report with the spectroscopic data of Clementi¹⁶² and will be reported at a later date.

d. Triatomic Gas (C_3)

Available spectroscopic constants for C_3 gas are at present estimated rather than experimentally determined values. The work of Engelke¹⁶³ offers further evidence that the $^1\Sigma$ state is the ground state of C_3 as indicated by Thorn and Winslow.¹⁶⁴ The fundamental frequencies were estimated by Pitzer and Clementi¹⁵⁸ by analogy with the allene molecule. It should be noted that the frequencies estimated by Pitzer and Clementi¹⁵⁸ are somewhat higher than those estimated earlier by Glockler.¹⁶⁵ The thermodynamic properties of C_3 in Table XVI were calculated using the linear polyatomic molecule computer program described earlier in this report with the following input data:

$$C-C = 1.281 \text{ \AA}$$

$$\text{Moment of inertia} = 65.448 \times 10^{-40} \text{ g cm}^2$$

$$\text{Symmetry number} = 2$$

$$\omega_1 = 1300 \text{ cm}^{-1}$$

$$\omega_2 = 550 \text{ cm}^{-1} (2)$$

$$\omega_3 = 220 \text{ cm}^{-1}$$

$$\text{Ground electronic state} = ^1\Sigma$$

5. Chromium

a. Solid-State Transitions of Chromium

The stable form of solid chromium at 25°C is the body-centered cubic crystal.¹⁶⁶⁻¹⁶⁸ A transition, believed to be antiferromagnetic, occurs at $38.5^\circ \pm 0.3^\circ\text{C}$. A second solid-state transition, of unknown type, occurs at $1375^\circ \pm 25^\circ\text{C}$. The transition from body-centered cubic to face-centered cubic occurs at $1815^\circ \pm 30^\circ\text{C}$. The melting point of chromium is $1875^\circ \pm 30^\circ\text{C}$, and the estimated standard boiling point is $2649^\circ \pm 200^\circ\text{C}$. These transitions and their accompanying heat effects are listed in Table XVII.

1) The 38.5°C transition

Abnormalities in several properties near 40°C were observed by a number of workers,¹⁶⁹ but only recently was an anomaly in the heat capacity experimentally observed.¹⁷⁰ The shape and position of the heat-capacity anomaly were consistent with those of an antiferromagnetic transition. The transition was observed to occur at $38.5^\circ \pm 0.3^\circ\text{C}$ with ΔH_t equal to 1.4 cal/g atom and ΔS_t equal to 0.0044 e. u. /g atom.

TABLE XVII

TRANSITION DATA FOR CHROMIUM

Transition	Temperature ($^\circ\text{K}$)	ΔH_t (cal/g atom)
Solid I $\longrightarrow$ Solid II	311.65 ± 0.3	1.4
Solid II $\longrightarrow$ Solid III	1648 ± 25	800 ± 200
Solid III $\longrightarrow$ Solid IV	2088 ± 30	350 ± 100
Solid IV $\longrightarrow$ Liquid	2148 ± 30	4920 ± 1000
Liquid $\longrightarrow$ Gas	2967 ± 200	$80,220 \pm 3150$
Solid I $\longrightarrow$ Gas	298.15	$94,820 \pm 500$

2) The 1375°C transition

The existence of a transition [Cr(II) $\rightarrow$ Cr(III)] at about 1400°C was indicated by the observation of an anomaly in magnetic susceptibility.¹⁷¹ More conclusive evidence was provided by heat capacity measurements recently reported by Krauss.¹⁷² The latter measurements showed a maximum in the heat capacity versus temperature curve at about 1375°C. Approximate graphical integration of the area under the observed heat capacity curve has yielded a heat of transition (ΔH_t) value of 800 ± 200 cal/g atom. A comparison of Lucks¹⁷³ enthalpies measured by the drop method in this temperature range and enthalpies estimated (assuming the nonexistence of any transition) by Kelley⁵⁶ has led to an estimated ΔH_t of about 800 cal/g atom. It should be noted that evidence for the existence of this transition was not observed by McCaldin and Duwez¹⁷⁴ in a thermal analysis study.

3) The body-centered cubic to face-centered cubic transition

The existence of the Cr(III) $\rightarrow$ Cr(IV) transformation was established by cooling-curve analysis.¹⁷⁵ The crystal structure of the new phase was studied by Abrahamson and Grant.¹⁷⁶ The temperature of the transition was reported to be $1840^\circ \pm 15^\circ\text{C}$,¹⁷⁵ but was herein revised downward since the melting point reported in the same paper was probably high. The difference between the melting-point and transition temperatures was not altered in doing this. Heat capacities have not been measured in the vicinity of this transition, and no experimental value for ΔH_t was available. The estimate of Stull and Sinke;⁷⁷ i. e., $\Delta H_t = 350$ cal/g atom, was accepted. The uncertainty in this value was estimated to be ± 100 cal/g atom. Again, the existence of a transition at this temperature was not observed by McCaldin and Duwez.¹⁷⁴

4) The melting point of chromium

Values of the melting point of chromium reported in the literature ranged from 1515° to 1903°C .¹⁶⁹ Even recent measurements using very pure chromium showed a considerable spread. The "best" values were the following:

¹⁷¹McGuire, T.R. and C.J. Krieseman, Phys. Rev. 85, 452 (1952).

¹⁷²Krauss, F., Z. Metallk 49, 386 (1958).

¹⁷³Lucks, C.F. and H.W. Deem, WADC Tech. Rept 55-496 (November 1955).

¹⁷⁴McCaldin, J.O. and F. Duwez, J. Metals 6; AIME Trans. 200, 619 (1954).

¹⁷⁵Bloom, D.S., J.W. Putman, and N.J. Grant, J. Metals 4, 626 (1952).

¹⁷⁶Abrahamson, E.P. and N.J. Grant, J. Metals 8; AIME Trans. 206, 975 (1956).

$1890 \pm 10^\circ\text{C}$, ¹⁷⁷

$1860 \pm 10^\circ\text{C}$, ¹⁷⁸

$1845 \pm 10^\circ\text{C}$, ¹⁷⁹

$1903 \pm 10^\circ\text{C}$, ¹⁷⁵

$1875 \pm 5^\circ\text{C}$. ¹⁸⁰

An average of these values was chosen as the most probable melting point, i. e., $1875^\circ \pm 30^\circ\text{C}$. The uncertainty was picked to include all the above values.

The heat of fusion at the melting point has also not been unambiguously established. Measured and estimated values reported include the following:

3650 cal/g atom, ¹⁸¹

4200 cal/g atom, ²⁶

3300 cal/g atom, ⁷⁷

4600 cal/g atom, ¹⁸²

5000 cal/g atom. ^{56, 76}

In the absence of conclusive experimental data, an estimated heat of fusion of 4920 cal/g atom was calculated from an assumed entropy of fusion of 2.3 e. u. /g atom.

In view of the wide range of reported values, an uncertainty of ± 1000 cal/g atom was assigned to the heat of fusion at the melting point.

5) The standard heat of sublimation at 298.15°K (ΔH_{s298}°)

Vapor pressure measurements for solid chromium have been reported by several workers during the past decade.¹⁸³⁻¹⁸⁹ The first four papers contained experimental vapor pressure values, whereas only vapor pressure equations were available from the other papers. ΔH_{s298}° values, calculated using reported vapor pressure values and free-energy functions from the present compilation, were as follows:

94,710 cal/g atom,¹⁸³

95,250 cal/g atom,¹⁸⁴

94,870 cal/g atom,¹⁸⁵

94,750 cal/g atom,¹⁸⁷

94,530 cal/g atom.¹⁸⁸

An average value of $\Delta H_{s298}^\circ = 94,820 \pm 500$ cal/g atom was chosen. The vapor pressure measurements of Nesmeyanov and Man,¹⁸⁶ and of Burlakov,¹⁸⁹ lead to appreciably lower ΔH_{s298}° values, and were not included.

6) The boiling point of chromium

A value of 2200°C was reported by Greenwood¹⁹⁰ for the boiling point of Cr, but it was considered to be low by later workers.^{77, 191} Baur and Brunner⁹² have calculated a value of 2660°C from vapor pressure measurements. Later workers^{76, 77} have estimated the boiling point from calculated values of ΔH_{vo}° or ΔH_{v298}° and free-energy functions for the gas and the condensed phase (i. e., the standard boiling temperature was taken as the temperature at which ΔF becomes zero for the change from condensed phase to gaseous phase).

¹⁹⁰Greenwood, H.C., Proc. Roy. Soc. A82, 396 (1905).

¹⁹¹Kelley, K.K., U.S. Bur. Mines Bull. 383 (1935).

Stull and Sinke⁷⁷ thus calculated a value of 2642°C, and Hultgren⁷⁶ calculated a value of 2665°C. For the present compilation, a boiling point of 2694° ± 200°C was adopted. The ΔH of vaporization could then be estimated from the value of ΔH₂₉₈^o and the enthalpy functions for the two phases at the standard boiling point. A value of ΔH of vaporization at the standard boiling point of 80, 220 ± 3150 cal/g atom was thus calculated in the present work.

b. Thermodynamic Functions for the Condensed Phases of Chromium

Recent compilations of the thermodynamic functions of solid and liquid chromium included those of Stull and Sinke,⁷⁷ Hultgren,⁷⁶ and Kelley.⁵⁶ Stull and Sinke used a rather low value for the ΔH of fusion and did not include the solid-solid transformations at 38.5° and 1375°C. The other two compilations did not include the solid-solid transformations at 38.5°, 1375°, and 1815°C. The values of enthalpy and entropy at 298.15°K listed by Hultgren were accepted in the present work.

$$H_{298}^o - H_0^o = 970 \text{ cal/g atom,}$$

$$S_{298}^o = 5.68 \text{ e.u./g atom.}$$

The enthalpy functions for solid chromium (i.e., $H_T^o - H_{298}^o$) in Table XVIII were those of Kelley,⁵⁶ corrected to include the various transitions given in Table XVII. The tabular entropy values for solid chromium were calculated by the method of Kelley.⁵⁶ Uncertainty estimates are summarized on the back of Table XVIII.

Values for the $-\left(\frac{F_T^o - H_{298}^o}{T}\right)$ function of solid chromium were calculated

from equation (108).

Heat capacity values for solid chromium were not well established (see section IV-A5d below), and very limited data were available near the various transitions.^{170, 172} Tabular values of C_p^o for solid chromium were therefore calculated from Kelley's equation.⁵⁶ These calculated values represented experimental values fairly accurately except in transition regions where experimental data were nonexistent or insufficient for complete evaluation.

The value of the heat capacity of liquid chromium was taken to be constant at 9.40 cal/°K g atom^{56, 76} even though the only experimental determination of C_p^o on liquid chromium yielded a value of 9.7 cal/°K g atom,¹⁸¹ because the chromium used in this single experimental determination must be considered to have been impure since the observed melting

point was about 350°C lower than the "true" value. Entropy values for liquid chromium were calculated, using the value of 9.40 cal/°K g atom for C_p° , according to the equation

$$S_T^\circ = C_p^\circ \ln T + C_1 \quad (138)$$

$H_T^\circ - H_{298}^\circ$ values for liquid chromium were calculated from the equation

$$H_T^\circ - H_{298}^\circ = C_p^\circ T + C_2 \quad (139)$$

The values of the constants, C_1 and C_2 , in the above equations were evaluated from the tabular values of S_T° and $H_T^\circ - H_{298}^\circ$ for liquid chromium at the melting point. The free-energy function for liquid chromium was evaluated in the same manner as that used for solid chromium.

c. Thermodynamic Functions for Gaseous Chromium

Thermodynamic properties for the ideal monatomic gas given in Table XIX were calculated using the spectroscopic energy levels listed by Moore.⁵² Energy levels and values not definitely established in these tables were estimated. The equations employed in these calculations have been summarized in two recent publications^{51, 75} (see Sect. III-D). Uncertainty estimates are summarized on the back of Table XIX. $H_{298}^\circ - H_0^\circ$ was found to be 1,481 cal/mole.

ΔH_f° , ΔF_f° , and $\log_{10} K_p$ for gaseous chromium were calculated by means of the equations in section III-D1g.

d. Uncertainties in Condensed Phase Functions

The available basic data for chromium included both heat capacity^{170, 172, 192, 193} and enthalpy^{173, 181, 194, 195} values. The error analysis used was based on the uncertainty of the C_p° data, as explained in section III-G1d.

1) Heat capacity

Sully¹⁶⁹ has critically reviewed reported C_p° values near room temperature and concluded that their accuracy was about ± 3 percent. A graphical comparison in this work also led to about the same uncertainty. The uncertainty in C_p° at 298.15°K was thus

taken to be $\pm 0.2 \text{ cal/}^\circ\text{K g atom}$. The uncertainty was taken to be the same at the first transition point of 311.65°K . An uncertainty of $\pm 0.7 \text{ cal/}^\circ\text{K g atom}$ was estimated from a comparison of reported values near 1000°K .^{172, 173, 181, 193, 195} The uncertainty at the 1648°K transition point was difficult to assign since direct C_p° values have been reported in only one paper,¹⁷² and other workers^{173, 181, 194} have measured enthalpies which included or partially included the heat of transition. The uncertainty was therefore increased to $\pm 1.2 \text{ cal/}^\circ\text{K g atom}$ at 1648°K .

The only measurements above 1800°K were those of Umino¹⁸¹ made on impure chromium. In the absence of experimental C_p° values, the uncertainties at 2000° , 2088° , and 2148°K were assumed to be the same as the uncertainty at 1648°K ; i. e., $\pm 1.2 \text{ cal/}^\circ\text{K g atom}$. As stated earlier, the C_p° of liquid chromium was measured by only one worker¹⁸¹ using impure chromium; an uncertainty of $\pm 1.0 \text{ cal/}^\circ\text{K g atom}$ was therefore arbitrarily assigned over the whole liquid range.

2) Entropy

Uncertainties in entropy values were calculated from assigned uncertainties in C_p° values and heats of transition as explained in Section IV-Gld. The uncertainty in S_{298}° was taken to be $\pm 0.07 \text{ e.u./g atom}$ after Kelley.¹³⁹

3) Enthalpy

Uncertainties in enthalpy values were calculated from C_p° uncertainties and assigned values of ΔH -of-transition uncertainties as explained in section III -Gld. The equations used for single-phase regions and transitions were as follows:

$$h_{T_2} = h_{T_1} + \delta C_p^\circ (T_2 - T_1) , \quad (140)$$

$$h_B = h_A + \delta \Delta H_t . \quad (141)$$

4) Free energy

The uncertainty in the free-energy function was calculated from calculated uncertainties in S_T° and $H_T^\circ - H_{298}^\circ$ using equations (119) and (120).

e. Uncertainties in Gas-Phase Functions

Uncertainty estimates for the calculated thermodynamic functions of the ideal monatomic gas were made with the machine program described in section III and are summarized on the back of Table XIX.

f. Other References Pertaining to the Thermodynamics of Chromium

Sully¹⁶⁹ has reviewed other heat capacity measurements not previously mentioned in the present discussion. His review included the work of Dewar,¹⁹⁶ Richards and Jackson,¹⁹⁷ Nordmeyer and Bernoulli,¹⁹⁸ Lammel,¹⁹⁹ Schimpff,²⁰⁰ Schubel,²⁰¹ and Mache.²⁰²

Heat capacity measurements at very low temperatures (below 20°K) have been reported and discussed by Rayne and Kemp,²⁰³ Wolcott,²⁰⁴ Friedberg, Estermann, and Goldman,²⁰⁵ and Estermann, Friedberg, and Goldman.²⁰⁶

Transitions in solid chromium have been reviewed by Sully,¹⁶⁹ and discussed more recently by Pursey²⁰⁷ and by Beaumont and co-workers.¹⁷⁰ The possible existence of a hexagonal modification of chromium has been discussed by Sully,¹⁶⁹ and in more recent papers; e. g., Brummer and Suwalski.²⁰⁸

A useful annotated bibliography of thermal properties of chromium was that of Goodwin.²⁰⁹ A recent review of the properties of high-purity chromium was that of Edwards, Nish, and Wain.²¹⁰

b. Hafnium

a. Selection of Condensed Phase Data

1) Crystal structure and solid-state transition

Hafnium exists in two known crystalline modifications.²¹¹ The ordinary room-temperature form has a hexagonal, close-packed structure, while the high temperature form has a body-centered cubic structure.

The transition temperature for equilibrium between the two crystalline modifications was taken to be $2033^{\circ} \pm 35^{\circ} \text{K}$, as found by Deardorff and Kato,²¹² and accepted by Thomas and Hayes.²¹¹ Other reported values mentioned by Hansen²¹³ are as follows:

<u>Temp. ($^{\circ} \text{K}$)</u>	<u>Source</u>
1603-1903	Zwicker ²¹⁴
1583	Duwez ²¹⁵
2223 ± 100	Fast ²¹⁶
1973	Hansen and Anderko ²¹³

It is noteworthy that the value chosen by Hansen and Anderko²¹³ does not differ markedly from the one chosen here which is based on newer data.

2) Melting point

A temperature of $2495^{\circ} \pm 30^{\circ} \text{K}$ was accepted as the melting point for hafnium metal. This value is based on the work of Deardorff and Hayes,²¹⁷ and has been accepted by Thomas and Hayes.²¹¹ Earlier data have been reviewed by Stull and Sinke⁷⁷ who chose a value of 2250°K . The more recent value recommended herein appears to be preferable.

²¹⁷ Deardorff, D.K. and E.T. Hayes, *Melting point determinations of hafnium metal*, *Trans. AIME* **206**, 509 (1956).

3) Heat of transition

No experimental data were available for the heat of transition of Hf. Stull and Sinke⁷⁷ combined the heats of transition and melting into a single quantity. For the present case, it was calculated from an entropy of transition estimated from those of titanium and zirconium (i. e., 0.822 and 0.806 e. u., respectively). The intermediate value of 0.811 e. u. was chosen for Hf, resulting in a heat of transition of 1650 ± 200 cal/mole at 2033° K.

4) Heat of fusion

The heat of fusion of Hf also had to be estimated. For titanium, the entropy of fusion was taken to be 2.10 e. u. This same value was used for Hf along with a melting point of 2495° K to give a ΔH_{fusion} value of 5239 ± 1000 cal/mole. This value of the heat of fusion agrees well (probably fortuitously) with that of Stull and Sinke,⁷⁷ who included the heat change associated with the transition to obtain a contribution of $\Delta H_{\text{fusion}} = 5200$ cal/g atom.

5) Low-temperature heat capacity and S_{298}°

Heat capacity data for the temperature range from 10° to 200° K have been reported by Burk *et al.*²¹⁸ For the range from 25° to 100° C, Adenstedt²¹⁹ has reported an average value of $C_p^{\circ} = 6.27$ cal/° K g atom. From the rate of change of C_p° with temperature given by Stull and Sinke,⁷⁷ values of C_p° , 298° K = 6.225 cal/° K g atom, C_p° , 375° K = 6.315 cal/° K g atom, and C_p° , 400° K = 6.345

cal/° K g atom were calculated with Adenstedt's²¹⁹ data. These values have been used with the data of Burk *et al.*²¹⁸ to determine that $H_{298}^{\circ} - H_0^{\circ} = 1.428$ Kcal/g atom and $S_{298}^{\circ} = 10.666$ e. u. This value of $H_{298}^{\circ} - H_0^{\circ}$, obtained by graphical integration, agreed well with a trapezoidal rule integration value of 1.429 Kcal/g atom. The entropy value was obtained by graphical integration of C_p°/T versus T data. The values of $H_{298}^{\circ} - H_0^{\circ}$ and S_{298}° found by Stull and Sinke⁷⁷ were 1.448 Kcal/g atom and 10.91 e. u. respectively.

6) High-temperature heat capacity

Experimental heat capacity data for elemental hafnium at elevated temperatures were not available. Accordingly, values were

²¹⁸Burk, D.L., I. Estermann, and S. Friedberg, Z. physik, chem. Neue Folge 16, 183 (1958).

²¹⁹Adenstedt, H.K., Trans ASM 44, 949 (1952).

estimated with the help of data on titanium and zirconium. C_p° data given by Kelley⁵⁶ for zirconium and titanium were plotted⁷⁷ against temperatures with the hafnium data from Stull and Sinke. The final choice was a set of data intermediate between the Ti, Zr, and Hf data. This corresponded to a line parallel to and about 0.18 cal/° K g atom above the Stull and Sinke data, but joining smoothly with the low temperature data discussed in Section IV-A6 above.

7) Heat of vaporization

Direct experimental values for the heat of vaporization were not known. However, Lewis and Randall²²⁰ have tabulated a value of 168 ± 10 Kcal/g atom. This value is the one used by Stull and Sinke⁷⁷ and was accepted here.

8) The liquid heat capacity

For temperatures above the accepted melting point, the liquid heat capacity was estimated to be 8.0 cal/° K g atom. This is the value used by Stull and Sinke.⁷⁷

9) Calculation of the reference-state table

The data used in the reference-state calculations for Table XXI are given in Table XX which provides a convenient summary of the "best" property values. Uncertainty estimates are summarized on the back of Table XXI.

b. Selection of Data for the Ideal Monatomic Gas

The energy levels given by Moore,²²¹ based on the work of Meggers,²²² were used to calculate the values of the ideal monatomic gas thermodynamic functions in Table XXII.

The values in Table XXII should be regarded as tentative, even though they supersede those of Stull and Sinke,⁷⁷ because Meggers²²³ has found 29 new even and 32 odd levels since his earlier work.^{221, 222} The table will be brought up to date as soon as Megger's new energy levels become available. The value of $H_{298}^\circ - H_0^\circ$ was found to be 1,481 cal/mole. Error estimates are summarized on the back of the table.

7. Iridium

The ideal gas thermodynamic functions in Table XXIII were calculated with the energy levels given by Moore²²¹ and the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table.

8. Magnesium

a. Crystal Structure and Melting Point

Elemental magnesium has a hexagonal, close-packed structure from room temperature to its melting point.⁵⁷ The latter temperature was taken to be $923^\circ \pm 3^\circ\text{K}$, in agreement with other recent compilations.^{76, 156, 77, 56, 78}

b. Thermodynamic Properties

1) Heat of fusion

Kelley¹³⁷ reviewed the early data on the heat of fusion of magnesium which was derived from phase studies of binary alloys. He gave a mean value of 2.16 Kcal/gfw. Stull and McDonald²²⁴ made heat content measurements on solid and liquid magnesium, and reported the heat of fusion to be 2.14 ± 0.05 Kcal/gfw. The Bureau of Standards⁷⁸ reviewed available solid and liquid heat content measurements for the period up to 1959 and arrived at a value of 2.127 Kcal/gfw. The value of 2.127 ± 0.03 Kcal/gfw was adopted for the heat of fusion of magnesium in the present work.

Other determinations of the heat of fusion of magnesium included the following:

Source	Heat of Fusion (Kcal/gfw)
Wittig (reported by Kubaschewski ⁷⁹)	1.83 ± 0.09
Reinartz (reported by Kubaschewski ⁷⁹)	2.03 ± 0.08
Treadwell ²²⁵	1.37
Treadwell ²²⁶	1.04
Zalesinski and Zulinski ¹³⁸	1.12
Awbery and Griffiths ²²⁷	1.13
Roos ²²⁸	1.70

²²⁴Stull, D.R. and R. McDonald, J. Am. Chem. Soc. 77, 5293 (1955).

²²⁵Treadwell, W.D., Schw. Anz. angew. Wiss. Technik 6, 69 (1940).

²²⁶Treadwell, W.D., A. Amann, and T. Zurrer, Helv. Chim. Acta 19, 1255 (1936).

²²⁷Awbery, J.H. and E. Griffiths, Proc. Phys. Soc. (London) 38, 378 (1926).

²²⁸Roos, G.D., Z. anorg. Chem. 94, 329 (1916).

Kubaschewski⁷⁹ arrived at a value for the heat of fusion of 2.00 ± 0.12 Kcal/gfw from these other results plus the analysis of Kelley.⁵⁶

2) Entropy and heat content at 298.15 °K

The reported entropy and heat content of magnesium at 298.15 °K have been based on the measurements of Craig *et al*²²⁹ (12 ° to 320 °K); Smith²³⁰ (1 ° to 20 °K); Logan, Clement, and Jeffers²³¹ (3 ° to 13 °K); and Estermann, Friedberg, and Goldman²⁰⁶ (1.8 ° to 4.2 °K). On the basis of these data, the Bureau of Standards⁷⁸ selected S_{298}° to be 7.800 ± 0.05 e.u., while Dergazarian *et al*⁷⁵ (JANAF Interim Thermochemical Panel Tables) selected the value 7.824 e.u. The difference is due to variations in adopted numerical techniques for smoothing and joining the low-temperature data to high-temperature data. Craig *et al*²²⁹ calculated S_{298}° to be 7.81 e.u. by graphical integration (using an unexplained correction factor of 1.0041).⁷⁶ A value of 7.800 ± 0.03 was adopted for the present work and was used to calculate $H_{298}^{\circ} - H_0^{\circ}$ equal to 1195 cal/gfw.

Other low-temperature data for the heat capacity of magnesium have been given by Mannchen and Bornkessel²³² (12 ° to 300 °K), Clusius and Vaughen¹⁴⁰ (11 ° to 228 °K), Eastman and Rodebush¹⁴⁴ (75 ° to 289 °K), and Nernst and Schwers²³³ (27 ° to 94 °K).

3) High-temperature heat content

Heat contents for magnesium from 298.15 °K to the melting point have been based on the measurements of Saba, Sterrett, Craig, and Wallace²³⁴ (298 ° to 543 °K), and Stull and McDonald²²⁴ (700 ° to 1100 °K). These data have been smoothed and joined by the Bureau of Standards.⁷⁸ The Bureau's compilation for magnesium up to the melting point was accepted with a re-calculation to fit the format used herein. In the NBS compilation, the low-temperature data (in cal/gfw) were joined smoothly at 475 °K with the high-temperature heat content equation

$$H_T^{\circ} - H_{298}^{\circ} = 4.689T + 1.718 \times 10^{-3}T^2 - 2.0776 \times 10^4T^{-1} - 1481. \quad (142)$$

²²⁹Craig, K.S., C.A. Krier, L.W. Coffey, E.A. Bates, and W.E. Wallace, J. Am. Chem. Soc. 76, 238 (1954).

²³⁰Smith, P.L., Phil. Mag. 46, 744 (1955).

²³¹Logan, J.K., J.R. Clement, and H.R. Jeffers, Phys. Rev. 105, 1435 (1957).

²³²Mannchen, W. and K. Bornkessel, Z. Naturforsch. 14a, 925 (1959).

²³³Nernst, W. and F. Schwers, Sitzb. Konig preuss. Akad. Wiss. 1, 355 (1914).

²³⁴Saba, W.G., K.F. Sterrett, R.S. Craig, and W.E. Wallace, J. Am. Chem. Soc. 79, 3637 (1957).

The accuracy of the tabulated heat contents was taken to be ± 1 percent. Other recent compilations using different smoothing procedures have used the same original data sources to derive slightly different thermodynamic functions.

Stull and McDonald²²⁴ measured the heat content of liquid magnesium up to 1100 °K and represented their data for the liquid phase (in cal/° K g) by the equation.

$$H_T^\circ - H_{298}^\circ = 0.2176T + 5.35 \times 10^{-5}T^2 + 484.63 T^{-1} + 16.851. \quad (143)$$

However, within the error of the measurements (± 2 percent) their data could be equally well-represented by a constant heat capacity of 7.8 cal/° K gfw, so that the heat content in cal/° K gfw from 923 ° to 1377 °K could be represented by

$$H_T^\circ - H_{298}^\circ = 7.8 T - 781. \quad (144)$$

Above 1100 °K, the uncertainty in the heat content was assumed to increase at the rate of 0.015 Kcal/gfw per 100 °C of temperature increase.

High-temperature heat content or heat capacity measurements have also been made on magnesium by Poppema and Jaeger²³⁵ (373 ° to 823 °K), Honda and Tokunaga²³⁶ (298 °K), Seekamp²³⁷ (271 ° to 773 °K), Awbery and Griffiths²²⁷ (525 ° to 1023 °K), Eastman, Williams, and Young¹³⁶ (373 ° to 888 °K), Schubel²³⁸ (373 ° to 773 °K), Magnus²³⁹ (373 ° to 812 °K), Kubaschewski²⁴⁰ (923 ° to 1123 °K), Lorenz²⁴¹ (293 ° to 403 °K), Losano²⁴² (293 ° to 573 °K), Stücker²⁴³ (293 ° to 923 °K), and Zalesinski and Zulinski¹³⁸ (295 ° to 1048 °K).

4) Heat of formation of the monatomic gas

The tabulated free-energy functions were used with vapor pressure data from the following sources to calculate the indicated heats of formation at 298.15 °K by use of the Third Law Method:

Source of Vapor Pressure Data	Temperature Range (°K)	Calculated ΔH_{f298}° (Kcal/gfw)
Smith and Smythe ¹⁵²	626-818	35.130 ± 0.020
Vetter and Kubaschewski ²⁴⁴	973-1073	35.180 ± 0.110
Schneider and Stoll ²⁴⁵	917-1002	35.260 ± 0.100
Schneider and Esch ²⁴⁶	1376 (b.p.)	35.320
Coleman and Egerton ²⁴⁷	700-738	35.300 ± 0.040
Baur and Brunner ⁹²	926-1283	35.355 ± 0.400
Leitgebel ²⁴⁸	1370 (b.p.)	35.190
Hartmann and Schneider ¹⁴⁸	1009-1293	35.660 ± 0.250
Ruff and Hartmann ¹⁵³	911-1344	34.910 ± 1.500
Greenwood ²⁴⁹	1393 (b.p.)	35.480
Ditte ²⁵⁰	1383 (b.p.)	35.700
Scheil and Wolf ²⁵¹	1016-1102	35.510 ± 0.040
Wejnarth ²⁵²	unavailable	---

With the exception of the results of Smith and Smythe¹⁵² and of Scheil and Wolf,²⁵¹ all of these calculations were based on the original data points. For the former only was an equation available; and for the latter, the data were taken from graphs.

²⁵⁰Ditte, B., Compt. Rend 73, 111 (1871).

²⁵¹Scheil, E. and F. Wolf, Z. Metallkunde 50, 229 (1959).

²⁵²Wejnarth, A., Tek. Tid. 72, 33 (1942).

The value of ΔH_{f298}° adopted was an average of the above values, excluding the results of Ruff and Hartmann¹⁵³ and of Ditte.²⁵⁰ This average value is $35,340 \pm 0.250$ Kcal/gfw. The error given was based on the spread in reported vapor pressures, and did not include uncertainties in condensed phase free-energy functions. The normal boiling point of magnesium was calculated to be $1377^\circ \pm 6^\circ\text{K}$. The uncertainty in the boiling-point value was estimated from an uncertainty of 0.21 e.u. in ΔS_v° and an uncertainty of 0.40 Kcal/gfw in ΔH_v° at the normal boiling point where ΔH_v equals 30.740 Kcal/gfw.

5) Thermodynamic functions

The reference state thermodynamic functions of magnesium are given in Table XXIV. The ideal monatomic gas thermodynamic functions of magnesium given in Table XXV were calculated using all the energy levels listed by Moore.⁵² Uncertainty estimates are summarized on the back of the tables. $H_{298}^\circ - H_0^\circ$ was found to be 1,481 cal/mole for the ideal gas.

9. Manganese

The ideal gas thermodynamic functions in Table XXVI were calculated with the energy levels given by Moore²⁵³ and the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table.

²⁵³Moore, C.E., Nat. Bur. Stds. Circ. 467, vol 2 (15 August 1952).

10. Molybdenum

The stable form of solid molybdenum at 25°C is the body-centered cubic crystal.²⁵⁴⁻²⁵⁶ There appears to be no conclusive evidence for solid-state transitions although the existence of a face-centered cubic modification has been reported.²⁵⁷ The body-centered cubic form has been taken as the stable form from room temperature to the melting point in the present work. The melting point of molybdenum is 2617° ±10°C, and the estimated standard boiling point is 4692° ±300°C.

a. The Melting Point of Molybdenum

The absolute value of the melting point of molybdenum has been somewhat in doubt, but the "best" value has been taken to be 2617° ±10°C by several workers.^{76, 77, 56} The most exhaustive study of the melting point appeared to be that of Worthing^{258, 259} who reported a value of 2622° ±10°C. Worthing²⁵⁹ discussed the results of earlier workers whose values ranged from 2562° to 2597°C. Melting-point values were also discussed in two recent general works dealing with molybdenum.^{254, 256}

The heat of fusion has not been directly established. Estimated values found in the literature included the following:

6660 cal/g atom	(Ref. 191)
6650 cal/g atom	(Ref. 56)
6600 cal/g atom	(Ref. 77)
3000 cal/g atom	(Ref. 256)
4800 cal/g atom	(Ref. 254)
6650 cal/g atom	(Ref. 76)
6700 cal/g atom	(Ref. 260)
8380 cal/g atom	(Ref. 261)

²⁵⁶Agte, C. and J. Vacek, Wolfram and Molybden, Akademik Verlag, Berlin (1959).

²⁵⁷Aggarwal, P.S. and A. Goswami, Proc. Phys. Soc. (London) 70B, 708 (1957).

²⁵⁸Worthing, A.G., J. Franklin Inst. 199, 549 (1925).

²⁵⁹Worthing, A.G., Phys. Rev. 25, 846 (1925).

²⁶⁰Molybdenum Metal, Climax Molybdenum Co., New York (1960).

²⁶¹Jones, H.A., I. Langmuir, and G.M. J. MacKay, Phys. Rev. 30, 201 (1927).

In the absence of conclusive experimental data, an estimated ΔH of fusion of 6650 cal/g atom was chosen for the present compilation. This value was based on an assumed entropy of fusion of 2.3 e. u. An uncertainty of ± 1000 cal/g atom was arbitrarily assigned to the ΔH of fusion at the melting point.

b. The Standard Heat of Formation at 298.15 °K (ΔH_{f298}°)

Vapor pressure measurements for solid molybdenum have been reported by Jones, Langmuir, and MacKay,²⁶¹ by Norris and Worthing,²⁶² and by Edwards, Johnston, and Blackburn.²⁶³ A ΔH_{f298}° value of $158,200 \pm 800$ cal/g atom was calculated using the vapor pressure values of Edwards and co-workers,²⁶³ and the free-energy functions from the present compilation. Norris and Worthing²⁶² did not report actual experimental vapor pressure values, and the data of Jones and co-workers²⁶¹ led to a rather marked temperature dependence of ΔH_{f298}° . The latter two studies were therefore given no weight in evaluating ΔH_{f298}° .

c. The Boiling Point of Molybdenum

The boiling point of molybdenum had not been clearly established. Estimated and/or quoted values ranged from 3650° to 5697°C; e.g.:

3560 °C	(Ref. 264)
3700 °C	(Ref. 256)
4651 °C	(Ref. 76)
4804 °C	(Ref. 191)
4827 °C	(Ref. 77)
5560 °C	(Ref. 260)
5687 °C	(Ref. 261)

From a calculated ΔH_{f298}° value of $158,200 \pm 800$ cal/g atom and free-energy functions for the gas and condensed phases from the present compilation, a standard boiling point of $4692^\circ \pm 300^\circ \text{C}$ was calculated in the present work.

²⁶²Norris, L. and A.G. Worthing, Phys. Rev. 44, 323 (1933).

²⁶³Edwards, J.W., H.L. Johnston, and P.F. Blackburn, J. Am. Chem. Soc., 74, 1539 (1952).

²⁶⁴Sidgwick, N.V., Chemical Elements and Their Compounds, vol. 2, Oxford University Press, London (1950).

The heat of vaporization at the standard boiling point was then estimated from the above value of ΔH_{f298}° and the enthalpy functions for the gaseous and condensed phases at the standard boiling temperature. The value thus calculated was $141,300 \pm 10,000$ cal/g atom.

In Table XXVII are summarized the heats of transformation for the various phase changes of molybdenum.

TABLE XXVII
TRANSFORMATION DATA FOR MOLYBDENUM

Transition	Temperature (°K)	ΔH (cal/g atom)
solid $\rightarrow$ liquid	2890 ± 10	6650 ± 1000
liquid $\rightarrow$ gas	4965 ± 300	$141,300 \pm 10,000$
solid $\rightarrow$ gas	298.15	$158,200 \pm 800$

d. Calculation of Thermodynamic Functions for Condensed Phases of Molybdenum

Recent compilations of the thermodynamic functions of solid and liquid molybdenum included those of Stull and Sinke,⁷⁷ Hultgren,⁷⁶ and Kelley.⁵⁶ Those three compilations were in essential agreement but did not take into account the recent heat capacity measurements of Rasor and McClelland^{27, 157} in the temperature range from about 1500 °K to the melting point. The values of enthalpy and entropy at 298.15 °K were as follows:

$$H_{298}^\circ - H_0^\circ = 1092 \text{ cal/g atom} \quad (\text{Refs. 76, 77})$$

$$S_{298}^\circ = 6.83 \text{ e.u.} \quad (\text{Refs. 76, 77, 265}).$$

For purposes of discussion, the thermodynamic properties of solid molybdenum will be considered first over the temperature range from 298.15 ° to about 1500 °K, and then from about 1500 °K to the melting point.

²⁶⁵ Clusius, K. and P. Franzosini, Z. Naturforsch. A14, 99 (1959).

The enthalpy functions for solid molybdenum (i.e., $H_T^\circ - H_{298}^\circ$), for the temperature range from 298.15° to 1500°K in the present table, were those of Stull and Sinke,⁷⁷ they are almost identical to those of Hultgren⁷⁶ and Kelley.⁵⁶ The tabular entropy values, S_T° , were calculated by the method of Kelley.⁵⁶ Values for $-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right)$ were then calculated from equation (108).

The tabular values of C_p° over this temperature range were those of Stull and Sinke⁷⁷ and Hultgren.⁷⁶

For the temperature range from 1500°K to the melting point, other compilers^{56, 76, 77} chose a linear function of C_p° based on enthalpy measurements of Kothen²⁶⁶ and Redfield and Hill²⁶⁷ over portions of this temperature range. However, Rasor and McClelland^{27, 157} have measured C_p° values over the whole temperature range and reported an appreciable deviation from linearity. The heat capacity values of Rasor and McClelland gave a poor "fit" with a $C_p^\circ(T)$ function of the form

$$A + BT + CT^{-2},$$

but gave a very good "fit" with a function of the form

$$A + BT + CT^2.$$

The equation employed herein was

$$C_p^\circ = 6.026 - 0.217 \times 10^{-3} T + 0.0880 \times 10^{-5} T^2. \quad (145)$$

This equation gave C_p° values which join those of the low range (298.15° to 1500°K) smoothly at 1500°K.

Tabular values of C_p° were calculated with equation (145). The equation was then used to calculate tabular values of entropy and enthalpy over the temperature range from 1600°K to the melting point. The entropy and enthalpy equations were

$$S_T^\circ = 6.026 \ln T - 0.217 \times 10^{-3} T + 0.440 \times 10^{-5} T^2 - 27.5066, \quad (146)$$

²⁶⁶Kothen, C., The High Temperature Heat Contents of Molybdenum and Titanium and the Low Temperature Heat Capacities of Titanium, Ph.D. Thesis, Ohio State Univ. (1952); Dissertation Abstracts 17, 2842 (1957); Univ. Mich., Microfilm, Ann Arbor, Pub. No. 23697.

²⁶⁷Redfield, T.A. and J.H. Hill, U.S. Atomic Energy Commission, Rept. ORNL-1087, Oak Ridge National Lab. (24 September 1951).

and

$$H_T^\circ - H_{298}^\circ = 6.026 T - 10.85 \times 10^{-5} T^2 + 29.333 \times 10^{-8} T^3 - 1785. \quad (147)$$

The values of the last constants in the above equations were evaluated from the tabular values of S_T° and $H_T^\circ - H_{298}^\circ$ at 1500°K. The free-energy function for solid molybdenum in this temperature range was then calculated using equation (108).

The heat capacity of liquid molybdenum was taken to be a constant value of 10.00 cal/°K g atom. This value was an estimate⁷⁶ since an experimental determination did not appear to have ever been made. Entropy and enthalpy values for liquid molybdenum were calculated using this value of C_p° according to equations (138) and (139).

The values of the constants C_1 and C_2 in equations (138) and (139) were evaluated from the tabular values of S_T° and $H_T^\circ - H_{298}^\circ$ for liquid molybdenum at the melting point. The free-energy function for liquid molybdenum was evaluated in the same manner as that used for the corresponding function of solid molybdenum.

e. Calculation of Thermodynamic Functions for Gaseous Molybdenum

Thermodynamic properties for the ideal monatomic gas were calculated using the spectroscopic energy levels listed by Moore.⁵² Energy levels and J values not definitely established in these tables were estimated. The equations employed in these calculations have been discussed in two recent publications^{75, 51} and are summarized in section III-D.

The ΔH_f° , ΔF_f° , and $\log_{10} K_p$ functions of gaseous molybdenum were calculated by the methods in section III-D.

f. Uncertainty in Condensed Phase Functions

The basic data for molybdenum included both heat capacity and enthalpy measurements.^{173, 194, 243, 27} Heat capacities could be calculated from measured enthalpies; therefore, for the present compilation, uncertainties were assigned to C_p° values and these uncertainties then used in calculating uncertainties in the other thermodynamic functions. These uncertainty estimates are summarized on the back of Table XXVIII.

1) Heat capacity

Heat capacity values reported near room temperature ranged from 5.6¹³⁹ to 6.3¹⁷³ with most values near 5.7^{268, 270, 274, 275, 276}. The uncertainty in C_p° at 298.15°K was therefore taken to be ± 0.3 cal/°K g atom. Comparison of reported values in a graphical fashion at 1000°K²⁷⁷ indicated an uncertainty of ± 0.5 cal/°K g atom. A similar comparison at 2000°K led to an uncertainty of ± 0.8 cal/°K g atom. From 2000°K to the melting point, the data of Rasor and McClelland^{27, 157} showed a rather rapid rise with temperature while the data of Kothien²⁶⁶ showed an almost linear rise with temperature. The uncertainty may therefore be as large as 2.0 cal/°K g atom at the melting point of 2890°K.

The heat capacity of liquid molybdenum had apparently never been experimentally measured; therefore, a rather large overall uncertainty was arbitrarily assigned to it. Particular uncertainties assigned were as follows:

± 2.0 cal/°K g atom at m.p. (2890°K)

± 2.0 cal/°K g atom at 3000°K

± 3.0 cal/°K g atom at 4000°K

± 4.0 cal/°K g atom at b.p. (4965°K).

2) Entropy

Uncertainties in entropy values were calculated from assigned uncertainties in C_p° values (assuming that uncertainties in C_p° were not functions of temperature and using average uncertainties over a temperature range) and assigned values of uncertainties for ΔH 's of transitions. The equations employed were as follows:

a) For single-phase regions

$$s_{T_2} = s_{T_1} + \delta C_p \ln \frac{T_2}{T_1} \quad (148)$$

where

s_{T_2} = entropy uncertainty at T_2 ,

s_{T_1} = entropy uncertainty at T_1 ,

δC_p° = average uncertainty in C_p° over the temperature range $T_1 < T < T_2$.

b) At transitions

$$s_B = s_A + \frac{\delta \Delta H_t}{T_t} \quad (149)$$

where

s_B = entropy uncertainty for phase B at temperature of transition T_t ,

s_A = entropy uncertainty for phase A at temperature of transition T_t ,

$\delta \Delta H_t$ = uncertainty in ΔH of transition.

The uncertainty in S_{298}° was taken to be ± 0.1 e.u. in view of the rather large uncertainty in C_p° near room temperature.

3) Enthalpy

Uncertainties in enthalpy values were calculated from C_p^0 uncertainties and assigned values of ΔH -of-transition uncertainties. The equations used for single-phase regions and transitions were

$$h_{T_2} = h_{T_1} + \delta C_p^0 (T_2 - T_1) \quad (150)$$

and

$$h_B = h_A + \delta \Delta H_t \quad (151)$$

4) Free energy

The uncertainty in the free energy function was calculated from calculated uncertainties in S_T^0 and $H_T^0 - H_{298}^0$ by means of equations (119) and (120).

g. Uncertainty in Gas Phase Functions

Uncertainties in the thermodynamic functions at the specified temperatures were computed as explained in section III-D2. They are summarized on the back of Table XXIX.

The uncertainties in ΔH_f^0 , ΔF_f^0 , and $\log_{10} K_p$ were calculated by means of equations (46), (47) and (48).

h. Other References Pertaining to Thermodynamics of Molybdenum

Heat capacity measurements at low temperatures have been reported and discussed by Boosz,²⁷⁸ Wolcott,²⁰⁴ Rayne,²⁷⁹ Horowitz and Daunt,²⁸⁰ and Simon and Zeidler.²⁷⁶ Recent work on heat capacities at higher temperatures has been that of Boggs and Wiebelt.²⁸¹

Vapor pressure data have also been reported by van Liempt.²⁸²

Useful annotated bibliographies on molybdenum were those of Goodwin,²⁰⁹

and of Richert, Beckett, and Johnston.²⁸³ A recent review article of Argent and Milne²⁸⁴ was examined but not used, since it did not provide any new data.

i. Thermodynamic Functions

The reference state thermodynamic functions of molybdenum are given in Table XXVIII. The ideal monatomic gas thermodynamic functions of molybdenum in Table XXIX were calculated using the energy levels given by Moore.⁵² $H^\circ_{298} - H^\circ_0$ was found to be 1,481 cal/mole for the ideal gas.

11. Niobium

The ideal monatomic gas thermodynamic functions of niobium in Table XXX were calculated with the energy levels given by Moore²⁵³ using the computer program described in section III-D. Uncertainty estimates are summarized on the back of the table.

12. Nitrogen

a. Molecular Nitrogen

Machine computations based on the treatment of the diatomic molecule outlined in section III-E of this report, were made of the thermodynamic functions of molecular nitrogen.

The $\underline{X} \ ^1\Sigma_g^+$ ground state and $\underline{A} \ ^3\Sigma_u^+$ and $\underline{B} \ ^3\Pi_g$ excited states of nitrogen were included in the calculation. The spectroscopic constants of Lofthus²⁸⁵ were used for the ground state of N_2^{14} . He combined his observations of the near-ultraviolet part of the emission spectrum of nitrogen with the Raman spectrum results on nitrogen obtained by Stoicheff.²⁸⁶ The resulting spectroscopic constants were slightly different from the ones listed by Herzberg.⁵⁴ Wilkinson and Houk²⁸⁷ have also recently given constants for the ground state, which were later slightly modified by Wilkinson.²⁸⁸ The constants listed by Herzberg⁵⁴ were used herein for the $\underline{A}$ and $\underline{B}$ states.

The spectroscopic constants adopted were corrected to correspond to the naturally occurring mixture of isotopic molecules although in the case of nitrogen, the resulting shift was less than the uncertainties assigned to the constants. According to custom for a process which does not involve separation of isotopes, the entropy of mixing of isotopes was not included. The entropy of nuclear spin was likewise omitted. No correction was necessary for the symmetry number of the heteronuclear isotopic molecule $N^{14}N^{15}$ since this correction has been shown to be unnecessary by Giauque and Overstreet.²⁸⁹

The effect of the presence of isotopic molecules was accounted for by the use of the average molecular weight on the chemical scale in the calculation of translational entropy and the use of averages of the spectroscopic constants of the isotopes weighted according to composition. The procedure given by Herzberg⁵⁴ was used to calculate the spectroscopic constants of $N^{15}N^{15}$ and $N^{14}N^{15}$ from those of $N^{14}N^{14}$.

²⁸⁸Wilkinson, P. G., Astrophys. J., 126, 1 (1957).

²⁸⁹Giauque, W. F. and R. Overstreet, J. Am. Chem. Soc. 54, 1731 (1932).

For discussion purposes, the properties of an isotopic molecule differing from those of the ordinary molecule are designated by the superscript i . If the parameter ρ is defined as

$$\rho = \sqrt{\mu/\mu^i}, \quad (152)$$

where μ is the reduced mass, then to a good approximation, the spectroscopic constants are related by equations (153)

$$\omega_e^i = \rho \omega_e, \quad \omega_e^i x_e^i = \rho^2 \omega_e x_e, \quad \omega_e^i y_e^i = \rho^3 \omega_e y_e, \quad B_e^i = \rho^2 B_e,$$

$$a_e^i = \rho^3 a_e, \quad \text{and} \quad D_e^i = \rho^4 D_e. \quad (153)$$

The values of ρ for the pairs $N^{14}N^{14}$, $N^{14}N^{15}$ and $N^{14}N^{14}$, $N^{15}N^{15}$ were 0.983243 and 0.966195, respectively, using the isotopic masses tabulated by Stehn and Clancy.²⁹⁰ The fractions of $N^{14}N^{14}$, $N^{14}N^{15}$, and $N^{15}N^{15}$ in naturally occurring molecular nitrogen were calculated from the isotopic abundances²⁹¹ by assuming that the equilibrium constant for the exchange process,

equaled 4; i. e., the distribution among the isotopic species was random.

The corrected spectroscopic constants and the assigned uncertainties (in cm^{-1}) which were used in the machine computations were as follows:

State	E	ω_e	$\omega_e x_e$	$\omega_e y_e$	B_e	a_e	$\gamma_e \times 10^5$	$D_e \times 10^6$
X $1\Sigma_g^+$	0.0	2357.93 ± 0.4	14.186 ± 0.12	-0.0124 ± 0.008	1.9981 ± 0.001	0.01709 ± 0.001	-4.6 ± 2.0	6 ± 0.5

²⁹¹Strominger, D. J. M. Hollander and G. T. Seaborg, *Rev. Mod. Phys.* **30**, 585 (1958).

The calculated thermodynamic functions of molecular nitrogen are given in Table XXXI. The indicated uncertainties in the spectroscopic constants made a difference of 0.0005 units in the entropy at 6000° K. The uncertainty estimates summarized on the back of the table reflect primarily the uncertainty in the value of the gas constant R.

No attempt was made to assess the uncertainties introduced by the approximations made here in the evaluation of the partition function of the diatomic molecule. However, values of the heat content and free-energy functions from the present calculation are compared immediately below at several temperatures with data from other sources to give an indication of the effect of the approximations.

^aRe-calculated from National Bureau of Standards values in Circ. 564 to a reference temperature of 298.15° K.

^bFrom JANAF Thermochemical Tables (31 March 1961). ("White sheet") provided in advance of publication through the courtesy of Dr. D. R. Stull.)

The NBS table was based largely on calculations of Goff and Gratch²⁹² (60° to 2800° K) and was extended to 5000° K by NBS using the same spectroscopic data. The spectroscopic data used were essentially those listed by Herzberg⁵⁴ except for somewhat smaller values of B_e and a_e . The JANAF table was a modification of the calculations of

²⁹²Goff, J. A. and S. Gratch, Trans. Am. Soc. Mech. Engrs. 72, 741 (1950).

Glatt, Belzer, and Johnston,²⁹³ who had used the spectroscopic data given by Herzberg.⁵⁴ The modifications in the JANAF tables were the addition of $-R \ln 9$ to the entropy to remove the effect of nuclear spin included by Glatt, Belzer, and Johnston²⁹³ and 0.012 e.u. to convert to the spectroscopic data of Stoicheff.²⁸⁶ The vibrational constants used herein for the ground state were slightly different from those given by Stoicheff,²⁸⁶ but that difference was within the uncertainties summarized above.

$(H_{298}^{\circ} - H_0^{\circ})$ for molecular nitrogen was calculated to be 2072.3 cal/gfw.

b. Monatomic Nitrogen

1) Dissociation energy of nitrogen

The dissociation energy of molecular nitrogen was a subject of dispute for many years. A set of possible values resulted from differences between the dissociation limits obtained from the predissociation of various excited states, particularly the $C^3\Pi_g$ state, and the energies of various combinations of three possible low-lying states of the atomic dissociation products.³ From this set, the alternative values of 9.76 and 7.38 eV appeared most likely, and a great amount of work has been done to confirm one or the other value. The subject was reviewed by Gaydon²⁹⁴ in 1953, and by Brewer and Searcy²⁹⁵ in 1956. Several other papers^{285, 287, 296-300} have appeared since Brewer and Searcy's review. There has been achieved a virtually unanimous agreement that the higher value is correct. The dissociation energy of N_2^{14} was therefore taken to be 225.07 ± 0.1 Kcal/gfw from Brewer and Searcy's recommended value of 78717 ± 40 cm⁻¹ (1 cm⁻¹ = 2.85927 cal/gfw). The correction to convert this to the naturally occurring isotopic mixture is negligible.²⁹⁴

2) Thermodynamic functions of monatomic nitrogen

The ideal gas thermodynamic functions in Table XXXII were calculated with the energy levels given by Moore⁵² and the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table. $H_{298}^{\circ} - H_0^{\circ}$ was found to be 1,481 cal/mole.

14. Oxygen

a. Molecular Oxygen

The thermodynamic functions of molecular oxygen were calculated with a computer program based on the treatment of the diatomic molecule outlined in section III-E of this report.

The electronic states and spectroscopic constants used for the oxygen molecule are given below with the assigned uncertainties:

Constant	$X^3\Sigma_g^-$	$a^1\Delta_g$	$b^1\Sigma_g^+$	$A^3\Sigma_u^+$	$1\Sigma_u^-$	$B^3\Sigma_u^-$

* Includes the $^3\Delta_u$ state on the assumption that its spectroscopic constants are the same as those of the $1\Sigma_u^-$ state.

Constants adopted for O_2^{16} were converted to those appropriate to a naturally occurring isotopic mixture by the procedure discussed in section IV-A12, using data for the isotopic masses and abundances from the same sources.

Constants used for the X, a, and b states of O_2^{16} were those listed by Herzberg.⁵⁴ The rotation and vibration-rotation interaction constants of the ground state have received recent confirmation in the Raman spectroscopic results of Weber and McGinnis.³⁰¹ Woolley's⁵⁵ additive correction of -0.244 cm^{-1} was used to account for the effect of the triplet splitting of the ground state. Constants for the A state were from the modification of Herzberg's³⁰² results by Broida and Gaydon.³⁰³

Herzberg³⁰⁴ reported two new states for molecular oxygen which have not been included in previous calculations of the thermodynamic functions. He gave constants for the $^1\Sigma_u^-$ state, which were adopted here, but noted that the constants were based on the assumption of a vibrational numbering which might have to be revised. Much less is known about the $^3\Delta_u$ state as the data are fragmentary. Moffitt³⁰⁵ had previously predicted the positions of these then unknown states, and concluded that they should be separated by less than 0.2 eV (1600 cm^{-1}) from the A state. Chamberlain³⁰⁶ stated that the $^3\Delta_u$ state probably lies slightly above the A state. Later theoretical calculations relating to the $^1\Sigma_u^-$ and $^3\Delta_u$ states were discussed by Itoh and Kimio.³⁰⁸ For the present calculation, the energies of the O-O bands of the two new states and their other spectroscopic constants were assumed identical. A total multiplicity of 7 was used. An uncertainty of 1000 cm^{-1} was assigned to the common electronic levels.

Spectroscopic constants for the B state were taken from Brix and Herzberg.³⁰⁷

The results of the computations of the thermodynamic functions of molecular oxygen are given in Table XXXIV. The entropies of isotopic mixing and nuclear spin were not included. The calculations of Woolley⁵⁵ have been almost universally accepted for recent compilations of thermodynamic functions.^{77, 156, 309} Woolley⁵⁵ broke off summation of rotational levels for a given vibrational level at the top of the dissociation or pre-dissociation applying to the vibrational level. present work, the sum has been taken to infinite energy. The effect of the alternative procedures will be evident only at the higher temperatures. Thus, at 5000°K, Woolley's⁵⁵ free-energy function would have been increased by 0.0003 cal/°K gfw had he summed to infinite energy, and his heat content would have been 14 cal/gfw greater. If levels for the two new states had been included, the differences in the two calculations for the free-energy function and heat content would have been 0.0005 cal/°K gfw and 30 cal/gfw, respectively, at 5000°K. Although some procedure for taking into account the effect of dissociation or pre-dissociation on the thermodynamic functions is certainly valid, it was preferred here to retain the simplicity of the present procedure. The uncertainty in the thermodynamic functions of oxygen which results is far less than the uncertainty in the functions of other substances with which the oxygen data will be combined. The uncertainties in the thermodynamic functions summarized on the back of Table XXXIV do not include a contribution from a summation to infinite energy.

The results of the present calculation are compared below with those in the JANAF compilation³⁰⁹ at selected temperatures:

Temp. °K	$(H_T^0 - H_{298}^0)$ Kcal/gfw		$-(F_T^0 - H_{298}^0)/T$ cal/°K gfw	
	Avco	JANAF	Avco	JANAF
298.15	0.000	0.000	49.007	49.004
1000	5.427	5.427	52.767	52.765
2000	14.148	14.149	57.138	57.136
3000	23.443	23.446	60.159	60.157
4000	33.196	33.201	62.479	62.476
5000	43.352	43.257	64.374	64.368
6000	54.677	53.479	65.996	65.970

The JANAF table was taken from Woolley,⁵⁵ with a reduction of the entropies by 0.0065 cal/°K gfw. This amount had been added by Woolley⁵⁵ to account for the difference in symmetry number between heteronuclear and homonuclear isotopes.

$(H_{298}^0 - H_O^0)$ was calculated to be 2074.7 cal/gfw.

b. Monatomic Oxygen

1) Dissociation energy of oxygen

The dissociation energy of O_2^6 was taken to be 117.973 ± 0.04 Kcal/gfw ($41260 \pm 15 \text{ cm}^{-1}$) from Brix and Herzberg.³¹⁰ The correction to a naturally occurring isotopic mixture was negligible.

2) Ideal monatomic gas thermodynamic functions

The ideal monatomic gas thermodynamic functions of oxygen in Table XXXV were calculated with the energy levels given by Moore⁵² and the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table. $H_{298}^\circ - H_0^\circ$ was found to be 1,607.50 cal/mole for the ideal monatomic gas.

³¹⁰Brix, P. and G. Herzberg, J. Chem. Phys. 21, 2240 (1953).

15. Platinum

The ideal monatomic gas thermodynamic functions of platinum in Table XXXVI were calculated from the energy levels given by Moore²²¹ with the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table.

16. Rhenium

The ideal monatomic gas thermodynamic functions of rhenium in Table XXXVII were computed from the energy levels listed by Moore²²¹ with the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table.

17. Rhodium

The ideal monatomic gas thermodynamic functions of rhodium in Table XXXVIII were calculated from the energy levels listed by Moore²²¹ with the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table.

18. Scandium

a. Crystal Structure, Transition Point and Melting Point

At room temperature, elemental scandium has a hexagonal, close-packed structure^{311, 312, 315, 316}. A face-centered cubic form reported by Meisel³¹³ has been attributed^{311, 314} to ScN. Spedding and Daane³¹⁵ reported an allotropic transition at 1608°K. Mardon et al³¹⁶ found a thermal arrest corresponding to a transition at $1646^{\circ} \pm 10^{\circ}\text{K}$. The last authors stated that the transition was expected to be to a body-centered cubic structure by analogy with certain of the rare earth elements.

Spedding et al^{311, 315} found the melting point of scandium to be $1812^{\circ} \pm 2^{\circ}\text{K}$. Mardon et al³¹⁶ reported a melting point of $1795^{\circ} \pm 5^{\circ}\text{K}$ for metal which had picked up an "appreciable" but unspecified amount of tantalum. The transition and melting points adopted herein were those reported by Spedding et al^{311, 315}. Uncertainties of $\pm 15^{\circ}$ and $\pm 5^{\circ}\text{K}$, respectively, were assigned. Other compilers^{56, 77} had recently assumed the melting point to be 1673°K.

b. Thermodynamic Properties

1) Heat of transition

The heat of transition of scandium at 1608°K was estimated to be $350 \pm 100 \text{ cal/gfw}$.

2) Heat of fusion

The heat of fusion of scandium had not been measured. It was estimated herein to be $3770 \pm 200 \text{ cal/gfw}$ on the assumption that

the entropy of transition plus the entropy of fusion was 2.3 cal/°K gfw. The same entropy of transformation was adopted by Stull and Sinke⁷⁷ and Kelley.⁵⁶

3) Entropy and heat content at 298.15°K

No data were available for the low temperature heat capacity of scandium. The estimate of Brewer³¹⁷ of 9.0 cal/°K gfw was adopted. This was also listed by Kelley and King³¹⁸ who assigned an uncertainty of 0.5 cal/°K gfw. $H_{298}^{\circ} - H_0^{\circ}$ was estimated to be 1280 ± 40 cal/gfw for the solid.

4) High-temperature heat content

In the absence of experimental data, Kelley's⁵⁶ estimated heat capacity (in cal/°K gfw) equation was used for the hexagonal-close-packed phase between 298.15° and 1608°K.

$$C_p^{\circ} = 5.68 + 1.08 \times 10^{-3}T \quad (155)$$

For the high-temperature phase (presumably body-centered cubic), a constant heat capacity of 8.00 cal/°K gfw was assumed. Kelley's⁵⁶ estimate of 8.00 cal/°K gfw was used for the heat capacity of liquid scandium.

5) Heat of sublimation, heat of vaporization, and boiling point

The vapor pressure of scandium was reported by Spedding *et al.*³¹¹ From their data and the free-energy functions tabulated here, the heat of sublimation at 298.15°K was calculated to be 89.50 ± 0.50 Kcal/gfw. The normal boiling point of scandium was calculated to be $3021^{\circ} \pm 140^{\circ}\text{K}$, and the heat of vaporization at the normal boiling point was found to be 79.521 ± 2.7 Kcal/gfw. Stull and Sinke⁷⁷ had previously estimated the heat of sublimation at 298.15°K to be 82.0 Kcal/gfw, the heat of vaporization to be 72.850 Kcal/gfw, and the normal boiling point to be 2750°K.

6) Thermodynamic functions

The reference state thermodynamic functions of scandium are given in Table XXXIX. The ideal monatomic gas thermodynamic functions of scandium given in Table XL were calculated from all the energy levels listed by Moore⁵² with the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the tables. $H_{298}^{\circ} - H_0^{\circ}$ was found to be 1,674 cal/mole for the ideal gas.

19. Silicon

The ideal monatomic gas thermodynamic functions of silicon given in Table XLI were calculated from the energy levels listed by Moore⁵² with the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table.

20. Strontium

a. Crystal Structure, Transition Point, and Melting Point

Three allotropic modifications of elemental strontium have been reported.^{319-321, 129, 322} They are α -Sr with a face-centered cubic structure, β -Sr with a hexagonal, close-packed structure, and γ -Sr with a body-centered structure. The transitions are summarized by equation (156):

Rinck,³¹⁹ using thermal analysis, dilatometric studies, and electrical measurements, gave T_1 as 508°K and T_2 as 813°K . Sheldon and King,³²⁰ using high-temperature X-ray techniques, found T_1 and T_2 to be $488^\circ \pm 10^\circ$ and $878^\circ \pm 10^\circ$, respectively. Hirst, King, and Kanda³²¹ reported $486^\circ \pm 10^\circ$ and $881^\circ \pm 10^\circ\text{K}$ to be the two transition temperatures, and Schottmiller, King, and Kanda¹²⁹ give the temperatures as $503^\circ \pm 6^\circ$ and $894^\circ \pm 6^\circ\text{K}$.

In view of Smith, Carlson, and Vest's¹²⁴ demonstration that two of the four reported allotropic modifications of calcium were caused by impurities, it would not be surprising to find a similar situation with strontium. Kelley⁵⁶ and Stull and Sinke⁷⁷ used a single transition at 862°K in their compilations. However, the evidence for this transition temperature is not at all conclusive. It has been reported by Eastman, Cubicciotti, and Thurmond,³²³ and was tabulated by Kubaschewski et al.⁷⁹ in their review. The latter authors did not specify the source of the data, and Kubaschewski and Evans¹⁸² later listed the data of Rinck³¹⁹ in their book. A single transition at 862°K (face-centered cubic to body-centered cubic) has been adopted here and assigned an uncertainty of $\pm 50^\circ\text{K}$.

The melting point of strontium was taken to be $1045^{\circ} \pm 4^{\circ}\text{K}$. The more reliable values in the literature^{132, 129, 321} ranged from 1041° to 1047°K . Stull and Sinke⁷⁷ and Kelley⁵⁶ used 1043°K .

b. Thermodynamic Properties

1) Heat of transition

The heat (or heats) of transition of strontium has not been measured. Stull and Sinke's⁷⁷ estimate of 200 cal/gfw for the single, assumed transition was adopted here. This estimate, arrived at by analogy with calcium, was assigned an uncertainty of 100 cal/gfw.

2) Heat of fusion

There were no measurements reported for the heat of fusion of strontium. Kubaschewski *et al*⁷⁹ estimated the sum of the entropies of fusion and transition to be 2.12 cal/ $^{\circ}\text{K}$ gfw from regularities among the alkali and alkaline earth metals. The heat of fusion was then calculated to be 1970 cal/gfw and was assigned an uncertainty of ± 150 cal/gfw. Stull and Sinke⁷⁷ and Kelley⁵⁶ used 2200 cal/gfw for the heat of fusion of strontium from the same total entropy of transformation, but without subtracting the entropy of transition. Kubaschewski's values were used herein.

3) Entropy and heat content at 298.15°K

The low-temperature heat capacity of strontium had not been measured. Kelley and King³¹⁸ estimated the entropy at 298.15°K to be 12.5 ± 0.5 cal/ $^{\circ}\text{K}$ gfw; this estimate was accepted here. Latimer³²⁴ and NBS Circular 500 reviewer estimated a value of 13.0 cal/ $^{\circ}\text{K}$ gfw for this quantity. $H_{298}^{\circ} - H_0^{\circ}$ for strontium was estimated to be 1550 ± 150 cal/gfw from a plot of $H_{298}^{\circ} - H_0^{\circ}$ versus S_{298}° for the alkali and alkaline earth metals and the estimated value of S_{298}° for strontium.

4) High temperature heat content

No experimental data were available for the high-temperature heat capacity or heat content of strontium. Stull and Sinke⁷⁷ and Kelley⁵⁶ in their compilations assumed that these quantities for $\alpha\text{-Sr}$ were essentially identical to those for $\alpha\text{-Ca}$, and extrapolated the $\alpha\text{-Ca}$ data to the transition point of strontium.

³²⁴Latimer, W. M., Oxidation Potentials, 2nd ed., Prentice-Hall, N. Y. (1952).

Stull and Sinke⁷⁷ extended this procedure for γ -Sr. Kelley⁵⁶ assumed a constant heat capacity of 9.16 cal/ $^{\circ}$ K gfw for γ -Sr. The latter was an average of heat capacities obtained by the application of an equation for the heat capacity of γ -Ca to γ -Sr.

The present compilation for α -Sr is based on assumed heat capacities (in cal/ $^{\circ}$ K gfw) over the range from 298.15 $^{\circ}$ to 862 $^{\circ}$ K given by equation (157).

$$C_p = 5.207 + 4.00 \times 10^{-3}T \quad (157)$$

This equation yields the adopted heat capacity of 6.400 cal/ $^{\circ}$ K gfw at 298.15 $^{\circ}$ K (compared with a heat capacity of 6.280 cal/ $^{\circ}$ K gfw for α -Ca at the same temperature) and a temperature coefficient of the heat capacity about 10 percent greater than that for α -Ca. The assigned uncertainties for the heat capacity of α -Sr were about double the value of those used previously for α -Ca.

Kelley's⁵⁶ estimate of 9.16 cal/ $^{\circ}$ K gfw was adopted for the heat capacity of γ -Sr with increased uncertainties over those used for γ -Ca.

Stull and Sinke⁷⁷ and Kelley⁵⁶ assumed a constant heat capacity of 7.4 cal/ $^{\circ}$ K gfw for liquid strontium. The somewhat larger value of 7.8 cal/ $^{\circ}$ K gfw was used here with an assigned uncertainty which increases with temperature.

5) Heat of formation of the monatomic gas

The free-energy functions tabulated here were used with vapor pressure data from the following sources to calculate the indicated heats of formation at 298.15 $^{\circ}$ K using the Third Law Method:

Source	Temperature Range ($^{\circ}$ K)	$\Delta H_f^{\circ} 298$ (Kcal/gfw)
Hartmann and Schneider ¹⁴⁸	1199-1379	39.490 $\pm$ 0.110
Priselkov and Nesmeyanov ¹⁴⁷	673- 873	38.640 $\pm$ 0.400
Ruff and Hartmann ¹⁵³	1217-1411	38.000 $\pm$ 2.500

Unsmoothed vapor pressure data were used for these calculations.

An average of the first two values, 39.070 ± 0.500 Kcal/gfw, was adopted for the heat of sublimation of strontium at 298.15°K .

The boiling point of strontium was calculated to be $1641^\circ \pm 90^\circ\text{K}$, and the heat of vaporization at the boiling point was found to be 33.012 ± 1.05 Kcal/gfw.

6) Thermodynamic functions

The reference state thermodynamic functions of strontium obtained here are given in Table XLII. The ideal monatomic gas thermodynamic functions of strontium given in Table XLIII were calculated from all the energy levels listed by Moore²⁵³ with the computer program described in section III-D. Uncertainty estimates are summarized on the back of the tables. $H_{298}^\circ - H_0^\circ$ was found to be 1,481 cal/mole for the ideal gas.

21. Tantalum

The ideal monatomic gas thermodynamic functions of tantalum in Table XLIV were calculated from the energy levels listed by Moore²²¹ with the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table.

22. Technetium

The ideal monatomic gas thermodynamic functions of technetium in Table XLV were calculated from the energy levels listed by Moore²²¹ with the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table.

23. Titanium

Prior to the publication of the JANAF Thermochemical Panel Interim Tables,⁷⁵ an analysis of the available basic data on titanium had been made on the present project. Since the results of the two analyses were in very close agreement, the values of the former analysis were accepted for the sake of compatibility and consistency with the addition of uncertainty limits from the new analysis. The following summary shows the extent of agreement of important quantities:

Quantity	Units	JANAF Table Value ⁷⁵	Avco RAD Analysis
T_t	° K	1155	1154
ΔH_t	Kcal/gfw	0.950	0.943
Melting Point	° K	1950	1945 ± 10
ΔH_m	Kcal/gfw	3.7	4.0 ± 0.5
S_{298}°	e. u.	7.33	7.334
ΔH_v	Kcal/gfw	102.5*	
Boiling Point	° K	3550	---
ΔH_{s298}°	Kcal/gfw	112.49	112.794

*Taken from monatomic gas table and rounded off.

a. Selection of Condensed-Phase Data

1) Crystal structure and solid-state transition

Titanium exists in two crystalline modifications.⁵⁷ The form stable at ordinary temperatures is close-packed hexagonal. This undergoes a transition^{325, 326} to the body-centered cubic form at about 1155° K. Hansen and Anderko²¹³ have reported a transition point value of 1158° K and Kothen²⁶⁶ has reported a value of 1154° K for it.

The 1155° K value used in the JANAF tables for this transition point was adopted for the present work.

³²⁵ Edwards, J. W., H. L. Johnston, and W. E. Dittmars, J. Am. Chem. Soc. 73, 4729 (1951).

³²⁶ McQuillan, A. D. Proc. Roy. Soc. (London) A204, 309 (1950).

*Taken from monatomic gas table and rounded off.

2) Melting point

There were many reported melting points for titanium. The recent compilation of Goldsmith *et al*²⁷⁷ listed five references with an average recommended value of 1944° K. Stull and Sinke⁷⁷ chose 1950° ± 20° K. Kelley⁵⁶ chose 1940° K which is based on the work of Deardorff and Hayes.³²⁷ A recent determination by Savitskii and Burkhanov³²⁸ yielded a value of 1953° K.

The JANAF table value of 1950° K was accepted for the present work with an estimated uncertainty of ± 10° K.

3) Heat of transition

Golutvin³²⁹ reported a solid-state heat of transition of 820 ± 20 cal/g atom while Schofield's value³³⁰ of 830 ± 100 cal/g atom was quoted by Kubaschewski and Evans.¹⁸² Stull and Sinke⁷⁷ chose a value of 950 cal/g atom, and Kothen's²⁶⁶ measurements yielded a value of 943 cal/g atom. The agreement between the last two values is good. The JANAF table value of 950 cal/g atom was chosen for the present work.

4) Heat of fusion

There were no experimental data available for the heat of fusion of titanium. Values have been estimated on the assumption that the entropy of fusion has a value characteristic of the change from a body-centered cubic structure to the liquid. The following estimates have been reported.

ΔH_{fusion} (cal/g atom)	Reference
3700	Stull and Sinke ⁷⁷
4500 ± 500	Kubaschewski and Evans ¹⁸²
4460	Kelley ⁵⁶

³²⁷Deardorff, D. K. and E. T. Hayes, *J. Metals* 8, 509 (1956).

³²⁸Savitskii, E. M. and G. S. Burkhanov, *Zhur. Neorg. Khim.* 2, 2609 (1957).

³²⁹Golutvin, Y., *Zhur. Fiz. Khim.* 33, 1798 (1959); *C. A.* 54, 9479i (1960).

³³⁰Schofield, T. H., *J. Inst. Metals* 85, 68 (1956).

Some intermediate value like 4400 ± 600 cal/g atom would appear to be called for in a conservative evaluation. However, Kelley's value of 3700 cal/g atom was chosen to maintain agreement with the JANAF tables.

5) Low-temperature heat capacity and S_{298}°

Several sets of low-temperature heat capacity data, needed for the calculation of the entropy at 298.15° K, were summarized by Beckett et al.³³¹

S_{298}° (e. u.)	Reference
7.32	Beckett <u>et al.</u> ³³¹
7.33 ± 0.02	Stull and Sinke ⁷⁷ and Kothen and Johnston ³³³
7.334	Kothen ²⁶⁶
7.37 ± 0.02	Clusius and Franzosini ³³²

The recent work of Clusius and Franzosini compared well with the earlier determinations of Kothen,²⁶⁶ and Kothen and Johnston.³³³ The value for S_{298}° chosen in the present work was 7.330, and the value for $H_{298}^\circ - H_0^\circ$ was 1150 cal/mole, in agreement with those of the JANAF tables.

6) High-temperature heat capacity

Heat capacity measurements above room temperature have been made by several investigators.^{266, 334, 335, 337, 338} From Goldsmith's²⁷⁷ plot of these data, it could be seen that the results of Kothen²⁶⁶ and Scott³³⁶ agree near the transition point, whereas those of Loewen³³⁵ and Rea³³⁴ appeared to be high. Kothen's³³³ data also agree in this range with those of Jaeger et al.^{337, 338}

³³¹Beckett, C. et al., Preliminary Report on the Thermodynamic Properties of Selected Light-Element Compounds, Nat. Bur. Stds. Rept. 6645 (1 January 1960); Amended (1 April 1960).

³³²Clusius, K. and P. Franzosini, Z. Physik. Chem. neue Folge 16, 194 (1958).

³³³Kothen, C. W. and H. L. Johnston, J. Am. Chem. Soc. 75, 3101 (1953).

³³⁴Rea, J. A., The Construction of a Furnace Calorimeter and the Evaluation of a Method of Thermal Analysis for Obtaining the Specific Heat of Solids at High Temperatures, M. S. Thesis, Oklahoma A and M, Stillwater (1953).

³³⁵Loewen, E. G., Trans. Am. Soc. Mech. Engrs. 78, 667 (1956).

³³⁶Scott, J. L., A Calorimeter Investigation of Zirconium, Titanium, and Zirconium Alloys from 60° to 960°C, Oak Ridge, Rept. ORNL-2328, AD-138-838. (1957)

³³⁷Jaeger, F. M., E. Rosenbohm, and R. Fonteyne, Proc. Acad. Sci. (Amsterdam) 39, 442 (1936).

³³⁸Jaeger, F. M., E. Rosenbohm, and R. Fonteyne, Rec. trav. chim. 55, 615 (1936).

The heat capacities beyond 1476° K used in the JANAF tables were accepted for the present work with some reservations since Kothen's³³³ value of 10.47 cal/g atom at 1900° K was somewhat higher and his data at lower temperatures appeared to be good. Additional measurements on titanium at high temperatures therefore appeared to be desirable, and this was included in the work in Phase III of the project.

7) Heat of sublimation

Vapor pressure measurements have been reported by Edwards, Johnston, and Ditmars,³³⁹ Blocker and Campbell,³⁴⁰ Carpenter and Mair,³⁴¹ and Carpenter and Reavell.³⁴² Edwards et al³³⁹ reported a heat of sublimation at 0° K of $\Delta H_{s0}^\circ = 112,763 \pm 83$ cal/mole. The last authors have corrected the work of the other investigators to obtain values of ΔH_{s0}° equal to 112,167 and 111,497 cal/mole. The JANAF table value of $\Delta H_{s298}^\circ = 112,490$ cal/mole was adopted.

8) The liquid heat capacity

The value of C_p° (liquid) = 8.000 cal/°K mole used in the JANAF tables for liquid titanium was adopted.

b. Calculations for Reference-State Tables

Thermodynamic function values from the JANAF tables for the reference state of titanium were adopted for Table XLVI with the addition of uncertainty estimates and extra entries to define discontinuities at transformations. Interpolations required for the extra entries were made by means of the Lagrangian interpolation formula³⁴³ to assure accuracy in the third decimal place. The uncertainty calculations, summarized on the back of the table, were made by the methods described in section III-G.

1) Uncertainties in C_p°

Uncertainties in C_p° values were estimated from an examination of the following available data and derived points:

Source	C_p° in cal/g atom °K					
	298° K	1000° K (α)	1155° K (α)	1155° K (β)	1950° K (β)	1950° K (λ)
JANAF Tables	5.970	7.47	7.67	7.67	8.51	8.00
Goldsmith <u>et al</u> ²⁷⁷	5.987	7.66	8.14	7.18	10.77	
Kelley ⁵⁶	6.00	7.77	8.16	7.50	7.50	8.00
Kothen ²⁶⁶	5.976	7.96	8.40	7.14	(10.77)*	
Golutvin ³²⁹	4.783	8.435		7.968	(7.968)**	
Clusius and Franzosini ³³²	5.998					

* Kothen²⁶⁶ reported a value of 10.47 at 1900° K. This was extrapolated for the value at 1950° K. Goldsmith's²⁷⁷ data were based on Kothen's²⁶⁶ determinations.

**Golutvin³²⁹ reported a value of 7.968 for the range from 1155° to 1400° K.

The following are the values adopted for the uncertainties in cal/°K mole:

Temp(° K)	δC_p°	Temp(° K)	δC_p°
298	± 0.05	2000	± 1.0
1000	± 0.5	3000	± 2.0
1155 (α)	± 0.5	3550	± 2.0
1155 (β)	± 0.5	4000(ν)	± 0.002
1950 (β)	± 1.0	5000(ν)	± 0.005
1950 (λ)	± 1.0	6000(ν)	± 0.010

2) Uncertainties in ($H_T^\circ - H_{298}^\circ$)

As explained in section III-G, average values of δC_p° over the appropriate temperature ranges were calculated from the δC_p° data as described just above, multiplied by the temperature interval, and summed cumulatively to obtain the uncertainties in ($H_T^\circ - H_{298}^\circ$) in Table XLVI up to the boiling point.

Above the boiling point, the equation used for calculating uncertainties was

$$\delta(H_T^\circ - H_{298}^\circ)_{(1)} = \delta \Delta H_{298}^\circ + \delta(H_T^\circ - H_{298}^\circ)_{(2)} \quad (158)$$

where subscript (1) = gas referred to solid at 298.15° K, and subscript (2) = gas referred to gas at 298.15° K.

It is evident from this equation that the uncertainty in ΔH_{298}° contributes nearly all the total uncertainty in the gas enthalpy function of titanium because the last term on the right is very small.

3) Uncertainty in entropy

The equations used in calculating the uncertainty in S_T° for condensed phases were discussed in section III-G. The mean errors in specific heat values for titanium presented in section IV-A23b(1) above were used for the numerical computations. For the gas phase above the boiling point, the errors in S_T° were taken from the machine calculation for the ideal monatomic gas described in section IV-A23c below.

4) Uncertainty in free-energy function

The method used for the calculation of the uncertainty in the free-energy function of the condensed phases was also discussed earlier in section III-G of this report. The uncertainties in the free-energy function of the gas phase were also taken from the machine computation for the ideal monatomic gas described in section IV-A23c below.

The uncertainty estimates for the free-energy function of the condensed phases obtained in this work were larger than those reported by Hultgren et al:⁷⁶

The difference between the estimates is attributable to the larger uncertainties assigned in this work to the heat capacity values of the solid and liquid at high temperatures because of the discrepancies discussed in section IV-A23b(1) above.

c. Ideal Monatomic Gas Calculations

The ideal monatomic gas functions in Table XLVII were calculated by the methods described in section III-D using the energy levels of Moore.⁵² The results agreed well with those in the JANAF tables. For the sake of consistency between tabulations, values of the thermodynamic functions in the latter tables were adopted with the uncertainty limits from the present computation summarized on the back of the table. The JANAF table value of $H_{298}^0 - H_0^0 = 1,802$ cal/mole for the gas was accepted herein.

24. Tungsten

a. Crystal Structure and Transition Temperatures

The stable form of solid tungsten at 25°C is the body-centered cubic crystal.³⁴⁴⁻³⁴⁷ A face-centered cubic form has been reported to be produced by electrolysis of fused tungstates, but it reverts irreversibly to the body-centered form if heated above 700°C.³⁴⁶ No true allotropes of tungsten have been observed.³⁴⁸ The body-centered cubic form was therefore taken as the stable form from room temperature to the melting point in this work. The melting point adopted for tungsten is 3650° ± 30°K and the estimated standard boiling point is 5891° ± 275°K

b. Melting Point

The "best" value of the melting point of tungsten has been taken to be 3650°K in recent compilations.^{76, 77, 349} Other reported values ranged from 3370° to 3660°K. These older values were reviewed by Smithells³⁴⁵ and by Richert, Beckett, and Johnston.²⁸³

The heat of fusion had not been experimentally determined. Estimated values ranged from 3000 to about 8400 cal/gfw.^{76, 77, 256} In the absence of conclusive experimental data, an estimated heat of fusion of 8395 cal/gfw was chosen for this compilation. This value is based on an assumed entropy of fusion of 2.3 e.u. An uncertainty of ± 1000 cal/gfw was arbitrarily assigned to the heat of fusion at the melting point.

c. Standard Heat of Sublimation at 298.15°K, ΔH_{s298}°

Vapor pressure measurements for solid tungsten have been reported by Jones, Langmuir and MacKay,²⁶¹ and by Zwikker.³⁵⁰ A ΔH_{s298}° value of 202,770 cal/gfw was calculated with the vapor pressure values

³⁴⁴Jette, E.R. and F. Foote, J. Chem. Phys. 3, 605 (1935).

³⁵⁰Zwikker, C., Physica 5, 249 (1925).

of Jones and co-workers,²⁶¹ and the free-energy functions from the present compilation. A similar calculation with the vapor pressure data of Zwicker³⁵⁰ over the same temperature range yielded a ΔH_{s298}° value of 203,380 cal/gfw. On the basis of these two calculated values, the one chosen in the present work was $203,100 \pm 1800$ cal/gfw.

d. Boiling Point

The boiling point of tungsten had not been experimentally determined.

Estimated and/or quoted values ranged from 5100° to 6970°K; e.g.,

5100 - 5200°K²⁵⁶

5400°K¹⁸²

5800°K⁷⁷

5808°K⁷⁶

6970°K.²⁶¹

The chosen ΔH_{s298}° value of $203,100 \pm 1800$ cal/gfw and free-energy functions for the gas and condensed phases from the present compilation were used to calculate a standard boiling point of $5891^\circ \pm 275^\circ\text{K}$ in the present work.

The heat of vaporization at the standard boiling point was then estimated from the value of ΔH_{s298}° and the enthalpy functions for the gaseous and condensed phases at the standard boiling temperature. The value thus calculated was $192,265 \pm 11,400$ cal/gfw.

In Table XLVIII are summarized the heats of transformation for the various phase changes of tungsten.

TABLE XLVIII

TRANSITION DATA FOR TUNGSTEN

Transition	Temperature (°K)	ΔH_t (cal/gfw)
solid $\longrightarrow$ liquid	3650 ± 30	8395 ± 1000
liquid $\longrightarrow$ gas	5891 ± 275	$192,265 \pm 11,400$
solid $\longrightarrow$ gas	298.15	$203,100 \pm 1800$

e. Thermodynamic Functions for Condensed Phases

Recent compilations of thermodynamic functions for tungsten include those of Stull and Sinke,⁷⁷ Hultgren,⁷⁶ and Kelley.⁵⁶ The compilations of Stull and Sinke⁷⁷ and Kelley⁵⁶ extend to only 3000°K, thereby only including data for the solid phase. None of these compilations takes into account the recent low-temperature heat capacity data of Clusius and Franzosini,⁴⁶⁵ or the heat capacity values at high temperatures very recently reported by workers at the Union Carbide Corporation.³⁵¹

f. Entropy and Enthalpy at 298.15°K

Kelley⁵⁶ has reported an S_{298}° value of 8.04 ± 0.10 e.u. based on the heat capacity measurements of Lange³⁵² (26° to 92°K), and of Zwikker and Schmidt³⁵³ (92° to 290°K). This value was used by Stull and Sinke.⁷⁷ It should be noted that the heat capacity values of Zwikker and Schmidt³⁵³ scatter over a range of ± 10 percent. Hultgren⁷⁶ reported an S_{298}° value of 7.95 ± 0.10 e.u. based on the C_p° values of Waite, Craig, and Wallace,³⁵⁴ and of Horowitz and Daunt²⁸⁰ for temperatures ranging up to 20°K; the C_p° data of Lange³⁵² and DeSorbo³⁵⁵ up to 90°K; and the data of Zwikker and Schmidt³⁵³ up to room temperature. DeSorbo³⁵⁵ reported an S_{298}° value of 8.2 ± 0.2 e.u. from his measured C_p° values combined with the data of Waite, Craig, and Wallace,³⁵⁴ and of Zwikker and Schmidt.³⁵³ Clusius and Franzosini⁴⁶⁵ had recently measured the heat capacity very accurately over the temperature range from 10° to 273°K and reported S_{298}° to be 7.83 e.u. The latter value has been accepted in the present work and assigned an uncertainty of ± 0.05 e.u. Integration of the heat capacity data of Clusius and Franzosini leads to a value of $H_{298}^{\circ} - H_0^{\circ}$ of 1195 ± 5 cal/gfw.

g. Thermodynamic Functions above 298.15°K

Several investigators have reported C_p° values for the range of room temperature and above. 87, 194, 269, 353, 356-359 Previous 56, 76, 77 compilers had given most weight to the work of Jaeger and Rosenbohm³⁵⁷ and of Magnus and Holzmann⁸⁷, and then, used an extrapolation of these data up to high temperatures. However, comparison of the C_p° values thus obtained with low-temperature measurements of Clusius and Franzosini,²⁶⁵ and the high-temperature measurements of Schomaker, Crist, and Lowrie³⁵¹ (1300°K - 2500°K), leads to the conclusion that values of previous compilers^{56, 76, 77} are too high near room temperature and too low at temperatures above 1300°K.

Accordingly, the values of Clusius and Franzosini²⁶⁵ were extended so as to join smoothly with the values of Schomaker, Crist, and Lowrie³⁵¹ at 1300°K. These C_p° values were included in the present tables. Above 1300°K, the C_p° values fit equation (159),

$$C_p^\circ = 4.70 + 1.5 \times 10^{-3} T, \quad (159)$$

which was used for extrapolation up to the melting point of 3650°K.

From 298.15° to 1300°K, values of $H_T^\circ - H_{298}^\circ$ and S_T° were evaluated by graphical integration. Values of $-\left(\frac{H_T^\circ - H_{298}^\circ}{T}\right)$ were obtained from equation (108).

Above 1300°K to the melting point, S_T° and $H_T^\circ - H_{298}^\circ$ values were calculated from equations (160) and (161).

$$H_T^\circ - H_{298}^\circ = 4.70T + 75 \cdot 10^{-5} T^2 - 1130, \quad (160)$$

$$S_T^\circ = 4.70 \ln T + 1.5 \cdot 10^{-3} T - 18.762. \quad (161)$$

The values of the constants of integration in the above equations were evaluated from the tabular values of S_T° and $H_T^\circ - H_{298}^\circ$ at 1300°K. The free-energy function was then calculated as indicated above.

⁸⁷ Jaeger, E.M. and L. Rosenbohm, Proc. Acad. Sci. (Amsterdam) 33, 457 (1930).

²⁶⁵ Magnus, A. and H. Danz, Ann. Phys., 8, 408 (1920).

³⁵¹ Foreyche, W.J. and A. W. Worthing, Astrophys. J., 3, 140 (1925).

No experimental value of C_p° for liquid tungsten had been published. The heat capacity of liquid tungsten was taken to be constant at 10.00 cal/°K gfw. This value was chosen from a comparison of the values used for chromium (9.4 cal/°K gfw), molybdenum (10.00 cal/°K gfw), and solid tungsten at the melting point (10.175 cal/°K gfw). Previous compilations have used an estimated value of 8.5 cal/°K gfw.^{76, 77}

Entropy and enthalpy values for liquid tungsten were therefore calculated with equations (162) and (163), respectively.

$$S_T^\circ = 10 \ln T - 54.460, \quad (162)$$

$$H_T^\circ - H_{298}^\circ = 10T - 2088. \quad (163)$$

The values of the constants of integration in the above equations were evaluated from the tabular values of S_T° and $H_T^\circ - H_{298}^\circ$ for liquid tungsten at the melting point. The free-energy function for liquid tungsten was calculated from these values of S_T° and $H_T^\circ - H_{298}^\circ$ in the manner described in section III-G.

The reference state thermodynamic functions of tungsten are given in Table XLIX. Uncertainty estimates are summarized on the back of the table.

h. Thermodynamic Functions for the Gaseous Phase

Thermodynamic properties for the ideal monatomic gas were calculated using the spectroscopic energy levels listed by Moore.²²¹ Energy levels and J values not definitely established in these tables were estimated. The equations employed in these calculations have been discussed in two recent publications,^{51, 75} and are summarized in section III-D. $H_{298}^\circ - H_0^\circ$ was calculated to be 1486 cal/mole.

The ΔH_f° , ΔF_f° , and $\log_{10} K_p$ functions of gaseous tungsten were calculated by means of equations (42), (43), and (44).

The ideal monatomic gas thermodynamic functions of tungsten are given in Table L. Uncertainty estimates are summarized on the back of the table.

i. Uncertainty in Condensed Phase Functions

Uncertainties in the condensed phase functions of tungsten were calculated by the methods described in section III-G.

1) Heat capacity

Graphical intercomparison of reported C_p° values for solid tungsten led to the following choices of uncertainties:

- $\pm 0.1 \text{ cal/}^\circ\text{K gfw at } 298.15^\circ\text{K}$
- $\pm 0.5 \text{ cal/}^\circ\text{K gfw at } 1000^\circ\text{K}$
- $\pm 0.5 \text{ cal/}^\circ\text{K gfw at } 2000^\circ\text{K}$
- $\pm 1.0 \text{ cal/}^\circ\text{K gfw at } 3000^\circ\text{K}$
- $\pm 1.5 \text{ cal/}^\circ\text{K gfw at m.p. (3650}^\circ\text{K)}.$

The heat capacity of liquid tungsten had apparently never been experimentally measured; therefore, a rather large overall uncertainty was arbitrarily assigned to the estimated value. Particular uncertainties assigned were as follows:

- $\pm 2.0 \text{ cal/}^\circ\text{K gfw at m.p. (3650}^\circ\text{K)}$
- $\pm 2.0 \text{ cal/}^\circ\text{K gfw at } 4000^\circ\text{K}$
- $\pm 3.0 \text{ cal/}^\circ\text{K gfw at } 5000^\circ\text{K}$
- $\pm 4.0 \text{ cal/}^\circ\text{K gfw at b.p. (5891}^\circ\text{K)}.$

2) Entropy

Uncertainties in entropy values were calculated from assigned uncertainties in C_p° values, and assigned uncertainties for heats of transitions by the method described in section III-G. Equation (149) was used at transitions.

3) Free energy

The uncertainties in free-energy function were calculated from uncertainties in S_T° and $H_T^\circ - H_{298}^\circ$ by means of equation (120).

j. Uncertainties in Gas-Phase Functions

Uncertainties in the ideal gas thermodynamic functions at the specified temperatures were computed as explained in section III-D2. The uncertainties in ΔH_f° , ΔF_f° , and $\log_{10} K_p$ were calculated by means of equations (46) (47), and (48).

k. Other Reference Pertaining to the Thermodynamics of Tungsten

Heat capacity measurements at low temperatures have also been reported and discussed by Boosz,²⁷⁸ Wolcott,²⁰⁴ and Rayne.²⁷⁹ Heat capacities at high temperatures have also been reported by Southern Research Insititute²⁹ workers.

The vapor pressure data of Jones, Langmuir, and MacKay²⁶¹ were re-calculated from the original data of Langmuir.³⁶⁰ The vapor pressure values reported by van Liempt²⁸² are smoothed values from Langmuir's original work.³⁶⁰

Useful annotated bibliographies on tungsten were those of Goodwin and Ayton,²⁰⁹ and of Richert, Beckett, and Johnston.²⁸³

25. Vanadium

The ideal monatomic gas thermodynamic functions of vanadium in Table LI were calculated from the energy levels listed by Moore⁵² with the computer program discussed in section III-D. Uncertainty estimates are summarized on the back of the table.

26. Zirconium

The reference state thermodynamic functions of zirconium are given in Table LII. Uncertainty estimates are summarized on the back of the table.

a. Condensed Phase Data

1) Crystalline forms and range of stability

Elemental zirconium is known to exist in two different crystalline modifications.³⁶¹ At room temperature, the stable modification has a hexagonal, close-packed structure which persists up to 1135°K. Above this temperature, the body-centered cubic structure is the stable one.

2) Transition temperatures

a) Solid state transition

Miller³⁶¹ accepted 1135°K (862°C) as the solid-state transition temperature, Hansen and Anderko²¹³ have used a value of 1138°K (865°C), Skinner³⁶² found a value of 1143°K, and Kelley⁵⁶ adopted a value of 1135°K. The last value is the one used in the present tabulation with an uncertainty of $\pm 10^\circ\text{K}$ to include all the above values.

b) Melting point

For pure, hafnium-free zirconium, Miller³⁶¹ tabulated melting points of 2118°K (1845°C), based on the work of Adenstedt²¹⁹ and $2128 \pm 15^\circ\text{K}$ ($1855 \pm 15^\circ\text{C}$), from the work of Deardorff and Hayes.³²⁷ Oriani and Jones³⁶³ obtained a melting point of 2141°K. Hultgren et al⁷⁶ interpreted the last results to obtain a melting point of 2125°K. The Hultgren et al value was accepted for the present compilation.

c) Boiling point

Accurate experimental determinations of the boiling point of zirconium appeared not to be available. Hultgren et al⁷⁶ have calculated a boiling point of 4688°K. Miller³⁶¹ reported a value of 3850°K (3577°C) based on the older work of Quill.³⁶⁴

Kubaschewski and Evans¹⁸² reported an approximate value of 5023°K (4750°C), and Stull and Sinke⁷⁷ obtained a value of 4650°K. From the data in the present compilation, a boiling point of 4743° ± 165°K was calculated and adopted.

3) Heats of transformation

a) Heat of transition

The following values had been reported for the solid-state heat of transition at 1135°K:

Heat of Transition (cal/mole)	Source
1040	Stull and Sinke ⁷⁷
920	Miller, ³⁶¹ p. 151, based on Coughlin and King's work ³⁶⁵
915	Kelley, ⁵⁶ p. 209

In the present tabulation, Kelley's value of 915 cal/mole was accepted.

b) Heat of fusion

There were several estimates available for the heat of fusion of zirconium.

Heat of Fusion (cal/mole)	Source
5500	Miller, ³⁶¹ p. 151, based on Quill ³⁶⁴
4000	Stull and Sinke ⁷⁷
4890	Hultgren ⁷⁶

A value of 4900 cal/mole as recommended by Kelley was used for the heat of fusion of zirconium in the present tabulation.

³⁶⁵Coughlin, J.P. and E.G. King, J. Am. Chem. Soc. 73, 2032 (1951).

c) Heat of sublimation

The only vapor pressure measurements reported for zirconium were those of Skinner, Edwards, and Johnston.³⁶⁶ Stull and Sinke⁷⁷ used these data to determine that $\Delta H_{f298}^\circ = 146,000$ cal/mole for the temperature range from 1949° to 2054°K assuming the condensation coefficient to be equal to unity. Hultgren *et al*⁷⁶ obtained a value of 145,760 cal/mole from the same data. Lewis *et al*²²⁰ have tabulated a value of $146,000 \pm 1000$ cal/mole. The latter was accepted in the present compilation.

4) Heat capacity

a) Low-temperature data

Low-temperature heat capacity data have been reported by Skinner and Johnston³⁶⁷ for the range from 14° to 300°K. Their data yield a standard state entropy of $S_{298}^\circ = 9.29 \pm 0.04$ e.u. Additional data have been reported by Todd³⁶⁸ for the range from 51° to 298°K and by Burk, Estermann, and Friedberg²¹⁸ for the range from 15° to 200°K. The latter data agree within 1 percent with those of Skinner and Johnston,³⁶⁷ which were accepted here since they cover a wider temperature range. The above value of the standard state entropy was also accepted. $H_{298}^\circ - H_0^\circ$ was taken to be 1313 cal/gfw.

b) High-temperature data

High-temperature heat capacity data for zirconium from various sources have been reviewed by Kelley.⁵⁶ His review included the recent work of Douglas and Victor.³⁶⁹ Other sources of data were as follows:

³⁶⁶Skinner, G.B., J.W. Edwards, and H.L. Johnston, J. Am. Chem. Soc. 73, 174 (1951).

³⁶⁷Skinner, G.B. and H.L. Johnston, J. Am. Chem. Soc. 73, 4549 (1951).

³⁶⁸Todd, S.S., J. Am. Chem. Soc. 72, 2914 (1950).

³⁶⁹Douglas, T.B. and A.C. Victor, J. Research Nat. Bur. Stds. 61, 13 (1958).

Temperature Range (°K)	Reference
298-1371	Coughlin and King ³⁷⁰
423-1273	Redmond and Lones ³⁷¹
363-1223	Scott ³³⁶
294-1074	Jaeger and Veenstra ³⁷²

The values chosen by Kelley were accepted herein, including his estimated value of $C_p^\circ = 8.000$ cal/gfw for the liquid.

c) Monatomic gas table

The ideal monatomic gas thermodynamic functions of zirconium in Table LIII were calculated from the energy levels listed by Moore⁵² with the computer program described in section III-D. Uncertainty estimates are summarized on the back of the table. $H_{298}^\circ - H_0^\circ$ was found to be 1,629 cal/mole for the ideal gas.

B. COMPOUNDS

1. Beryllium Oxide (BeO)

a. Crystal Structure and Melting Point

Beryllium oxide has a hexagonal (wurtzite-type) structure at room temperature.²³¹ Jeffrey, Parry, and Mozzi³⁷³ determined some of the structural details by X-ray analysis. The hexagonal structure appears to be thermally stable. Klein³⁷⁴ found the thermal expansion of BeO to be isotropic up to at least 2025°K. The heat content measurements of Kandyba et al³⁷⁵ from 1200°K to the melting point gave no indication of any solid-state transformation.

Recent reported values for the melting point of BeO have ranged from 2723° to 2843°K.³⁷⁵⁻³⁸⁰ A melting point of 2820° ± 15°K³⁷⁵ was selected for this compilation.

b. Thermodynamic Properties of Condensed Phases

1) Heat of fusion

Kandyba et al³⁷⁵ made heat content measurements on solid and liquid BeO. From one heat content measurement on liquid BeO at 2840°K, the heat of fusion was calculated to be 15.440 Kcal/gfw. An uncertainty of ± 0.500 Kcal/gfw was assigned. The entropy of fusion was thus 5.475 ± .180 cal/°K gfw. The heat of fusion had been estimated to be 14 Kcal/gfw in the JANAF compilation,⁷⁵ and to be 17 Kcal/gfw (from an estimated entropy of fusion of 6.0 cal/°K gfw) by Erway and Seifert.³⁸¹

³⁸¹Erway, N.D. and R.L. Seifert, J. Electrochem. Soc. 98, 83 (1957).

2) Entropy and heat content at 298.15°K

Low-temperature heat capacity measurements of BeO made by Gunther¹⁴³ (76° to 85°K) and by Kelley³⁸² (55° to 292°K) were not in agreement. Kelley¹³⁹ gave S_{298}^0 as 3.37 ± 0.02 cal/°K gfw from his measurements. The National Bureau of Standards⁷⁸ joined the low-temperature data of Kelley³⁸² smoothly at 400°K with the unpublished high-temperature heat content measurements of Victor and Douglas and calculated S_{298}^0 to be 3.376 ± 0.050 cal/°K gfw. This value was adopted here. C_p^0 at 298.15°K was thereby changed from 6.07 cal/°K gfw as given by Kelley¹³⁹ to 6.105 cal/°K gfw. $H_{298}^0 - H_0^0$ was taken as 686.6 cal/gfw from the National Bureau of Standards.⁷⁸

3) High-temperature heat content

High-temperature heat content measurements on BeO have been made by Magnus and Danz³⁵⁸ (293° to 1175°K), Nilson and Pettersson³⁸³ (273° to 293°K), Victor and Douglas⁷⁸ (273° to 1200°K), and Kandyba et al³⁷⁵ (1200° to 2840°K). The results of Magnus and Danz³⁵⁸ were 0 to 1.5 percent higher than those of Victor and Douglas⁷⁸ over the temperature range of measurement. At 1200°K, Magnus and Danz³⁵⁸ and Kandyba et al³⁷⁵ were one percent higher and lower, respectively, than Victor and Douglas.⁷⁸ Equations representing heat content data from these three sources were:

- a) Magnus and Danz³⁵⁸ (298° to 1200°K in cal/gfw)

$$H_T^0 - H_{298}^0 = 8.45T + 2.00 \times 10^{-3}T^2 + 3.17 \times 10^5T^{-1} - 3700. \quad (164)$$

- b) Victor and Douglas⁷⁸ (298° to 1200°K in cal/gfw)

$$H_T^0 - H_{298}^0 = 14.088T + 4.878 \times 10^{-5}T^2 - 5548.7 \log T + 9522.88. \quad (165)$$

A small correction term, negligible above 500°K, is omitted.

c) Kandyba et al.³⁷⁵ (1200° to 2820°K in cal/gfw)

$$H_T^0 - H_{298}^0 = 9.471T + 1.045 \times 10^{-3}T^2 - 3540. \quad (166)$$

For the present compilation, the extrapolated heat capacity data of Victor and Douglas⁷⁸ were joined at 1500°K with the heat capacity data of Kandyba et al.³⁷⁵. The result of this procedure was a heat content at 2800°K, 3.5 percent greater than that tabulated by the National Bureau of Standards⁷⁸ from an extrapolation of the data of Victor and Douglas.⁷⁸

The uncertainty assigned to the heat content was one percent up to 1500°K, and was increased to two percent at the melting point.

The heat capacity of liquid BeO was assumed to be 17 cal/°K gfw. Thermodynamic functions of the condensed phases of BeO are given in Table LIV. Analyses of heat-of-formation data had not been completed at the time of report writing.

c. Thermodynamic Properties of Ideal Molecular Gas

The thermodynamic functions of BeO gas were calculated with the computer program based on the treatment of the diatomic molecule outlined in section III-E of this report. The spectroscopic constants used were those given by Herzberg.⁵⁴ All the electronic states listed in that reference were included in the calculation. The constants were converted to those for a naturally occurring isotopic mixture by the procedure discussed in section IV-A12 from data for the isotopic masses and abundances from the same sources. Values of D_e for some of the states were estimated from Dunham's⁵³ equations. The constants (in units of cm^{-1}) used were as follows:

Constant	$X^1\Sigma^+$	$A^1\Pi$	$B^1\Sigma^+$	$C(^1\Sigma)$	$D^1\Pi$
E	0	9234.93	211196.7	38917.9	41130

$H_{298}^{\circ} - H_0^{\circ}$ was calculated to be 2076.6 cal/gfw.

The results of all the calculations are given in Table LV. The National Bureau of Standards⁷⁸ has reported thermodynamic functions of gaseous BeO calculated from spectroscopic constants for the ground state alone.

No attempt has been made to give uncertainties for the above calculations at this time. The real uncertainty results from the effect of neglecting triplet states, which doubtless exist, but which have not been reported. Because BeO is isoelectronic with C₂, a similar sequence of states might be expected in the two gaseous molecules. Among other states, C₂ has a $^1\Sigma^+$ ground state, a $^3\Pi_u$ state only 610 cm⁻¹ above the ground state, and a $^3\Sigma_g^-$ state 6243.5 cm⁻¹ above the ground state.¹⁶² It is intended that additional calculations for gaseous BeO will be made after reasonable estimates of additional states are obtained.

The analysis of the heat-of-formation data had not been completed at time of report writing, and ΔH_f° , ΔF_f° and $\log_{10} K_p$ could not be included.

2. Calcium Oxide (CaO)

a. Crystal Structure and Melting Point

Calcium oxide has a face-centered cubic (NaCl type) structure at room temperature⁵⁷ which presumably persists up to the melting point. Beale and Cook³⁸⁴ measured the lattice parameters up to 1500°K by X-ray methods.

Ol'shanskii³⁷⁶ gave the melting point of CaO as 2893°K. Schumacher³⁸⁵ reported it to be 2849°K, and Kanolt³⁸⁶ gave a value of 2843°K. The average for these values of $2860^{\circ} \pm 30^{\circ}\text{K}$ was adopted here.

b. Thermodynamic Properties of the Condensed Phases

1) Heat of fusion

The entropy of fusion of CaO was assumed to be $6.0 \pm 0.5 \text{ cal/}^{\circ}\text{K gfw}$, which corresponded to a heat of fusion of $17.2 \pm 1.4 \text{ Kcal/}^{\circ}\text{K gfw}$. Kubaschewski and Evans¹⁸² estimated the latter quantity to be 19 Kcal/gfw. Kelley¹³⁷ used a heat-of-fusion value of 12.24 Kcal/ $^{\circ}\text{K gfw}$ from melting points in the CaO-ZrO₂ system.

2) Entropy and heat content at 298.15°K

The low-temperature heat capacity of CaO was measured by Nernst and Schwes²³³ (28° to 90°K) and by Parks and Kelley³⁸⁷ (87° to 293°K). From these data, S_{298}° was calculated to be $9.561 \pm 0.15 \text{ cal/}^{\circ}\text{K gfw}$, and $H_{298}^{\circ} - H_0^{\circ}$ was calculated to be 1668 cal/gfw.

3) High-temperature heat content

The heat content equation given by Kelley⁵⁶ in cal/gfw for use up to 2000°K was adopted here and extrapolated to the melting point.

$$H_T^{\circ} - H_{298}^{\circ} = 11.67T + 0.54 \times 10^{-3}T^2 + 1.56 \times 10^3T^{-1} - 4051 \quad (167)$$

³⁸⁴Beale, R. and R. Cook, J. Am. Ceram. Soc. 40, 279 (1957).

³⁸⁵Schumacher, E. E., J. Am. Chem. Soc. 48, 396 (1926).

³⁸⁶Kanolt, L., J. Wash. Acad. Sci. 3, 315 (1931).

³⁸⁷Parks, G. S. and E. E. Kelley, J. Phys. Chem. 30, 47 (1926).

The uncertainty assigned to the heat content up to 1000°K was 1 percent and this was increased to 2 percent at the melting point. Kelley's⁵⁶ equation was based primarily on the data of Lander³⁸⁸ (298° to 1177°K).

The heat capacity of liquid CaO was assumed to be 16.5 cal/°K gfw. The calculated thermodynamic functions for the condensed phases of CaO are given in Table LVI. The analysis of the heat-of-formation data in the literature was not completed at the time of report writing. Uncertainty estimates are summarized on the back of the Table.

c. Thermodynamic Properties of the Gaseous Phase

The thermodynamic functions of gaseous, molecular calcium oxide were calculated with the computer program based on the treatment of the diatomic molecule outlined in section III-E of this report. The spectroscopic constants used (in units of cm^{-1}) were taken from Hultin and Lagerqvist,³⁸⁹ and Lagerqvist.³⁹⁰

Constant	$X \cdot 10^3$	$A \cdot 10^3$	$B \cdot 10^3$	$C \cdot 10^3$

The thermodynamic functions of molecular CaO (gas) calculated with the above spectroscopic constants are given in Table LVII. It is not certain³⁹¹⁻³⁹³ that the ground state of CaO (g) is a singlet state. Therefore, uncertainties have not been determined for the present calculation pending further analysis of the effect of assuming other possible energy level schemes. Thermodynamic functions based on the assumption of the singlet ground state were also given by Kelley,⁵⁶ and Veits and Gurvich.³⁹⁴ $H_{298}^{\circ} - H_0^{\circ}$ was found to be 2,140 cal/mole.

The review of data for the heat of formation of CaO(g) was not completed at the time of report writing, and ΔH_f° , ΔF_f° , and $\log_{10} K_p$ could not be included.

3. Chromium Oxides

The compilation of thermodynamic data for both condensed and gaseous phases of the chromium oxides was in progress at the time of report writing. The thermodynamic functions for gaseous chromium dioxide (CrO_2) and gaseous chromium trioxide (CrO_3) were included in this report; the remainder will be reported later.

a. Chromium Dioxide (CrO_2)

No experimental spectroscopic data had been reported for gaseous chromium dioxide. All of the molecular constants required in the calculation of the thermodynamic functions of CrO_2 were therefore estimated. The thermodynamic functions for gaseous CrO_2 given in Table LVIII were calculated by means of the computer program described in section III-F with the following molecular data:

Molecular configuration

Symmetric nonlinear molecule with

$$\angle \text{O}-\text{Cr}-\text{O} = 107 \text{ deg.}$$

$$r_0 = 1.627 \text{ \AA}$$

Product of moments of inertia

$$I_A I_B I_C = 340637 \times 10^{-120} \text{ g}^3 \text{ cm}^6$$

Symmetry number

$$\sigma = 2$$

Fundamental frequencies

$$\omega_1 = 870 \text{ cm}^{-1}$$

$$\omega_2 = 388 \text{ cm}^{-1}$$

$$\omega_3 = 926 \text{ cm}^{-1}$$

Ground electronic state

$$^1\Sigma$$

1) Molecular configuration

The molecular configuration of CrO_2 was unknown. Consideration of the periodic group to which chromium belongs and the work of Walsh³⁹⁵ on bonding and structural relations led to the conclusion that CrO_2 was a symmetric, nonlinear molecule. Therefore, it was so considered in the present work. In the absence of experimental evidence, it is to be expected that some other workers would accept the alternative conclusion that it is linear symmetric. For example, the free-energy function of CrO_2 at several selected temperatures was recently calculated by Grimley, Burns, and Inghram³⁹⁶ on the assumption of Chandrasekharaiah and Brewer³⁹⁷ that the Group IV, V, and VI transition metal dioxides all form linear symmetric molecules. An O-Cr-O angle of 107 degrees was chosen in the present work as representing a reasonable value in comparison to known compounds of similar bonding. The Cr-O bond distance was assumed to be identical with the known corresponding distance for the chromium monoxide (CrO) molecule; i. e., 1.627 Å.³⁹⁸

2) Moments of inertia

The moments of inertia of CrO_2 were calculated from the above bond angles and bond distances by means of equations³⁹⁹ (168), (169), (170), and (171).

$$I_x = \left(\frac{2M_o M_{Cr}}{2M_o + M_{Cr}} \right) r_o^2 \cos^2 \left(\frac{\zeta}{2} \right) \quad (168)$$

$$I_y = 2M_o r_o^2 \sin^2 \left(\frac{\zeta}{2} \right) \quad (169)$$

$$I_z = I_x + I_y \quad (170)$$

$$I_A I_B I_C = I_x I_y I_z \quad (171)$$

³⁹⁵Walsh, A. D., J. Chem. Soc. 2266 (1953).

³⁹⁷Chandrasekharaiah, M. S. and L. Brewer, U.S. AEC Rept UCRL-8736 (April 1959).

³⁹⁸Ninomiya, M., J. Phys. Soc. (Japan) 10, 829 (1955).

³⁹⁹Moelwyn-Hughes, E. A., Physical Chemistry, Pergamon Press, London (1957).

where

M_o = mass of oxygen atom

M_{Cr} = mass of chromium atom

and r_o = Cr - O bond distance

ζ = O - Cr - O bond angle.

3) Fundamental frequencies

The estimation of the fundamental frequencies of CrO_2 was based on the following three assumptions:

a) The fundamental vibrations may be described by a valence force-field method.⁴⁰⁰

b) The stretching force constant (k_1) for CrO_2 is the same as that for CrO . This assumption has been employed by previous workers.^{396, 397} The stretching force constant for CrO was calculated from experimental spectroscopic data^{398, 401} by means of equation (172).

$$k_1 = 4\pi^2 c^2 \mu \omega^2, \quad (172)$$

where

k_1 = stretching force constant

c = velocity of light

μ = reduced mass of CrO molecule

and

ω = vibrational frequency.

c) The ratio of the bond-bending and bond-stretching force constants is 0.0940, the average of those observed for several nonlinear molecules.⁴⁰⁰

$$k_2/k_1 l^2 = 0.0940. \quad (173)$$

⁴⁰⁰ Herzberg, G., Molecular Spectra and Molecular Structure, II. Infrared and Raman Spectra of Polyatomic Molecules, Van Nostrand, N.Y. (1945).

⁴⁰¹ Brewer, L. and M. S. Chandrasekharan, U.S. AEC Rept. UCRL-8717 Rev. (June 1960).

The values of the fundamental frequencies (ω_1 , ω_2 , and ω_3) were therefore calculated from equations (174), (175), and (176).

$$\omega_3^2 = \frac{\left[1 + \frac{2M_o}{M_{Cr}} \sin^2 a\right] \frac{k_1}{M_o}}{0.3548 \times 10^{23}} \quad (174)$$

$$\omega_1^2 + \omega_2^2 = \frac{\left[1 + \frac{2M_o}{M_{Cr}} \cos^2 a\right] \frac{k_1}{M_o} + \frac{2}{M_o} \left[1 + \frac{2M_o}{M_{Cr}} \sin^2 a\right] \frac{k_\delta}{\lambda^2}}{0.3548 \times 10^{23}} \quad (175)$$

$$\omega_1^2 \omega_2^2 = \frac{2 \left[1 + \frac{2M_o}{M_{Cr}}\right] \frac{k_1}{M_o^2} \frac{k_\delta}{\lambda^2}}{0.1259 \times 10^{46}}, \quad (176)$$

where

$$a = \frac{\angle}{2} \quad (177)$$

4) Electronic states

The electronic states of CrO_2 were unknown. The general practice, when no data are available, of considering only the ground state and assuming it to be a $^1\Sigma$ state has been followed in this work. This procedure is simpler and is believed to be as correct as that used by other workers^{397, 401} who have estimated electronic levels from a crude ionic central atom model.

It should be emphasized that the thermodynamic functions of gaseous CrO_2 in Table LVIII represent "reasonable" estimates only; the numerical values could be appreciably altered should experimentally determined molecular constants become available for CrO_2 . $H_{298}^\circ - H_0^\circ$ was found to be 2,640 cal/mole.

b. Chromium Trioxide (CrO_3)

Experimental spectroscopic data also had not been reported for gaseous chromium trioxide. All of the molecular constants required in the calculation of the thermodynamic functions of CrO_3 were again estimated. The thermodynamic functions for gaseous CrO_3 given in Table LIX were also calculated by means of the machine program described in section III-F with the following molecular data:

Molecular configuration

Planar, symmetrical, cart-wheel molecule with

$\angle \text{O}-\text{Cr}-\text{O} = 120 \text{ deg.}$

$r_0 = 1.627 \text{ \AA}$

gfw = 100.01

Product of moments of inertia

$$I_A I_B I_C = 2346881 \times 10^{-120} \text{ g}^3 \text{ cm}^6$$

Symmetry number

$$\theta = 6$$

Fundamental frequencies

$$\omega_1 = 840 \text{ cm}^{-1}$$

$$\omega_2 = 397 \text{ cm}^{-1}$$

$$\omega_3 = 1023 \text{ cm}^{-1} (2)$$

$$\omega_4 = 347 \text{ cm}^{-1} (2)$$

Ground electronic state

$$1\Sigma$$

1) Molecular configuration

The molecular configuration of CrO_3 was unknown. The molecule was assumed to be of the symmetrical, planar, cart-wheel type. The only reasonable alternative structure was pyramidal, but the pyramidal structure was considered to be unlikely in view of the known planar structure of other molecules having central atoms in the same periodic group as chromium; e. g., SO_3 . The Cr - O bond distance was also assumed in this case to be identical with the known distance for the chromium monoxide (CrO) molecule; i. e., 1.627 Å.³⁹⁸

2) Moments of inertia

The moments of inertia of CrO_3 were calculated for the assumed structure by means of equations³⁹⁹ (170), (171), and (178).

$$I_{xx} = I_y = \frac{3M_o r_o^2}{2}, \quad (178)$$

where the symbols are as defined in section IV-B3a above.

3) Fundamental frequencies

The estimation of the fundamental frequencies of CrO_3 was based on the following assumptions:

- a) Assumption (a) in paragraph a(3) above for CrO_2 .
- b) The stretching force constant (k_1) for CrO_3 may be calculated from an estimated value for the corresponding frequency ω_1 according to equation (179).

$$k_1 = 0.3548 \times 10^{23} M_o \omega_1^2 \quad (179)$$

The value of ω_1 was estimated on the assumption that the CrO_3 molecule could be considered approximately a CrO_2 molecule ($\angle \text{O}-\text{Cr}-\text{O} = 120^\circ$) with an additional O atom attached. A value of ω_1^* corresponding to this pseudo-molecule was then calculated by the procedure described in the preceding section on the CrO_2 molecule.

The value 847 cm^{-1} was thus obtained for ω_1^* . It was then arbitrarily lowered to take into account the additional mass of the third oxygen atom. The final value for ω_1 was 840 cm^{-1} .

- c) The other force constants (k_Δ and k_δ) may be evaluated by averaging the ratios of force constants calculated from observed frequencies for several planar, symmetrical, cart-wheel molecules.⁴⁰⁰ These averages for CrO_3 were

$$k_\delta/k_1 l^2 = 0.0440 \quad (180)$$

$$k_\Delta/k_1 l^2 = 0.1160. \quad (181)$$

The values of the fundamental frequencies were then calculated from equations (182), (183), (184), and (185).

$$\omega_1^2 = \frac{k_1}{0.3548 \times 10^{23} M_o} \quad (182)$$

$$\omega_2^2 = \frac{\left[1 + \frac{3M_o}{M_{\text{Cr}}} \right] \left(\frac{1}{M_o} \right) \left(\frac{k_\Delta}{l^2} \right)}{0.3548 \times 10^{23}} \quad (183)$$

$$\omega_3^2 + \omega_4^2 = \frac{\left[1 + \frac{3M_O}{2M_{Cr}}\right] \left[\frac{k_1}{M_O} + \frac{3k_8}{M_O \lambda^2}\right]}{0.3548 \times 10^{23}} \quad (184)$$

$$\omega_3^2 \omega_4^2 = \frac{3 \left[1 + \frac{3M_O}{M_{Cr}}\right] \left(\frac{k_1}{M_O}\right) \left(\frac{k_8}{\lambda^2}\right)}{0.1259 \times 10^{46}} \quad (185)$$

4) Electronic states

The electronic states of CrO_3 were unknown. The general practice, when no data are available, of considering only the ground state and assuming it to be a $^1\Sigma$ state was also followed herein.

It should be emphasized here also that the thermodynamic functions for CrO_3 in Table LIX represent "reasonable" estimates only, and that the numerical values may be appreciably altered should experimental molecular constants become available for CrO_3 . $H_{298}^\circ - H_0^\circ$ was found to be 3,108 cal/mole.

4. Magnesium Oxide (MgO)

a. Crystal Structure and Melting Point

Crystalline magnesium oxide has a face-centered cubic (NaCl type) structure at room temperature,⁵⁷ which was assumed to persist up to the melting point. Engberg and Zehms³⁷⁸ found the coefficient of expansion to be practically constant from 1300° to 2300°K. The melting point of MgO has been given as 2913°K by Ebert and Cohn⁴⁰² from phase studies in the MgO-ZrO₂ system. However, it has been almost universally accepted as 3075°K. This latter value was given by Kanolt,³⁸⁶ Ruff and Schmidt,⁴⁰³ and Wartenberg, Reusch, and Saran,³⁸⁰ and was adopted here. An uncertainty of $\pm 50^\circ\text{K}$ was assigned to it.

b. Thermodynamic Properties of Condensed Phases

1) Heat of fusion

The heat of fusion of MgO was calculated by Kelley¹³⁷ to be 18.5 Kcal/gfw from melting-point measurements in the MgO-ZrO₂ system. This value, which gave a reasonable value of 6.0 cal/°K gfw for the entropy of fusion, was adopted and assigned an uncertainty of 1.5 Kcal/gfw.

2) Entropy and heat content at 298.15°K

The low-temperature heat capacity of MgO has been measured by Gunther¹⁴³ (21° to 84°K), Parks and Kelley³⁸⁷ (94° to 291°K), Giauque and Archibald⁴⁰⁴ (20° to 301°K), Barron, Berg, and Morrison⁴⁰⁵ (10° to 270°K), and Lien and Philips⁴⁰⁶ (1.5 to 4°K). The data of Giauque and Archibald,⁴⁰⁴ and Lien and Philips,⁴⁰⁶ were from microcrystalline samples, and those of the other authors were from macrocrystalline samples. Results for these two crystalline states of MgO differed appreciably. For purposes of this compilation, the macrocrystalline state was taken as the standard state and data for it alone were tabulated.

The National Bureau of Standards⁷⁸ joined the low-temperature data for the macroscopic solid phase with the unpublished data of Victor and Douglas (273° to 1173°K). The results of this analysis, which were accepted here, yielded a value for S_{298}° of 6.439 ± 0.020 cal/°K gfw and for $H_{298}^{\circ} - H_0^{\circ}$ of 1234.6 cal/gfw. Kelley¹³⁹ reported S_{298}° to be 6.4 ± 0.1 cal/°K gfw for macrocrystalline MgO.

3) High-temperature heat content

Results of the analysis of the unpublished data of Victor and Douglas by the National Bureau of Standards⁷⁸ was adopted for the high-temperature heat content of MgO. According to this analysis, the heat capacity of MgO from 450° to 1200°K in cal/°K gfw was given by equation (186).

$$C_p^{\circ} = 13.7146 - 4.494 \times 10^{-5}T - 1418/T . \quad (186)$$

The NBS report also stated that the enthalpies derived from this equation could be extrapolated from 1200° to 2100°K with an uncertainty of ± 2 percent. This uncertainty was presumably arrived at by comparison with Kelley's⁵⁶ tabulation. Kelley⁵⁶ derived equation (187) for the enthalpy in cal/gfw,

$$H_T^{\circ} - H_{298}^{\circ} = 10.18T + 0.87 \times 10^{-3}T^2 + 1.48 \times 10^5/T - 3609 . \quad (187)$$

from the data of Magnus⁴⁰⁷ (288° to 1040°K) and Wilkes⁴⁰⁸ (303° to 2073°K). The enthalpies tabulated by the NBS are from 1 to 5 percent higher than those given by Kelley,⁵⁶ with the maximum difference in the range from 700° to 800°K.

The heat capacity of liquid MgO was assumed to be 14.6 cal/°K gfw.

Thermodynamic functions of the condensed phases of MgO are given in Table LX. Analyses of heat-of-formation data had not been completed at the time of report writing. Uncertainly estimates are summarized on the back of the table.

⁴⁰⁷Magnus, A., Phys. Z. 14, 5 (1913).

⁴⁰⁸Wilkes, G.B., J. Am. Ceram. Soc. 15, 72 (1932).

c. Thermodynamic Properties of the Ideal Molecular Gas

The thermodynamic functions of MgO gas were calculated with the computer program based on the treatment of the diatomic molecule outlined in section III-E of this report. The spectroscopic constants

for the assumed $^1\Sigma$ ground state given by the National Bureau of Standards⁷⁸ were used. These constants had been corrected to those appropriate for the naturally occurring isotopic mixture. Spectro-

scopic constants for the A $^1\Pi$ and B $^1\Sigma$ states were taken from

Herzberg.⁵⁴ Values of D_e for the excited states were estimated from Dunham's equations.^{53, 54} Other electronic states of higher energy were listed by Herzberg,⁵⁴ but their positions with respect to the assumed ground state were not known. The constants used (in units of cm^{-1}) were as follows:

Constant	$X^1\Sigma$	$A^1\Pi$	$B^1\Sigma$
E	0	3494.4	20004.7
ω_e	782.84	664.4	824.1
$\omega_e x_e$	5.15	3.91	4.76
$\omega_e y_e$	---	---	---
B_e	0.5711	0.5056	0.5822
a_e	0.005	0.0046	0.0045
γ_e	---	---	---
$D_e (\times 10^6)$	1.22	1.2	1.2
g	1	2	1

$\cdot H_{298}^{\circ} - H_0^{\circ}$ was calculated to be 2129.2 cal/gfw.

The results of all the computations are given in Table LXI. The National Bureau of Standards⁷⁸ has reported thermodynamic functions for gaseous MgO from spectroscopic constants for the ground state alone. Veits and Gurvich³⁹⁴ used essentially the same constants as those adopted here to calculate thermodynamic functions up to 3500°K.

The calculations leading to Table LXI are subject to the same uncertainties as encountered with similar calculations discussed previously for BeO and CaO in sections IV - B1 and IV - B2, respectively, of this report. It is not certain that the lowest state of the observed singlet systems is the ground state. If one were to adopt the energy level diagram of MgO(g) given by Brewer and Porter³⁹¹

in which the ground state was postulated to be the $^3\Sigma$ state (with an adjacent $^3\Pi$ state) and to make reasonable estimates of spectroscopic constants of the triplet states, the free-energy functions at 298.15° and 6000°K would change from 50.960 and 70.453 cal/°K gfw, respectively (as tabulated in Table LXI), to 55.143 and 73.060 cal/°K gfw, respectively. However, the interpretation of the ultraviolet bands on which Brewer and Porter's³⁹¹ energy-level diagram was based is itself not certain as those bands may have been due to MgOH or a polyatomic oxide.⁴⁰⁹ Analysis of the above uncertainties will therefore be a continuing activity.

The analysis of the heat-of-formation data of MgO(g) had not been completed at the time of report writing.

5. Molybdenum Oxides

The important oxides of molybdenum for which thermodynamic properties were available are molybdenum monoxide (MoO), molybdenum dioxide (MoO_2) and molybdenum trioxide (MoO_3). Although polymeric species of MoO_3 ; i. e., $(\text{MoO}_3)_2$, $(\text{MoO}_3)_3$, etc., are known to exist, there were insufficient basic data to permit the calculation of thermodynamic tables for them.

a. Molybdenum Monoxide (MoO)

Molybdenum monoxide does not appear to exist in the condensed phase,²⁶⁴ but its existence in the vapor phase at high temperatures has been verified by mass spectrographic work.⁴¹⁰ Consequently, only the thermodynamic functions for gaseous MoO in Table LXII were prepared for the present compilation.

These thermodynamic functions were calculated by means of the computer program described in section III-F with the following estimated molecular data:

Bond distance

$$r_0 = 1.73 \text{ \AA}.$$

Moment of inertia

$$I = 68.139 \times 10^{-40} \text{ g cm}^2.$$

Symmetry number

$$\sigma = 1.$$

Fundamental frequency

$$\omega = 840 \text{ cm}^{-1}.$$

Ground electronic state

$$^1\Sigma$$

1) Bond distance

The Mo-O bond distance had not been experimentally determined. A value of 1.66 $\text{\AA}$ has been calculated⁴¹⁰ by means of the

⁴¹⁰DeMaria, G., R. Burns, J. Drowart, and M. Inghram, J. Chem. Phys. 32, 1373 (1960).

Guggenheimer relation⁴¹¹ and the estimated fundamental frequency of Swaminathan and Krishnamurty.⁴¹² A value of 1.73 Å has also been estimated by Brewer and Chandrasekharaiah⁴¹³ who interpolated between values for the monoxides of transition metals. The 1.73 Å value was chosen for the present work.

2) Moment of inertia

The moment of inertia, I , was calculated from the above assumed value for the Mo-O bond distance by means of equation (188),

$$I = \mu r_o^2 = \left(\frac{M_{Mo} M_o}{M_{Mo} + M_o} \right) r_o^2, \quad (188)$$

wherein

μ = reduced mass

M_{Mo} = mass of molybdenum atom

M_o = mass of oxygen atom

and

r_o = Mo-O bond distance.

3) Fundamental frequency

The fundamental frequency, ω , of MoO had not been accurately determined. An approximate bond analysis by Swaminathan and Krishnamurty⁴¹² yielded a value of 950 cm⁻¹. However, Brewer and Chandrasekharaiah⁴¹³ estimated this value to be 840 cm⁻¹. The value of 840 cm⁻¹ was chosen for the present work as being more in accord with the postulate that the bonding in CrO is similar to that in MoO. Mass effects alone ($M_{Mo} > M_{Cr}$) would therefore indicate the choice of a lower fundamental frequency for MoO than for CrO. In view of the large uncertainty associated with the value of ω , no attempt was made to take into account anharmonicity effects and interaction terms. The thermodynamic functions given in Table LXII therefore apply to a rigid rotator-harmonic oscillator model.

⁴¹²Swaminathan, T.M. and S.G. Krishnamurty, Current Sci. 23, 258 (1954).

⁴¹³Brewer, L. and M.S. Chandrasekharaiah, U.S. AEC Rept. UCRL-8713 Rev. (June 1960).

4) Electronic states

The electronic states of MoO were unknown. The general practice, when no data are available, of considering only the ground state and assuming it to be a $^1\Sigma$ state was followed in this work. This procedure is simpler and is believed to be as correct as that used by other workers^{410, 413} who have estimated electronic levels from a crude ionic central atom model.

The standard heat of formation of gaseous MoO at 298.15°K, ΔH_{298}° , had not been directly determined. It was therefore determined by indirect methods. DeMaria and co-workers,⁴¹⁰ in a mass spectrographic study of Al₂O₃ using Mo crucibles, measured the partial pressures of MoO and monatomic oxygen in equilibrium with solid Mo at several temperatures in the range from 2200° to 2500°K. These measured pressures were used to obtain values for the equilibrium constant (K) of reaction (189).

$$K = \frac{P_{\text{MoO}_{(g)}}}{P_{\text{O}_{(g)}}} \quad (190)$$

The standard free-energy change, ΔF° , for this reaction at the several temperatures was evaluated by means of equation (191).

$$\Delta F^\circ = -RT \ln K_p \quad (191)$$

The value of ΔH_{298}° for reaction (189) was then obtained by means of equation (192).

$$\frac{\Delta H_{298}^\circ}{T} = \frac{\Delta F^\circ}{T} - \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{MoO}_{(g)}} + \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{Mo}_{(s)}} + \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{O}_{(g)}} \quad (192)$$

The values of the free-energy functions for $\text{MoO}_{(g)}$, $\text{Mo}_{(s)}$, and $\text{O}_{(g)}$ were taken from Tables LXII, XXVIII, and XXV of this report. A value for ΔH_{298}° was calculated at each temperature for which DeMaria and co-workers⁴¹⁰ reported measured pressures. The average of all the ΔH_{298}° values was combined with the ΔH_{298}° of dissociation of oxygen gas (O_2) to yield the heat of formation of gaseous MoO in accordance with the reaction scheme

The value of the heat of formation so obtained was 87400 ± 5000 cal/gfw. The value of $H_{298}^\circ - H_0^\circ$ for MoO was found to be 2116 cal/gfw.

The values of ΔH_f° , ΔF_f° , and $\log_{10} K_p$ were then evaluated from the value of ΔH_{f298}° and equations (44), (196) and (197).

$$\Delta H_f^\circ = \Delta H_{f298}^\circ + (H_T^\circ - H_{298}^\circ)_{\text{MoO}_{(g)}} - (H_T^\circ - H_{298}^\circ)_{\text{Mo}_{(s)}} - \frac{1}{2}(H_T^\circ - H_{298}^\circ)_{\text{O}_{2(g)}} \quad (196)$$

$$\Delta F_f^\circ = \Delta H_{f298}^\circ + (F_T^\circ - H_{298}^\circ)_{\text{MoO}_{(g)}} - (F_T^\circ - H_{298}^\circ)_{\text{Mo}_{(s)}} - \frac{1}{2}(F_T^\circ - H_{298}^\circ)_{\text{O}_{2(g)}} \quad (197)$$

The statement concerning the approximate nature of the functions for CrO_2 and CrO_3 in Tables LVIII and LIX also applies to those for MoO in Table LXII.

b. Molybdenum Dioxide (MoO_2)

1) Solid state

Thermodynamic properties of solid MoO_2 , based on the low-temperature heat capacity measurements of King,⁴¹⁴ the high-temperature enthalpy data of King, Weller, and Christensen,⁴¹⁵ and the heat-of-formation data of Mah⁴¹⁶ have been reported.

⁴¹⁵King, E.G., W.W. Weller, and A.V. Christensen, U.S. Bur. Mines Rept. Inv. 5664 (1960).

⁴¹⁶Mah, A.D., J. Phys. Chem. 61, 1572 (1957).

The only experimental investigation of the low-temperature heat capacity of MoO_2 was that of King⁴¹⁴ which extended from 53° to 296°K. The value of $S_{298.15}^\circ$ obtained from these experimental data was 11.06 ± 0.05 e. u. /gfw.

King, Weller, and Christensen⁴¹⁵ had reported the only experimental enthalpy values for MoO_2 at high temperatures (400° to 1800°K). The enthalpy functions for solid MoO_2 in Table LXIII are accordingly the smoothed values reported by King and co-workers⁴¹⁵ after extrapolation to 2000°K and to room temperature.

The tabular entropy values for solid MoO_2 were calculated from the enthalpy functions by the method of Kelley.⁵⁶

Values for the free-energy function were calculated from equation (108). Tabular values of C_p° (in cal/°K gfw) were calculated from equation (198) due to King and co-workers.⁴¹⁵

$$C_p^\circ = 14.11 + 5.82 \times 10^{-3}T - 2.18 \times 10^{-5}T^{-2} \quad (198)$$

MoO_2 does not exhibit a true melting point since disproportionation occurs to yield solid Mo and MoO_3 vapor (including MoO_3 polymeric species) before melting occurs.^{417, 418}

The standard heat of formation, ΔH_{f298}° of solid MoO_2 was recently determined by Mah⁴¹⁶ from experimental measurements of the heat of combustion of $\text{Mo}_{(s)}$ to $\text{MoO}_3(s)$ and of $\text{MoO}_{2(s)}$ to $\text{MoO}_3(s)$. These measurements led directly to the heat of formation of $\text{MoO}_{2(s)}$. Mah obtained a value for ΔH_{f298}° of -140640 ± 130 cal/gfw, and after critical comparison of this value with earlier values,⁴¹⁹⁻⁴²³ recommended a value of -140800 ± 200 cal/gfw. This recommended value was accepted in the present compilation.

Values of ΔH_f° , ΔF_f° and $\log_{10} K_p$ were calculated from equations (44), (199), and (200).

$$\Delta H_f^\circ = \Delta H_{f298}^\circ + (H_T^\circ - H_{298}^\circ)_{\text{MoO}_2(s)} - (H_T^\circ - H_{298}^\circ)_{\text{Mo}(s)} - (H_T^\circ - H_{298}^\circ)_{\text{O}_2(g)} \quad (200)$$

2) Gaseous Phase

No experimental spectroscopic data had been reported for gaseous MoO_2 . All of the molecular constants required in the calculation of its thermodynamic functions were therefore estimated. The thermodynamic functions for gaseous MoO_2 given in Table LXIV were calculated by means of the machine program described in section III-F with the following molecular data:

Molecular configuration

Symmetric, nonlinear molecule with

$$\angle \text{O-Mo-O} = 107^\circ$$

$$r_0 = 1.73 \text{ \AA}$$

Product of moments of inertia

$$I_A I_B I_C = 628260 \times 10^{-120} \text{ g}^3 \text{ cm}^6$$

Symmetry number

$$\sigma = 2$$

Fundamental frequencies

$$\omega_1 = 824 \text{ cm}^{-1}$$

$$\omega_2 = 367 \text{ cm}^{-1}$$

$$\omega_3 = 857 \text{ cm}^{-1}$$

Ground electronic state

$$^1\Sigma$$

a) Molecular configuration

The molecular configuration of MoO_2 was unknown. Consideration of the periodic group to which molybdenum belongs and the work of Walsh³⁹⁵ on bonding and structural relations led to the conclusion that MoO_2 is a symmetric, nonlinear molecule. It therefore was so considered in the present work. DeMaria and co-workers⁴¹⁰ also assumed it to have a nonlinear structure, whereas Chandrasekharaiah and Brewer³⁹⁷ assumed it to have the linear structure of all of the Group IV, V, and VI transition metal dioxides.

An O-Mo-O angle of 107 degrees was chosen in the present work as representing a reasonable value in comparison with known compounds of similar bonding.

The Mo-O bond distance was assumed to be identical to the estimated corresponding distance for the molybdenum monoxide (MoO) molecule; i. e., $1.73\text{\AA}$.

b) Moments of inertia

The moments of inertia of MoO_2 were calculated in a manner analogous to that used for the corresponding CrO_2 molecule.

c) Fundamental frequencies

The fundamental frequencies of MoO_2 were estimated by the same method used for the corresponding CrO_2 molecule (see section IV-B3a above), except that the stretching force constant for MoO was calculated from estimated spectroscopic data.⁴¹³ The frequencies so obtained are somewhat lower than those estimated by DeMaria and co-workers.⁴¹⁰

d) Electronic states

The electronic states for MoO_2 were treated in the same manner as those of the CrO_2 molecule.

The standard enthalpy of formation, ΔH_{298}° , of gaseous MoO_2 had not been directly determined but could be indirectly evaluated by two different calculations. The first calculation was based on results of the mass spectrographic study of Al_2O_3 reported by DeMaria and co-workers⁴¹⁰ using molybdenum crucibles. These workers measured the partial pressures of MoO_2 and monatomic oxygen in equilibrium with solid molybdenum at several temperatures

in the range from 2200° to 2500°K. From these pressures, the equilibrium constant, K, in equation (202) and the standard free energy change, ΔF° , for reaction (201) could be calculated

$$K = \frac{P_{\text{MoO}_{2(g)}}}{P_{\text{O}_{(g)}}^2} \quad (202)$$

as explained in the preceding section of the report concerning MoO.

A value of ΔH_{298}° for the above reaction at each temperature for which measured pressures were reported was then calculated by the Third Law Method, which assumes the form of equation (203).

$$\frac{\Delta H_{298}^\circ}{T} = \frac{\Delta F^\circ}{T} - \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{MoO}_{2(g)}} + \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{Mo}_{(s)}} + 2 \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{O}_{(g)}} \quad (203)$$

The values of the free-energy functions for $\text{MoO}_{2(g)}$, $\text{Mo}_{(s)}$, and $\text{O}_{(g)}$ were taken from Tables LXIV, XXVIII, and XXV of this report. The average of all the ΔH_{298}° values for reaction (201) was then combined with the ΔH_{298}° of dissociation of oxygen gas (O_2) to yield the heat of formation of gaseous MoO_2 in accordance with the reaction scheme

The first value of the heat of formation of MoO_2 gas so obtained was 5380 ± 4500 cal/gfw at 298.15°K.

The second calculation was based on results of the mass spectrographic study of the gaseous species in equilibrium with solid MoO_2 reported by Burns and co-workers.⁴¹⁸ Partial pressures of $\text{MoO}_{2(g)}$ in equilibrium with $\text{MoO}_{2(s)}$ were reported at several temperatures in the range from 1560° to 1780° K. From these measured pressures, the standard free-energy change, ΔF° , for the sublimation of MoO_2 as in reaction (207) could be calculated at each temperature.

by means of equation (208),

$$\Delta F^\circ = -RT \ln P_{\text{MoO}_{2(g)}} \quad (208)$$

values of ΔH_{298}° corresponding to each calculated ΔF° value were then calculated from equation (129).

The values of the free-energy function used for $\text{MoO}_{2(s)}$ and $\text{MoO}_{2(g)}$ were taken from Tables LXIII and LXIV of this report. The average of all values of ΔH_{298}° for reaction (207) was combined with the heat of formation of solid MoO_2 to yield the heat of formation of gaseous MoO_2 in accordance with the reaction scheme at 298.15°K .

The second value of the heat of formation of MoO_2 gas so obtained was -5700 ± 2000 cal/gfw. The average of the two values, after rounding off to the nearest hundred calories, was -200 ± 6000 cal/gfw. The value of $H_{298}^\circ - H_0^\circ$ for $\text{MoO}_{2(g)}$ was found to be 2670 cal/gfw.

Values of ΔH_f° , ΔF_f° , and $\log_{10} K_p$ were calculated by methods already described.

c. Molybdenum Trioxide (MoO_3)

1) Condensed phase

a) Melting point and heat of fusion

The melting point of MoO_3 had been determined by Hoermann⁴²⁴ (1068°K), Cosgrove and Snyder⁴²⁵ (1068°K), Babadzhan⁴²⁶ (1070°K), and King, Weller, and Christensen⁴¹⁵ (1074°K). The average value of $1070^\circ \pm 5^\circ\text{K}$ was adopted for the present compilation.

The heat of fusion, as determined from enthalpy values of the solid and liquid at the melting point, was 11,683 cal/gfw. An uncertainty of 500 cal/gfw was arbitrarily assigned to this heat of fusion. The ΔH value is almost identical to that reported by King, Weller, and Christensen⁴¹⁵ (11,690 cal/gfw), but appreciably lower than the value reported by Cosgrove and Snyder⁴²⁵ (12,540 cal/gfw).

b) Boiling point

The equilibrium vapor above MoO_3 consists primarily of $(\text{MoO}_3)_3$, $(\text{MoO}_3)_4$, and $(\text{MoO}_3)_5$ according to Berkowitz, Inghram, and Chupka.⁴²⁷ Evidence for the existence of polymeric MoO_3 vapor species is also furnished by the work of Blackburn, Hoch, and Johnston,⁴¹⁷ Babadzhan,⁴²⁶ and of Zelikman, Gorovits, and Prosenkova.⁴²⁸ No attempt has been made in the present work to define a boiling point for MoO_3 . A temperature of about 1450°K had been quoted²⁶⁴ as the temperature at which the total pressure above MoO_3 becomes one atmosphere. No attempt was made to estimate thermodynamic functions for these polymeric vapor species because of the lack of basic data.

⁴²⁸Zelikman, A. N., N. N. Gorovits, and T. E. Prosenkova, Zhur. Neorg. Khim. 1, 632 (1956).

c) Entropy at 298.15° K (S_{298}°)

Kelley and King³¹⁸ recommended 18.58 ± 0.10 e. u. / gfw as the value of S_{298}° for MoO_3 . This value was based on the low-temperature heat capacity measurements of Seltz, Dunkerley, and DeWitt,⁴²⁹ and of Smith, Brown, Dworkin, Sasmor, and Van Artsdalen.⁴³⁰

d) Thermodynamic functions for the condensed state

Enthalpy measurements by dropping methods have been reported by Cosgrove and Snyder⁴²⁵ (300° to 1300°K) and by King, Weller, and Christensen⁴¹⁵ (400° to 1400°K). The results of the latter workers were arbitrarily chosen for this compilation. The results reported by Cosgrove and Snyder⁴²⁵ were about 2 percent higher than the former results.

The C_p° values (in cal/°K gfw) for solid MoO_3 from 298.15°K to the melting point (1070°K) given in Table LXV were calculated by means of equation (212) given by King, Weller and Christensen.⁴¹⁵

$$C_p^{\circ} = 17.97 + 7.80 \times 10^{-3}T - 2.10 \times 10^{-5}T^{-2}. \quad (212)$$

The derived equations used to calculate the enthalpy and entropy functions for solid MoO_3 were

$$H_T^{\circ} - H_{298}^{\circ} = 17.97T + 390.0 \times 10^{-5}T^2 + 2.10 \times 10^5 T^{-1} - 6409 \quad (213)$$

$$S_T^{\circ} = 17.97 \ln T + 7.80 \times 10^{-3}T + 1.05 \times 10^5 T^{-2} - 87.313. \quad (214)$$

Values for the free-energy function were calculated by means of equation (108).

The heat capacity of liquid MoO_3 was reported to be constant at 30.20 cal/°K gfw by King and co-workers.⁴¹⁵ This value was chosen in the present work in preference to the rather

unexpected values reported by Cosgrove and Snyder.⁴²⁵

$H_T^\circ - H_{298}^\circ$, S_T° , and $-\left(\frac{F_T^\circ - H_{298}^\circ}{T}\right)$ for liquid MoO_3 were then calculated by means of equations (215), (216), and (108).

$$H_T^\circ - H_{298}^\circ = 30.20T - 3150 \quad (215)$$

$$S_T^\circ = 30.20 \ln T - 153.265. \quad (216)$$

e) Standard heat of formation at 298.15°K (ΔH_{f298}°)

The standard heat of formation, ΔH_{f298}° , of solid MoO_3 was recently determined by Mah,⁴¹⁶ from experimental measurements of the heat of combustion of $\text{Mo}_{(s)}$ to $\text{MoO}_{3(s)}$, to be $-178,160 \pm 110$ cal/gfw. From a comparison of this value with that of earlier workers,^{419,420,431-433} Mah⁴¹⁶ chose a "recommended" value of $-178,100 \pm 100$ cal/gfw. This "recommended" value was adopted in the present compilation.

The values of ΔH_f° , ΔF_f° , and $\log_{10} K_p$ were then calculated according to equations (217), (218), and (44).

$$\begin{aligned} \Delta F_f^\circ = & \Delta H_{f298}^\circ + (F_T^\circ - H_{298}^\circ)\text{MoO}_{3(c)} - (F_T^\circ - H_{298}^\circ)\text{Mo}_{(s)} \\ & - 3/2(F_T^\circ - H_{298}^\circ)\text{O}_{2(g)} \end{aligned} \quad (217)$$

$$\begin{aligned} \Delta H_f^\circ = & \Delta H_{f298}^\circ + (H_T^\circ - H_{298}^\circ)\text{MoO}_{3(c)} - (H_T^\circ - H_{298}^\circ)\text{Mo}_{(s)} \\ & - 3/2(H_T^\circ - H_{298}^\circ)\text{O}_{2(g)}. \end{aligned} \quad (218)$$

2) Gaseous phase

No experimental spectroscopic data had been reported for gaseous MoO_3 . All of the molecular constants required in the calculation of the thermodynamic functions were therefore estimated. The thermodynamic functions for gaseous MoO_3 given in Table LXVI were calculated by means of the machine program described in section III-F with the following molecular data:

⁴³¹Delepine, M., Bull. Soc. Chim. 29, 1166 (1903).

⁴³²Moose, J. E. and S. W. Paar, J. Am. Chem. Soc. 46, 2656 (1924).

⁴³³Newmann, B., C. Kroger, and H. Kunz, A. anorg. u. allgem. Chem. 218, 379 (1934).

Molecular configuration

Planar, symmetrical, cart-wheel molecule with

$$\angle \text{O} - \text{Mo} - \text{O} = 120 \text{ deg.}$$

$$r_{\text{O}} = 1.73 \overset{\circ}{\text{\AA}}.$$

Product of moments of inertia

$$I_A I_B I_C = 3392032 \times 10^{-120} \text{ g}^3 \text{ cm}^6.$$

Symmetry number

$$\theta = 6.$$

Fundamental frequencies

$$\omega_1 = 800 \text{ cm}^{-1}$$

$$\omega_2 = 344 \text{ cm}^{-1}$$

$$\omega_3 = 897 \text{ cm}^{-1} (2)$$

$$\omega_4 = 317 \text{ cm}^{-1} (2).$$

Ground electronic state

$$^1 \Sigma$$

These molecular constants were estimated by the procedures employed in the case of the corresponding CrO_3 molecule (see section IV-B3b). The Mo-O bond distance was assumed to be the same as the estimated distance for the corresponding bond in MoO^{413} ; i. e., $1.73 \overset{\circ}{\text{\AA}}$.

The standard enthalpy of formation, ΔH_{f298}° , of gaseous MoO_3 had not been directly determined but could be indirectly evaluated by two calculations similar to those described in connection with MoO_2 ; see section IV-B5c(2).

The first calculation was based on the mass spectrographic study of Al_2O_3 reported by DeMaria and co-workers⁴¹⁰ using molybdenum crucibles. These workers measured the partial pressures of MoO_3 and monatomic oxygen in equilibrium with solid molybdenum at

several temperatures in the range from 2200° to 2500°K. From the partial pressures of these workers, the equilibrium constant, K , and the standard free-energy change, ΔF° , for reaction (219) could be evaluated

$$K = \frac{P_{\text{MoO}_{3(g)}}}{P_{\text{O}_{(g)}}^3} \quad (220)$$

as explained in section IV-B5a for the case of MoO .

A value of ΔH_{298}° for the above reaction was calculated at each temperature for which a measured pressure was reported by the Third Law Method as explained in section IV-B5a which takes the form of equation (221).

$$\frac{\Delta H_{298}^\circ}{T} = \frac{\Delta F^\circ}{T} - \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{MoO}_{3(g)}} + \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{Mo}_{(s)}} + 3 \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{O}_{(g)}} \quad (221)$$

The values of the free-energy functions for $\text{MoO}_{3(g)}$, $\text{Mo}_{(s)}$ and $\text{O}_{(g)}$ were taken from Tables LXVI, XXVIII, and XXV of this report. The average value of ΔH_{298}° was then combined with the heat of dissociation of oxygen gas (O_2) to yield the heat of formation of gaseous MoO_3 , in accordance with the reaction scheme at 298.15°K

The first value of the heat of formation so obtained was $-77,100 \pm 3000$ cal/gfw at 298.15°K.

Likewise the second calculation was based on the mass spectrographic study of the gaseous species above solid MoO_2 reported by

Burns and co-workers.⁴¹⁸ Partial pressures of $\text{MoO}_3(\text{g})$ in equilibrium with $\text{MoO}_2(\text{s})$ and $\text{Mo}(\text{s})$ were reported at several temperatures in the range from 1560° to 1780°K . From these measured pressures, the standard free-energy change, ΔF° , at each temperature was calculated for reaction (225)

by methods already described in connection with MoO and MoO_2 . Values of ΔH_{298}° corresponding to each calculated ΔF° value calculated by means of equation (226).

$$\begin{aligned} \frac{\Delta H_{298}^\circ}{T} = \frac{\Delta F^\circ}{T} - \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{MoO}_3(\text{g})} - (1/2) \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{Mo}(\text{s})} \\ + (3/2) \left(\frac{F_T^\circ - H_{298}^\circ}{T} \right)_{\text{MoO}_2(\text{s})} \end{aligned} \quad (226)$$

The values of the free-energy functions used for $\text{MoO}_3(\text{g})$, $\text{Mo}(\text{s})$ and $\text{MoO}_2(\text{s})$ are given in Tables LXVI, XXVII, and LXIII of this report. The average of all the values of ΔH_{298}° for equation (225) was then combined with the heat of formation of solid MoO_2 to yield the heat of formation of gaseous MoO_3 , in accordance with the reaction scheme at 298.15°K ,

The second value of the heat of formation so obtained was $-84,900 \pm 1000 \text{ cal/gfw}$.

The average of the values obtained by two different methods for the heat of formation of gaseous MoO_3 was $-81,000 \pm 6000 \text{ cal/gfw}$. The value of $H_{298}^\circ - H_0^\circ$ for $\text{MoO}_3(\text{g})$ was found to be 3227 cal/gfw .

Values of ΔH_f° , ΔF_f° , and $\log_{10} K_p$ were calculated by methods previously described.

6. Strontium Oxide (SrO)

a. Crystal Structure and Melting Point

Strontium oxide has a face-centered cubic (NaCl type) structure⁵⁷ at room temperature which was assumed to persist to the melting point. The thermal expansion was measured by Beals and Cook³⁸⁴ up to 1500°K. The melting point of SrO was taken as 2690° ± 50°K from the results of Schumacher³⁸⁵ (corrected to the International Temperature Scale of 1948).

b. Thermodynamic Properties of the Condensed Phases

1) Heat of fusion

The heat of fusion of SrO was assumed to be 16.1 ± 1.4 Kcal/gfw from an estimated entropy of fusion of 5.985 ± 0.5 Kcal/°K gfw. Kubaschewski and Evans¹⁸² estimated the entropy of fusion to be 6.1 Kcal/°K gfw.

2) Entropy and heat content at 298.15°K

The low-temperature heat capacity of SrO was measured by Anderson.⁴³⁴ From these data, S_{298}^0 was calculated to be 13.060 ± 0.200 cal/°K gfw. $H_{298}^0 - H^0$ was found to be 2037.7 cal/gfw.

3) High-temperature heat content

The high-temperature heat content of SrO was measured by Lander³⁸⁸ (298° to 1266°K). Kelley⁵⁶ fitted Lander's data in cal/gfw to equation (230).

$$\frac{H^0}{T} - \frac{H_{298}^0}{298} = 12.13T + 0.63 \times 10^{-3}T^2 + 1.55 \times 10^5/T - 4192 \quad (230)$$

Equation (230) was adopted here and extrapolated to the melting point. An uncertainty of ± 3 percent was assigned to the enthalpy.

The heat capacity of liquid SrO was estimated to be 17.0 cal/°K gfw.

Thermodynamic functions of the condensed phases of SrO are given in Table LXVII. Analyses of the heat-of-formation data had not been completed at the time of report writing. Uncertainty estimates are summarized on the back of the table.

⁴³⁴Anderson, C. T., *J. Am. Chem. Soc.* 57, 429 (1935).

c. Thermodynamic Properties of the Ideal Molecular Gas

The thermodynamic functions of SrO gas were calculated with the computer program based on the treatment of the diatomic molecule outlined in section III-E of this report. The spectroscopic constants used for the electronic states (in units of cm^{-1}) were:

Constant	$X'^1\Sigma$	$A'^1\Sigma$	$B'^1\Pi$	$C'^1\Sigma$
E	0	10885.0	24004.0	28546.4
ω_e	653.47	619.6	520.0	480.2
$\omega_e x_e$	3.95	0.9	3.5	2.6
$\omega_e y_e$	---	---	---	---
B_e	0.3379	0.3047	0.2936	0.2742
a_e	0.0021	0.0011	0.0020	0.0021
γ_e	---	---	---	---
$D_e (\times 10^6)$	0.42	3.2	0.37	0.35
g	1	1	2	1

The above spectroscopic constants were not corrected to those appropriate for a naturally occurring isotopic mixture. Constants for the assumed ground state were from Kovacs and Budo,⁴³⁵ and were practically identical to those given by Lagerqvist and Selin.⁴³⁶ Constants for the A' state were from Almkvist and Lagerqvist.⁴³⁷ The data of Mahanti⁴³⁸ and Lagerqvist³⁹⁰ were used for the B' state, and those of Lagerqvist and Almkvist⁴³⁹ were used for the C' state. The results of the computation are given in Table LXVIII. $H^\circ_{298} - H^\circ_0$ was calculated to be 2160.9 cal/gfw. Veits and Gurvich³⁹⁴ tabulated thermodynamic functions of $\text{SrO}_{(g)}$ up to 3500°K using the first two electronic states

⁴³⁵Kovacs, I. and A. Budo, Ann. Physik 12, 17 (1953).

7. Titanium Borides

a. Titanium Diboride

The available data on the thermodynamics of titanium diboride have been reviewed, and work was started on the preparation of tables of thermodynamic functions.

The value of the heat of formation of TiB_2 has been subject to considerable uncertainty. The following values which range from -72 to -32 Kcal/mole have been reported:

Reference	ΔH_{f298}° (Kcal/mole)
Brewer and Haraldsen ⁴⁴⁰	-72
Samsonov ^{441, 442}	-70
Schissel and Williams ¹²⁰	-32
Williams ⁴⁴³	~ -50

Studies of the heat capacity had also been made, and reports containing C_p° data in the temperature range from 300° to 1200°K were available. However, additional data were necessary at high temperatures, and determinations were instituted in Phase III of this project. The latter work is discussed in section V-B.

Investigators	Temperature Range (°K) for Available C_p° Data
Margrave, <u>et al</u> ⁴⁴⁴	420-1180
Krestovnikov and Vendrikh ⁴⁴⁵	300-1000
Walker, Ewing, and Miller ⁴⁴⁶	303-977
Ihnat (section V-B of this report)	Up to 2400
Pears, <u>et al</u> ⁴⁴⁷	Up to destruction temperature

⁴⁴⁷Pears, C.D. and S. Oglesby, The Thermophysical Properties of Refractory Materials from 2000°F to Their Destruction Temperatures, Southern Research Inst. Quart. Rept. 2, for WADD AF33(616)-7319 (November 1960).

Final calculations of thermodynamic functions were postponed temporarily until more high-temperature heat capacity data become available because of uncertainties encountered in extrapolating existing data to high temperatures. It was also considered worthwhile to review carefully the literature that has been uncovered for other thermochemical data that might be used in obtaining a better estimate of the heat of formation.

b. Other Borides (Ti_2B , TiB , and Ti_2B_5)

1) Physical property and structural data

In the Ti-B system there are several phases of somewhat lower stability than TiB_2 which are known. Hansen and Anderko²¹³ have given much of the basic physical property and structural data on these compounds.

a) Ti_2B

The compound Ti_2B was reported to have a tetragonal structure. Its temperature range of stability was in some doubt but was considered to be in the range from 1800° to 2200°C.

b) TiB

Conflicting data existed for the crystal structure of TiB . The reported structures were a cubic structure of the zinc blende type, a cubic structure of the NaCl type, and an orthorhombic structure of the FeB type. The compound has been considered to be stable from room temperature up to ~2060°C.

c) Ti_2B_5

Ti_2B_5 is reported to be hexagonal with a structure isotypic with that of W_2B_5 . No actual melting point data have been presented for this compound, but the melting point appears to be lower than that of TiB_2 .

2) Thermodynamic data

Brewer and Haraldsen⁴⁴⁰ have discussed the titanium boride compounds and set limits for their heats of formation. However, there were insufficient data available in general for thermodynamic function calculations to be undertaken.

8. Titanium Carbide (TiC)

Titanium carbide has long been used as a tool material because of its characteristic hardness. Its high-temperature stability and its low density have made it very useful for many high-temperature applications. Typical uses have been discussed by Schwarzkopf and Kieffer.⁴⁴⁸

There have been several recent thermodynamic property compilations which included tables of data^{75, 449, 450} for titanium carbide. However, experimental data have been reported since then which could affect these tables markedly. For example, Fujishiro and Gokcen⁴⁵¹ have reported vaporization experiments yielding a heat of formation for TiC of $\Delta H_{f298}^{\circ} = -31,333$ cal/gfw, whereas the earlier combustion experiments of Humphrey⁴⁵² (used in the aforementioned tabulations) yielded a value of $\Delta H_{f298}^{\circ} = -43,800$ cal/gfw.

The heat of formation of TiC is of considerable interest because of its usefulness in checking the heat of sublimation of Ti, which is uncertain, and because it can be used to evaluate the data of other refractories such as the titanium borides. It was therefore felt that a particularly careful evaluation of the heat of formation of TiC should be made. This evaluation was not complete at the time of report writing. Therefore, it was only possible to include the partial summary presented below.

a. Heat of Formation

1) Direct determinations

Fujishiro and Gokcen's⁴⁵¹ and Humphrey's⁴⁵² heats of formation of TiC given above appeared to be the only directly measured values reported.

2) Equilibrium data based on the reduction of TiO₂

The older work of Brantley and Beckman⁴⁵³ has been often referred to as a source of thermochemical data for TiC. Those authors

⁴⁴⁸Schwarzkopf, P. and R. Kieffer, Refractory Hard Metals, Macmillan, N.Y. (1953).

⁴⁴⁹Beckett, C.W. et al., Preliminary Report on the Thermodynamic Properties of Selected Light Element Compounds, Nat. Bur. Stds. Rept. 6928 (1 July 1960).

⁴⁵⁰Elliott, J.F. and M. Gleiser, Thermochemistry for Steel-making, vol. I., Addison-Wesley, Reading, Mass. (1960).

⁴⁵¹Fujishiro, S. and N. Gokcen, J. Phys. Chem., 65, 161 (1961).

⁴⁵²Humphrey, G.L., J. Am. Chem. Soc., 73, 2261 (1951).

⁴⁵³Brantley, L.R. and A.O. Beckman, J. Am. Chem. Soc., 52, 3956 (1930).

determined the equilibrium pressure of CO in a system which initially contained TiO_2 and C at temperatures from 1278° to 1428°K. They felt that reaction (231) was the one occurring.

Richardson⁴⁵⁴ attempted to interpret their data but found it to yield free energies of formation equal to -64,500 cal/gfw at 1200° K and -54,480 cal/gfw at 1400° K. He concluded that their data must be in error or needed to be interpreted differently.

A more specific criticism of the Brantley and Beckman⁴⁵³ work was made by Meerson and Krein⁴⁵⁵ who stated that reaction (232) should be the final step.

Furthermore, they pointed out that TiO and TiC form a continuous series of solid solutions.

Kutsev and Ormont⁴⁵⁶ also conclude from high-temperature reduction studies in the range from 1880° to 2600°K that TiC and TiO form solid solutions. They stated that only three phases exist at equilibrium (i. e., TiC_xO_y , C, and CO) at the temperatures and pressures of their experiments although they suggested that the existence of a fourth-phase (Ti_2O_3) might be possible at lower temperatures.

Because Brantley and Beckman⁴⁵³ claimed to have identified TiO_2 in their equilibrium mixture, their paper was carefully reviewed. X-ray diagrams were reproduced in their figure 5. From an examination of this figure, it appeared that the observed lines could be ascribed to TiC and graphite and the existence of TiO_2 in their mixture seemed to be seriously in doubt. Brantley and Beckman's⁴⁵³ results were therefore interpreted here as pertaining to the TiC_xO_y -C-CO system for which the equilibrium is given by reaction (233).

⁴⁵⁴Richardson, F.D., J. Iron Steel Inst. 175, 33 (1953).

⁴⁵⁵Meerson, G.A. and O.E. Krein, Russian J. Appl. Chem. 25, 143 (1952).

⁴⁵⁶Kutsev, V.S. and B.F. Ormont, Zhur. Fiz. Khim. 31, 1866 (1957).

Further thermodynamic calculations were not possible because concentrations or activities of the TiO and TiC in solution were not reported.

The results of Meerson and Krein⁴⁵⁵ and Kutsev and Ormont⁴⁵⁶ for the Ti-C-O system were being studied in more detail at the time of report writing to determine whether they could be used as a source of thermodynamic data.

3) Equilibrium data in the Ti-Ta-C system

Since the TiC and TaC compounds have approximately the same thermodynamic stabilities, a search of the literature was made for more specific data on the Ti-Ta-C system. The work of McMullin and Norton⁴⁵⁷ yielded an isothermal section of the ternary diagram at 1820°C . They found that three phases (β - γ - δ) coexisted in equilibrium. These phases had the following compositions in atomic percent:

Phase	Atomic percent Ta	Atomic percent Ti	Atomic percent C
β	60	38	2
γ	67	0	33
δ	22	50	28

The β -phase is essentially a solid solution of Ta and Ti; the γ -phase is essentially Ta_2C ; and the δ -phase is a solid solution of TiC-TaC . The equilibrium involved can be represented by reaction (234).

The following activities were calculated from Raoult's law applied to the components in high concentration in the solid solutions:

⁴⁵⁷McMullin, J.G. and J.T. Norton, *J. Metals* 5, 1205 (1953).

Phase	Composition	a_{Ta}	a_{Ti}	a_{Ta_2C}	a_{TiC}
β	$Ta_{0.60} Ti_{0.38} C_{0.02}$	0.60	0.38	---	---
γ	$Ta_{0.67} C_{0.33}$	---	---	1	---
δ	$\left\{ \begin{array}{l} (TiC)_{0.28} Ti_{0.22} Ta_{0.22} \\ \text{or} \\ (TiC)_{0.388} Ti_{0.305} Ta_{0.305} \end{array} \right.$	---	---	---	0.388

The equilibrium constant in equation (235),

$$K = \frac{a_{Ta_2C} a_{Ti}}{a_{TiC} a_{Ta}^2} \quad (235)$$

is therefore equal to 2.77, and the standard free-energy change for reaction (234) is -4232 cal/gfw when calculated from equation (191).

Since equation (236) holds for reaction (234),

$$\Delta F^\circ = \Delta F_{Ti}^\circ + \Delta F_{Ta_2C}^\circ - \Delta F_{TiC}^\circ - 2\Delta F_{Ta}^\circ \quad (236)$$

and the free energies in the standard state are zero for the elements, equation (237) obtains.

$$\Delta F^\circ = \Delta F_{Ta_2C}^\circ - \Delta F_{TiC}^\circ \quad (237)$$

Since Elliott and Gleiser⁴⁵⁰ have reported that $\Delta F_{Ta_2C}^\circ, 2093^\circ K = -31,200$ cal/mole, it was possible to calculate that $\Delta F_{TiC}^\circ, 2093^\circ K = -26,968$ cal/mole from equation (237). With the free-energy functions from the JANAF tables,⁷⁵ it was then found that $\Delta H_{298}^\circ, TiC = -33,768$ cal/mole.

The above analysis therefore gave a ΔH_{298}° value in good agreement with that of Fujishiro and Gokcen⁴⁵¹ of $\Delta H_{298}^\circ = -31,333$. This provides evidence in support of the validity of their data rather than the heat-of-combustion data of Humphrey.⁴⁵² (At this stage, too much emphasis should not be placed on this analysis since further work is planned.)

The principal source of uncertainty in the latter analysis is the application of Raoult's law to the solid solutions. An analysis of the work in the Ti-C-O system by Kutsev and Ormont⁴⁵⁶ may make possible an independent check of these results.

b. Condensed Phase Data

1) Crystalline forms

TiC has a face-centered cubic structure of the NaCl type.²¹³ The lattice parameter for the stoichiometric composition is $a = 4.329 \pm 0.001 \text{ \AA}$.

2) Phase-transformation temperatures

a) Melting Point

Several reported melting points have been reviewed by Hansen and Anderko.²¹³

m. p. (°C)	Reference
3160	Friederich and Sittig ⁴⁵⁸
3140	Agte and Moers ⁴⁵⁹
3030	Geach and Jones ⁴⁶⁰
3250	Schwartzkopf and Kieffer ⁴⁴⁸

The average of these determinations is 3145°C (3418°K), and is in good agreement with the value (3410°K) used by the Bureau of Standards⁴⁴⁹ and the JANAF tables.⁷⁵ The latter value was adopted and an estimated uncertainty of $\pm 100^\circ\text{K}$ was assigned to it.

b) Boiling point

There were few published data regarding the boiling point of TiC. The National Research Council tables⁴⁶¹ listed a value

⁴⁵⁸Friederich, E. and L. Sittig, Z. anorg. Chem. 144, 171 (1925).

⁴⁵⁹Agte, C. and K. Moers, Z. anorg. Chem. 198, 233 (1931).

⁴⁶⁰Geach, G.A. and F.O. Jones, Plaussee Proc. p. 80 (1955).

⁴⁶¹Silverman, A., Data on Chemicals for Ceramic Use, Nat. Research Council Bull. 118 (June 1949).

of 4300°C (4573°K) but did not give an original reference. On the basis of the work of Fujishiro and Gokcen⁴⁵¹ and of Chupka, Berkowitz, Giese, and Inghram,⁴⁶² who showed that the primary vaporization products are the elemental species, it should be possible to calculate the temperature at which the decomposition pressure reaches one atmosphere.

3) Heat changes

a) Heat of fusion

Reports of experimental determinations of the heat of fusion of TiC were not found. Experimental measurements would be rather difficult to make because of the very high melting point of this compound. An NBS report³³¹ gave an estimate of this quantity obtained on the assumption of an entropy of fusion of 2.5 e.u./g atom or 5 e.u./mole of TiC. On this basis, the heat of fusion was thus calculated to be 17,050 cal/mole. The latter value has been used in both the NBS⁴⁴⁹ and JANAF tables⁷⁵ and was accepted here.

b) Heat of vaporization

Calculations of the heat of sublimation or vaporization can be made if the heat of formation of the compound is known together with the heats of sublimation of the elemental species. On the assumption that TiC dissociates into atoms (e.g., species such as C₂, C₃ are neglected) and that $\Delta H_f^\circ \text{TiC}, 298 = -43.8$ Kcal/mole, NBS workers found a value of $\Delta H_{\text{sublimation}}^\circ, 298^\circ\text{K} = 328.51$ Kcal/mole. It is expected that this value will be lowered somewhat by the acceptance of a more positive value of the heat of formation.

4) Heat capacity

a) Low-temperature data

Experimental heat capacity data by Kelley⁴⁶³ for the temperature range from 55° to 295°K have been analyzed by the NBS³³¹ who found that $S_{298}^\circ = 5.80 \pm 0.10$ e.u. This value was adopted for the present tabulation.

⁴⁶²Chupka, W.A., J. Berkowitz, C.F. Giese, and M.G. Inghram, J. Phys. Chem. 62, 611 (1958).

⁴⁶³Kelley, K.K., Ind. Eng. Chem. 36, 865 (1944).

b) High-temperature data

The heat capacity data of Naylor⁴⁶⁴ in cal/°K gfw over the temperature range from 298° to 1735°K have been reviewed and accepted by Kelley⁵⁶ who gave equation (238)

$$C_p^\circ = 11.83 + 0.80 \times 10^{-3}T - 3.58 \times 10^{-5}T^{-2} \quad (238)$$

for the temperature range from 298° to 2000°K. C_p° data obtained on the present project are discussed in section V-B below and compared with data from other sources.

c) Liquid heat capacity

The heat capacity of liquid TiC was reported by the NBS³³¹ to be the estimated value of 7.8 cal/g atom °K (15.6 cal/mole °K) at the melting point. It was felt here that their further assumption of a negative temperature coefficient was not sufficiently justified, and that a better choice will be possible when better data on the solid become available.

⁴⁶⁴Naylor, B.F., J. Am. Chem. Soc. 68, 370 (1946).

9. Titanium Oxides (TiO , Ti_2O_3 , Ti_3O_5 , and TiO_2)

The Ti-O system is relatively complicated as indicated by its phase diagram.²¹³ The known oxides of titanium for which data were available are TiO , Ti_2O_3 , Ti_3O_5 , and TiO_2 . A δ -phase of approximately Ti_4O_3 composition in the system had been reported, but its existence had not been established with certainty. The literature on the first four above-listed compounds was reviewed, and the data were under analysis at the time of report writing. Complete tables of thermodynamic function were under preparation for all solid phases.

10. Tungsten Oxides

The important oxides of tungsten for which thermodynamic properties have been compiled are tungsten monoxide (WO), tungsten dioxide (WO₂), and tungsten trioxide (WO₃). Although polymeric species of WO₃; i. e., (WO₃)₃, (WO₃)₄, etc., are known to exist, virtually no thermodynamic data were available on them. Estimation of the thermodynamic properties of these polymeric species was not attempted.

a. Tungsten Monoxide (WO)

Tungsten monoxide does not appear to exist in a pure condensed phase, but may be part of the solid oxide layer formed during surface oxidation of tungsten metal.²⁶⁴ The existence of WO in the gas phase at high temperatures has been verified by mass spectrographic work.⁴¹⁰ Only the thermodynamic functions for gaseous WO are given in the present compilation. The thermodynamic functions for gaseous WO given in Table LXIX were calculated by means of the computer program described in section III-F with the following estimated molecular data:

Bond distance

$$r_o = 1.78 \text{ \AA}.$$

Moment of inertia

$$I = 77.426 \times 10^{-40} \text{ g cm}^2.$$

Symmetry number

$$\theta = 1.$$

Fundamental frequency

$$\omega = 803 \text{ cm}^{-1}.$$

Ground electronic state

$$^1\Sigma$$

1) Bond distance

The W-O bond distance had not been experimentally determined. A value of 1.70 Å had been calculated⁴¹⁰ by means of the Guggenheimer relation⁴⁶⁵ and the estimated fundamental frequency of Vittalachar

⁴⁶⁵Guggenheimer, K. M., Proc. Phys. Soc. (London) 58, 456 (1946).

TABLE LXIX
TUNGSTEN MONOXIDE IDEAL MOLECULAR GAS

OW

Reference State for Calculating ΔH_f° , ΔF_f° , and $\log K_p$: Solid W from 298.15° to 3650°K,

and Krishnamurty.⁴⁶⁶ A value of $1.78\text{\AA}$ had been estimated for this distance by Brewer and Chandrasekharaiah.⁴⁰¹ The value $1.78\text{\AA}$ was chosen for the present work.

2) Moment of inertia

The moment of inertia, I , was calculated from the assumed value for the W-O bond distance by means of equation (239)

$$I = \frac{M_W M_O}{M_W + M_O} r_o^2 \quad (239)$$

where

M_W = mass of tungsten atom

M_O = mass of oxygen atom

r_o = W-O bond distance.

3) Fundamental frequency

The fundamental frequency ω , of WO had not been experimentally determined. An approximate band analysis by Vittalachar and Krishnamurty⁴⁶⁶ was the basis for a suggested value of 1060 cm^{-1} . This same value was also used in a paper by Gatterer and Krishnamurty.⁴⁶⁷ However, the 1060 cm^{-1} value was estimated from a comparison with other transition monoxides, and the value employed for a key item in the comparison (i. e., ω for TaO) was incorrect.⁴⁶⁸ Brewer and Chandrasekharaiah⁴⁰¹ estimated the fundamental frequency to be 803 cm^{-1} . The 803 cm^{-1} value was chosen in the present work as being more in accord with the postulate that the bonding in CrO, MoO, and WO are very similar. Mass effects alone would therefore indicate a frequency order of $\omega_{Cr} > \omega_{Mo} > \omega_W$. In view of the large uncertainty associated with the value of ω , no attempt was made to include anharmonicity and interaction terms in the calculation of thermodynamic functions for the WO molecule.

4) Electronic states

The electronic states of WO were unknown. As in the similar case of MoO, only the ground state was included; and it was assumed to be a $^1\Sigma$ state.

⁴⁶⁶Vittalachar, V. and S. G. Krishnamurty, Current Sci. 23, 357 (1954).

⁴⁶⁷Gatterer, A. and S. G. Krishnamurty, Nature 169, 543 (1952).

⁴⁶⁸Prernaawarup, D. and R. F. Barrow, Nature 180, 602 (1957).

The standard enthalpy of formation, ΔH_f° , had not been directly determined. The value of ΔH_f° was, therefore, determined by an indirect method identical to that employed in the case of MoO described in section IV-B5a of this report. The required partial pressures of WO and monatomic oxygen in equilibrium with solid tungsten were those measured by DeMaria and co-workers⁴¹⁰ in their mass spectrographic study of Al_2O_3 in tungsten containers. The value of the heat of formation so obtained was $+97,400 \pm 4500$ cal/gfw. $H^\circ_{298} - H_0$ for gaseous WO was found to be 2122 cal/gfw.

Values of ΔH_f° , ΔF_f° , and $\log_{10} K_P$ were calculated in a fashion identical to that described in section IV-B5a for the corresponding MoO molecule.

b. Tungsten Dioxide (WO_2)

1) Condensed phase

The thermodynamic properties of solid WO_2 have been based on the low-temperature heat capacity data of King, Weller, and Christensen,⁴¹⁵ the high-temperature enthalpy data of the same workers, and the heat-of-formation data of Mah.⁴⁶⁹

The only experimental investigation of the low-temperature heat capacity of WO_2 has been that of King, Weller, and Christensen⁴¹⁵ who made measurements over the temperature range from 52° to 297°K . Their data yield an S°_{298} value of 12.08 ± 0.07 e. u. /gfw.

The only experimental high-temperature enthalpy data were those of King, Weller, and Christensen⁴¹⁵ (400° to 1800°K). The smoothed values reported by these workers were employed in the present compilation, except that those near room temperature were altered slightly to join the low-temperature data smoothly at 298.15°K . Tabular entropy values were calculated by the procedure of Kelley.⁵⁶ The free-energy functions in Table LXX were calculated from equation (108). Heat capacity values were calculated from equation (240)

$$C_p^\circ = 15.49 + 3.58 \times 10^{-3}T - 2.80 \times 10^{-5}T^{-2} \quad (240)$$

except for the values calculated near room temperature which were altered slightly to join the low-temperature data smoothly at 298.15°K .

⁴⁶⁹Mah, A. D., J. Am. Chem. Soc. 81, 1582 (1959).

WO₂ does not exhibit a true melting point since disproportionation occurs to yield solid W and WO₃ vapor (probably including WO₃ polymeric species) before melting occurs.^{470, 346}

The standard enthalpy of formation, ΔH_{f298}° , of solid WO₂ was determined by Mah⁴⁶⁹ from the heats of combustion of W_(s) to WO_{3(s)} and of WO_{2(s)} to WO_{3(s)}. Mah's⁴⁶⁹ value of $-140,940 \pm 210$ cal/gfw was accepted in the present compilation. Other less accurate values have been reported by Delepine⁴⁷¹ and Hallopeau,⁴⁷¹ by Coughlin,⁴⁷² and by Griffis.^{473, 474}

Values of ΔH_f° , ΔF_f° , and $\log_{10} K_P$ were calculated from equations (44), (241), and (242).

$$\Delta H_f^{\circ} = \Delta H_{f298}^{\circ} + (H_T^{\circ} - H_{298}^{\circ})_{\text{WO}_{2(s)}} - (H_T^{\circ} - H_{298}^{\circ})_{\text{W}_{(s)}} - (H_T^{\circ} - H_{298}^{\circ})_{\text{O}_{2(g)}} \quad (241)$$

$$\Delta F_f^{\circ} = \Delta H_{f298}^{\circ} + (F_T^{\circ} - H_{298}^{\circ})_{\text{WO}_{2(s)}} - (F_T^{\circ} - H_{298}^{\circ})_{\text{W}_{(s)}} - (F_T^{\circ} - H_{298}^{\circ})_{\text{O}_{2(g)}} \quad (242)$$

2) Ideal gas

All of the molecular constants required in the calculation of the thermodynamic functions for gaseous WO₂ have been estimated since no experimental spectroscopic data have been reported. The thermodynamic functions for gaseous WO₂ given in Table LXXI were calculated by means of the machine program described in section III-F with the following molecular data:

Molecular configuration

Symmetrical, nonlinear molecule with

$\angle \text{O-W-O} = 107 \text{ deg}$

$r_{\text{O}} = 1.78 \text{ \AA}$

Product of moments of inertia

Symmetry number

$$\theta = 2$$

Fundamental frequencies

$$\omega_1 = 794 \text{ cm}^{-1}$$

$$\omega_2 = 351 \text{ cm}^{-1}$$

$$\omega_3 = 812 \text{ cm}^{-1}$$

Ground electronic state

$$^1\Sigma$$

a) Molecular configuration

The molecular configuration of the WO_2 molecule was unknown. Consideration of the periodic group to which tungsten belongs and the work of Walsh³⁹⁵ on bonding and structural relations led to the conclusion that WO_2 is a symmetric, nonlinear molecule, and it was so considered in the present work. DeMaria and co-workers⁴¹⁰ also assumed it to have a nonlinear structure, whereas Chandrasekharaiah and Brewer³⁹⁷ assumed it to have the linear structure which they assumed for all of the Group IV, V, and VI transition metal dioxides. An O-W-O angle of 107 degrees was chosen in the present work as representing a reasonable value in comparison with known compounds of similar bonding. The W-O bond distance was assumed to be identical to the estimated corresponding distance for the tungsten monoxide (WO) molecule; i. e., 1.78 Å.

b) Moments of inertia

The moments of inertia of WO_2 were calculated in a manner analogous to that used for the corresponding CrO_2 molecule.

c) Fundamental frequencies

The fundamental frequencies of WO_2 were estimated by the same method used for the corresponding CrO_2 molecule (see section IV-B3a), except that the stretching force constant for WO was calculated from estimated spectroscopic data.⁴⁰¹ The frequencies so obtained are somewhat lower than those estimated by DeMaria and co-workers.⁴¹⁰

d) Electronic states

The electronic states for WO_2 were treated in the same manner as those of the CrO_2 molecule (section IV-B3a).

The standard enthalpy of formation, ΔH_{f298}° , of gaseous WO_2 had not been directly determined. The value of ΔH_{298}° was, therefore, determined by an indirect method identical to that employed in the case of MoO_2 (see section IV-B5b) based on the mass spectrographic study of Al_2O_3 in tungsten containers by DeMaria and co-workers.⁴¹⁰ The value of ΔH_{f298}° so obtained was $+13,900 \pm 5000$ cal/gfw. $H_{298}^\circ - H_0^\circ$ for gaseous WO_2 was found to be 2693 cal/gfw.

Values of ΔH_f° , ΔF_f° , and $\log_{10} K_P$ were calculated in an identical fashion to that described in section IV-B5b for the corresponding MoO_2 molecule.

c. Tungsten Trioxide (WO_3)

1) Condensed phase

a) The 1050°K transition

Tungsten trioxide is monoclinic at room temperature but undergoes a transition to the tetragonal form at 1050°K. A value of about 725°C for the transition temperature has been quoted,³⁴⁶ but the recent work of King, Weller, and Christensen⁴¹⁵ has established $1050^\circ \pm 10^\circ\text{K}$ as the best value. The heat of transition, from enthalpy measurements on the two forms,⁴¹⁵ was found to be 410 cal/gfw. An uncertainty of ± 40 cal/gfw has been arbitrarily assigned to the heat of transition.

b) Melting point and heat of fusion

The works of Jaeger and Germs⁴⁷⁵ and of King and co-workers⁴¹⁵ are in excellent agreement on the melting point of $1745^\circ \pm 10^\circ\text{K}$ for WO_3 . The heat of fusion, as determined from enthalpy measurements,⁴¹⁵ is 17,550 cal/gfw. An uncertainty of ± 1000 cal/gfw has been arbitrarily assigned to the heat of fusion.

⁴⁷⁵Jaeger, F.M. and H.C. Germs, Z. anorg. Chem. 119, 149 (1921).

c) Boiling point

The equilibrium vapor above WO_3 consists primarily of $(\text{WO}_3)_3$, $(\text{WO}_3)_4$, and $(\text{WO}_3)_5$ according to Berkowitz, Chupka, and Inghram.⁴⁷⁶ Other investigations concerning the vapor pressure of WO_3 are those of Blackburn, Hoch, and Johnston,⁴¹⁷ and of Meyer, Oosterom and deRoo.⁴⁷⁷ No attempt has been made in the present work to define a boiling point for WO_3 . A temperature of about 2100°K has been quoted⁴⁷⁰ as the temperature at which the total pressure above WO_3 becomes one atmosphere. No attempt was made to estimate thermodynamic functions for the polymeric vapor species.

d) Entropy at 298.15°K

Low-temperature heat capacity data for $\text{WO}_{3(s)}$ have been reported by King, Weller, and Christensen,⁴¹⁵ and by Seltz, Dunkerley, and DeWitt.⁴²⁹ The results of Seltz and co-workers were appreciably higher than those of King and co-workers, and were believed to be subject to some systematic error.⁴¹⁵ The data of King and co-workers yielded an S_{298}° value of 18.15 ± 0.12 e. u.

e) Thermodynamic properties

The only experimental high-temperature enthalpy measurements on WO_3 are those of King, Weller, and Christensen⁴¹⁵ over the temperature range from 400° to 1840°K. Equation (243) for the heat capacity in cal/°K gfw, derived from their enthalpy data for the monoclinic form of WO_3 ,

$$C_p^\circ = 21.26 + 3.38 \times 10^{-3}T - 4.42 \times 10^{-5}T^{-2}, \quad (243)$$

was used to calculate C_p° values from 400°K to the transition point (1050°K). These C_p° values were then extrapolated to join the low-temperature heat capacity data smoothly at 298.15°K. Enthalpy and entropy values in the range from 298.15° to 400°K were determined by graphical integration with these extrapolated heat capacity values. Enthalpy and entropy values in units of calories, °K, and moles were calculated at other temperatures up to the transition point from equations (244) and (245).

⁴⁷⁶Berkowitz, J., W.A. Chupka, and M.G. Inghram, *J. Chem. Phys.* **27**, 85 (1957).

⁴⁷⁷Meyer, G., J.F. Oosterom, and J.L. deRoo, *Rec. trav. chim.* **78**, 412 (1959).

$$H_T^\circ - H_{298}^\circ = 21.26T + 1.69 \times 10^{-3}T^2 + 4.42 \times 10^5 T^{-1} - 7962 \quad (244)$$

$$S_T^\circ = 21.26 \ln T + 3.38 \times 10^{-3}T + 2.21 \times 10^5 T^{-2} - 106.448 \quad (245)$$

Free-energy functions for monoclinic WO_3 were calculated in the usual manner.

Heat capacities of tetragonal WO_3 in cal/ $^\circ\text{K}$ gfw were calculated from the transition point (1050 $^\circ\text{K}$) to the melting point (1745 $^\circ\text{K}$) by means of equation (246) derived from the enthalpy data of King and co-workers.

$$C_P^\circ = 20.79 + 2.75 \times 10^{-3}T \quad (246)$$

Enthalpy and entropy values in units of calories, $^\circ\text{K}$, and moles were calculated for tetragonal tungsten trioxide from equations (247) and (248).

$$H_T^\circ - H_{298}^\circ = 20.79T + 1.375 \times 10^{-3}T^2 - 6290 \quad (247)$$

$$S_T^\circ = 20.79 \ln T + 2.75 \times 10^{-3}T - 101.928 \quad (248)$$

Free-energy functions were calculated from the enthalpy and entropy values in the usual manner.

The heat capacity of liquid WO_3 was found to be 31.50 cal/ $^\circ\text{K}$ gfw;⁴¹⁵ hence, enthalpy and entropy values in units of calories, $^\circ\text{K}$, and moles were obtained from equations (249) and (250).

$$H_T^\circ - H_{298}^\circ = 31.50T - 3242 \quad (249)$$

$$S_T^\circ = 31.50 \ln T - 167.017 \quad (250)$$

The thermodynamic functions of the condensed phases of WO_3 are summarized in Table LXXII.

f) Standard heat of formation at 298.15 $^\circ\text{K}$ (ΔH_{f298}°)

The standard enthalpy of formation, ΔH_{f298}° , of solid WO_3 was determined by Mah⁴⁶⁹ from the heat of combustion of tungsten metal. Mah's value of $-201,460 \pm 200$ cal/gfw was accepted

Symmetry number

$$\theta = 6$$

Fundamental frequencies

$$\omega_1 = 780 \text{ cm}^{-1}$$

$$\omega_2 = 298 \text{ cm}^{-1}$$

$$\omega_3 = 791 \text{ cm}^{-1} (2)$$

$$\omega_4 = 314 \text{ cm}^{-1} (2)$$

Ground electronic state

$$^1\Sigma$$

The above molecular constants were estimated by the procedures employed in the case of the corresponding CrO_3 molecule (see section IV-B3b). The W-O bond distance was assumed to be the same as the estimated distance for the corresponding bond in WO_3 ,⁴⁰¹ i. e., 1.78 Å. The estimated fundamental frequencies above are somewhat lower than those of DeMaria and co-workers⁴¹⁰ and of Ackermann and Thorn.⁴⁸⁷

The standard enthalpy of formation, ΔH_{f298}° , of gaseous WO_3 had not been directly determined, and was therefore determined by the indirect method employed in the case of MoO_3 (see section IV-B5c) based on the mass spectrographic study of Al_2O_3 in tungsten containers by DeMaria and co-workers.⁴¹⁰ The value of the heat of formation so obtained was $-65,100 \pm 5000 \text{ cal/gfw}$. $H_{298}^\circ - H_0^\circ$ for gaseous WO_3 was found to be 3296 cal/gfw .

Values of ΔH_f° , ΔF_f° , and $\log_{10} K_P$ were calculated in an analogous fashion to that described in section IV-B5c for the corresponding MoO_3 molecule.

⁴⁸⁷Ackermann, R.J. and R.J. Thorn, U.S. AEC Rept. ANL-5824 (January 1958).

V. EXPERIMENTAL STUDIES

A. PREPARATION AND ANALYSIS OF COMPOUNDS AND SPECIMENS

1. The three following methods were used to obtain specimens for heat capacity measurements:

a. Solid pieces of various refractory compounds were obtained from commercial sources and machined to specifications by the use of diamond tools and electric discharge (Elox) techniques. Materials obtained in this way were titanium diboride, zirconium diboride, tungsten boride, molybdenum boride, molybdenum carbide, titanium carbide, and zirconium carbide (all obtained from Carborundum Co.) and titanium metal (obtained from Foote Mineral Co.). X-ray diffraction analysis showed that the molybdenum boride and carbide specimens were multiphase systems, and further analyses were, therefore, discontinued. In the case of all the other specimens however, complete X-ray and chemical analyses were performed. The results are given with the heat capacity data for the respective specimens in section V-B, 4 below.

b. Materials were also obtained in the form of powders from commercial sources and fabricated into solid bodies which were subsequently machined to specifications. In most cases, the fabrication was accomplished by hot pressing the powders in graphite dies at temperatures above 1300°C and at pressures of from 2000 to 2500 psi. The details of the fabrication of each specimen are given in Table LXXIV.

Attempts to prepare elemental boron specimens by hot pressing in graphite dies with and without boron nitride liners and punches were unsuccessful. However, sound bodies were prepared by a cold-pressing and sintering technique. Boron powder was mixed with a small amount of stearic acid and compacted by cold pressing at 20,000 psi. The stearic acid was eliminated by heating at 400°F, and the boron body was then sintered at 1300°C for 2 hours in an argon atmosphere. Rods, 0.5 inch in diameter and 1-1/2 inches in length with a density between 1.30 and 1.38 g/cc, were fabricated by this method. β -rhombohedral boron was the only phase detected in these specimens, but there was an increase of 0.8 percent in carbon content over that detected in the original boron powder. This increase was probably due to incomplete elimination of the stearic acid binder.

c. Work was also started on the laboratory preparation of compounds. Silicon hexaboride, tantalum boride, and tantalum nitride were prepared in small quantities from the elements.

2. Chemical Analysis

a. Oxygen Determination

The need for a rapid, accurate, and reliable method for the determination of oxygen in refractory compounds motivated the development and adaption of the inert-gas fusion method to this problem. Vacuum fusion and vacuum extraction have both been used in the past, but they did not lend themselves to rapid determinations. Often, in the past, the oxygen content was not determined but estimated as the difference between the major-constituents analysis and 100 percent.

Figure 5 is a schematic diagram of the apparatus fabricated for the inert-gas fusion method of determining oxygen in refractory materials. Argon was passed through a purifying train (containing "Ascarite", concentrated sulfuric acid, and heated titanium metal chips) and then, to a flow-regulating valve and meter. A pressure-relief valve was used to maintain a constant pressure throughout the system. The argon flowed to the main furnace chamber which contained a high-purity (spectrographically pure) graphite crucible packed in powdered graphite. The crucible contained a platinum bath and was maintained at 2100°C by means of induction heating. After outgassing of the system by heating until the blank run gave constant results, the platinum bath was allowed to become saturated with carbon from the graphite crucible before the specimen was introduced.

A sample of 10 to 60 milligrams of finely ground refractory compound was weighed in a small, high-purity tin capsule which served as a vehicle. The sample was inserted in the furnace by means of a loading valve. The oxygen in the sample reacted with the carbon in the platinum bath to form carbon monoxide which was entrained by the flow of argon. The gases then passed through a tube containing copper oxide maintained at 750°C. The carbon monoxide was thus converted to carbon dioxide which was then carried to the conductimetric carbon determinator where the CO_2 was absorbed and measured.

The conductimetric carbon determinator functioned on the principle of a Wheatstone bridge, measuring the conductivity of a barium hydroxide solution. The argon gas carrying the carbon dioxide was dispersed through the solution where the CO_2 and $\text{Ba}(\text{OH})_2$ reacted to form barium carbonate, thus changing the conductivity of the solution by an amount which was a measure of the CO_2 absorbed.

Oxygen analyses were performed on five samples of unalloyed titanium, which were received from the Watertown Arsenal, to check the validity of the inert-gas fusion method of oxygen determination. These samples were previously analyzed for oxygen by a task force of 15 different laboratories. The results confirm the validity of the inert-gas fusion method used at Avco RAD.

Figure 5 SCHEMATIC OF INERT-GAS FUSION APPARATUS

b. After dissolution by one of the usual methods as required (i.e., acid, fusion and leaching, etc.), metal determinations were made as follows:

1) Titanium with Jones Reductor (zinc amalgam) and titration with potassium dichromate

A solution of the titanium (Ti^{+++}) was passed through a standard Jones reductor where the titanium was reduced to Ti^{++} . The resulting solution, containing the reduced titanium, was then titrated with an oxidizing agent (potassium dichromate). The titanium content was calculated from the standard value of titanium for the volume of the dichromate solution used.

2) Chromium by oxidation with perchloric acid and titration of the resulting dichromate

The chromium solution was oxidized to a dichromate solution by heating to fumes in perchloric acid. The oxidized solution was then cooled and titrated with a reducing solution (ferrous ammonium sulphate) for which a standard chromium value had been previously established.

3) Molybdenum by precipitation with alphanitroso-beta-naphthol

The sample containing molybdenum was dissolved and alphanitroso-beta-naphthol solution was added. The molybdenum was thus precipitated as the organic complex. The precipitate was then filtered and dried to constant weight. The molybdenum content was then computed from the weight of the precipitate in the usual way.

4) Tungsten by precipitation with cinchonine

The tungsten compound was dissolved by means of an alkali fusion. A solution of cinchonine was then added to the tungsten solution and the mixture heated gently to precipitate the tungsten complex. This precipitate was then filtered and dried to constant weight. The amount of tungsten was then computed in the usual way from the weight of the precipitate.

5) Niobium, tantalum, and hafnium by separation from other metals by ion exchange and gravimetric determination as the oxide

Niobium, tantalum and hafnium compounds were put into an acid solution, and passed through a resin column where the metals were absorbed. By means of varying acid strengths, the metals were selectively eluted from the resin. The individual solutions were brought to dryness, and the metals were converted to oxides by standard ashing techniques. The weight of the metal oxide was then computed and converted to the weight of the metal.

c. Nonmetal determinations were made as follows:

1) Boron by conversion to acid with mannitol and titration

The boron compound was converted to soluble boric acid by means of alkali fusion. Mannitol or glycerine was added to the boric acid solution to form a readily titratable solution with sodium hydroxide. The boron content was computed from the amount and the standard value of the sodium hydroxide solution required for neutralization.

2) Nitrogen by Kjeldahl digestion and titration

The nitrogen compound was dissolved by means of acid digestion in a Kjeldahl flask. The flask was then transferred to a Kjeldahl distillation apparatus where the nitrogen-containing solution was made ammoniacal by addition of caustic solution. The ammonia thus formed was distilled and trapped in distilled water. The resultant solution was then titrated with a standard hydrochloric acid solution.

3) Carbon by combustion and volumetric measurement of liberated CO₂ with a Leco apparatus

The total carbon was determined volumetrically by means of a Leco combustion furnace and a Leco volumetric carbon determinator.

The free carbon was determined by means of combustion in air at a temperature below the decomposition temperature of the carbide. Thus, the loss in weight was a direct measure of the free carbon content. The combined-carbon content was obtained by difference from these two results.

d. Trace-Impurity Determinations

Spectrographic analytical curves for known concentrations of trace impurities in refractory compounds had been established, and it was possible to determine quantitatively the concentrations of the trace impurities.

3. X-Ray Diffraction Analysis

Diffraction diagrams of the specimens were obtained with a 114.59 mm Debye-Scherrer camera with Ni-filtered Cu radiation. Lattice constants calculated from reflections above $\theta = 50$ degrees were plotted against $\frac{\cos^2 \theta}{\sin \theta} + \frac{\cos^2 \theta}{\theta}$, and the best straight-line fit (visual) was extrapolated to $\theta = 90$ degrees for the lattice constant. The precision of the measurements

was ($\pm 0.0005\text{\AA}$). The results for the individual heat capacity measurement specimens are given with the heat capacity data in section V-B below.

Reaction between the specimens and the carbon vapor in the high-temperature heat capacity furnace was first noticed in the case of TiN. The outer surface of the specimen turned blue, and the lattice constant of this blue material was found to be larger than that of the starting TiN. Drillings were then taken (perpendicular to the rod axis) to a depth of approximately 1.60 mm and the X-ray measurement repeated to reveal the depth of carbon penetration. Results are summarized in Table LXXV.

TABLE LXXV
VARIATION OF LATTICE CONSTANT VERSUS
DEPTH IN TiN SPECIMENS AFTER
HIGH-TEMPERATURE HEAT
CAPACITY DETERMINATION

Lattice Constant ($\text{\AA}$)	Approximate Composition	Depth (mm)
4.28	$\text{TiN}_{0.5}\text{C}_{0.5}$	0.40
4.27	$\text{TiN}_{0.65}\text{C}_{0.35}$	0.80
4.24	TiN	1.20
4.24	TiN	1.60

Carbon concentrations were calculated on the basis of the following assumptions. (a) all the nonmetal sites were filled, and (b) the TiN - TiC solid solutions obey Vegard's straight-line relationship. Subsequent analyses on other specimens revealed carbide layers of 0.4 mm (TiC) in the case of TiB_2 , and 0.3 mm (WC) in the case of WB. The presence of ZrC was also found on the surface of the ZrB_2 specimen.

The presence of tungsten carbides at the contact areas of the TaC and NbC specimens with the tungsten electrodes and the absence of them in the TiN case indicated the possibility of some reaction between the tungsten and carbide specimens only.

The TiC, TaC, and NbC specimens were found in post-test analyses to be one-phase systems of the same lattice constants as the starting materials (except for a slight lattice-constant increase on the surface, probably due to increased carbonization). The ZrC specimen exhibited weak reflections of ZrO_2 similar to those of the starting material.

Since the first NbC specimen showed unusual behavior in the specific heat measurements, a second specimen (931C) was prepared and characterized. The lattice constant of the first NbC specimen was $4.4673\text{\AA}$. This corresponded to a C/Nb ratio of 0.93 according to the data of Kempter and Storms.⁴⁸⁸ Since chemical analyses had also been made, it was possible to check the X-ray result. The analytical data on NbC are summarized in Table LXXVI. The C/Nb ratios obtained by chemical analysis were calculated directly from the total niobium (or niobium plus tantalum where tantalum is not reported). In most cases, the diffraction pattern indicated extremely weak additional reflections in the front-reflection region that could be indexed (although with some ambiguity because of their weak diffuse intensity) as Nb_2O_5 . It was, therefore, assumed that the majority of the oxygen reported by chemical analysis was not in solution with the NbC although the nitrogen and tantalum were, since there was no indication of NbN or Ta in the X-ray diagrams. The lattice constants reported are not corrected for the decrease due to tantalum in solution (approximately $0.0003\text{\AA}$ per percent Ta) or the increase due to nitrogen in solution (approximately equal to a corresponding amount of carbon, assuming the carbon radius to be $0.76\text{\AA}$ and the nitrogen radius to be $0.71\text{\AA}$).⁴⁴⁸

B. SPECIFIC HEAT DETERMINATIONS

1. Introduction

Two experimental techniques were adopted for specific heat determinations. The two were used because of the broad temperature coverage required and the inherent limitations of each system.

The Bunsen type of ice calorimeter⁴⁸⁹ shown in figure 6 was chosen for "low" temperature determinations (room temperature to 1900°C). The maximum temperature of operation for this apparatus is determined by the radiant heat transfer from the associated furnace to the calorimeter and by other losses that occur with the transfer of the sample from the furnace to the calorimeter. The photograph in figure 7 shows a cutaway view of internal details of the calorimeter chamber.

A modified pulse technique was adopted for the high-temperature determinations of specific heat. The technique used is similar to that of Rasor and McClelland.²⁷ The practical limits of temperature coverage of this "high" temperature apparatus shown in figure 8 are approximately 1800° to 3900°K.

Considerable care was exercised to ensure the accuracy of temperature measurements throughout the specific heat measurements. Secondary calibration standards were continuously maintained in the laboratory, and frequent calibration checks were made of the instruments. The calibration standards used were a gold melting-point apparatus, NBS-certified tungsten strip lamps, NBS-certified freezing point metals, an NBS-certified platinum-resistance thermometer, and platinum - platinum 10 percent rhodium thermocouples with the associated NBS-certified Müller bridge and Werner potentiometer.

An extended range, DK-2, ratio-recording spectrophotometer was used to determine the transmissivity characteristics of any associated glass or quartz windows used during the experimental determinations.

2. The Bunsen Ice Calorimeter

The Bunsen ice calorimeter is extensively used to make specific heat determinations in a number of laboratories. A few innovations were introduced into the one used for this work. The designs of the furnace and calorimeter components are shown schematically in figures 9 and 10.

Figure 9 ICE CALORIMETER FURNACE

Figure 10 BUNSEN ICE CALORIMETER

The furnace was multiply wound with separate controls associated with each winding. The end windings allowed for the usual end losses and permitted a long hot zone in the vicinity of specimen heating.

A stabilizing slug, (F) in figure 9, was also used along the central furnace area to improve the temperature gradient characteristics. There were seven thermocouples of the platinum - platinum 10 percent rhodium variety located in the vicinity of the furnace center to provide continuous monitoring of the sample area temperature. The distribution of thermocouples consisted of two at the furnace center, located in opposite positions at 0 and 180 degrees; two located 2 inches above the center at 90 and 270 degrees; two located 2 inches below the center at 45 and 225 degrees; and one which traversed the center of the furnace and was inserted in a hole in the sample container (G).

The sample, placed in the sample container in a helium atmosphere, was held in position by a suspension wire (D) and the release washer (B). The release washer was held by an electromagnetic coil until the drop temperature was reached and stabilized.

Considerable care had to be used in the construction of the calorimeter drop tube because of the tendency for failures to occur at joints between dissimilar metals. The finned tube assembly had to be made from a solid copper rod to eliminate the need for welded joints at the bottom plug. A graded weld was found to be necessary to attach the copper, finned tube to the stainless steel at the top of the drop tube.

Located at the top of the drop tube was a silvered radiation gate which was opened prior to, and closed immediately following, a drop to prevent radiant heat transfer. A cooling coil was also incorporated with the drop tube to reduce the heat conduction from the furnace to the calorimeter.

In operation, the inner container to which the drop tube is welded was filled with gas-free water through the water-filler tube. After filling of the entire inner chamber with water, mercury was admitted through the mercury-metering system until it filled the mercury chamber and rose approximately three-fourths of an inch in the water chamber. The latter operation displaced water which flowed out through the water-filler tube. The water-filler tube was then sealed off by means of a suitable valve. The system then expelled mercury when ice was formed from cooling of the water in the inner container.

At first, ice mantles were formed on the finned tube by lowering a container of dry ice into the drop tube and oscillating it over the tube length until a sufficient thickness of ice was formed. Later, it was found to be more convenient to form the mantle by injecting into the lower drop tube area a flow of air which had been pre-cooled by passing through a copper

coil immersed in liquid air. This reduced the time required for mantle formation from two days to approximately two hours.

The amount of mercury displaced during melting (or additional freezing) of the previously formed ice mantle after a sample drop gave a measure of the enthalpy change.

CO₂ gas in the intermediate container shown in figure 10 reduced heat leakage to the inner container because of the gas' low thermal conductivity. The entire inner calorimeter assembly was kept at a temperature of approximately 273°K during operation by crushed ice between the outer and intermediate shells. The mercury-metering tube and the helium gas tube were passed through the crushed-ice bath to pre-cool the fluids. The helium gas was passed up the drop tube since its presence assisted in the heat transfer from the sample container to the copper finned tube. A negligible amount of heat was carried away by the helium.

A number of checkout tests were run on the Bunsen ice calorimeter apparatus. One important test was conducted on the heat-leak rate and its effect on the life of the ice mantle. Heat-leak values, as evaluated from short time observations, are plotted in figure 11. The average value of the heat-leak rate from the short-time observations (taken as representative for normal operating conditions) was determined to be 2.06 cal/hr or 18.84 grams of mercury per day using a calibration factor of 62.560 cal/g.

From the results in figure 12, it appears that a heat-leak value of 5.77 cal/hr or 52.8 grams of mercury per day is applicable in the case of long-term tests (not normally used). The higher leak rate for the long-term tests was ascribed to the depletion of ice during over-night interruptions of the experiments.

The lower value was chosen as the characteristic heat-leak rate under actual test conditions where ice depletion will not occur. The latter value is sufficiently low to indicate a negligible effect upon specific heat measurements in the apparatus regardless of furnace alignment or temperature. The further precaution was taken of adopting the standard procedure of moving the furnace away from the drop tube after a sample drop (corresponding to the case of no furnace alignment in figure 11). Further tests planned for the future included some at higher furnace temperatures.

Another test revealed that the average temperature reading of the six thermocouples in the sample region of the furnace could not be used as the drop temperature. It was therefore decided to incorporate a permanent thermocouple in such a way as to read the temperature in a small well in the capsule for this measurement.

A brief study was made of the properties of the drop-capsule material. The results are summarized in Table LXXVII.

The calorimeter was calibrated with synthetic sapphire as a standard which had been established by the measurements of Ginnings and Furukawa.²⁸ As a result of 12 determinations at approximately 450°K, the calibration factor was found to be 62.560 ± 0.675 cal/g of mercury or 261.707 ± 2.824 international joules/g of mercury. The factor is lower by 3.20 percent than

the value of Ginnings and Corrucini³⁰ of 270.37 ± 0.06 international joules/g of mercury. Electrical calibration will be used to determine whether this uncertainty is inherent in the use of synthetic sapphire as a calibration standard.

3. High-Temperature Pulse Method of Specific Heat Determination

The pulse-method apparatus used for high-temperature specific heat measurements is illustrated schematically in figure 13. This apparatus was used at temperatures above 1900°K because radiative and convective losses make it very difficult to use the drop method at such high temperatures.

The furnace used in the pulse-method apparatus was of the graphite-resistance type with a flowing helium atmosphere. The original working chamber, 4 inches in diameter by 8 inches in length, was capable of operation at temperatures up to 3000°K when used as designed. As adapted for specific heat determinations however, the maximum operating temperature was found to be 2600°K .

Since the inside of the furnace chamber is essentially a blackbody enclosure, emissivity corrections were not needed for optical pyrometer temperature determinations on enclosed samples.

The operating procedure was first to heat the sample with the furnace heater (K) to the desired temperature. Power for the heaters was supplied by a 20 kilowatt a-c source (M), capable of raising the furnace temperature to nearly 2500°K in a period of about 30 minutes. After sufficient time for the ambient temperature to stabilize, a high current from the d-c power supply (A) was pulsed through the sample (I). Contact with the sample was provided by the water-cooled electrodes (E, E') and the tungsten electrodes (F, F'). The graphite shields (G, G'), located on the tungsten electrodes, served to reduce end-radiation losses and acted as an alignment guide for the sample.

The d-c through the specimen caused a constant power to be dissipated uniformly throughout the sample volume. If no significant amount of heat were lost or measurements were made before such losses became sizable, the temperature of any sample region increased linearly with time. The specific heat at constant pressure, C_p° , could then be computed from the current, I, through the specimen, the potential drop, E, across a uniformly heated region of mass, m, and the rate of temperature increase as a function of time, dT/dt . The relationship between these quantities and C_p° is given by equation (253),

A	DC POWER SUPPLY	H-H'	POTENTIAL PROBES-TUNGSTEN

G-G'	RADIATION SHIELDS-GRAPHITE		

Figure 13 HIGH-TEMPERATURE SPECIFIC HEAT APPARATUS

$$C_P^o = \frac{EI}{J_m(dT/dt)} \quad (253)$$

where J is the mechanical equivalent of heat.

The specimens, 1/2 inch in diameter and 4 inches in length, were slotted over a 2-inch center portion. The slots which were 1/16-inch wide and 1/4-inch deep extended the measurement time from less than 0.1 to 0.2 sec. This is due to the fact that the rate of rise of the specimen surface temperature was influenced sooner than the rate of rise of the center temperature by radiation losses to the heater element after a heat pulse.

The ambient temperature in the furnace was determined with a pyro-optical pyrometer, C, calibrated against NBS-calibrated tungsten-strip lamps, and corrected for the error introduced by an interposed quartz window. Periodical cross checks of the strip lamps were made with a gold melting-point apparatus. Typical pyrometer and quartz-window corrections are plotted in figure 14. Results of 20 pyrometer and lamp cross checks are summarized in Table LXXVIII. It can be seen that very little variation occurred in the calibration factor during the period of the project (1 year).

An optical pyrometer similar to that described by Rasor and McClelland²⁷ was used to record the temperature as a function of time on a Dynagraph recorder. The pyrometer used in this work employed a type 925 phototube with an S-1 spectral response. It was capable of response times of less than 0.01 sec. Calibration of this recording optical pyrometer, B in figure 13, was accomplished by comparison of a reading from a corrected, separate, micro-optical pyrometer with the phototube output recorded on a channel in the Offner Electronics Dynagraph recorder.

The determination of the rate of change of temperature as a function of time was done by means of equation (254),

$$\frac{de}{dt} \cdot \frac{ds}{de} \cdot \frac{dT}{ds} = \frac{dT}{dt} \quad (254)$$

where

e = applied voltage

t = time

s = number of scale divisions

T = temperature.

* High-purity gold strip 1/6-inch wide x 0.005-inch thick.

** Platinum-platinum 10 percent rhodium, reference grade.

The first term on the left-hand side of equation (254) was obtained directly from the Dynagraph chart. The second term is a calibration term which was obtained by applying a known potential from a K-3 type potentiometer directly to the Dynagraph. The third term is the optical pyrometer calibration obtained as described above.

The potential drop, E , needed for equation (253) was obtained from the spring-loaded tungsten potential probes (H , H'). The current was determined from the potential drop across a high capacity shunt (2000 amperes maximum). Each of the needed quantities was recorded on a separate channel simultaneously.

The Dynagraph was well-suited for these measurements since it provided zero suppression in each channel, and only the deflections caused by the current pulse were recorded. Its response time of less than $1/120$ sec and its chart speed of 25 cm/sec were also advantageous. Typical curves from Dynagraph records are illustrated in figure 15.

The specific heat values obtained by the techniques described were estimated to be accurate to within ± 5 percent.

4. Discussion of Results of High-Temperature Determinations

High-temperature specific heat determinations were completed with the pulse technique apparatus on four carbides, four borides, and one nitride. Average results at 2000° , 2300° , and 2500°K are summarized in Table LXXIX for purposes of discussion. These data were treated in the same way as those in Table II (section III-C 5) of this report.

Most of the values are very large compared to the classical high-temperature limit of lattice harmonic vibration contributions ($3R$), but this is not unexpected. A few of the values are surprisingly high and still increasing with the temperature. These extremely large values are from samples of low purity (TiC and TiB_2). Because there is not enough past experience with data on these compounds at such high temperatures, it would be desirable to make a more detailed theoretical analysis, but that is not possible without the use of several other types of unavailable data in very complete form (refer to section III-C of this report for the applicable theoretical background).

For the reasons just-mentioned, it is important to subject high-temperature heat capacity data of this type to the test of comparison with the results of other workers. In the discussions that follow, the advantages of doing this will be evident. A number of positive checks support the general validity of the measurements made on this project. In the cases where there is not the required agreement, further work is required to find out the reasons which very likely will vary from one case to another.

One particularly important aspect of the work has been the verification of the purity of all test samples. This was done in pre-test analyses in nearly all cases. It resulted in the discontinuation of studies on the molybdenum boride sample because it was found to consist of four phases, Mo_2B , MoB , MoC , and Mo . A few post-test analyses were carried out to investigate any chemical or phase changes that might occur during the specific heat determinations.

a. Carbon

Carbon is a common element which has many uses in high-temperature technology in the form of graphite because of its extremely high melting point (in fact, it sublimates at one atmosphere without melting). Yet, its thermodynamic properties at high temperatures are still not known with any degree of assurance. Outstanding deficiencies in its available thermodynamic data are its equilibrium vapor species, the heats of vaporization of its vapor species, spectroscopic data for the vapor species other than C_2 , and the specific heat of the solid at high temperatures. It was stated in section IV-A4a of this report that thermodynamic functions of graphite up to 6000°C could not be provided until better specific heat data became available. A review of the available data is therefore in order.

The available specific heat data for carbon are plotted in figure 16 for comparison purposes. Some of the additional points obtained on this project are given in Table LXXX and plotted in the figure also. The agreement between sets of data from different sources^{27, 29, 173} is not very good except for that between the points from this project and the curve of Rasor and McClelland.²⁷ The sharp rise above 3000°C needs confirmation. Extrapolation to the sublimation point is obviously impossible.

b. Niobium Carbide (NbC)

The X-ray diffraction pattern of the niobium carbide specimen used in the specific heat determinations was that of NbC plus a weak pattern of Nb_2O_5 . The results of the chemical analyses were as follows:

Element	Percent
Nb	86.66
Total C	10.81
Free C	<0.01
(continued on p. 1-354)	

Figure 16 THE SPECIFIC HEAT OF CARBON VERSUS TEMPERATURE

Fe	0.06
Mg	0.0003
N	0.47, 0.46
O	0.22

Al, V, Ti, Zr, Ni, Mn, Hf, and Cr were not detected.

Since an unreported transition was discovered at $\sim 2440^\circ\text{K}$ and heat capacity values were high in the first series of specific heat measurements on NbC, the work was repeated with another sample to avoid any possibility of an accidentally wrong or impure sample. The temperature region in the vicinity of the transition point was extensively studied; several runs were made in both directions of increasing and decreasing temperature. Another purpose of repeated re-cycling of test runs was to detect any drift in specific heat with time due to reduction of the sample by the carbon vapor in the furnace.

The results are summarized in Table LXXXI and figures 17 and 18.

The transition was found to be completely reversible. A transition temperature of 2437°K was chosen. The nature of this transition remains to be clarified. The available information about the phase diagram of the Nb-C system^{241, 490} provides no clues as to its nature since a broad homogeneity range exists at the stoichiometric composition. Other investigators²⁹ have not reported evidence for its existence, but the density of points in their work in the region of the transition temperature was not sufficient for this purpose.

The only available data from two sources are compared in figure 19. It is evident from this comparison that more experimental work will be required on the heat capacity of NbC.

c. Tantalum Carbide (TaC)

X-ray analysis of the tantalum carbide test specimen showed it to be a single phase of TaC. The results of the chemical analyses were as follows:

⁴⁹⁰Storms, E. K. and N. M. Krikorian, J. Phys. Chem. 64, 1471 (1960).

The results of the high-temperature specific heat measurements are summarized in Table LXXXII and figure 20. A comparison of data from all sources is made in figure 21. The Southern Research Institute data²⁹ appear to have the best overall temperature dependence, but their general level appears to be slightly low in comparison with that of the other two sets of data.

Better agreement between the TaC specific heat data from various sources^{29, 491} would be desirable for the preparation of thermodynamic tables. Further measurements were being made on a second specimen at the time of report writing to help resolve these discrepancies.

⁴⁹¹Margrave, J.L. Private Communication (21 March 1961).

Figure 21 COMPARISON OF TANTALUM CARBIDE SPECIFIC HEATS

d. Titanium Diboride (TiB_2)

The X-ray diffraction diagram of the titanium diboride specimen was composed of a TiB_2 pattern and weak additional lines that were not identified. The following results of the chemical analyses showed that the specimen was only about 92 percent pure:

Element	Percent
O	0.77
C	1.24
B	26.61
Total Ti	64.90
Cu	0.005
Al	<0.1
Mn	----
Zr	0.51
Nb	0.09
Hf	<0.1
Fe	0.17
Cr	----
V	----
Mg	<0.001
Ni	----

Specific heat measurements were continued on the impure TiB_2 specimen since it was felt that corrections could be made later for the impurities and that the results would provide information on the effect of impurities on C_p° values at high temperatures. The results are summarized in Table LXXXIII and figure 22.

TABLE LXXXIII

TITANIUM DIBORIDE (TiB_2) HEAT CAPACITY
(Approximately 92 percent purity)

2203	0.604	13.10
2246	0.607	13.17
2310	0.675	14.65
2364	0.647	15.00
2396	0.680	15.76
2417	0.680	15.76

Figure 22 SPECIFIC HEAT OF TITANIUM DIBORIDE VERSUS TEMPERATURE

A comparison of these results with those of Margrave⁴⁹¹ (purity unspecified) is shown in figure 23. The specific heat of the impure specimen appears to be exceedingly high. Nothing else was found in the measurements to account for these high results. The surprisingly large apparent effect of the impurities in this specimen should be further investigated.

e. Titanium Carbide (TiC)

X-ray diffraction analysis of the titanium carbide specimen showed it to consist of a single phase of TiC. The following results of chemical analyses showed its purity to be approximately 95 percent:

Element	Percent
Cu	0.004
Al	<0.1
Mn	----
Zr	0.56
Nb	0.09
Hf	<0.1
Fe	0.12
Cr	----
V	----
Mg	<0.001
Ni	----
Total Ti	77.41
Free Ti	0.5
Total C	17.78
Free C	0.43

Figure 23 COMPARISON OF TITANIUM DIBORIDE SPECIFIC HEATS

The results of the specific heat measurements are summarized in Table LXXXIV and figure 24. Figure 25 shows a comparison of available specific heat data on TiC . 56, 464 The agreement between different sets of data is very poor. Impurities here again appear to have a large effect on both the level and slope of the specific heat versus temperature line obtained on this project.

f. Titanium Nitride (TiN)

The specific heat determinations on TiN were made in connection with another project wherein analytical data were not obtained. The results are reported here because of their importance to this project.

The results are summarized in Table LXXXV and figure 26. The data from various sources are compared in figure 27. The agreement between the sets of data is better in this case than in the others already considered. The purity of the TiN specimen used on this project was therefore probably satisfactory.

g. Tungsten Boride (WB)

X-ray diffraction analysis of the tungsten boride specimen revealed the existence of a single phase of WB . The following results of the chemical analyses showed that the sample purity was approximately 98.9 percent:

Element	Percent
W	93.7
B	5.16
C	0.09
O	0.16
N	0.01
Impurities	~ 0.88

The results of the specific heat determinations are summarized in Table LXXXVI and figure 28. The values in units of cal/°K avg g atom seem reasonable for the temperature range covered.

2086	0.102	9.93			

h. Zirconium Diboride (ZrB_2)

The X-ray diffraction diagram of the zirconium diboride specimen contained a pattern of hexagonal ZrB_2 plus a weak pattern of ZrC . The following results of the chemical analyses indicated a purity of approximately 95.8 percent:

Element	Percent
Zr	78.94
B	16.86
O	1.36
Total C	0.37
Hf	<0.25
Fe	0.18
Ti	0.14
Mg	<0.01
Cu	<0.05
Mn	<0.01
V	<0.2
Nb	<0.01
Ni	<0.5
Cr	<0.1
Al	<0.3
N	0.14

Results of the specific heat determinations are summarized in Table LXXXVII and figure 29.

Repeated runs on the same specimen of ZrB_2 revealed no drift in specific heat versus time. This was taken as evidence that the effect of reactions with the carbon vapor in the furnace was negligible.

Specific heat determinations were repeated several times in this case also in an attempt to detect any effect of the carbon vapor. No effect can be detected in the data which are summarized in Table LXXXVIII and figure 30. Specific heat data from various sources are compared in figure 31. Sample impurities (~4.3%) are probably again the cause of the high values in the figure 30 data.

C. SPECTROSCOPIC STUDIES

1. Introduction

Two important experimental techniques for the study of the vapors of refractory materials are as follows: (a) the vapor effusion technique with mass spectrometric identification of vapor species, and (b) the recording of the optical absorption or emission spectra of the vapors. These two techniques complement each other in that each provides needed data which the other cannot give.

The effusion-mass spectrometer technique, which has provided most of the published data, provides species identification and vapor pressures as a function of temperature of the various species in equilibrium with the condensed phase. From these quantitative data, one can calculate a number of thermodynamic properties, but a complete thermodynamic analysis requires the use of molecular parameters provided by optical spectroscopy.

Experiments utilizing optical spectroscopy can also be made to give quantitative data on the overall vapor-condensed phase equilibria, but usually not as easily and unambiguously as the effusion-mass spectrometer method. The great value of the optical spectroscopic technique is that it can give information on the intrinsic properties of the vapor species themselves. For example, the optical spectra yield molecular vibration frequencies which are needed for statistical mechanical calculations of free-energy functions, entropies, and enthalpies. Optical spectra also yield molecular configurations, force constants, bond strengths, and bond lengths, which are necessary for a basic understanding of chemical bonding and chemical reactions at high temperature. The latter parameters of similar compounds are often used to estimate vibration frequencies, moments of inertia, etc., for statistical mechanical calculations on species whose spectra have not been studied.

Part of the program of experimental studies in Phase III of this project was concerned with the determination of the molecular quantities just discussed for the vapor species in equilibrium with the solid phases of the refractory compounds included in the scope of the contract.

2. Experimental Technique

Absorption spectroscopy has been utilized in these studies of refractory compound vapors in preference to emission spectroscopy because it presents fewer basic experimental difficulties. The emission spectrum of a high-temperature vapor can be observed if the radiation emitted by the gaseous molecules can be distinguished from that scattered and emitted by hot particles condensed from the vapor. If condensation is successfully minimized or avoided, the use of a sensitive detection system will permit the emission

spectrum to be observed over a short optical path. Unfortunately, it is experimentally difficult to avoid condensation in systems at very high temperature, and other measures must be taken to circumvent the problem. When an absorption spectrum is recorded, the problems presented by emitting and scattering condensate particles can be greatly reduced by modulation of the light from the source before passing it through the vapors. A tuned detection system can then discriminate the transmitted light from the light which originates in the hot zone. This does, however, require a relatively long optical path.

The present absorption work was performed with light paths of up to 200 feet through the hot vapors. Such long paths were achieved by the use of the White multiple reflection technique.⁴⁹² The absorption spectrum could be observed conveniently when the vapor pressure above the refractory sample was only a few microns. Being able to work at low vapor pressure presented a number of advantages, among which were the following:

- a. Small quantities of material could be used and the sample was not lost rapidly.
- b. It was not necessary to have inert gas present. Hence, convection currents were eliminated, and particle condensation was greatly reduced.
- c. Reactions between the hot container and the material under study were usually not serious when the vapor pressure of the material was low.
- d. Since convection currents were eliminated, it was not necessary to confine the vapors to a uniformly heated tube, and the refractory material could be evaporated from a hot filament, thus keeping power input and heat removal requirements down to a minimum.

A schematic diagram of the experimental apparatus is given in figure 32. Figure 33 is a photograph of the experimental apparatus (not including the power supply), and figure 34 shows some details of the interior of the reaction chamber. The entire heating, cooling, and optical assembly was mounted on an aluminum channel which slid out of the vacuum tank as shown in figure 34.

The heating element from which the material was evaporated consisted of a tungsten ribbon 0.004 inch thick, 1-1/2 inches wide, and 24 inches long. This ribbon was heated by the current from a bank of batteries and could reach temperatures above 3000°K. One end of the tungsten ribbon was connected directly to the electrically grounded channel. The other end went to

⁴⁹²White, J. N., J. Optical Soc. Am. 32, 285 (1942).

Figure 32 SCHEMATIC OF APPARATUS WITH FOLDED LIGHT PATH

the plus side of the batteries through a flexible cable which was spring-loaded to prevent the tungsten ribbon from going slack when it expanded on heating.

The heat radiated by the hot filament was removed from the interior of the vacuum tank by means of a water-cooled copper shield (shown in Fig. 34) which surrounded the sample. The heating element was sufficiently remote from the mirrors so that the latter did not heat up excessively or become coated with the condensed refractory vapor.

The vacuum chamber consisted of a steel pipe 8 inches in diameter and 11 feet long. The ends of the pipe were closed with Lucite discs in which were mounted KBr or CsI windows. It was evacuated by means of mechanical pumps to about 2 microns of pressure.

The spherical mirrors were aluminum-coated and had a 10-foot radius of curvature.

In operation, light from the Nernst glower source was projected into the White mirror system as a 4X-enlarged image; and, after being passed the desired number of times through the vapors, it was focused as a much-reduced image into the Perkin-Elmer monochromator. The number of light passes through the vacuum chamber depended on the angle between the mirrors paired at one end of the cell. When a total light path of 1000 feet was used (200 feet over the filament), the transmitted light was still detectable over the spectral region accessible with sodium chloride optics. The 13-cycle light modulation took place prior to traversal through the vapor. The tuned detection system responded only to light which had been passed through the vapors and not to unmodulated light emitted or scattered by hot particles or gases in the tank. By the use of various prisms and detectors, the spectral region from 0.2 and 40 microns could be covered.

A typical experiment was performed as follows:

- 1) The powdered refractory was sprinkled on the tungsten ribbon.
- 2) The carriage was pushed into the vacuum tank, water and power connections were made, and the optical system was adjusted for the desired number of traversals, which might be 100 or less.
- 3) The tank was evacuated to a pressure of 1 or 2 microns.
- 4) The desired current, usually between 200 and 500 amperes, heated the filament and slowly vaporized the refractory powder.

- 5) The absorption spectrum of the vapors was recorded while they were diffusing to and depositing on the water-cooled shield.
- 6) The filament temperature was read by sighting with an optical pyrometer through the Lucite disc at one end of the vacuum chamber.

3. Experimental Results

a. Silicon Carbide

Silicon, evaporated from a carbon filament, and silicon carbide, evaporated from a tungsten filament, both yielded the absorption spectrum shown in figure 35. The light path through the heated vapors was approximately 150 feet long.

According to Drowart et al the vapors in equilibrium with silicon carbide at 2200°K include approximately 5×10^{-6} atmosphere each of SiC_2 and Si_2C .⁴⁹³ They are the most predominant species in the vapor, except for silicon atoms.

In the optical spectrum, there appeared to be one strong broad band centered at about 1080 cm^{-1} and two weaker bands centered at about 850 cm^{-1} and 600 cm^{-1} , respectively. The breadth of the bands was considerably greater than one is accustomed to seeing in absorption spectra at ordinary temperatures. This breadth may be attributed both to the spreading of the rotational structure due to the high temperature and to the superposition of "hot" bands on the fundamental band. It appears to be impossible to locate the band origin exactly. Therefore, the best that can be done is to choose the center of the band and to assign to it the corresponding vibrational frequency.⁴⁹³

Kleman has observed blue-green electronic emission bands, which he ascribed to SiC_2 , and from an analysis of the spectrum, predicted infrared bands at 1742 and 591 cm^{-1} , but not at 1080 cm^{-1} .⁴⁹⁴ It, therefore, seemed likely that the emitter of the 1080 cm^{-1} band was Si_2C . Drowart assumed Si_2C to be a linear asymmetric molecule, by analogy with SiC_2 , and estimated its vibration frequencies to be $\omega_1 = 799 \text{ cm}^{-1}$, $\omega_2 = 265 \text{ cm}^{-1}$, and $\omega_3 = 446 \text{ cm}^{-1}$. It appeared more likely, however, that the structure of the SiC_2 molecule was linear symmetric (Si-C-Si) because the magnitude of the vibrational force constants shows definitely that the Si-C bond is stronger than that of Si-Si (for Si-C, $k = 3.1 \times 10^5$ dynes per cm, and for Si-Si, $k = 2.1 \times 10^5$ dynes per cm).⁴⁹³

⁴⁹⁴Kleman, B., Astrophys. J. 123, 162 (1956).

Figure 35 INFRARED ABSORPTION SPECTRUM OF VAPORS FROM A SILICON-CARBON SYSTEM HEATED TO 2200° K

The assumption that the structure is Si-C-Si permits the calculation of the force constants from the observed infrared spectrum.⁴⁰⁰ Only the ω_3 band is expected to occur in the region from 2 to 15 microns. ω_1 is not infrared active because of symmetry considerations; and ω_2 , the bending mode, will occur at longer wavelengths. The 1080 cm^{-1} band must therefore be associated with ω_3 , and the corresponding force constant is $k = 3.4 \times 10^5$ dynes per cm. This value of k corresponds to the bond strength of the Si-C bonds in SiC_2 , where $k = 2.9 \times 10^5$ dynes per cm, and to that in SiC , where $k = 3.1 \times 10^5$ dynes per cm. ω_1 , associated with the symmetric stretching vibration, was calculated from k to be 447 cm^{-1} . If the bending force constant, k_δ , is similar to that measured for CO_2 and CS_2 , or approximately 0.65×10^{-11} dyne-cm/rad, the doubly degenerate vibrational mode, ω_2 , will occur at about 435 cm^{-1} . No particular band is evident at that frequency in figure 35. If the band exists, it must be very weak and is probably overlapped by the broad 591 cm^{-1} ω_1 band of SiC_2 which is perhaps discernible in the spectrum.

The somewhat narrower band which shows in the spectrum at 850 cm^{-1} may possibly be due to an impurity; it does not seem likely that it would be due to any species containing only silicon and carbon. Pure silicon was vaporized, and its spectrum was recorded to see whether this band might possibly be due to Si_3 . This was found not to be the case. The silicon vapor showed no absorption bands in the region from 2 to 15 microns even at high partial pressure.

b. Molybdenum Trioxide

As stated in section IV-B5, there were no spectroscopic data reported for the gaseous species of molybdenum oxides. The properties of these oxides made them good candidates for study by the techniques described in section V-C2 above, and the investigation was undertaken.

The infrared absorption spectrum of the vapors from MoO_3 is shown in figure 36. It consists of one strong band centered at about 810 cm^{-1} . MoO_3 was reported 427, 417 to vaporize principally as the trimer, Mo_3O_9 . A likely structure for this trimer appears to be a puckered, 6-membered ring of alternating molybdenum and oxygen atoms with the other 6 oxygen atoms doubly bonded to the molybdenum atoms, 3 above the ring and 3 below.

The vibrational pattern of such a large molecule is undoubtedly extremely complicated, but it can be expected to have as a predominant feature the stretching of the 6 Mo=O bonds. Hence, it seems reasonable to attribute the one strong band observed to the stretching vibration between oxygen and the rest of the molecule. This permits the calculation

Figure 36 INFRARED ABSORPTION SPECTRUM OF VAPORS FROM
MOLYBDENUM TRIOXIDE HEATED TO 1040° K

of the stretching force constant, k , from equation (255), where μ is the reduced mass, and ν the frequency.

$$\nu = \frac{1}{2\pi} \sqrt{\frac{k}{\mu}} \quad (255)$$

The value thus obtained is $k = 6.0 \times 10^5$ dynes/cm.

This value of k can then be used to calculate vibrational frequencies for the molecules MoO_2 and MoO_3 if the reasonable assumption is made that the $\text{Mo}=\text{O}$ bonds in MoO_2 , MoO_3 , and Mo_3O_9 are similar. This calculation yields the values $\omega_1 = 794 \text{ cm}^{-1}$ and $\omega_3 = 915 \text{ cm}^{-1}$, for a linear MoO_2 molecule. The estimated value of the k used in the calculation of section IV-B5b of this report would yield $\omega_1 = 778 \text{ cm}^{-1}$ and $\omega_3 = 898 \text{ cm}^{-1}$ for a linear MoO_2 . The experimental observations thus tend to confirm the estimates used in the calculations. To revise the calculations to correct for the slight discrepancy between the estimated and experimentally measured values does not seem justified at present since the uncertainties would still remain in the value of ω_2 , and they would affect the thermodynamic functions to a greater extent than the uncertainties in ω_1 and ω_3 .

Further spectroscopic study of the gaseous molecules CrO_3 , MoO_3 , and WO_3 over the full spectral range out to 250 cm^{-1} will undoubtedly provide a better insight into the molecular properties, and reduce the uncertainties involved in estimating the molecular configurations and vibrational frequencies of these species.

c. Tungsten Trioxide

Tungsten trioxide, like molybdenum trioxide, was reported to vaporize chiefly as the trimer,⁴¹⁷ which probably has the same structure as the latter, consisting of a 6-membered ring of alternating tungsten and oxygen atoms plus 6 other oxygen atoms doubly bonded to the tungstens. Its one strong infrared absorption band, which is shown in figure 37, could therefore also be assigned to the stretching vibration between oxygen and the rest of the molecule just as in the case of molybdenum trioxide. In fact, the MoO_3 and WO_3 molecules are analogous in most respects; and for the reasons outlined in the preceding paragraph, calculations based on the W_3O_9 spectrum will not be made until further experiments have been conducted.

Figure 37 INFRARED ABSORPTION SPECTRUM OF VAPORS FROM TUNGSTEN TRIOXIDE HEATED TO 1640° K

d. Boron Oxides

1) B_2O_3

The infrared absorption spectrum of the vapors from B_2O_3 is shown in figure 38. The path length through the gas for this experiment was approximately 200 feet. Analytical reagent-grade boric anhydride powder was sprinkled on the tungsten ribbon and vaporized at the temperatures given in the figure. From the appearance of the ribbon, there seemed to be no appreciable amount of reaction between the B_2O_3 and the tungsten.

In an article on gaseous B_2O_3 and B_2O_2 , White et al⁴⁹⁵ have published an infrared emission spectrum of B_2O_3 , and from it, have calculated force constants, vibrational frequencies, and thermodynamic functions. The three bands they observed in emission are marked in dotted lines at the bottom of figure 38. The band at 2050 cm^{-1} was the strongest in emission, the one at 1300 cm^{-1} was less strong, and the one at 740 cm^{-1} was the weakest. As figure 38 shows, the relative intensities in absorption are much different from this. Actually, the 2050 cm^{-1} band, White's strongest, does not appear at all in the absorption spectrum, except at the highest temperatures. The effect of the Planck function on the emission intensity would account for only a small part of this intensity discrepancy.

Dows and Porter⁴⁹⁶ also studied the infrared emission of B_2O_3 and observed a band in the vicinity of 2000 cm^{-1} . This was the only band they observed. The present results are, therefore, in disagreement with those of two previous groups of investigators on the presence of a strong B_2O_3 band near 2000 cm^{-1} . The absorption spectrum of solid B_2O_3 does not show a band in the vicinity of 2000 cm^{-1} ; however, it is similar to (but not identical with) the spectrum presented herein for the vapor. The solid shows bands near 3400 cm^{-1} (O-H?), 1470 cm^{-1} , and 750 cm^{-1} . The spectrum of the solid was recorded from Baker-purified boric anhydride dispersed in a KBr pellet.

An investigation of the vapor of B_2O_3 by the matrix isolation technique has also been reported.⁴⁹⁷ The spectrum in this case differs from both of those described above.

⁴⁹⁵ White, D., D. E. Mann, P. N. Walsh, and A. Sommer, J. Chem. Phys. 32, 481 (1960).

⁴⁹⁶ Dows, D. A. and R. F. Porter, J. Am. Chem. Soc. 78, 5165 (1956).

⁴⁹⁷ Union Carbide Corp., Research in Physical and Chemical Principles Affecting High Temperature Materials for Rocket Nozzles, Semiannual Progress Report to ARPA, Union Carbide Research Inst., Tuxedo, N. Y. and Parma Research Center, Cleveland (31 December 1960).

Figure 38 INFRARED ABSORPTION SPECTRUM OF VAPORS FROM BORIC ANHYDRIDE AT TEMPERATURES BETWEEN 1400° AND 1600° K

Because agreement between investigators on the spectrum of B_2O_3 was not achieved, it did not seem justified to make vibrational assignment until the discrepancies had been resolved. If the 1350 cm^{-1} and the 720 cm^{-1} bands in the absorption spectrum in figure 37 come from the same molecule as the 1300 and 740 cm^{-1} emission bands of White et al,⁴⁹⁵ then the 2040 cm^{-1} emission band of White et al⁴⁹⁵ must have come from some other boron-containing species.

This may also have been the case in the work of Dows and Porter.⁴⁹⁶ The investigation of B_2O_3 is being continued at present. Conclusions from the spectrum of B_2O_3 should be held in abeyance until the above discrepancies are removed.

2) B_2O_2

B_2O_2 was prepared both by reaction of MgO with boron and by reaction of B_2O_3 with boron. In each case, a material was produced which gave the infrared absorption spectrum shown by the solid curve in figure 39. The powdered B_2O_3 -boron and MgO -boron mixtures were reacted on the tungsten ribbon at a ribbon temperature of approximately $1400^\circ K$. The light path through the vapor was approximately 200 feet.

Boron which was isotopically enriched to 90 percent B^{10} was also reacted with MgO and the spectrum of the product recorded. This spectrum is shown by the dotted curve in figure 39. The isotopically enriched elemental boron must have been purer than the naturally occurring isotopic mixture because the 940 cm^{-1} and 1180 cm^{-1} bands are weaker in the B^{10} spectrum. The weakening of these bands plus the fact that they were not isotopically shifted would identify them as impurity bands. The 2550 cm^{-1} band was also not shifted. The 3500 cm^{-1} and 500 cm^{-1} bands were not investigated for isotopic shift. The 3500 cm^{-1} band was most likely due to hydrated species of some kind. Only the 1410 cm^{-1} was isotopically shifted, the shift being between 30 and 50 wave numbers. The latter band was therefore the only one that could be attributed definitely to B_2O_2 . If B_2O_2 were a linear, symmetric molecule like its isoelectronic analog, C_2N_2 , it should have only one fundamental band in this part of the infrared spectrum.

White et al⁴⁹⁵ attributed an emission band at 1890 cm^{-1} to B_2O_2 , and from it, calculated thermodynamic functions. However, no absorption was observed at that wavelength in the present work.

The infrared active ω_3 vibration of linear symmetric B_2O_2 should experience an isotopic shift of $+42\text{ cm}^{-1}$ in going from B^{11} to B^{10} .

Figure 39 INFRARED ABSORPTION SPECTRUM OF B_2O_2 VAPORS
FORMED AT $1400^\circ K$

The observed shift of +30 to +50 cm^{-1} thus tends to confirm the chemically plausible assumptions that B_2O_2 is the actual species produced in these reactions and is a linear, symmetric molecule.

The effect of an unknown amount of condensate-particle contamination is an ever-present problem in this type of work. The present apparatus was used in an attempt to minimize the problem, but it remained to be proved that this goal had been achieved. Several experiments were planned at the end of the report period to settle this question. For example, in the case of the B_2O_3 spectrum, it is possible that the 2040 cm^{-1} emission band of White et al.⁴⁹⁵ comes from B_2O_3 monomer and the 1300 cm^{-1} and 740 cm^{-1} bands come from polymers or condensate particles.

VI. RECOMMENDATIONS

This report naturally does not bring down the final curtain on the subject of the thermodynamics of highly refractory compounds. A number of important theoretical problems remain to be solved, complete and accurate basic data are still not available for a majority of the species of interest, and many refinements remain to be made in the methods and procedures in current use for estimating missing property data.

The specific heat of condensed phases at high temperatures is a subject worthy of further attention both from the theoretical and experimental standpoints. The theory of vibrational contributions to the specific heat of solids is sufficiently well-advanced, but this suffices only at low temperatures as defined in this project. Some progress has been made in elucidating anharmonicity corrections,^{498, 499} but much more needs to be done in applying the theory to specific crystal systems. It appears from what few data are available that other important contributions arise at high temperatures, and that theoretical expressions for their temperature dependence are unavailable.

This lack of theoretical background is felt most in extrapolations of C_p° data to temperatures beyond those of the available data. Such extrapolations should be carried out separately on the various contributions to C_p° from an understanding of how each contribution depends upon the temperature. Such practices as assuming C_p° to be constant or extrapolating empirical equations for its total value introduce large uncertainties which are difficult to estimate since changes in curvature may occur in C_p° versus T at high temperatures (see Fig. 2).

The situation with respect to liquids is the least satisfactory; no attempts have been made to base estimates of C_p° values for liquids on sound theories.

The difficulties of measuring specific heats of condensed phases at high temperatures are very great, and data from various sources most often do not agree. Resorting to experimentation, therefore, does not necessarily result in a reduction in the uncertainties associated with high-temperature thermodynamics. A high degree of confidence in high-temperature thermodynamic property values will come after convincing theoretical interpretations are found for reproducible measurements of C_p° versus temperature.⁵⁰⁰

Samples of interesting high-refractory compounds with a high degree of purity are not readily available, and it is very likely that many of the property determinations in the past have been on samples of doubtful purity unless this has been specifically determined. It would appear that some more work in refining

preparative methods is desirable, so that basic property measurements can be made on pure rather than technical grade samples.

Related to the latter problem is the fact that many interesting refractory compounds can be nonstoichiometric in composition. In fact, theoretical considerations indicate that all compounds can be included in the nonstoichiometric category.⁵⁰¹ Their composition can change whenever some vaporization is allowed to occur at high temperature before it becomes congruent during preparation, study, or end use. Recent studies^{501, 502} have shown that this behavior is related to the existence of lattice defects. Nonstoichiometry is an important high-temperature thermodynamic phenomenon which should receive increased attention both from the basic and applied standpoints.

The two types of data most often missing in connection with refractory compounds and their vapor species are heats of formation and spectroscopic constants. Methods for estimating heats of formation have not been developed, and more experimental measurements are needed to fill the gaps in existing data. Although the estimation of spectroscopic constants is often done, eventual confirmation of the values is desirable. In the case of complex polymeric vapor species such as those of the Mo-O and W-O systems, some information about the molecular structure must be available before any estimation of the spectroscopic constants can be attempted. Optical spectroscopic methods appear to be the most neglected of those that can be used in the study of refractory compound vapors.
