ABSTRACT

Our current objective, process optimization, appears to be nearing completion. The work done during this report period is leading to the optimization of two methods of treatment and treatment of samples for in-use or simulated in-use testing. Descriptions of the treatments of samples listed below are included in the report.

- 1) Water lubricated shaft bearings for U.S. Navy Engineering Experiment Station.
- 2) Retractable mast seals (chevron) for Portsmouth Naval Shipyard.
- 3) B138 and B142 experimental compounds from Puget Sound Naval Shipyard.
- 4) Four inch I.D. Buna N butterfly valve liners.

"This document may not be reproduced or published in any form, in whole or in part, without prior approval of the Bureau of Ships. Since this is a progress report, the information herein is tentative and subject to changes, corrections and modifications."

SAMPLE TREATMENT

During this period, samples were treated for three separate sources within the Navy and one industrial source with direct naval application. These samples have been returned to their sources and we are awaiting the return of test data.

Two sets of samples were received from the Puget Sound Naval Shipyard. One set consisted of four "O" rings; the other, tensile slabs and compression-set buttons of new compound formulations.

The "O" rings were identical in size to the "O" rings described in previous reports. No information on these rings was received except that they conformed to the specifications listed in Mil P5516. The treatment given these samples is described in Experiment 264. All were treated on the steel mandril constructed for a previous set of samples. All were slippery on the outer half and virtually unchanged on the inner half. These samples were returned via Code 634C.

The second set of samples consisted of tensile slabs and compression-set buttons fabricated from two special compounds developed at the Puget Sound Naval Shipyard. These compounds were identified by the numbers B138 and B142. Our objective was to find a satisfactory treatment for each of the compounds; treat and return any available tensile slabs and all the compression-set buttons. Initial treatments were done on tensile slabs; frictional and physical tests were run (see Exp. 236). Good coefficients of friction were

obtained by the various treatments, and it should be noted that although several samples ran extremely hot, they did not seize. The frictional surfaces also became extremely hard due to post cure effects. No significant loss of tensile properties was evidenced by comparison with the retain samples. The retains, however, exhibited much lower physical properties than were originally recorded. Puget Sound Naval Shipyard was notified by a letter report of our findings. Because of the extreme loss of properties on room-temperature storage, we do not plan any further work on these compounds unless specifically requested to do so.

During this period in Experiment 234, we treated four BFA butterfly valve liners for the W. W. Lockwell Co., of Fairfield, Connecticut. Mr. A. Zelle, Director of Engineering, informed us that these liners will be tested and the results reported to us as soon as previously started tests are completed. This data should be available by the end of the next report period.

A visit was made to the Portsmouth Naval Shipyard, Kittery, Maine to explain the possible advantages of the "Slippery Rubber" process in their particular applications. As a result we obtained a set of chevron seals currently being tested for retractable mast applications. These seals were highly filled elastomer, typified by the AN623.40 specification. These samples were treated in Experiment 262. The effect of the treatment was to produce a very slippery surface. Tensile properties, however, were severely reduced. Since there is no flexing required in the application,

it was deemed of sufficient interest to warrant testing. These tests will be run by the Portsmouth Naval Shipyard and reported to us via Code 6342 when completed.

A set of six water-lubricated shaft bearings were received from the U. S. Navy Engineering Experiment Station at Annapolis, Maryland. These samples are prototypes of the external propeller shaft bearings used on large ships. They are fabricated from Ina N glass-cer bonded to brass supporting plates. These specimens were tested in Experiment 220. A reduction of at least two-thirds in the low-speed unlubricated μ_f was obtained. These samples were returned to the U. S. Navy Engineering Experiment Station for subsequent in-use testing. The results of these tests will be furnished to us when they are completed.

FLUORINATION PROCEDURE

During this report period the high-speed wear tests on Experiment 210, 216, 222 and 224 have been approximately two-thirds completed. These test results will be found at the beginning of the experimental portion of this report. The results completed to date indicate the following:

1. That the use of the BF_3 complex produces a more slippery surface. The increased slipperiness is, however, offset by severe hardening of the surface which produces cracking on flexure.

2. That increased temperature in the fluorination procedure produces an increase in wear life.

3. That the time of fluorination is not directly related to the temperature of fluorination, but is also a function of the permeability of the elastomer itself and/or the previous history of the compound.

The lack of reproducibility of apparently duplicate samples remains inexplicable. Two possible solutions remain. The first, poor circulation of the fluorinating medium, will be eliminated by the installation of a magnetically driven fan in the pressure container. The second must be a function of the base elastomer itself. If the compounding ingredients are not homogeneously dispersed in the rubber matrix, this can be resolved by master batching a compound in the normal manner and then milling portions for longer periods of time. By this method it should be possible to determine whether or not the specific composition of small areas of the test specimen contributes significantly to the wear life.

A series of 13 runs, Experimental 246, evaluating the effect of time, temperature, $\text{BF}_3 \cdot \text{SF}_4$ complex concentration and SF_4 concentration on samples having no treatment other than cleaning and drying has been made. All data except highspeed wear testing are tabulated in the experimental section of this report. Our initial evaluation of this series is reported in the following section of the report.

CONCLUSIONS

Our tentative conclusions that the entire treatment could be accomplished within the pressure vessel have been borne out by the results of Experiment 226. Wear lives of 2000 hours for Buna N, 52 hours for Neoprene, 2000 hours for Natural rubber and 166 hours for SBR were obtained. These samples treated for one hour at 115°C under autogeneous pressure show the feasibility of this time-saving method. A more complete experiment, No. 246, covering three temperatures, SF_6 and $BF_3 \cdot SF_4$ complex loadings, and three pressure levels has been partially evaluated. Complete evaluation of these results should indicate the proper treatment for this evaluation of samples received for the slippery rubber treatment.

We now have two graft fluorination methods available for treating samples. Both of these methods involve the use of an unfluorinated monomer as one of the starting materials and SF_4 to produce the final slippery surface. Neither of these methods will be satisfactory for all samples, but by using either one, or a combination of both, we have been able to successfully slipperyize all samples which have thus far been submitted. We are looking forward to receiving more samples for treatment and subsequent testing.

FUTURE WORK

During the coming period we will complete the wear tests on the one-step graft fluorination procedure and investigate the possibility of using sulfur dichloride and sodium fluoride to

accomplish the fluorination of samples in the low-pressure reaction vessel. In addition, we plan to prepare low molecular weight

oligomers having the basic chain unit of $\left(\text{CH}_2\text{CH} \begin{array}{c} \text{CF}_3 \end{array} \right)_n$. It will be necessary to prepare these oligomers by indirect methods, since low

molecular weight polyacrylic acid polymers are inaccessible by direct methods. Methods for grafting these oligomers to base glass

surfaces are being developed and the resultant surfaces collected in

the same test program as currently produced samples.

Experiment No. 262 - Treatment of Chevron seals for Portsmouth Naval
Shipyard

Retractable Mast seals

Treated with one-step graft-fluorination method

Time @ temperature	60 min.
Average temperature	115°C
Maximum psi	11.3
SF ₄ used	20.0
Acrylic Acid used	10.0 g.

Samples were slightly harder but with a sufficiently low coefficient of friction to warrant in application testing. Testing will be done at Portsmouth Naval Shipyard and results forwarded through Code 634C.

Experiment No. 264 - Evaluation of new rubber stocks

Samples of Buna N - SBR - Natural rubber

Fluorination by one-step graft fluorination method

Time @ temperature	60 min.
Average temperature	115°C
Maximum psig	16.2
SF ₆ used	30.0 g.
Acrylic acid used	13.0 g.

All samples have satisfactory appearance and are comparable to previous stocks.

Experiment No. 266 - "O" Rings (Mil P 5516) for Puget Sound Naval Shipyard

All rings treated as previous on outside surface only

Fluorination by one-step graft-fluorination method with

Experiment 264
