ABSTRACT.

The following outline covers the various phases of work accomplished during the period from October 1, 1962 to December 31, 1962.

- A. Assembly and production tooling has proceeded to the point of completion with minor exceptions. All of the preproduction component parts have been received and subjected to incoming quality inspection. These component parts have been assembled into various sub-assemblies using the assembly tooling, and changes improving component quality and facilitating assembly have been proposed.
- B. Arrangements have been made with our Quality Acceptance Group to perform the necessary qualification tests; and as an alternative, we have discussed these tests with a Government Approved outside testing company and have received a quotation. The Quality Acceptance Group will also arrange to perform certain acceptance tests requiring unique environmental conditions.
- C. A study of the required acceptance tests has been completed and a testing procedure devised. These test procedures have been discussed with our Laboratory Engineering Group and the required test apparatus was decided upon. Work on the test apparatus has

advanced to 33 percent completion and prototype test equipment is being received by Product Engineering.

PURPOSE:

The purpose of Contract DA-36-039-SC-78926 is to:

- A. Provide 18 Engineering samples for the purpose of evaluation in the following ranges:

<u>RESISTANCE</u>	<u>QUANTITY</u>	<u>TYPE OF RESISTOR</u>
200 Ohms	6 each	Toroid
50 K Ohms	6 each	Spiral
200 K Ohms	6 each	Spiral

The above samples were submitted accompanied with test data as specified in the contract.

- B. Provide 300 Preproduction units for the purpose of evaluating the production tooling and obtain the most suitable assembly procedures prior to the production run.

The ranges are as follows:

<u>RESISTANCE</u>	<u>QUANTITY</u>	<u>TYPE OF RESISTOR</u>
200 Ohms	100 each	Toroid
50 K Ohms	100 each	Spiral
200 K Ohms	100 each	Spiral

The preproduction run has been started and the problems encountered are covered in the narrative and data section of this report.

- C. Provide 3750 production units in the ranges outlined in the contract. This phase will be performed with production type equipment and production type pilot run necessary to manufacture and test 350 acceptable units per eight (8) hour shift conforming to the applicable specifications as follows:

<u>RESISTANCE</u>	<u>QUANTITY</u>	<u>TYPE OF RESISTOR</u>
200 Ohms	750 each	Toroid
50 K Ohms	750 each	Spiral
200 K Ohms	750 each	Spiral
Lower than 200 Ohms and as low as possible within specifications	750 each	Toroid
Above 200 K Ohms and as high as possible within specifications	750 each	Spiral

The production manufacturing tooling to produce the component parts have been completed except for minor exceptions.

The assembly tools for the production type pilot run are approximately 65% completed.

NARRATIVE AND DATA:

Component Parts

The Multi-Turn Metal-Film Trimmer Resistor uses a combination of forty (40) various components of which twenty-three (23) different parts make one complete unit of a toroid or spiral type trimmer. It was decided to sub-contract 31% of the parts to vendors who specialize in a specific phase of manufacturing such as ceramics, cold heading , teflon, moulding, etc. The vendors who are manufacturing the parts were selected on the basis of successful past performance in producing specialized items for Weston.

Operation sheets were written for all parts made at Weston to provide the manufacturing departments with all necessary data for producing the parts within specified tolerances. The Methods Specification sheets furnish information such as: method of operation; type of machine used; tools required, etc. The following are typical examples of operation sheets being used by manufacturing departments to complete a specific part.

Preproduction Sample Parts:

All sample parts were received for use in our preproduction run of 300 units per contract specifications. We have encountered difficulties with some parts in our sub-assembly operations and have taken corrective action before proceeding with the final production run of manufactured parts. Some of the difficulties were:

Trimmer Molded:

Our drawing indicated a .145" dia. X .020" deep recess at the head adjuster end of the Resistor, to make certain the head adjuster moves freely after epoxy molding. A prototype single cavity mold was made, eliminating this recess, and it was found that no binding occurs after molding. This will help facilitate the making of a multi-cavity mold and will offer a better epoxy seal around the adjuster. We also added a bead of epoxy around the outer edges of each end cap assembly at the teflon insulator. This will help locate the angular position of the terminal, prevent molding pressure from compressing the teflon bushing on terminal end and thus shifting the contact path on the film strip, and also prevent seepage of epoxy into the assembly during the mold cycle.

Wound Contact:

It was originally planned to produce a contact with 90 to 92 turns in a .370" length, however, at visual inspection the openings

between turns appeared excessive. This was revised to obtain 120 to 126 turns within the specified length to offer more contact points.

Lead Screw Spiral Type:

The spiral type resistor is designed with a rigid lead screw, allowing the follower to move freely along the metallized path of the ceramic tube. The lead screw is positioned by soldering it to the end cap assembly. We encountered some difficulty obtaining a consistent solder joint and found that in some instances the lead screw would disengage by finger pressure. This was corrected by increasing the length of the lead screw .040" at the solder joint end to obtain additional surface for soldering the two components together.

Header Assembly:

This unit consists of three parts: the adjuster head, bushing insert, and molded teflon material in which the two parts are bonded. The sub-contractor encountered some difficulty in molding the teflon over the head and insert because of a burr at the slot end of the adjuster head. The mold is constructed using the slotted end of the head as a locating point. Corrective action was taken by adding a tumbling operation to remove the burr and thus insure proper seating of the part in the mold cavities.

Sleeve Adjuster:

Due to the symmetry of this part, it was difficult to detect which end of the sleeve is bored to fit the header assembly without trial and error or close visual inspection. This will be overcome in the production run by adding a groove mark on one side to facilitate assembly.

Support Driver Contact:

We were successful in procuring extruded stock per specifications to eliminate secondary milling operations and thus finish the part accurately in one machine operation. A small burr formed on the inside of the slot at the cut-off station of the screw machine operation, and thus prevented the contact spiral element from seating properly in the slot. This will be corrected by tumbling the part to remove all burrs prior to plating.

Lead Screw Toroid Type:

This part is pressed to the header assembly in one of the sub-assembly operations. Both ends of the lead screw are similar, therefore, it was difficult to visually denote which end is pressed into position. A small countersink was added on the end of the lead screw pressed into position to facilitate the assembly operation.

Resistance Blanks:

A range of resistance blanks was made in accordance with the theoretical formula devised by Product Engineering. The blanks were then spiralled by Product Engineering using the Research and Development facilities. The data taken for the 25 turn spiralled blanks verifies the validity of the theoretical formula. No conclusion can be made for the 10 turn spiralled blanks, since it was discovered while spiralling that the particular range of resistance blanks used had defective resistance films.

It will be recalled from Quarterly Report No. 1, Page 10, that for the 25 turn unit the theoretical formula is given by:

$$R_f = C N R_b + R_b \quad \text{Where} \quad R_f = \text{Final Resistance (ohms)}$$
$$R_b = \text{Blank Resistance (ohms)}$$
$$N = \text{Number of Spirals}$$
$$C = 31$$

This formula was solved for C.

$$C = \frac{R_f - R_b}{R_b N}$$

The experimental data obtained from spiralling resistance blanks having theoretically predicted nominal values of 25 turns, 50 K

Ohms and 25 turns, 200 K ohms was inserted in the preceding expression for C. Four groups of approximately 10 blanks each were used to compile the following data.

<u>Group</u>	<u>Nominal Resistance</u>	<u>Nominal Turns</u>	<u>Average C</u>
1	50 K Ohms	25	28.77
2	50 K Ohms	25	30.9
3	50 K Ohms	25	29.5
4	200 K Ohms	25	<u>33.38</u>
			30.6 Average

Note that the experimental average of $C = 30.6$ deviates only slightly from the theoretical value of $C = 31$. Some slight deviation is to be expected due to the finite, slightly variable width of the actual spiral cut.

Inspection Procedures:

An Inspection and Quality Control Plan Manual is being prepared and will be completed prior to the production run of the Trimmer Resistor. This manual describes the in-process and final inspection of a completed unit, as well as quality control techniques used in the production of the individual parts and sub-assemblies.

The instrument or equipment that will be used for the various tests, such as total and end resistance, contact resistance variation, rotational life, etc., will be specified for each inspection station.

The manufactured parts, either made at Weston or purchased, are being inspected per AQL specifications. The Inspection Department has been provided with Inspection Procedure Data Sheets for checking the individual parts. Typical examples of completed inspection procedure sheets for parts manufactured at Weston or purchased are enclosed on the following pages.

SHEET 1 OF 1 SHEETS

APPROVED BY DATE

SEQ. NO.	C/D NO.	CLASS	% AQL.	CHARACTERISTIC	SPECIFICATION	METHOD
				INSPECT AFTER OPERATION 20 OF METHOD SPECIFICATION FOR ASS'Y 197602		
1	201	Min	1.5	Assembly	Must have the following parts: 1 End Cap 244501 1 Insulator 244500 1 Bearing 197630 1 Terminal 197615 1 Lead Wire 244806	Visual
2	202	Min	1.5	Rivet soldered to terminal	per print	Visual
3	203	Min	1.5	Lead soldered to terminal lug	per print	Visual (Solder should have a fillet from the terminal to the wire. The wire must be free of nicks or cut strand and insulation must not enter the solder).

Sub-Assembly Tooling:

Lead Screw Assembly - Spiral Type

A manual collet type fixture was designed to position the lead screw and end cap assembly prior to soldering.

The initial soldering fixture as designed did not position the lead screw precisely in a vertical position. A revision is being made to attain positive positioning by providing a locating hole in the vertical stop of the fixture.

Strip Terminal Assembly

We designed and made a fixture to simultaneously stake the three terminals to the formica wafer using an Air Press. Due to the nature and size of the parts involved, we could not consistently obtain a good mechanical stake at all three positions. This fixture was redesigned to stake one terminal at a time using a sliding type fixture to position the part under the staking tool.

End Cap Assembly

The operation of pressing the end cap assemblies onto the spiralled tube was to be performed with a positioning fixture mounted in a manual type housing. This was a cumbersome operating tool during the sample run and

would be impractical for production runs. We will mount the positioning fixture in a precision Pneumatic Press that has variable control ram travel and micrometer stop depth control that will provide repeat tolerances to meet our specifications.

End Cap Assembly - Toroid Type

A small inexpensive multi-holding block was made to hold the end cap assembly while soldering the end bearing and the wire lead to the terminal. Although this fixture performed satisfactorily during the sample run, it is a little awkward to use for production purposes and will be replaced with a rotary type fixture that will facilitate this operation.

Adjuster Assembly - Toroid Type

A manual type fixture was designed and fabricated to press and position the lead screw in the adjuster head assembly to the correct length per drawing specifications. The fixture was producing inconsistent sub-assemblies on the sample run and will be redesigned to obtain positive positioning in the fixture instead of relying on a screw stop.

TEST EQUIPMENT:

Qualification Tests:

The qualification tests per MIL-R-22097B will be either performed by our Quality Acceptance Laboratory, or will be contracted out to a Government Approved testing organization at the discretion of Quality Acceptance. All necessary test equipment is available to Quality Acceptance, and the specialized fixturing is either available or in the process of being fabricated.

Acceptance Tests:

The acceptance tests per MIL-R-22097B have been segregated into the following categories:

1. General - Tests that are performed repeatedly during environmental or miscellaneous tests, i. e., total resistance, setting stability, etc.
2. Environmental - Tests that require unique environmental conditions, i. e., shock, acceleration, etc.
3. Miscellaneous - Tests that fall in neither the general nor environmental test categories, i. e., solderability, etc.

The above categorizing of tests was done in order to minimize

design duplication, since a given general test apparatus can be used in more than one environmental or miscellaneous test, as well as the general test per se.

The acceptance tests will be performed by either Quality Control personnel at the product assembly site or by the Quality Acceptance Laboratory, depending upon the nature of the test. For instance, the environmental and miscellaneous tests which require highly specialized equipment will be performed by the Quality Acceptance Laboratory using the same fixturing that will be used for the qualification tests. The test equipment and fixturing for the acceptance tests performed by the Quality Control Group is being furnished by the Laboratory Engineering Group. The following tables are breakdowns of the acceptance tests, covering the salient points made self-explanatory by the table headings:

CONCLUSIONS:

As a result of the work performed during the period of October 1, 1962 to December 31, 1962, the following summations are made:

1. The pre-production run of parts used to produce sub-assemblies necessitated some drawing changes, however, the revisions were mainly to facilitate and improve quality. These changes will not alter the capacity of the Trimmer Resistor to meet or exceed the requirements of MIL-R-22097B.
2. The test procedures have been developed and the test equipment is in the process of fabrication.
3. The Inspection and Quality Control Plan outlining the in-process and final inspection procedures of the Trimmer Resistor is approximately 80% completed and will be finished within the next reporting period.
4. The Quality Acceptance Tests as outlined in Mil Spec 22097B have been developed by the contractor and a Government Approved sub-contractor, and either or both sources are available to meet the contract commitments.
5. The work development and performance indicates that the

schedule as outlined in the U. S. Signal Corps contract
No. DA-36-039-SC-86734 will be held.

It is estimated that 25% of the overall program has been completed.

The task of inspecting and testing component parts before proceeding with final production runs, the testing and revising of assembly tools, and the final development work of the acceptance and quality tests will now enable us to actually start production on the Trimmer to the accorded specifications.

PROGRAM FOR THE NEXT QUARTER:

1. Issue all work orders to produce sufficient amount of component parts to complete the final production run per contract DA-36-039-SC-86734.
2. Use of production tooling incorporating all tool revisions for starting the production run of 300 pre-production units per contract specifications.
3. Final installation of the pilot line in a totally enclosed area.
4. Completion and tryout of all test equipment furnished by the Laboratory Engineering Group.

PUBLICATIONS AND REPORTS:

There were no technical articles published during
this reporting period.

CONFERENCES:

There were no conferences held during this reporting
period.

BACKGROUND OF ADDITIONAL PERSONNEL

WORKING ON PROJECT:

VAUGHN F. PIERSON

Mr. Pierson has been with Weston since 1953 in various engineering capacities. Product improvement and cost reduction were typical Product Engineering assignments. While a Project Engineer in the Thermometry Research and Development Section, he assisted in the development of the Ruggedized High-Shock Thermometers now in use on our atomic submarine fleet.

His experience includes project assignments in the development group assigned to metal film applications, where fields of interest include fixed resistors, trimmer resistors and large variable potentiometers. Mr. Pierson holds a M. E. degree from Stevens Institute of Technology and M. S. from Newark College of Engineering. He is currently with the product group covering metal film resistors.

ROBERT PAUL:

Since joining Weston in 1956, Mr. Paul has undertaken various assignments in the Chemical Engineering section as a Technician.

His functions included varied jobs, such as: work on organic and inorganic finishes of paints, electro-plating, plastisols, etc., development of anti-static solution for plastics commercially known as "Statnol", and helped establish laboratory acceptance tests for checking electrical instruments.

Mr. Paul has been assigned to the Product Engineering group for the past three years, covering metal film applications. One of his functions is the responsibility of applying the metal film to the inner diameter of the tubular substrate per desired specifications.

JAMES P. KEELLEN

Mr. Keelen has been employed by Weston for the past eleven (11) years with extensive experience in quality control and inspection procedures. His responsibilities covered a broad area of activity in instrumentation of all types, as well as metal film resistor process control systems.

Mr. Keelen has attended special courses in the statistical quality control and instrumentation field at Newark College of Engineering and Rutgers University. He is currently the Department Head of the Quality Control and Inspection Section concerned with metal film resistors, and is directly responsible

for preparing the Inspection Manual for the Rectilinear Film
Resistor.
