Report No. 8926-087

Materials - Finishes and Coatings - Anti-Galling -
For Titanium Fasteners

Seizure Characteristics

Abstract

The number of turns required to cause 1/2 inch hexagonal Ti 6Al-4V nuts to seize on 1/2 x 3 inch, MS 20008-43 type, Ti 4Al-4Mn bolts under a tension (axial) load applied to a nut and bolt assembly was used as a comparison criterion. Uncoated, fluoride-phosphate (Titanium Metallurgical Laboratory Memo, date 30 October 1956), Ti-Oxide anodic treated (San Diego Plating Co., San Diego, California) Hardax anodic treated (Anachrome Corp., South Gate, California), Electrofilm 66C (baked epoxy resin - molybdenum disulfide finish, San Diego Plating Co.), silver- and nickel-plated (Steel Improvement and Forge Co., Cleveland, Ohio), and heat treated (1000°F, 4 hours in air, air cool) nuts were treated. The test results showed that nuts which were silver-plated or electrofilm coated were about equal to each other and superior to the other surface treatments in resisting galling. The anodic treatments used had the greatest tendency for seizure, in some cases greater than that of the bare nuts used as a standard of comparison.

[illegible]

Report No. MP-58-287Titanium Anti-Galling Treatment
for Threaded Assembly - RJA 7028OBJECT:

To determine the torque-tension relationship and galling characteristics of titanium nuts, bare and as surface treated by seven different processes, when installed on bare titanium bolts.

CONCLUSION:

Tests show that silver plating on titanium and electrofilm 66C per Convair Specification O-05000 are two surface treatments which will greatly reduce any galling or seizure of titanium nuts to bare titanium bolts. Nickel plating on titanium, heat treating of titanium at 1000°F for four hours, and the Hardas Process anodic treatment by Anachrome Corp. are three surface treatments that are no better, and in some instances less resistant to galling than bare to bare titanium nut and bolt.

The fluoride-phosphate treatment for titanium and the Ti-oxide anodic treatment by San Diego Plating Co. are about equal and slightly more resistant to galling than the bare nut used as a standard.

TEST SPECIMEN:

1. * Bolts: - Type 64, 1/2" x 3" titanium bolts with the configuration of the type MS 20008-43 for steel bolts.
2. Wafers: - Type 64, 1/8" x 7/8" hexagonal titanium wafers processed along with the nuts. Wafers were used as a standard to measure any dimensional increase or decrease of titanium nuts due to process treatment.
3. Nuts: - Type 64, 1/2" titanium hexagonal nuts were processed by each of the following methods:
 - a) Eight bare titanium nuts - no processing, used as a standard.
 - b) Eight nuts and two wafers processed by the Fluoride-Phosphate chemical conversion method as outlined in the Battelle memo of 10-30-56. Processing done in the Materials and Processes Laboratory.
 - c) Eight nuts and two wafers given the Ti-Oxide anodic treatment by the San Diego Plating Co.
 - d) Eight nuts and two wafers processed by the Anachrome Corp., South Gate, Calif. and given the Hardas Process anodic treatment.

* Bolts - 5 Al-6 titanium alloy

** Nuts - 6 Al-6 V

TEST SPECIMEN: (Continued)

- e) Eight nuts and two washers Electrofilmed 66C per Convair Specification 0-05000 by the San Diego Plating Co.
- f) Two silver-plated nuts processed by the Steel Improvement and Forge Co. of Cleveland, Ohio. Silver plate thickness .0005 in.
- g) Two nickel-plated nuts processed by the Steel Improvement and Forge Co. of Cleveland, Ohio. Nickel plate thickness .0005 in.
- h) Three titanium nuts and one washer heat treated at 1000°F for four hours and removed from furnace and air cooled. Heat treatment done by Materials and Processes Metallurgical Heat Treat Lab.

TEST PROCEDURE:

A special jig was constructed (Fig. 1) which would permit the mounting of the bolt and nut on the Tinius Olsen Universal Testing Machine, thereby providing a means of applying a tension load of 10,000 lbs. for the start of each test. This load was used as the starting point before doing any torquing of the nut with a hand torque wrench.

The torque wrench was applied to the nut and rotated to the right through a 90° arc. At this same time the greatest torque in ft-lbs shown on the wrench dial was recorded. The load shown on the Tinius testing machine was also recorded. At this point the wrench was backed off 90° to the starting position. Break torque was recorded and also tension shown on the test machine was recorded when the wrench reached the starting position.

The starting load of 10,000 lbs was then again applied to the jig before torquing the nut the second, third, fourth, etc. times. This procedure was repeated until in some tests seizure or extreme galling of the nut and bolt threads was evident.

A new cadmium plated steel washer was inserted between the treated nut and steel plate each time a treated nut was tested. (Fig. 1)

Due to the shortage of titanium bolts, two nuts were tested on each bolt. One at the shank end of the bolt and then one at the very end of the bolt.

RESULTS:

Test results are listed in Table 2 and shown graphically in Figure 2.
