6 A COLLECTION OF THE BAND-HEAD WAVELENGTHS OF N_2 AND N_2^+

L. WALLACE

Yerkes Observatory, University of Chicago, Williams Bay, Wisconsin

Received September 28, 1961; revised October 27, 1961

ABSTRACT

The wavelengths of the band heads of N_2 and N_2^+ , extending from the vacuum ultraviolet into the far infrared, are tabulated according to the electronic transition involved. Supplementary material is provided to facilitate problems of identification.

This summary includes all the band-head wavelengths of gaseous N_2 and N_2^+ found in the literature, limited only by the requirement that the observations have been fitted into the energy-level schemes of N_2 or N_2^+ or have been arranged in Delandres schemes and are generally accepted as being due to N_2 . Into the latter category fall the green bands, Herman's infrared bands, and the Hepner-Herman bands. While I am aware that such an extensive listing as this cannot replace Pearse and Gaydon's (1950) tabulation, which contains the pertinent data on all the more readily observed systems, the utility of the present work, under many circumstances, is obvious.

Upon completion of this summary, I became aware of Lofthus' (1960) work, which is an extensive survey containing not only the wavelengths given here but also a summary of the important work that has been done on the structure of N_2 and N_2^+ . Lofthus' survey is directed toward problems in molecular structure, whereas this was compiled to facilitate problems in identification.

In all possible cases I have used Herzberg's (1950) notation for the electronic state designations. Failing this, that of Pearse and Gaydon (1950) was used, and where the bands are discussed by none of these authors, I have used the notation of the original investigator with minor modifications, where necessary, to maintain consistency with earlier designations. In several instances where rotational analyses have not been performed, I have relied on the deductions of Mulliken (1957) as to the type of electronic state involved. The vibrational assignments, particularly in the fragmentary singlet-singlet transitions, are in some instances uncertain. It is likely that some of these systems observed in emission actually have common upper electronic states.

In Table 1 are listed the states of N_2 and N_2^+ , along with the observed transitions, the system origins, the extent of the systems, and the names sometimes associated with them. It is intended that this table should serve as an index to the wavelength listings in the succeeding tables. The latter are arranged in four successive groups: the triplet-triplet and higher multiplicity bands, the triplet-singlet bands, and the singlet-singlet bands of N_2 , followed by the bands of N_2^+ . Within each group the systems are listed according to increasing wave number of the system origin.

The intensities listed for the first and second positive and first negative systems are on a linear scale. The remainder are the usual eye-estimates on a quasi-logarithmic scale.

Calculated wavelengths have been given in some cases where the observed wavelengths are of low quality.

In the appendix are listed the vibrational intervals, $\Delta G_{v+1/2}$. References to rotational analyses and to other works on the vibrational analyses are given in connection with the observed band systems in Tables 2-59.

* The research reported in this paper was supported by the Geophysics Research Directorate of the Air Force Cambridge Research Center, Air Research and Development Command, under contract AF 19(604)-3044 with the University of Chicago.

Mrs. Pamela Stuefen typed the manuscript, and Mr. T. H. Rau did part of the proof-reading. Mr. Rau and Mr. Joseph Wampler also assisted in some of the calculations.

TABLE 2-3

4448 cm⁻¹ System

Three heads. Degraded to the Red.

Hopner and Herman (1957). The authors illustrate the appearance of the bands. The three heads increase in intensity going to long wavelengths.

λ (Å)	v', v''	λ	v', v''	λ	v', v''
19079. 178. 255.	1,0	22334. 477. 585.	0,0	- 2.971 μ	0,1
20385. 480. 585.	2,1	23930. 24092. 205.	1,1		

6536 cm⁻¹ System

Similar to First Positive. Degraded to Red.

The wavelengths and intensities are from LeBlanc, Tanaka, and Jursa (1958). [For the historical background see Brook (1953), Carroll and Sayers (1953) and Kistiakowsky and Warnak (1957).] Carroll and Rubalcava (1959 and 1960) and Dieke and Heath (1960) have performed the rotational analysis and Sayers and Kistiakowsky (1958) appear to have established the vibrational numbering from isotopic analysis.

LeBlanc, Tanaka and Jursa include a half-tone of the spectrum.

TABLE 4

9337 cm^{-1} System

FIRST POSITIVE

Four heads at moderate dispersion. Degraded to the table.

The wavelengths for this $\text{B}^3\Pi_0 - \text{A}^3\Sigma_u^+$ bands were taken from Carroll and Sayers (1933), Isenhardt G. Sauer and Neuman (1937), Isenhardt H. and Binks and Heath (1939). These wavelengths agree to within a few tenths of an Angstrom with those given by Fowler and Scrutt (1911) and Bingham (1934) but not with those by Neuman (1938) which appear to be for other bands (Carroll and Sayers, 1933). The calculated wavelengths marked with an asterisk, the calculated and observed intensities on a linear scale, and a review of the work on vibrational and rotational analyses are also given by Binks and Heath. [See also Carroll (1932) and Feast (1930).]

HERMAN'S INFRARED BANDS

Six heads. Degraded to the Violet.

The wavelengths and intensities are from Carroll and Sayers (1953). The shortest wavelength head is the strongest. [See also Herman (1951)]

Carroll and Sayers also give a half-tone of the spectrum.

TABLE 6

17907 cm^{-1} System

GREEN BANDS

Complex appearance. Degraded to the Violet.

The wavelengths are from Gair (1934), labelled G, and Gair and Geyser (1939). Gair's features c, d, and e appear to be Gair's and Gair's i, v, and vi. Gair's i is the strongest and is the nearest to the violet. The Gair and Geyser bands are very similar in appearance to those of the fourth positive system and, consequently may be due to a $3\Sigma - 3\P$ transition.

Gair has included a half-tone of the spectrum.

TABLE 7

SECOND POSITIVE

Three very close heads. Degraded to the Violet.

The wavelengths for the P₁ (long wavelength) heads, are from Carroll and Sayers (1953) and Dicks and Heath (1958) and agree to within 0.1 Å with those of Parkhurst (1950). The intensities, on a linear scale, are from Wallace (unpublished). Dicks and Heath summarize the work on the vibrational and rotational analyses.

TABLE 8-9

38270 cm⁻¹ System

GOLDSTEIN - KAPLAN

Three heads. Degraded to the Red.

The first series of measurements is by Hamada (1937) and the second by Gaydon (1944). Gaydon was not able to find the 2863-2923 Å bands and felt they belonged to a different system from the 4166-5056 bands. The blue bands appeared to Gaydon to originate from a $^3\Sigma$ or a $^3\Delta$ state.

Gaydon has included a half-tone of the spectrum.

2863.5	0,2	3326.1	0,5	4432.2	0,10

44266 cm⁻¹ System

FOURTH POSITIVE

Five close heads. Degraded to the Violet.

The wavelengths and intensities are from Fowler and Strutt (1911). The five heads appear to correspond to the Q_1 , P_1 , P_2 , O_1 , and O_2 branches. Gero and Schmid (1940) have performed a rotational analysis of the O_1 and O_2 bands. Gero and Schmid's band head wavelengths are from 0.2 to 0.5 Å greater than those given by Fowler and Strutt.

49757 cm⁻¹ System

VEGARD - KAPLAN

$$A^3 \Sigma_u^+ \rightarrow X^1 \Sigma_g^+$$

Single heads. Degraded to the Red.

The wavelengths are from Bernard (1935), labelled B, Janin (1943b and 1946a), labelled J, Herman (1946), not labelled (the same list is also given by Herman and Herman, 1946), and Wilkinson (1939), labelled W. Those marked with an asterisk were calculated from the A-state analysis of Blake and Heath (1939), the X-state analysis by Wilkinson (1937), and the system origin determined from the analysis of the 6,0 and 7,0 bands by Wilkinson (1939). The intensities have been scaled from Vegard's (1932) figure 5. Below about 3200 Å the wavelengths appear to be accurate to about 0.1 Å but above this the observed and calculated wavelengths diverge in a peculiar fashion. The measurements by Janin (1946a) and Wilkinson (1939) are the most accurate. Wilkinson's (1939) report contains the most recent rotational analysis.

Wulf and Melvin (1939) present an interesting half-tone of two of the bands.

LYMAN - BIRGE - HOPFIELD

$$o^1 \Pi_g \leftarrow x^1 \Sigma_g^+$$

Single heads. Degraded to the Red.

The first four vacuum wavelengths are from Riese and Hopfield (1956) and the remaining have been calculated from the constants summarized by Wilkinson (1957). The air wavelengths are from Norman (1945) and the intensities are from Riese and Hopfield. The calculated wavelengths agree with the observations of Riese and Hopfield to about 0.1 Å and those of Wilkinson and Riese (1956), Leitch (1956), and Wilkinson (1957), labelled N, L, and W respectively, to about 0.01 Å. The literature cited for 1956 and 1957 and the report by Wilkinson and Wilkinson (1957) deal with the fine structure analysis.

N_2^+ FIRST NEGATIVE

TABLE 57

$$B^2\Sigma_u^+ \rightarrow X^2\Sigma_g^+$$

Mostly single heads. Degraded to the Violet.

The intensities, on an expanded scale, and the wavelengths of the main (violet degraded) part of the system are from Herzberg (1928), augmented with the data of Merton and Filley (1925). Perturbations cause some of the bands to appear double headed. The rotational and vibrational constants are summarized by Douglas (1932).

The wavelengths of the tail bands are from Herzberg (1928), labelled H, Douglas (1932), labelled D, and Janin and Eyraud (1954). The latter wavelengths are only accurate to about 0.5 Å. The intensities are from Janin and Eyraud.
