THE DEVELOPMENT AND EVALUATION
OF TUNGSTEN-BASE ALLOYS

Prepared under Bureau of Naval Weapons

Contract No. NOW 62-0419-c

Fourth Quarterly Report

15 December 1962 to 15 March 1963

CLIMAX MOLYBDENUM COMPANY OF MICHIGAN
DETROIT, MICHIGAN

ABSTRACT

Tungsten-base alloys and W-3% Mo-base alloys containing nominally 1% Cb, 0.1% Hf, or 0.05% Zr have been successfully converted to 1/2-inch diameter bar stock by extrusion and swaging operations. Short-time tensile tests have been performed to 4000 F. Tentative tensile transition temperatures are reported.

INTRODUCTION

The objective of Contract No. NOW 62-0419-c is the development of wrought tungsten-base alloys having high elevated temperature strengths and adequate ductility at low temperatures. This report covers the work conducted during the period 15 December 1962 to 15 March 1963.

Earlier in the program the following seven tungsten-base alloys were successfully vacuum-arc-cast, machined and canned in molybdenum, extruded, and swaged to 1/2-inch diameter bar stock:

Heat No.	Analysis, %
4136	W + 0.93 Cb + 0.001 C
4138	W + 3.18 Mo + 1.00 Cb + 0.001 C
4137	W + 0.11 Hf + 0.002 C
4139	W + 3.05 Mo + 0.10 Hf + 0.001 C
4140	W + 0.05 Zr + 0.002 C
4142	W + 3.10 Mo + 0.04 Zr + 0.001 C
4141	W + 0.05 Zr + 0.003 B + 0.001 C

Processing details for these alloys were presented in earlier Progress Reports.

Recrystallization temperatures (1 hour exposures) have also been reported. The minimum temperatures corresponding to complete recrystallization based on metallographic observations are given in Table 1.

TABLE 1

Recrystallization Temperatures for 1/2" Diameter
Tungsten-Base Alloy Bars

Heat No.	Analysis, %	Recrystallization Temperature, F
4136	W + 0.93 Cb + 0.001 C	3500
4138	W + 3.18 Mo + 1.00 Cb + 0.001 C	3500
4137	W + 0.11 Hf + 0.002 C	3350
4139	W + 3.05 Mo + 0.10 Hf + 0.001 C	3200
4140	W + 0.05 Zr + 0.002 C	3350
4142	W + 3.10 Mo + 0.04 Zr + 0.001 C	3200
4141	W + 0.05 Zr + 0.003 B + 0.001 C	3200

Tensile Test Results

The available tensile strength and ductility values for the alloys successfully converted to 1/2-inch diameter bar stock are listed in Table 2. The materials were tested at 1000, 2000, 2500, and 3000 F in the stress-relieved and recrystallized conditions and at 3500 and 4000 F in the recrystallized condition.

Specimen reduced-section dimensions were 0.25 in. diameter by 1.25 in. long. Strain rates of 0.005 min^{-1} and 0.05 min^{-1} were employed through the elastic and plastic deformation periods, respectively. Tests at 1000 and 2000 F were conducted in a 90% argon + 10% hydrogen atmosphere, while those at 2500 F and above were conducted in a vacuum of 10^{-4} torr.

Ultimate strengths are plotted against test temperatures in Figures 1, 2, and 3. In the stress-relieved condition, Figure 1, the strength of the 0.05% Zr + 0.003% B alloy was well above those of the remaining dilute tungsten-base alloys. In the recrystallized condition (Figures 2 and 3) this alloy showed outstanding strength at 3000 F; at higher and lower test temperatures, its strength was, however, not significantly higher than those of the other alloys included in this investigation.

The 3% Mo additions to the nominally 1% Cb, 0.1% Hf, or 0.05% Zr alloys did not consistently improve the strength properties. Carbon has been shown to exert a potent strengthening effect in tungsten, and it may well be that the differences in carbon content in the present series of alloys are sufficient to overshadow the effects of the 3% molybdenum additions.

At 4000 F very little difference existed between the strengths of the tungsten-base alloys. It would not be anticipated that the solid solution strengthening effects of the relatively minor alloy additions employed here would be effective at temperatures as high as 4000 F.

Tensile Transition Test Results

Tensile transition tests are presently being conducted on all of the alloy bars. Both stress-relieved and fully recrystallized specimens are being evaluated. Test specimen configurations and strain rates were identical to those employed for the elevated temperature tensile tests. As the tests to date are incomplete, the actual results obtained will not be presented at this time. Sufficient data are available, however, to indicate the tentative transition temperature ranges presented in Table 3.

TABLE 3

Tentative Tensile Transition Temperatures for 1/2" Diameter
Swaged Tungsten-Base Alloy Bars

Heat No.	Analysis, %	Transition Temperature, F*	
		Stress Relieved	Recrystallized
4136	W + 0.93 Cb + 0.001 C	<1000	>1000
4138	W + 3.18 Mo + 1.00 Cb + 0.001 C	705-800	>3000
4137	W + 0.11 Hf + 0.002 C	450-500	650-700
4139	W + 3.05 Mo + 0.10 Hf + 0.001 C	450-500	700-725
4140	W + 0.05 Zr + 0.002 C	400-500	600-700
4142	W + 3.10 Mo + 0.04 Zr + 0.001 C	400-500	<500
4141	W + 0.05 Zr + 0.003 B + 0.001 C	<600	<600

* Temperature corresponding to a tensile elongation of 10%

On the basis of the incomplete test results presented in Table 3, significantly higher transition temperatures are indicated for the two columbium-containing alloys than for the materials containing hafnium or zirconium. Further, the recrystallization process raised the transition temperatures of the W-Cb and W-Mo-Cb to a much greater extent than the remaining tungsten-base alloys investigated. Metallographic examination of the vacuum-arc-cast ingots prepared for this program indicated that the W + 1% Cb and W + 3% Mo + 1% Cb alloys were high in oxygen content relative to the remaining alloys (Second Quarterly Report, 15 June 1962 to 15 September 1962). This fact could account for the high transition temperatures of the W-Cb alloys in the stress-relieved condition, and, without a doubt, accounts for the large increase in transition temperature after recrystallization.
