PREFACE

The angular correlation of annihilation radiation by slit geometry can be used to obtain the momentum distribution of annihilating electron-positron pairs in matter. The purpose of this thesis is to describe, evaluate and compare two types of apparatus employing rectangular slits and two methods of data analysis that can be used in this work.

The author wishes to express his gratitude to the United States Air Force and the National Science Foundation for their support in this work.

This research was suggested and directed by Dr. W. E. Millett, to whom the author wishes to express his most sincere appreciation.

The author is also indebted to his wife, Martha Kaye, for her constant support and encouragement, to Mr. Louis Deiterman for many stimulating discussions, and to the staff of the Physics Shop, especially Mr. George Olewin, who made possible the construction of the apparatus that was finally decided upon.

CHAPTER I

DESCRIPTION OF THE TYPES OF APPARATUS

When a positron-electron pair annihilates by two photon annihilation, the photons will be emitted in exactly opposite directions if the pair is initially at rest. A deviation of the angle between the emitted photons from 180° indicates an initial component of momentum. This deviation from 180° has rarely been found to exceed 15 milliradians. Angular correlation of these photons over this range yields information about the momentum distribution of the annihilating pairs.

The experimental configuration that employs rectangular detectors is referred to as slit geometry. Two types of apparatus employing slit geometry have been used. One type^{1,2} consists of two very long and narrow slits with a single coincidence channel while the other type^{3,4} consists of eight narrow slits

(four at each end) with sixteen coincidence channels. It was originally planned to construct a multiple coincidence channel apparatus here, but this plan was later changed because of the reasons that will be discussed in this thesis. Some work was done on this type of apparatus, however, and Figure 1 shows a sketch of the original plan modeled after Trumpy's⁵ apparatus. This was later modified for single coincidence channel work, and a sketch of this apparatus is shown in Figure 2.

The major difference between the two instruments is the slit and photomultiplier tube arrangement. Instrument 1 (Figure 1) was to have used eight RCA 6342A photomultiplier tubes with a $1\frac{1}{2}$ inch diameter by $\frac{1}{4}$ inch thick NaI(Tl) crystal mounted directly on the photocathode of each. Four of these were to be mounted at each end of the instrument with lead shielding placed in such a way that only a lower slice of each crystal, the thickness of which would subtend an angle of 0.4 milliradian at the target, could detect radiation. The crystal slices at the stationary end were to have been 0.6 milliradian apart, and those at the movable end were to have been 2.4 milliradians apart making it possible to simultaneously measure 16 values of θ covering 9.6 milliradians in steps of 0.6 milliradian. Instrument 2 (Figure 2) uses two RCA 6342A photomultiplier tubes,

each looking into the end of a 1 inch diameter by 8 inch long NaI(Tl) crystal. One tube and crystal are placed in lead shielding at each end of the instrument in such a manner that an 8 inch by .032 inch portion of the crystals is visible to the targets. The result is an instrument that employs one very long and very narrow slit at each end.

Three 32 inch high cinder block piers were constructed along a straight line 2 meters apart. The center pier supports the source and target holder, and the other two piers support the detectors. An 86 inch long platform made of aluminum was constructed so that one end pivots on a support at the central pier and the other end travels up and down on a precision screw mounted on one of the outer piers. The pitch of the screw is such that one full turn will increase or decrease the angle that the platform makes with the horizontal by 0.6 milliradian. The screw is linked to a four-pole Geneva Movement by one to four gear ratio so that one operation of the Geneva Movement will turn the screw through 360° . The Geneva Movement is powered by a reversible electric motor that can be programmed to turn the screw whenever a change in the angle between the slits is desired. A sketch of this mechanism is shown in Figure 3.

The source and target holder (see Figure 4) consists of a lead cylinder 10 inches in diameter by 10 inches long. Suitable means for adjusting the orientation of

SOURCE AND TARGET HOLDER
(NOT TO SCALE)

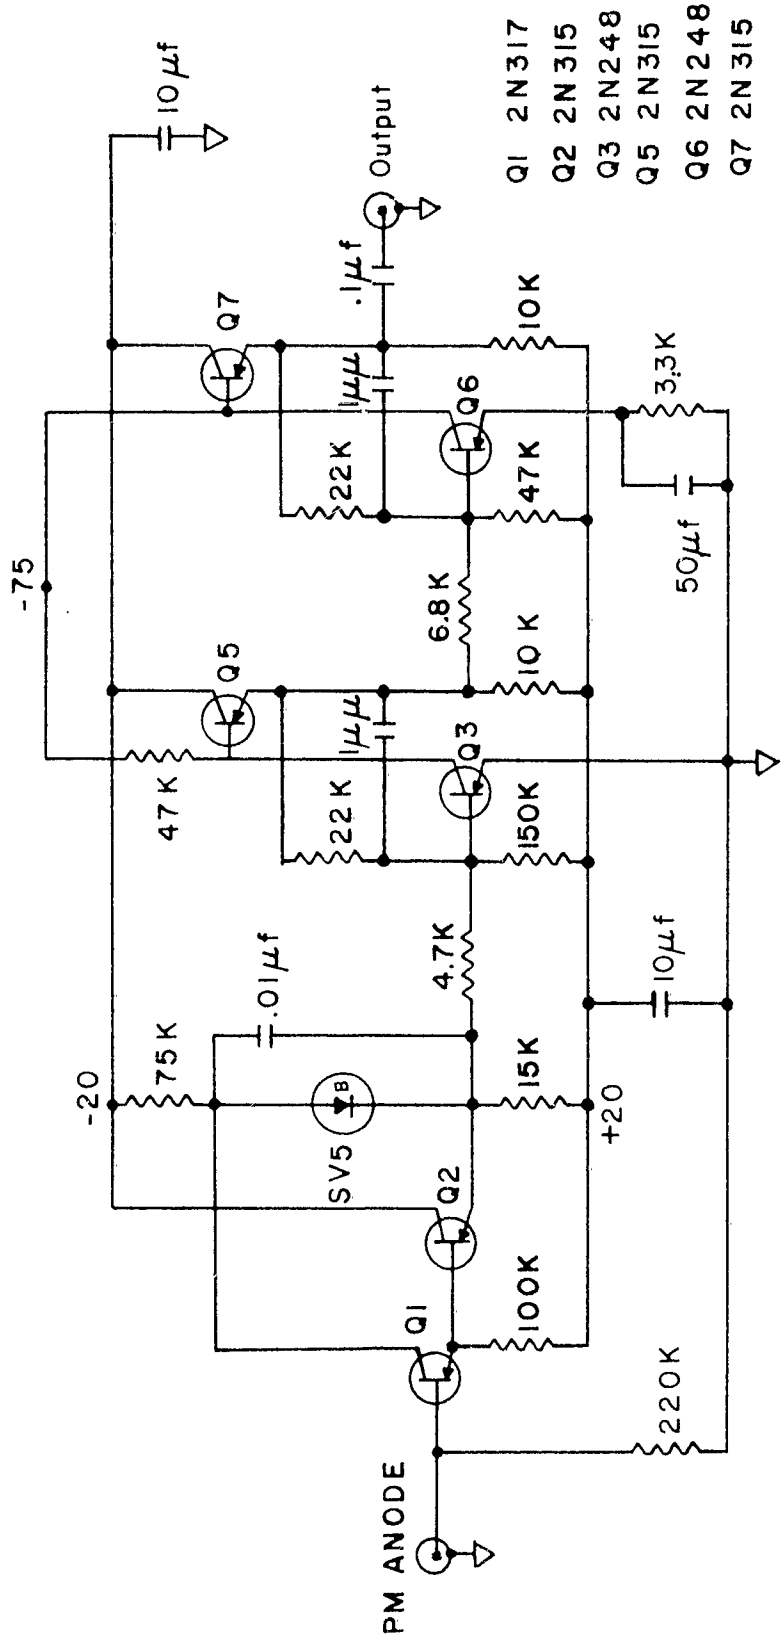

the holder are provided so that its axis can be aligned with the axis of the instrument. The source is mounted on the end of a brass cylinder (S) that is inserted from the top. The depth of penetration is controlled by two brass screws (Sc_1). The target is mounted on a circular brass plate (Ta) that is connected to the face of a brass cylinder (T) by three equally spaced spring-loaded screws. This arrangement allows an orientation of the target that is independent of the orientation of the source and target holder. The target cylinder fits into the source and target holder from the bottom, and the brass cylinder rests upon a screw (Sc_2) that controls the depth of penetration. The collimators are two lead-filled brass cylinders (C) having rectangular slits (S1) machined in the lead. These cylinders fit into each end of the source and target holder. O-ring grooves are provided wherever necessary so that the interior of the source and the target holder can be evacuated if later desired.

Solid state electronics is being used wherever possible. The output of each photomultiplier tube goes to a preamplifier and pulse shaper. The outputs from the pulse shapers go to the coincidence circuit, and the coincidence counts are scaled down by a factor of four. The output of the scale of four is then directed to the registers through a driver and switch. Schematics⁶

of the preamplifier, pulse shaper, and coincidence circuit are indicated in Figure 5, 6 and 7 respectively. The original plan (16 coincidence channels) called for a complex switch to direct the output of each coincidence circuit to the correct sequence of registers. This switch was designed and is shown in Figures 8 and 9 in case it might be of future use.

CHAPTER II

RESOLUTION AND DATA ANALYSIS

The momentum distribution of annihilation photons can be obtained from the data in two ways. The first method to be discussed (Method A) is to determine the resolution of the instrument in the z direction and from the data corrected in this manner to calculate the distribution in the z component of the momentum. The second method to be discussed (Method B) is to determine the θ resolution of the instrument (where $\pi - \theta$ is the angle between the photons) and from the data corrected in this manner to calculate the distribution in the ρ -component (where $\rho = \sqrt{p_x^2 + p_z^2}$) of the momentum. The results obtained from each method allow calculation of the total momentum distribution of annihilation photons.

The following discussion will refer to a coordinate system that is centered at the target with the z -axis vertical and the y -axis along the horizontal line defined by the source and the stationary slit.

A. Method A

This method has been used by several authors^{7,8} and will be discussed in some detail. The finite resolution of the apparatus is a result of the finite dimensions of the target and of the slits. Since the z component of the momentum is being measured, it is desirable to have as narrow a resolution function in the z direction as possible. The calculation of the resolution function will show that this requirement makes it necessary to use a target and slits that are very narrow in the z direction. The stationary slit will be referred to as Slit A and the movable slit will be referred to as Slit B. Each slit has the dimensions of $2b_0$ in the z direction and $2a_0$ in the x direction and is a distance r_0 from the target.

If an annihilation pair at the origin have a momentum component in the z direction of p_z and if one photon passes along the y-axis through the center of Slit A (see Figure 10), the other photon must necessarily arrive at the plane of Slit B at a distance

$$z = \frac{p_z r_0}{m c} \quad (1)$$

from the x-y plane and a distance $r = \sqrt{x^2 + z^2}$ from the

⁷ L. G. Lang, "Angular Correlation of Annihilation Radiation from Solids," Carnegie Institute of Technology Report, Sept. 1956.

⁸ R. E. Green and A. T. Stewart, Phys. Rev., 98, 486 (1955).

Figure 10
Diagram of the Geometry

y-axis where z is a constant for a particular p_z and where

$$x = \frac{p_x r_0}{mc} \quad (2)$$

varies from $x = 0$ to $x = \frac{p_x \max r_0}{mc}$.

If an annihilation pair at the origin have a momentum component in the z direction of p_z and if one photon passes through Slit A at the point a, b , the other photon must necessarily arrive at the plane of Slit B a distance of $z-b$ above the $x-y$ plane and a distance r from the y -axis where

$$r = \sqrt{(z-b)^2 + (x-a)^2} \quad (3)$$

and z is again a constant for a particular z . If Slit B is a set distance z_0 above the $x-y$ plane, then a coincidence can only be detected if $z_0 - b_0 \leq z - b \leq z_0 + b_0$ and if $-a_0 \leq x - a \leq a_0$. This condition assumes constant efficiency of the scintillators in the x direction and in the z direction.

If the condition that $-a_0 \leq x - a \leq a_0$ is satisfied, coincidences will begin to occur for $z = z_0 - 2b_0$, will increase until $z = z_0$, and will decrease to zero at $z = z_0 + 2b_0$. Hence, the resolution curve for an annihilation at the origin will have a base width of $4b_0$ centered about $z = z_0$. The increase is identical to the decrease because of the symmetry about z_0 and is linear, assuming constant efficiency of the scintillators in the

z direction. Therefore, the resolution function will be an isosceles triangle with a base width of $4b_0$ or twice the width of the slit in the z direction.

This resolution function can be generalized for a target of finite thickness in the following manner.⁹ Consider a target having a width of $2t$ in the z direction. A single isosceles triangle of unit height centered at z_0 is given by

$$f(z_0, z) = \begin{cases} 1 - \frac{|z-z_0|}{2b_0} & , |z-z_0| < 2b_0 \\ 0 & , |z-z_0| > 2b_0 \end{cases} \quad (4)$$

so

$$\frac{\partial f(z_0, z)}{\partial z_0} = \frac{1}{2b_0} \quad (5)$$

$$df(z_0, z) = \frac{dz_0}{2b_0} \quad (6)$$

Hence, the total resolution function is given by

$$R(z) = \int_{-t}^t f(z_0, z) \frac{dz_0}{2b_0} = \int_{-t}^t \left(1 - \frac{|z-z_0|}{2b_0}\right) \frac{dz_0}{2b_0} \quad (7)$$

The function must be integrated in three parts.

$$\begin{aligned} R_I(z) &= \int_{-t}^{z+2b_0} \left[1 - \left(\frac{z_0}{2b_0} - \frac{z}{2b_0}\right)\right] \frac{dz_0}{2b_0} ; \quad -t-2b_0 \leq z \leq t-2b_0 \\ &= \frac{1}{2} \left[\left(\frac{z}{2b_0} + 1\right) + \frac{t}{2b_0} \right]^2 \end{aligned} \quad (8)$$

⁹ This follows the derivation given by L. G. Lang.

$$\begin{aligned}
 R_{II}(z) &= \int_{-t}^t \left[1 - \left(\frac{z_0}{2b_0} - \frac{z}{2b_0} \right) \right] \frac{dz_0}{2b_0} ; \quad t - 2b_0 \leq z \leq -t \\
 &= \frac{t}{b_0} \left(1 + \frac{z}{2b_0} \right)
 \end{aligned}
 \tag{9}$$

$$\begin{aligned}
 R_{III}(z) &= \int_{-t}^z \left[1 - \left(\frac{z}{2b_0} - \frac{z_0}{2b_0} \right) \right] \frac{dz_0}{2b_0} + \int_z^t \left[1 - \left(\frac{z_0}{2b_0} - \frac{z}{2b_0} \right) \right] \frac{dz_0}{2b_0} ; \quad -t \leq z \leq t \\
 &= \frac{t}{b_0} - \frac{t^2}{4b_0^2} - \frac{z^2}{4b_0^2}
 \end{aligned}
 \tag{10}$$

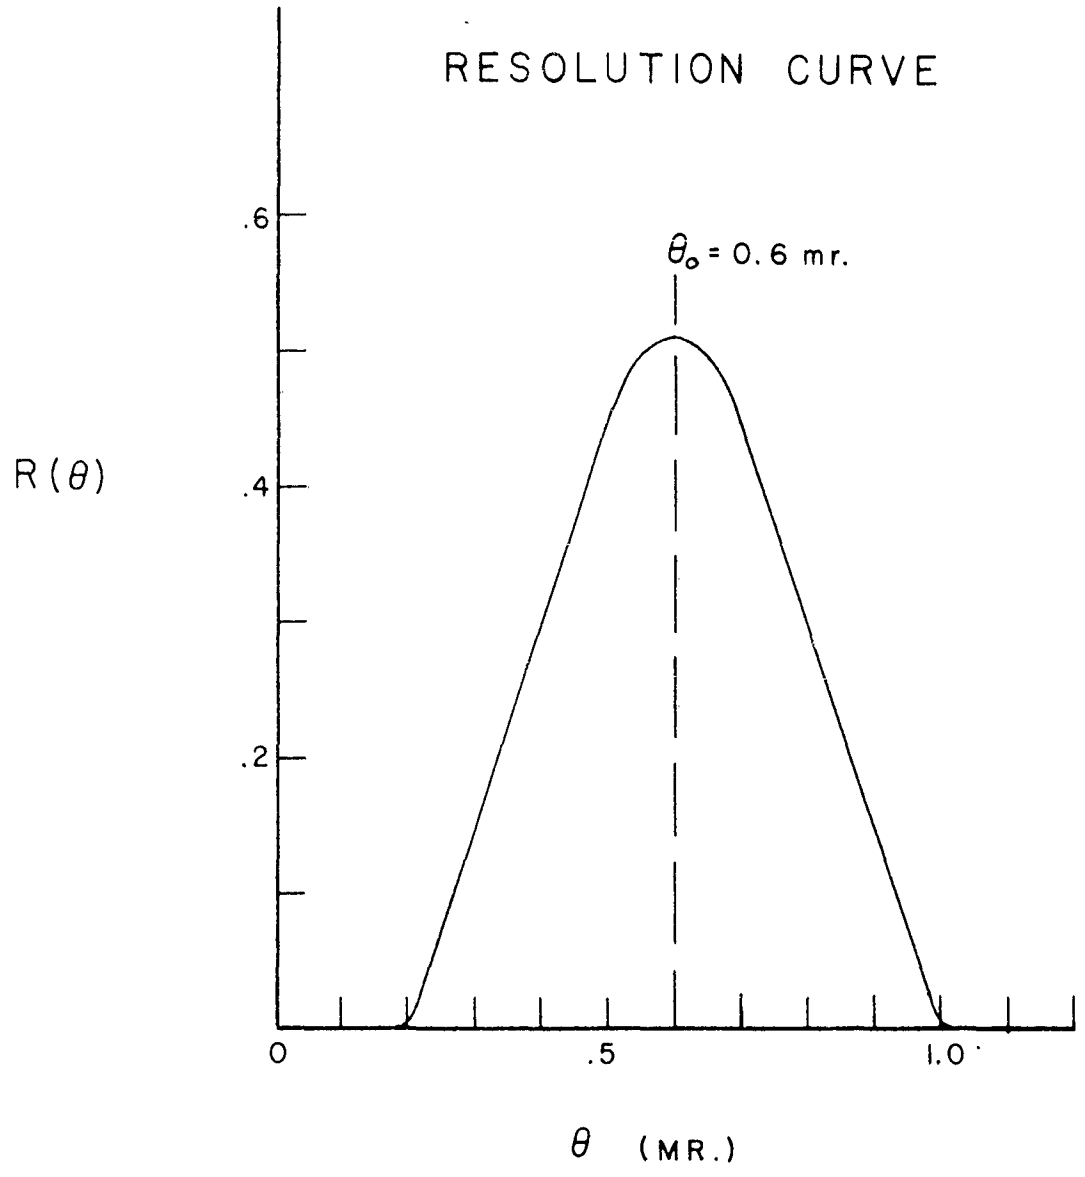

The result of equations 8, 9 and 10 is plotted in Figure 11 for $t = 0.12$ milliradians and $b_0 = .2$ milliradians. Figure 11 gives the total resolution curve in the z direction for a target that is 0.24 milliradians wide and for slits that are 0.4 milliradians wide. The curve is almost Gaussian shaped and has a half-width at half-maximum of about 0.23 milliradians.

If the condition $-a_0 \leq x - a \leq a_0$ for a point target is not fulfilled, a correlation cannot be detected even though the photon pair has a p_z that lies within the proper range.

The resolution function in the x direction can be calculated in exactly the same manner as above. For a point target located at the origin, it will have a total base width of $4a_0$, assuming constant crystal efficiency in the x direction. It is, therefore, possible to detect a correlated photon pair having a p_z in the proper range if $p_x \leq \frac{2a_0 mc}{r_0}$. Extending the resolution function to a

Figure 11
Resolution Curve for Method A

RESOLUTION CURVE

finite target in the same manner as above will give a base width even greater than $4a_0$.

If $2a_0 \gg \frac{p_x \max r_0}{mc}$, it can be assumed that all

photon pairs having a p_z in the proper range will be detected except when a is close to $\pm a_0$. If $2a_0$ is large enough, the correlations that are not counted because a is close to $\pm a_0$ can be neglected. Since $\frac{p_x \max}{mc} \cong 10$ milliradians, the condition for making this approximation means that the slit length ($2a_0$) must be much greater than 10 milliradians.

The first step in the analysis of the data is to correct for the z direction finite resolution of the apparatus. This is done by employing the parabolic method of Eckart¹⁰ at each of the data points. The effect of this correction is to increase the height of the peak and to sharpen the corners of the angular correlation curves.

When Slit B is displaced an amount z above the axis, the corrected coincidence counting rate $D(p_z)$ is proportional to the total number of pairs annihilating per unit time having $p_z = \frac{mcz}{r_0}$. When $2a_0 \gg \frac{p_x \max r_0}{mc}$, the following relationship exists:

$$D(p_z) = \text{const.} \int_0^\infty \int_0^{2\pi} \rho(p) P_p dp_p d\phi \quad (11)$$

¹⁰ Eckart, C., Phys. Rev. 51, 735 (1937).

where $\rho(p)$ is the momentum space density of annihilating pairs and the integral is taken over the plane of constant p_z . It is assumed that variations in $\rho(p)$ are small within a region Δz corresponding to the slit width and that $\rho(p)$ is spherically symmetrical about the origin in momentum space. Now

$$p_\rho = \sqrt{p^2 - p_z^2} \quad (12)$$

so

$$dp_\rho = \frac{p dp}{\sqrt{p^2 - p_z^2}} \quad (13)$$

and a transformation of the variable p_ρ to p in the integral gives

$$D(p_z) = 2\pi \text{const.} \int_{p_z}^{\infty} \rho(p) p dp \quad (14)$$

since when $p_\rho = 0$, $p = p_z$ and when $p_\rho = \infty$, $p = \infty$.

Equation 14 can be differentiated with respect to p_z

which gives

$$\frac{dD(p_z)}{dp_z} = -2\pi \text{const.} \rho(p_z) p_z \quad (15)$$

and solving for $\rho(p_z)$,

$$\rho(p_z) = -\frac{1}{2\pi \text{const.} p_z} \frac{dD(p_z)}{dp_z} \quad (16)$$

Now $p_z = \frac{mcz}{r_0}$, so

$$\rho(p_z) = -\frac{r_0^2}{2\pi m^2 c^2 \text{const.}} \frac{dD(p_z)}{dz} \frac{1}{z} \quad (17)$$

Since $\rho(p)$ was assumed spherically symmetrical about the origin, $\rho(p_z) = \rho(p_x) = \rho(p_y) = \rho(p)$. Hence,

$$\rho(p) = - \text{const.} \frac{dD(p_z)}{dz} \frac{1}{z} \quad (18)$$

The momentum distribution $N(p)$ is given by

$$N(p) = 4\pi p^2 \rho(p) \quad (19)$$

where $4\pi p^2$ is the surface area of a sphere of radius p in momentum space. Substituting equation 18 into equation 19 gives the desired relation between corrected data and momentum distribution. The preceding derivation is due to Stewart.¹¹

$$N(p) = - \frac{z}{\text{const.}} \frac{dD(p_z)}{dz} z \quad (20)$$

When the length of the slit ($2a_0$) is not much greater than $\frac{p_x \max r_0}{mc}$ then equation 20 does not hold for the relation between corrected data and momentum distribution. In this case, the corrected counting rate $D(p_z)$ is related to the total number of pairs annihilating per unit time having $p_z = \frac{mc z}{r_0}$ by the equation

$$D(p_z) = \int_{-a_0}^{a_0} \int_{-2_0+a}^{2_0-a} \int_{-\infty}^{\infty} \rho(p) p_\rho dp_y dp_x da \quad (21)$$

where a is the distance from the y - z plane that one of the photons of each detected annihilation pair entered Slit A. Without specific knowledge of the dependence of

11

Stewart, A. T., op. cit.

$\rho(p)$ on p_x and p_y it is impossible to reduce equation 21 any further.

B. Method B

This method has been used by several authors^{12,13,14} to analyze angular correlation data obtained by instruments employing cylindrical geometry but can also be used for slit geometry. The major problem is obtaining the resolution of the instrument as a function of θ and θ_0 where θ_0 is the correlation angle of the instrument and $\pi - \theta$ is the angle between annihilation photons.

Since θ and θ_0 will always be very small, the following approximations can be made. (See Figure 10)

$$y = r_0 \cos \theta_0 \cong r_0 \quad (22)$$

$$r = r_0 \sin \theta \cong r_0 \theta \quad (23)$$

$$z_0 = r_0 \sin \theta_0 \cong r_0 \theta_0 \quad (24)$$

If an annihilation pair at the origin have correlation angle θ and if one photon passes along the y-axis through the center of Slit A, the other photon must necessarily arrive at the plane of Slit B at a distance $r \cong r_0 \theta$

¹² Millett, W. E., and Castillo-Bahena, R., Phys. Rev. 108, 257, (1957).

¹³ Castillo-Bahena, R., Ph.D. dissertation, The University of Texas, (1957) unpublished.

from the y-axis where

$$r = \sqrt{x^2 + z^2} = \frac{p_{\theta} r_0}{mc} = \frac{\sqrt{p_x^2 + p_z^2}}{mc} r_0. \quad (25)$$

If Slit B is set at a distance z_0 above the x-y plane, then a coincidence can be detected if $z_0 - b_0 \leq r \leq \sqrt{(z_0 + b_0)^2 + a_0^2}$.

If an annihilation pair at the origin have a correlation angle θ and if one photon passes through the opening of Slit A at the point a,b, the other photon must necessarily arrive at the plane of Slit B ($y \approx r_0$) along the perimeter of a circle of radius $r \approx r_0 \theta$ and with its center located at the point -a,-b. If Slit B is set at a distance z_0 above the x-y plane, then there is a chance for a coincidence being detected if some portion of the perimeter of the circle overlaps Slit B.

Assuming an isotropic momentum distribution, the probability that one photon of an annihilation pair located at the origin and having correlation angle θ will go through the area $\Delta a \Delta b$ at the point a,b in Slit A will be

$$P(A) = \frac{\Delta a \Delta b}{4\pi r_0^2} \quad (26)$$

Let the probability that if one photon of an annihilation pair located at the origin and having correlation angle θ goes through the area $\Delta a \Delta b$ at the point a,b in Slit A, the other will pass through Slit B when it is set at an angle θ_0 be called $P(B)$. Then the resolution function $R(\theta, \theta_0)$ of the instrument for a point target

located at the origin when Slit B is set at an angle θ_0 will be given by

$$R(\theta, \theta_0) = \frac{1}{2\pi r_0^2} \int_0^{a_0} \int_{-b_0}^{b_0} P(B) da db \quad (27)$$

$P(B)$ will depend on θ_0, θ , and the point a, b , at which one of the photons of an annihilation pair enters Slit A.¹⁵ It will be assumed that for each particular θ, θ_0, a, b that $P(B)$ is equal to the ratio of the arc of the circle whose radius is $r \approx r_0 \theta$ that overlaps Slit B to the total perimeter of the circle.

There are nine different ways in which the arc of the circle can overlap the slit depending on the values of θ, θ_0, a, b , and the dimensions of the slit. These nine cases and the calculation of $P(B)$ for each are shown in Figures 12-20.

15

This is only true when the annihilation takes place at the origin where the coordinates are 0,0.

For each value of θ_0 , it is necessary to divide θ into nine ranges in order to integrate equation 27. Each of these ranges includes one or more of the special cases of $P(B)$. It is possible to calculate $R(\theta, \theta_0)$ using only the approximations of equations 22, 23 and 24 for six of the ranges of θ . These ranges are found to be more than sufficient to define the important portion of the resolution curve.

In the following equations, r, z_0, b_0, a_0 are measured in milliradians so that r corresponds to θ and z_0 corresponds to θ_0 . Also let $M = a_0 - \sqrt{r^2 - c^2}$,
 $N = a_0 - \sqrt{r^2 - e^2}$, and $C = \frac{1}{2\pi r_0^2}$. For $r \leq z_0 - 2b_0$:

$$R(\theta, \theta_0)_I = C \int_{-b_0}^{b_0} \int_0^{a_0} P(B)_A d\alpha db \quad (28)$$

For $z_0 - 2b_0 \leq r \leq z_0$:

$$\begin{aligned} R(\theta, \theta_0)_{II} = & C \int_{-b_0}^{z_0 - b_0 - r} \int_0^{a_0} P(B)_A d\alpha db \\ & + C \int_{z_0 - b_0 - r}^{b_0} \int_0^M P(B)_B d\alpha db \\ & + C \int_{z_0 - b_0 - r}^{b_0} \int_M^{a_0} P(B)_C d\alpha db \end{aligned} \quad (29)$$

For $z_0 \leq r \leq z_0 + 2b_0$:

$$\begin{aligned}
 R(\theta, \theta_0)_{\text{III}} &= C \int_{-b_0}^{z_0+b_0-r} \int_0^M P(B)_B d\alpha db + C \int_{-b_0}^{z_0+b_0-r} \int_M^{a_0} P(B)_C d\alpha db \\
 &+ C \int_{z_0+b_0-r}^{b_0} \int_0^M P(B)_D d\alpha db + C \int_{z_0+b_0-r}^{b_0} \int_M^N P(B)_E d\alpha db + C \int_{z_0+b_0-r}^{b_0} \int_N^{a_0} P(B)_F d\alpha db
 \end{aligned} \tag{30}$$

For $z_0 + 2b_0 \leq r \leq \sqrt{(z_0 - 2b_0)^2 + a_0^2}$:

$$\begin{aligned}
 R(\theta, \theta_0)_{\text{IV}} &= C \int_{-b_0}^{b_0} \int_0^M P(B)_D d\alpha db + C \int_{-b_0}^{b_0} \int_M^N P(B)_E d\alpha db \\
 &+ C \int_{-b_0}^{b_0} \int_N^{a_0} P(B)_F d\alpha db
 \end{aligned} \tag{31}$$

For $\sqrt{(z_0 - 2b_0)^2 + (\lambda a_0)^2} \leq r \leq \sqrt{z_0^2 + (\lambda a_0)^2}$:

$$R(\theta, \theta_0)_{\text{VIII}} = C \int_{-b_0}^{b_0} \int_{\sqrt{\lambda^2 - e^2} - a_0}^{a_0} P(B)_H d\alpha db + C \int_{-b_0}^{b_0} \int_0^{\sqrt{\lambda^2 - e^2} - a_0} P(B)_I d\alpha db \tag{32}$$

For $\sqrt{(z_0 + 2b_0)^2 + (\lambda a_0)^2} \leq r$:

$$R(\theta, \theta_0)_{\text{IX}} = C \int_{-b_0}^{b_0} \int_0^{a_0} P(B)_I d\alpha db \tag{33}$$

There are three ranges of r between $\sqrt{(z_0 - 2b_0)^2 + z_0^2}$ and $\sqrt{(z_0 - 2b_0)^2 + (2\theta_0)^2}$ that contribute nothing of interest to the $R(\theta, \theta_0)$ curve and since they are difficult to evaluate they will be neglected.

Since $P(B)_A = 0$, the first range of r gives a value of zero for $R(\theta, \theta_0)_I$. Similarly, since $P(B)_I = 0$, the last range of r gives a value of zero for $R(\theta, \theta_0)_{IX}$. The complete calculation of $R(\theta, \theta_0)_{IV}$ is shown in the Appendix. The same type integrals with different limits also had to be evaluated for the other ranges of r . These calculations give the following expressions for $R(\theta, \theta_0)$. For $r \leq z_0 - 2b_0$:

$$R(\theta, \theta_0)_I = 0 \quad (34)$$

For $z_0 - 2b_0 \leq r \leq z_0$:

$$R(\theta, \theta_0)_{II} = \frac{z_0 r}{2\pi^2 r_0^2} \left[\sqrt{1 - \alpha^2} - \alpha \cos^{-1} \alpha \right] - \frac{1}{8\pi^2 r_0^2} (2b_0 - z_0 + r)^2 \quad (35)$$

For $z_0 \leq r \leq z_0 + 2b_0$:

$$R(\theta, \theta_0)_{III} = \frac{1}{8\pi^2 r_0^2} (r^2 + z_0^2 - 2rz_0 - 4b_0^2 + 4b_0 z_0 - 4rb_0) + \frac{r z_0}{2\pi^2 r_0^2} \left[\sqrt{1 - \alpha^2} - \alpha \cos^{-1} \alpha + 2\gamma \cos^{-1} \gamma - 2\sqrt{1 - \gamma^2} \right] \quad (36)$$

For $z_0 + 2b_0 \leq r \leq \sqrt{(z_0 - 2b_0)^2 + 2a_0^2}$:

$$R(\theta, \theta_0)_{\text{IV}} = \frac{r a_0}{2\pi^2 r_0^2} \left[2\gamma \cos^{-1} \gamma - 2\sqrt{1-\gamma^2} - \alpha \cos^{-1} \alpha + \sqrt{1-\alpha^2} - \delta \cos^{-1} \delta + \sqrt{1-\delta^2} \right] - \frac{b_0^2}{\pi^2 r_0^2} \quad (37)$$

For $\sqrt{(z_0 - 2b_0)^2 + (2a_0)^2} \leq r \leq \sqrt{z_0^2 + (2a_0)^2}$:

$$R(\theta, \theta_0)_{\text{VIII}} = \frac{b_0 r}{2\pi^2 r_0^2} \left[\frac{2a_0}{r} \sin^{-1} \frac{2a_0}{r} + \sqrt{1 - \left(\frac{2a_0}{r}\right)^2} \right] - \frac{b_0 z_0}{2\pi^2 r_0^2} - \frac{b_0^2}{2\pi^2 r_0^2} + \frac{r a_0}{2\pi^2 r_0^2} \left[\gamma \cos^{-1} \gamma - \sqrt{1-\gamma^2} - \delta \cos^{-1} \delta + \sqrt{1-\delta^2} \right] \quad (38)$$

For $\sqrt{(z_0 + 2b_0)^2 + (2a_0)^2} \leq r$

$$R(\theta, \theta_0)_{\text{IX}} = 0 \quad (39)$$

In Figure 21, the resolution function is plotted for $a_0 = 6.35$ milliradians, $b_0 = .2$ milliradians, $r_0 = 1000$ milliradians, and $z_0 = .6$ milliradians and 3.6 milliradians to show how the function varies for different positions (z_0) of the movable slit. These values of the parameters correspond to an apparatus with slits one inch long by .016 inches wide and each slit a distance of 2

meters from the target. The resolution function is plotted in Figure 22 for an apparatus with 8 inch long slits when z_0 is again .6 milliradians and 3.6 milliradians. Figure 23 shows the $z_0 = .6$ milliradian curves of both Figure 21 and Figure 22 plotted on the same scale to compare areas and Figure 24 shows the $z_0 = .6$ milliradian curves of both Figure 21 and Figure 22 with the maximum points normalized to compare shapes.

No attempt was made to generalize the resolution function to include targets of finite size. This can probably be done satisfactorily by employing the methods of numerical integration and will certainly broaden the curves. The generalized resolution curves for each position of the movable slit can then be used to correct the raw data using the general method developed by Eckart¹⁶.

The corrected coincidence counting rate at θ is proportional to the total number of annihilation pairs per unit time having a p_ρ component of momentum. The relation is

$$D(p_\rho) = \text{const.} \int_0^\infty \int_0^{2\pi} \rho(p) p_\rho d\phi dp_y \quad (40)$$

where

$$p_\rho = \sqrt{p_x^2 + p_z^2} \quad (41)$$

RESOLUTION CURVES

Equation 40 can be written as

$$\frac{D(P_\rho)}{P_\rho} = \text{const.} \int_0^\infty \int_0^{2\pi} \rho(p) d\phi dp_y \quad (42)$$

Since an isotropic momentum distribution has been assumed, equation 42 can be integrated over ϕ to get

$$\frac{D(P_\rho)}{P_\rho} = \text{const.} 2\pi \int_0^\infty \rho(p) dp_y \quad (43)$$

From this relation Bahena¹⁷ has shown that the distribution of momentum is given by

$$N(p) = N(p_z) = \text{const.} p^2 \int_0^\infty \frac{1}{\theta} \frac{dD(\theta)}{d\theta} dp_x \quad (44)$$

where

$$\theta = \frac{r}{r_0} = \frac{P_\rho}{mc} \quad (45)$$

CHAPTER III

EVALUATION AND COMPARISON OF METHODS

A. Speed in Taking Data

The study of the angular correlation of annihilation radiation is always a rather time-consuming experiment since the solid angles utilized by the crystal scintillators have to be very small, of the order of 10^{-5} steradians. The decay of the source, the possibility of the apparatus getting knocked out of alignment while taking data, and drift in the electronic circuits make it advisable to collect the data in as short a time as possible. This becomes even more desirable if the target is being held at low temperature or under a vacuum.

The factor of speed in taking data is the big advantage of the multiple coincidence channel apparatus. If four properly spaced slits are used at each end of the apparatus, it is possible to collect data for 16 angles in the same time that a single coincidence channel apparatus with the same size slits requires for one angle. The data must be taken with frequent change of the angle between the two sets of slits, however, because the response of a single channel can vary slightly due to

electronic drift and temperature changes, so that the sensitivity cannot be considered as constant from day to day. By changing the position of the movable slits stepwise up and down again, part of a coincidence curve is obtained for each counter pair. Independently of single channel sensitivities, these 16 curves can then be joined together to make one curve.

The usual arrangement of the photomultiplier tubes and slits^{18,19} in this type apparatus restrict the maximum length of the slits to about 2 inches. No such restriction exists for the single coincidence channel apparatus; so it is possible to use slits much greater than 2 inches long and thereby reduce the counting time advantage of the multiple coincidence channel apparatus.

B. Structural Complexity

The SCC apparatus (single coincidence channel) is easier to construct than the MCC apparatus (multiple coincidence channel). The MCC apparatus requires the construction of four times as many precision slits and photomultiplier tube supports. The design of the lead shielding is necessarily more complicated.

C. Electronic Components

The MCC apparatus requires far more circuitry than the SCC apparatus. It requires four times as many tube bases, preamplifiers, and pulse shapers; sixteen times

¹⁸Trumpy, G., op. cit.

¹⁹Lovseth, J., op. cit.

as many coincidence circuits; and a complex switch for directing the output of each coincidence circuit to the correct sequence of registers.

D. Expense

The MCC apparatus costs more to build than the SCC apparatus. It requires more photomultiplier tubes, far more electronic equipment, and far more man-hours to construct.

E. Alignment

The MCC apparatus is harder to align than the SCC apparatus. Eight slits have to be adjusted as opposed to just two for the single coincidence channel apparatus.

F. Analysis of Data

It is much easier to correct the data for instrumental resolution by Method A because the resolution curve is symmetrical and is the same for all positions of the movable slit, while the resolution curve for Method B is asymmetrical and varies greatly with the position of the movable slit. (Compare Figure 11 with Figures 21 and 22.) It is also much easier to obtain the momentum distribution by Method A because it only involves the determination of slopes as opposed to the determination of areas required by Method B.

In order to Use Method A, however, it is necessary that the effective slit length be much greater than 10 milliradians. As stated earlier, the maximum slit length that can be used in the multiple coincidence

channel apparatus is about 2 inches which corresponds to about 25 milliradians at a distance of 2 meters. In order to fit a standard photomultiplier tube and still cover the length of the slit, the scintillators are usually cut in the shape of short right cylinders. This means that the efficiency of the counter drops from a maximum at the center of the slit to zero at each edge which reduces the effective slit length by about half and invalidates the use of equation 21 which assumes a constant crystal efficiency.

With a maximum effective slit length of about 12.5 milliradians, the use of Method A to analyze the data obtained by a multiple coincidence channel apparatus is not entirely justified. Several alternatives exist: 1) use Method B to evaluate the data; 2) devise a way to use longer slits with the multiple coincidence channel apparatus; 3) collect the data with a long slit single coincidence channel apparatus and use either or both methods to analyze the data; and 4) devise a method (for varying crystal efficiency) of relating the count rate to the momentum distribution from equation 21.

At the present, alternative 3 appears to be the best method.

APPENDIX

The complete calculation of $R(\theta, \theta_0)_{IV}$.

For $z_0 + 2b_0 \leq r \leq \sqrt{(z_0 - 2b_0)^2 + a_0^2}$.

$$R(\theta, \theta_0)_{IV} = c \int_{-b_0}^{b_0} \int_0^M P(B)_D d\alpha db + c \int_{-b_0}^{b_0} \int_M^N P(B)_E d\alpha db + c \int_{-b_0}^{b_0} \int_N^{a_0} P(B)_F d\alpha db \quad (A-1)$$

Each of these integrals will be calculated separately and the results added. The integral for $P(B)_D$ is

$$c \int_{-b_0}^{b_0} \int_0^M P(B)_D d\alpha db = c \int_{-b_0}^{b_0} \int_0^{a_0 - \sqrt{r^2 - c^2}} \frac{1}{\pi} \cos^{-1} \frac{c}{r} d\alpha db - c \int_{-b_0}^{b_0} \int_0^{a_0 - \sqrt{r^2 - c^2}} \frac{1}{\pi} \cos^{-1} \frac{e}{r} d\alpha db \quad (A-2)$$

Integrating over the variable α gives

$$\begin{aligned} c \int_{-b_0}^{b_0} \int_0^M P(B)_D d\alpha db &= \frac{c}{\pi} \int_{-b_0}^{b_0} a_0 \cos^{-1} \frac{c}{r} db - \frac{cr}{\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{c}{r}\right)^2} \cos^{-1} \frac{c}{r} db \\ &+ \frac{cr}{\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{c}{r}\right)^2} \cos^{-1} \frac{e}{r} db - \frac{c}{\pi} \int_{-b_0}^{b_0} a_0 \cos^{-1} \frac{e}{r} db \end{aligned} \quad (A-3)$$

The integral for $P(B)_E$ is

$$\begin{aligned} c \int_{-b_0}^{b_0} \int_M^N P(B)_E d\alpha db &= c \int_{-b_0}^{b_0} \int_M^N \frac{1}{2\pi} \cos^{-1} \frac{c}{r} d\alpha db + c \int_{-b_0}^{b_0} \int_M^N \frac{i}{2\pi} \sin^{-1} \left(\frac{a_0 - \alpha}{r} \right) d\alpha db \\ &- c \int_{-b_0}^{b_0} \int_M^N \frac{1}{\pi} \cos^{-1} \frac{e}{r} d\alpha db \end{aligned} \quad (A-4)$$

Let these integrals be called I, II, and III respectively.

$$I = \frac{c}{2\pi} \int_{-b_0}^{b_0} \int_{a_0 - \sqrt{r^2 - c^2}}^{a_0 - \sqrt{r^2 - e^2}} \cos^{-1} \frac{c}{r} da db \quad (\text{A-5})$$

Integrating over the variable a gives

$$I = -\frac{cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{c}{r} db + \frac{cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{c}{r}\right)^2} \cos^{-1} \frac{c}{r} db \quad (\text{A-6})$$

Integral II is

$$II = \frac{c}{2\pi} \int_{-b_0}^{b_0} \int_{a_0 - \sqrt{r^2 - c^2}}^{a_0 - \sqrt{r^2 - e^2}} \sin^{-1} \left(\frac{a_0 - a}{r} \right) db da \quad (\text{A-7})$$

Let $A = \frac{a_0 - a}{r}$ so $da = -r dA$.

When $a = a_0 - \sqrt{r^2 - e^2}$, $A = \frac{\sqrt{r^2 - e^2}}{r}$ and when $a = a_0 - \sqrt{r^2 - c^2}$,

$A = \frac{\sqrt{r^2 - c^2}}{r}$, so integral II becomes

$$II = -\frac{Cr}{2\pi} \int_{-b_0}^{b_0} \int_{\frac{\sqrt{r^2 - c^2}}{r}}^{\frac{\sqrt{r^2 - e^2}}{r}} \sin^{-1} A dA \quad (\text{A-8})$$

Integrating over the variable A gives

$$II = -\frac{Cr}{2\pi} \int_{-b_0}^{b_0} \frac{2b_0}{r} db - \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \sin^{-1} \sqrt{1 - \left(\frac{e}{r}\right)^2} db \\ + \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{c}{r}\right)^2} \sin^{-1} \sqrt{1 - \left(\frac{c}{r}\right)^2} db \quad (\text{A-9})$$

Integral III is

$$\text{III} = -\frac{C}{\pi} \int_{-b_0}^{b_0} \int_{a_0 - \sqrt{r^2 - c^2}}^{a_0 - \sqrt{r^2 - e^2}} \cos^{-1} \frac{e}{r} da db \quad (\text{A-10})$$

Integrating over the variable a gives

$$\text{III} = \frac{Cr}{\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{e}{r} db - \frac{Cr}{\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{c}{r}\right)^2} \cos^{-1} \frac{e}{r} db \quad (\text{A-11})$$

The total integral for $P(B)_E$ is then

$$\begin{aligned} C \int_{-b_0}^{b_0} \int_M^N P(B)_E da db &= -\frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{e}{r} db \\ &+ \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{c}{r}\right)^2} \cos^{-1} \frac{c}{r} db - \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \frac{2b_0}{r} db \\ &- \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \sin^{-1} \sqrt{1 - \left(\frac{e}{r}\right)^2} db + \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{c}{r}\right)^2} \sin^{-1} \sqrt{1 - \left(\frac{c}{r}\right)^2} db \\ &+ \frac{Cr}{\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{e}{r} db - \frac{Cr}{\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{c}{r}\right)^2} \cos^{-1} \frac{e}{r} db \end{aligned} \quad (\text{A-12})$$

The integral for $P(B)_F$ is

$$C \int_{-b_0}^{b_0} \int_N^{a_0} P(B)_F da db = C \int_{-b_0}^{b_0} \int_{a_0 - \sqrt{r^2 - e^2}}^{a_0} \frac{1}{2\pi} \cos^{-1} \frac{c}{r} db da - C \int_{-b_0}^{b_0} \int_{a_0 - \sqrt{r^2 - e^2}}^{a_0} \frac{1}{2\pi} \cos^{-1} \frac{e}{r} db da \quad (\text{A-13})$$

Integrating over the variable a gives

$$c \int_{-b_0}^{b_0} \int_{\partial_0}^{\partial_0} P(B)_F da db = \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{c}{r} db - \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{e}{r} db \quad (\text{A-14})$$

Therefore, the total expression for $R(\theta, \theta_0)_{II}$ is

$$\begin{aligned} R(\theta, \theta_0)_{II} &= \frac{c}{\pi} \int_{-b_0}^{b_0} \partial_0 \cos^{-1} \frac{c}{r} db - \frac{Cr}{\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{c}{r} db \\ &+ \frac{Cr}{\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{e}{r} db - \frac{c}{\pi} \int_{-b_0}^{b_0} \partial_0 \cos^{-1} \frac{e}{r} db \\ &- \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{c}{r} db + \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{c}{r} db \\ &- \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \frac{2b_0}{r} db - \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \sin^{-1} \sqrt{1 - \left(\frac{e}{r}\right)^2} db \\ &+ \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \sin^{-1} \sqrt{1 - \left(\frac{e}{r}\right)^2} db + \frac{Cr}{\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{e}{r} db \\ &- \frac{Cr}{\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{e}{r} db \quad (\text{A-15}) \\ &+ \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{c}{r} db - \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{e}{r} db \end{aligned}$$

After cancellations, this becomes

$$\begin{aligned}
 R(0, \theta_0)_{IV} &= \frac{C\partial_0}{\pi} \int_{-b_0}^{b_0} \cos^{-1} \frac{c}{r} db - \frac{C\partial_0}{\pi} \int_{-b_0}^{b_0} \cos^{-1} \frac{e}{r} db - \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \frac{2b_0}{r} db \\
 &\quad - \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{c}{r}\right)^2} \cos^{-1} \frac{c}{r} db + \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \cos^{-1} \frac{e}{r} db \\
 &\quad - \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{e}{r}\right)^2} \sin^{-1} \sqrt{1 - \left(\frac{e}{r}\right)^2} db \\
 &\quad + \frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1 - \left(\frac{c}{r}\right)^2} \sin^{-1} \sqrt{1 - \left(\frac{c}{r}\right)^2} db
 \end{aligned} \tag{A-16}$$

Let these integrals be numbered I through VII respectively.

$$I = \frac{C\partial_0}{\pi} \int_{-b_0}^{b_0} \cos^{-1} \left(\frac{z_0 - b_0 - b}{r} \right) db \tag{A-17}$$

$$\text{Let } A = \frac{z_0 - b_0 - b}{r} \text{ so } db = -r dA$$

When $b = b_0$, $A = \frac{z_0 - 2b_0}{r} = \alpha$ and when $b = -b_0$,
 $A = \frac{z_0}{r} = \gamma$, so integral I becomes

$$I = -\frac{C\partial_0 r}{\pi} \int_{\gamma}^{\alpha} \cos^{-1} A dA = -\frac{C\partial_0 r}{\pi} \left[A \cos^{-1} A - \sqrt{1 - A^2} \right]_{\gamma}^{\alpha} \tag{A-18}$$

$$I = -\frac{C\partial_0 r}{\pi} \left[\alpha \cos^{-1} \alpha - \sqrt{1 - \alpha^2} - \gamma \cos^{-1} \gamma + \sqrt{1 - \gamma^2} \right] \tag{A-19}$$

In a similar manner,

$$\text{II} = \frac{C\partial_0 r}{\pi} \left[\gamma \cos^{-1} \gamma - \sqrt{1-\gamma^2} - \delta \cos^{-1} \delta + \sqrt{1-\delta^2} \right] \quad (\text{A-20})$$

$$\text{III} = -\frac{Cr}{2\pi} \int_{-b_0}^{b_0} \frac{2b_0}{r} db = -\frac{2Cb_0^2}{\pi} \quad (\text{A-21})$$

$$\text{IV} = -\frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1-\left(\frac{c}{r}\right)^2} \cos^{-1} \frac{c}{r} db \quad (\text{A-22})$$

Let $\cos A = \frac{c}{r} = \frac{z_0 - b_0 - b}{r}$ so $db = r \sin A dA$.

When $b = b_0$, $A = \cos^{-1} \frac{z_0 - 2b_0}{r} = \cos^{-1} \alpha$ and when $b = -b_0$,

$A = \cos^{-1} \gamma$, so integral IV becomes

$$\text{IV} = -\frac{Cr^2}{2\pi} \int_{\cos^{-1} \gamma}^{\cos^{-1} \alpha} A \sin^2 A dA \quad (\text{A-23})$$

$$\text{IV} = -\frac{Cr^2}{2\pi} \left[\frac{A^2}{4} - \frac{A \sin 2A}{4} - \frac{\cos 2A}{8} \right]_{\cos^{-1} \gamma}^{\cos^{-1} \alpha} \quad (\text{A-24})$$

In a similar manner,

$$\text{V} = \frac{Cr^2}{2\pi} \left[\frac{A^2}{4} - \frac{A \sin 2A}{4} - \frac{\cos 2A}{8} \right]_{\cos^{-1} \delta}^{\cos^{-1} \gamma} \quad (\text{A-25})$$

$$\text{VI} = -\frac{Cr}{2\pi} \int_{-b_0}^{b_0} \sqrt{1-\left(\frac{c}{r}\right)^2} \sin^{-1} \sqrt{1-\left(\frac{c}{r}\right)^2} db \quad (\text{A-26})$$

$$\text{Let } \cos A = \frac{e}{r} = \frac{z_0 + b_0 - b}{r} \quad \text{so } db = r \sin A dA$$

When $b = b_0$, $A = \cos^{-1} \gamma$ and when $b = -b_0$,
 $A = \cos^{-1} \delta$, so integral VI becomes

$$\text{VI} = - \frac{Cr^2}{2\pi} \int_{\cos^{-1} \delta}^{\cos^{-1} \gamma} A \sin^2 A dA \quad (\text{A-27})$$

$$\text{VI} = - \frac{Cr^2}{2\pi} \left[\frac{A^2}{4} - \frac{A \sin 2A}{4} - \frac{\cos 2A}{8} \right]_{\cos^{-1} \delta}^{\cos^{-1} \gamma} \quad (\text{A-28})$$

In a similar manner,

$$\text{VII} = \frac{Cr^2}{2\pi} \left[\frac{A^2}{4} - \frac{A \sin 2A}{4} - \frac{\cos 2A}{8} \right]_{\cos^{-1} \gamma}^{\cos^{-1} \alpha} \quad (\text{A-29})$$

Again there are possible cancellations in the expression for $R(\theta, \theta_0)_{\text{IV}}$ and the final result is

$$\begin{aligned} R(\theta, \theta_0)_{\text{IV}} &= \frac{2C a_0 r}{\pi} \left[\gamma \cos^{-1} \gamma - \sqrt{1 - \gamma^2} \right] - \frac{2C b_0^2}{\pi} \\ &\quad - \frac{C a_0 r}{\pi} \left[\alpha \cos^{-1} \alpha - \sqrt{1 - \alpha^2} + \delta \cos^{-1} \delta - \sqrt{1 - \delta^2} \right] \end{aligned} \quad (\text{A-30})$$

where

$$\gamma = \frac{z_0}{r} \quad (\text{A-31})$$

$$\alpha = \frac{z_0 - 2b_0}{r} \quad (\text{A-32})$$

$$\delta = \frac{z_0 + 2b_0}{r} \quad (\text{A-33})$$

VITA

Charles Joseph Vesely was born in Omaha, Nebraska, on June 20, 1939, the son of Charles Edward Vesely and Marguerite Marie Vesely. He was graduated from Wurtzsmith Memorial High School, Clark Air Force Base, Luzon, Philippine Islands, in May, 1957 and entered The University of Southern California the following September. In September, 1958, he transferred to The University of Texas, where he received a Bachelor of Science degree in physics and a Bachelor of Arts degree in mathematics in January, 1962. During the summers of 1958 and 1959 he attended San Antonio Junior College. While in college he was a member of the A. F. R. O. T. C. and upon graduation he was commissioned a Second Lieutenant in the United States Air Force. Since then, he has been assigned to the graduate school of The University of Texas under the Air Force Institute of Technology Civilian Institutions Program.
