Bartlesville, Oklahoma†*

(Received 19 September 1962)

Thermodynamic data were obtained for 1,2-difluorobenzene and correlated by methods of statistical mechanics to derive values of the chemical thermodynamic properties in the ideal-gas state from 0° to 1500°K. A vibrational assignment consistent with the calorimetric data was obtained. The experimental studies provided the following information: values of heat capacity for the solid (14°K to the triple point), the liquid (triple point to 357°K), and the vapor (355° to 500°K); the triple-point temperature; the heat of fusion; thermodynamic functions for the solid and liquid (0° to 370°K); heat of vaporization (327° to 367°K); parameters of the equation of state; and vapor pressure (304° to 403°K).

### INTRODUCTION

COMPREHENSIVE thermodynamic studies of 1,2-difluorobenzene were made by the Bureau of Mines as part of continuing research on organic fluorine compounds. Experimental data were obtained by low-temperature calorimetry, vapor-flow calorimetry, and comparative ebulliometry. These experimental results and the results of combustion calorimetry reported elsewhere<sup>1</sup> were used with spectral and molecular structure information to calculate a table of chemical thermodynamic properties for the ideal-gas state.

An outcome of these studies was a vibrational assignment for 1,2-difluorobenzene consistent with accurate calorimetric values of the vapor heat capacity

and entropy. This reliable assignment for one ortho-disubstituted benzene contributes to understanding the molecular vibrations of ortho-disubstituted benzenes in general.

<sup>a</sup> Used second time.

The first section of this paper is on the vibrational assignment and the chemical thermodynamic properties in the ideal-gas state, and the second section is on the experimental measurements. For convenience, the calorimetric values of entropy, heat capacity, and heat of formation<sup>1</sup> needed for discussion in the first section are collected in Table I.

#### VIBRATIONAL ASSIGNMENT AND CHEMICAL THERMODYNAMIC PROPERTIES

##### Vibrational Assignment

A complete vibrational assignment was required to correlate the calorimetric values of entropy and heat capacity in Table I by methods of statistical mechanics and to calculate thermodynamic functions at higher temperatures. The assignment made in this work was based on the molecular spectra in Table II, supplied by J. R. Nielsen of the University of Oklahoma. The Raman spectrum in Table II was obtained with some of the same highly purified sample used in the calorimetric studies of this research. The infrared spectra, however, were obtained earlier with a less pure sample; some observed bands obviously caused by fluorobenzene impurity are omitted in Table II.

The assignment for the in-plane symmetry species ( $a_1$  and  $b_1$ ) was made with the help of force-constant calculations done by Dr. James R. Scherer of the Dow Chemical Company. These calculations were for the Kekulé model of the Urey-Bradley force field. All force constants were transferred from structurally related molecules and were *not* adjusted in any way to improve agreement between the calculated and observed frequencies of 1,2-difluorobenzene. The calcu-

lated frequencies are in columns 1 and 3 of Table III, and the observed frequencies assigned by reference to the calculated ones are in columns 2 and 4. The observed frequencies are gratifyingly near to the calculated ones, the maximum difference being  $32 \text{ cm}^{-1}$ . Only one assignment of an observed frequency to an in-plane symmetry species is not very certain; the  $1252 \text{ cm}^{-1}$  frequency assigned as a  $b_1$  fundamental appears weakly in the Raman spectrum alone and has an alternative explanation as a sum combination. Another possibility is that the  $b_1$  fundamental coincides with the  $a_1$  fundamental at  $1279 \text{ cm}^{-1}$  and is obscured by this fundamental in both spectra. The C—H stretching frequencies have the usual uncertainties from incomplete resolution and interference from Fermi resonance. The average frequency of the strong Raman and infrared bands in the C—H stretching region is about  $3080 \text{ cm}^{-1}$ ; this value was used for all four fundamentals in the thermodynamic calculations. These C—H stretching frequencies are unimportant thermodynamically except at higher temperatures.

No force-constant calculations were made for the out-of-plane symmetry species ( $a_2$  and  $b_2$ ). However, with the in-plane fundamentals eliminated from the observed spectra, all but one of the out-of-plane fundamentals could be assigned from the selection rules and knowledge of the regions of the spectra in which these fundamentals would be expected. The observed frequencies assigned to species  $a_2$  and  $b_2$  are in columns 5 and 6 of Table III. The reported polarization of the  $746 \text{ cm}^{-1}$  Raman band was considered to be unreliable because of interference from the much stronger neighboring band at  $762 \text{ cm}^{-1}$ . The contour of the corresponding infrared band is correct for a  $b_2$  fundamental. Assignment of the very weak Raman bands at 240 and  $585 \text{ cm}^{-1}$  as  $a_2$  fundamentals is supported by the sum combination,  $240 + 585 = 825 A_1$ . The one out-of-plane fundamental not assigned from the observed spectra was located approximately from the characteristic vibrational frequencies of ortho-disubstituted benzenes tabulated by Randle and Whiffen.<sup>2</sup> These workers find a characteristic frequency of species  $a_2$  near  $860 \text{ cm}^{-1}$  that appears weakly in the spectra when permitted by the selection rules. In 1,2-difluorobenzene, this characteristic  $a_2$  fundamental must nearly coincide with the  $b_1$  fundamental at  $855 \text{ cm}^{-1}$  and may be obscured by it in the observed spectra. The  $a_2$  fundamental therefore was assigned the same frequency as the  $b_1$  fundamental. The eleven other characteristic frequencies of ortho-disubstituted benzenes tabulated by Randle and Whiffen are included in the assignment of Table III.

##### Moments of Inertia

Calculating thermodynamic properties required (in addition to the complete vibrational assignment) a

<sup>a</sup> To retain internal consistency, some values are given to one more decimal place than is justified by the absolute accuracy.<sup>b</sup> The standard heat and free energy, and common logarithm of the equilibrium constant of formation by the reaction,

value of the product of the principal moments of inertia of the molecule. Moments of inertia were calculated for an assumed structure with all bond angles 120° and the following bond distances: C—C, 1.402 Å; C—H, 1.077 Å; and C—F, 1.299 Å. These distances are based on the fluorobenzene model with a regular hexagon benzene nucleus, consistent with the microwave spectra of fluorobenzene<sup>3</sup>; they differ somewhat from the electron-diffraction values.<sup>4</sup> For the assumed structure, the product of the principal moments of inertia is  $6.113 \times 10^{-113} \text{ g}^2 \text{ cm}^6$ . The symmetry number is 2.

### Thermodynamic Functions

Thermodynamic functions were computed from the usual formulas of statistical mechanics. An empirical anharmonicity function<sup>5</sup> with  $\nu = 1250 \text{ cm}^{-1}$  and  $Z = 0.97 \text{ cal/deg mole}$  was used to obtain better agreement with the vapor heat capacity data. The contributions of anharmonicity, according to this empirical function, are only 0.0004 and 0.004 cal/deg mole in  $S^\circ$  and  $C_p$  at 298.15°K but increase to 0.74 and 1.45 cal/deg mole at 1500°K. The calculated values of

entropy and heat capacity are compared with the observed values in Table I. The excellent agreement shows that the vibrational assignment in Table III is substantially correct. Liquid-state values were used for the lowest frequencies in Table III because gas-state values have not been determined. Sometimes liquid-state values of low frequencies differ enough from the gas-state values to affect the calculated entropy significantly,<sup>6</sup> but seemingly that does not occur for 1,2-difluorobenzene. The calculated values of the thermodynamic functions for selected temperatures up to 1500°K are in columns 2–6 of Table IV.<sup>7</sup>

### Heat, Free Energy, and Equilibrium Constant of Formation

The calculated values of the thermodynamic functions, the experimental value of  $\Delta H_f^\circ_{298.15}$  (Table I), and values of the thermodynamic functions of C (c, graphite),<sup>8</sup> H<sub>2</sub> (g),<sup>9</sup> and F<sub>2</sub> (g)<sup>9</sup> were used in calcu-

<sup>a</sup>  $T$  is the mean temperature of each heat capacity measurement.<sup>b</sup>  $C_p$  is the heat capacity of the condensed phase at saturation pressure.\* Values of  $C_p$  for crystals are not corrected for the effects of premelting caused by impurities.lating values of  $\Delta H_f^\circ$ ,  $\Delta F_f^\circ$ , and  $\log_{10} K_f$ . The results are in columns 7-9, Table IV.

## EXPERIMENTAL

The basic experimental techniques are described in published accounts of apparatus and methods for low-temperature calorimetry,<sup>10</sup> vapor-flow calorimetry,<sup>11</sup> and comparative ebulliometry.<sup>12</sup> The reported values are based on a molecular weight of 114.092 g/mole (1951 International Atomic Weights),<sup>13</sup> the 1951 values

<sup>10</sup> H. M. Huffman, Chem. Rev. **40**, 1 (1947); H. M. Huffman, S. S. Todd, and G. D. Oliver, J. Am. Chem. Soc. **71**, 584 (1949); D. W. Scott, D. R. Douslin, M. E. Gross, G. D. Oliver, and H. M. Huffman, *ibid.* **74**, 883 (1952).

<sup>13</sup> E. Wichers, J. Am. Chem. Soc. **74**, 2447 (1952). Use of the unified atomic weight scale [Chem. Eng. News, November 20, 1961, p. 43] would not change any of the results significantly.

of fundamental physical constants,<sup>14</sup> and the relations  $0^\circ\text{C} = 273.15^\circ\text{K}$ <sup>15</sup> and  $1 \text{ cal} = 4.184 \text{ J}$  (exactly). Measurements of temperature were made with platinum resistance thermometers calibrated in terms of the International Temperature Scale<sup>16</sup> between  $90^\circ$  and  $500^\circ\text{K}$  and the provisional scale<sup>17</sup> of the National Bureau of Standards between  $11^\circ$  and  $90^\circ\text{K}$ . All electrical and mass measurements were referred to standard devices calibrated at the National Bureau of Standards.

## Material

The sample of 1,2-difluorobenzene used for low-temperature calorimetry and comparative ebulliometry had a purity of 99.998 mole %, as determined by calorimetric studies of melting point as a function of fraction melted. The source and purification of this sample, which was used also for combustion calorimetry, are reported elsewhere.<sup>1</sup> A sample of somewhat lower purity was used for vapor-flow calorimetry.

## Heat Capacity in the Solid and Liquid States

Low temperature calorimetric measurements were made with 0.54821 mole of sample sealed in a platinum calorimeter with helium (34 mm pressure at room temperature) added to promote thermal equilibration. The observed values of heat capacity at saturation pressure  $C_p$  are given in Table V. Temperature increments used in the measurements were small enough to obviate corrections for curvature; that is, 10% of the

TABLE VI. 1,2-difluorobenzene: Melting point summary.  $T_{10} = 226.01 \pm 0.05^\circ\text{K}$ ;  $N_2 = \lambda T (T_{10} - T_F) = 0.00002$ ;  $\lambda = 0.02601 \text{ deg}^{-1}$ ;  $B = 0.00356 \text{ deg}^{-1}$ .

\* Calculated from a straight line through points at  $r = 0.1104$  and  $0.7058$ .

<sup>14</sup> F. D. Rossini, F. T. Gucker, Jr., H. L. Johnston, L. Pauling, and G. W. Vinal, J. Am. Chem. Soc. **74**, 2699 (1952).

<sup>15</sup> Some of the results originally were computed with constants and temperatures in terms of the relation  $0^\circ\text{C} = 273.16^\circ\text{K}$ . Only results affected significantly by the newer definition of the absolute temperature scale [H. F. Stimson, Am. J. Phys. **23**, 614 (1955)] were recalculated. Therefore, numerical inconsistencies, much smaller than the accuracy uncertainty, may be noted in some of the reported data.

<sup>a</sup> The reference compound from 71.87 to 132.95 mm was pure benzene and that from 149.41 to 2026.0 mm was pure water.

<sup>b</sup> From vapor pressure data for benzene [F. D. Rossini, K. S. Pitts, R. L. Arnett, R. M. Braun, and G. C. Pimentel, *Selected Values of Physical and Thermodynamic Properties of Hydrocarbons and Related Compounds* (Carnegie Press, Pittsburgh, Pennsylvania, 1953), Table 21k] and for water [N. S. Osborne, H. F. Stimson, and D. C. Ginnings, *J. Research Natl. Bur. Standards* 23, 261 (1939)].

absolute temperature below 50°K, 5° to 6° from 50°K to the triple point, and 10° or less above the triple point. Above 30°K, the accuracy uncertainty of the results is estimated to be no greater than 0.2%. The heat capacity values for the liquid may be represented between the triple point and 357°K by the empirical equation

$$C_p(\text{liq}) = 46.535 - 0.20805T + 8.9687 \times 10^{-4}T^2 - 9.8958 \times 10^{-7}T^3, \text{ cal/deg mole} \quad (1)$$

with an average deviation of 0.04%.

#### Heat of Fusion, Triple-Point Temperature, Cryoscopic Constants, and Purity of Sample

Three determinations of the heat of fusion  $\Delta H_m$  gave the average value  $2639.8 \pm 0.3$  cal/mole with the maximum deviation from the mean taken as the uncertainty. A correction for premelting caused by impurities was applied in obtaining the foregoing value. The results of a study of the melting temperature,  $T_f$ ,

as a function of the fraction of total sample melted  $F$  are in Table VI. Also in Table VI are the values obtained for the triple-point temperature  $T_{tp}$ , the mole fraction of impurity in the sample  $N_2^*$ , and the cryoscopic constants<sup>18</sup>  $A = \Delta H_m/RT_{tp}^2$  and  $B = 1/T_{tp} - \Delta C_m/2\Delta H_m$ , calculated from the observed values of  $T_{tp}$ ,  $\Delta H_m$ , and  $\Delta C_m$  (4.565 cal/deg mole).

#### Thermodynamic Properties in the Solid and Liquid States

Values of thermodynamic functions for the condensed phases were computed from the calorimetric data for selected temperatures between 10° and 370°K. The results are given in Table VII. The values from 10° to 14°K were computed from a Debye function for 5 degrees of freedom with  $\theta = 108.2^\circ$ ; these parameters were evaluated from the heat capacity data between 15° and 21°K. Corrections for the effects of premelting have been applied to the "smoothed" data in Table VII.

#### Vapor Pressure

Values of vapor pressure determined by comparative ebulliometry are in Table VIII. The condensation temperature of the sample was 0.004° lower than the ebullition temperature at 1 atm pressure. The Antoine and Cox equations selected to represent the results are

$$\log_{10} p = 7.00003 - 1298.053/(t + 221.197) \quad (2)$$

and

$$\log_{10}(p/760) = A(1 - 367.072/T)$$

$$\log_{10} A = 0.841936 - 6.77698 \times 10^{-4}T + 6.52099 \times 10^{-7}T^2.$$

(3)

In these equations,  $p$  is in mm,  $t$  is in °C, and  $T$  is in °K. The observed and calculated vapor pressure for both the Antoine and Cox equations are compared in Table VIII. The normal boiling point is 93.92°C (367.07°K).

### Heat of Vaporization, Vapor Heat Capacity, and Effects of Gas Imperfection

The experimental values of heat of vaporization and vapor heat capacity are in Tables IX and X. The estimated accuracy uncertainties of the values of  $\Delta H_v$  and  $C_p^\circ$  are 0.1% and 0.2%, respectively. The heat of vaporization may be represented by the empirical equation

$$\Delta H_v = 11710 - 7.487T - 0.937 \times 10^{-2} T^2 \text{ cal/mole} \\ (327^\circ\text{--}367^\circ\text{K}). \quad (4)$$

The effects of gas imperfection were correlated by the procedure described in an earlier paper.<sup>19</sup> The empirical equation for  $B$ , the second virial coefficient in the equation of state,  $PV = RT(1 + B/V)$ , is

$$B = -80 - 73.05 \exp(1000/T) \text{ cc/mole} (327^\circ\text{--}500^\circ\text{K}). \quad (5)$$

Observed values of  $B$  and

$$-T(d^2B/dT^2) = \lim_{p \rightarrow 0} (\partial C_p / \partial P)_T$$

| $S^\circ(\text{obs}) \pm 0.16^d$     | 79.38  | 80.94  | 82.71  |

<sup>a</sup> By interpolation in Table VII.

<sup>b</sup> The entropy in the ideal-gas state less that in the real-gas state calculated from Eq. (5).

<sup>c</sup> Entropy of compression, calculated from Eq. (3).

<sup>d</sup> Estimated accuracy uncertainty.

and those calculated from Eq. (5) are compared in Tables IX and X.

The heat of vaporization at 298.15°K was calculated by extrapolation with Eq. (4) (8.64 kcal/mole), by use of the Clapeyron equation with Eqs. (3) and (5) (8.64 kcal/mole), and by use of a thermodynamic network with the thermodynamic functions of Table IV (8.63 kcal/mole). The last value was selected as most reliable. By use of Eq. (5), the standard heat of vaporization (to the hypothetical ideal gas) is calculated to be 0.02 kcal/mole greater than the heat of vaporization (to the real gas); thus,  $\Delta H_v^\circ_{298.15} = 8.65$  kcal/mole.

### Entropy in the Ideal-Gas State

The entropy in the ideal-gas state at 1 atm pressure was calculated as shown in Table XI.

### ACKNOWLEDGMENTS

The authors thank Professor J. Rud Nielsen of the University of Oklahoma for furnishing the molecular spectral data and Dr. James R. Scherer of the Dow Chemical Company for performing the force-constant calculations. The help of Student Trainee R. C. Hartman in some of the experimental work is gratefully acknowledged.
