NOTICES

When Government drawings, specifications, or other data are used for any purpose other than in connection with a definitely related Government procurement operation, the United States Government thereby incurs no responsibility nor any obligation whatsoever; and the fact that the Government may have formulated furnished, or in any way supplied the said drawings, specifications, or other data, is not to be regarded by implication or otherwise as in any manner licensing the holder or any other person or corporation, or conveying any rights or permission to manufacture, use, or sell any patented invention that may in any way be related thereto.

Qualified requesters may obtain copies of this report from the Defense Documentation Center (DDC), (formerly ASTIA), Cameron Station, Bldg. 5, 5010 Duke Street, Alexandria, Virginia, 22314.

This report has been released to the Office of Technical Services, U.S. Department of Commerce, Washington 25, D. C., in stock quantities for sale to the general public.

Copies of this report should not be returned to the Research and Technology Division, Wright-Patterson Air Force Base, Ohio, unless return is required by security considerations, contractual obligations, or notice on a specific document.

FOREWORD

This report was prepared by the University of Brussels, Belgium, under USAF Contract No. AF61(052)-225. The contract was initiated under Project No. 7350, "Refractory Inorganic Non-Metallic Materials," Task No. 735001, "Non-graphitic." The work was administered under the direction of the Air Force Materials Laboratory, Research and Technology Division, Air Force Systems Command, Wright-Patterson Air Force Base, Ohio. Mr. F. W. Vahldiek was the project engineer.

ACKNOWLEDGMENTS.

The authors wish to thank Professor P. Goldfinger for his interest and encouragement. The samples were kindly given to us by Dr. Lawson, Royal Radar Institute, U. K. Mr. D. Detry has greatly assisted us in making some calculations.

ABSTRACT

In a mass spectrometric investigation of the vapor in equilibrium with solid SnSe and solid SnTe, a number of reaction enthalpies were measured which combined with known thermochemical data yield:

The dissociation energies are compared to the available spectroscopic data.

This technical documentary report has been reviewed and is approved.

THERMODYNAMIC STUDY OF TIN SELENIDE AND TIN TELLURIDE USING A MASS SPECTROMETER

INTRODUCTION

Mass spectrometric studies of the vaporization of Group IV (Me)-Group VI (X) compounds or systems include those of SiO_2 and $\text{SiO}_2 + \text{Si}^{(1)}$, $\text{GeO}_2^{(2)}$, $\text{PbSe}^{(3)}$, $\text{PbTe}^{(3)}$, $\text{SnS}^{(4)}$ and $\text{PbS}^{(4)}$. These investigations have shown the presence in the gas phase of MeX_2 molecules and $(\text{MeX})_n$ polymers in addition to the spectroscopically well known MeX molecules⁽⁵⁾.

The composition of the saturated vapor of other group IV-group VI compounds have now been studied mass spectroscopically in this laboratory⁽⁶⁾. This paper reports the details of the study of SnSe and SnTe .

The total pressure of both tin selenide and telluride have been measured by Nesterova, Pashinkin and Novoselova⁽⁷⁾ and Hirayama, Ichikawa and De Roo⁽⁸⁾ using classical techniques. In both cases the evaporation was carried out below the known melting points⁽⁹⁾. A standard heat of formation $\Delta H_{298, f}^\circ = -14.6 \pm 0.3$ kcal/mole has been obtained for SnTe(s) by McAteer and Seltz⁽¹⁰⁾.

The spectroscopic data⁽¹¹⁾ for SnSe(g) and SnTe(g) include the vibrational frequencies of the ground state and of several excited states. For one of the electronically excited states of SnSe , the E state, a precise value for the convergence limit is known. A graphical extrapolation gives 4.41 eV., while estimates of the onset of continuous absorption gives 4.54 eV. On the assumption that the E state dissociates into a pair of ground state atoms

$^3P + ^3P$, Vago and Barrow⁽¹¹⁾ had proposed a value for the dissociation energy of SnSe, $D'_0(\text{SnSe}) = 4.54 \text{ eV}$. For SnTe there are no well known convergence limits. For the E state there seems to be a region of continuous absorption which leads to a convergence limit of 4.07 eV. Vago and Barrow state⁽¹¹⁾ however ... "since we have not been able to put forward a satisfactory vibrational analysis for the E-X system..., this estimate... must be treated with considerable reserve". Nevertheless those authors proposed a value for the dissociation energy $D'_0(\text{SnTe}) = 4.1 \text{ eV}$ based both on this convergence limit and the linear Birge-Sponer extrapolation for the ground state.

The purpose of this study was to establish the nature of the atomic and molecular species composing the saturated vapor of SnSe and SnTe, to determine their stability and in particular that of the SnX molecules in order to compare the thermochemical value of the dissociation energies with the convergence limits of the excited states observed spectroscopically.

EXPERIMENTAL PROCEDURE

The main features of the mass spectrometer and Knudsen effusion cell as well as the experimental procedure have been described previously^(4, 12-15). For the present study a small quartz cell with an effusion orifice of $0.48 \cdot 10^{-2} \text{ cm}^2$ was used. After evaporation the cell showed no signs of reaction with the samples. The temperatures were measured with a Pt-PtRh (10%) thermocouple.

RESULTS

A. Composition of the Vapors.

The atomic and molecular ions, identified from their mass and isotopic distribution, characteristic of the SnSe and SnTe systems were

Relative ion intensities for nominal 33 eV electrons were respectively

at the average temperatures of the experiments:

$$\text{SnSe}(870^\circ\text{K}) : 4.6 \times 10^{-2}; 9.3 \times 10^{-3}; 3.5 \times 10^{-4}; 1; 4.4 \times 10^{-3}$$

$$\text{SnTe}(910^\circ\text{K}) : 6.3 \times 10^{-2}; 2.1 \times 10^{-2}; 4.1 \times 10^{-3}; 1; 4.0 \times 10^{-3}; 6.9 \times 10^{-3}$$

The interception of the molecular beam⁽¹⁵⁾ showed that these ions were formed from neutral species originating from the cell. Ionization efficiency curves were measured for several of these ions and the linear extrapolation method used to obtain approximate appearance potentials, the energy scale being calibrated with the known appearance potential of water⁽¹⁶⁾.

In the SnSe system, the relative intensities and appearance potentials showed that SnSe^+ and Sn_2Se_2^+ are parent ions. The appearance potential of SnSe^+ (9.7 ± 0.5 eV) can be compared to the ionization potentials of the isoelectronic diatomic molecules As_2 : 11 ± 0.3 eV,⁽¹⁷⁾ and Sb_2 : 8.4 ± 0.3 eV⁽¹⁸⁾. In the same manner the appearance potential of Sn_2Se_2^+ (9.8 ± 0.5 eV) can be compared to the ionization potentials of As_4 : 9.0 ± 0.5 ⁽¹⁷⁾ and Sb_4 : 7.7 ± 0.3 ⁽¹⁸⁾. The Se_2^+ ion can be attributed to direct ionization of Se_2 molecules present in the vapor and not to fragmentation of Sn_2Se_2 by analogy with the behavior under electron impact of Sn_2S_2 ⁽⁴⁾. The presence of Se_2 molecules in the gas phase is further sustained by thermodynamic calculations to be presented below. From the comparison of the measured appearance potentials of Sn^+ (12.8 ± 0.5 eV) and Se^+ (12.7 ± 0.5 eV) with the ionization potentials of tin (7.30 eV)⁽¹⁹⁾ and selenium (9.73 eV)⁽¹⁹⁾ it was concluded that these ions are fragment ions. The saturated vapor of SnSe is thus mainly composed of SnSe molecules and small quantities of Sn_2Se_2 and Se_2 molecules.

The ionization efficiency curve of the Te^+ ion in the SnTe system showed that two processes lead to the formation of this ion. The first appearance potential of Te^+ (9.5 ± 1.0 eV) agrees within experimental error with the ionization potential of tellurium⁽¹⁹⁾ (9.95 eV) and was

therefore attributed to direct ionization of atomic tellurium. The second (12.1 ± 1.0 eV) was due to the fragmentation of SnTe. The measured appearance potential of the SnTe^+ ion, 9.1 ± 0.5 eV shows it to be a parent ion. Although no appearance potential were measured, it can be concluded that Sn_2Te_2^+ and Te_2^+ are also parent ions. The SnTe_2^+ ions were considered as parent ions on the basis that the usual fragmentation⁽⁴⁾ of Me_2X_2 dimers of the group IV-group VI molecules by electron impact yields Me_2X^+ and Me_2^+ ions. The ion intensity of SnTe_2^+ was also larger than that of the Sn_2Te_2^+ ions. It should be noted that the SnTe_2 molecule is of the same general formula as the well known CO_2 , CS_2 and SiO_2 ⁽¹⁾ molecules and that other group IV-group VI molecules of this type have been identified⁽²⁰⁾: SiS_2 , SiSe_2 , SiTe_2 and GeTe_2 . The saturated vapor above SnTe is thus mainly composed of SnTe with small concentrations of Sn_2Te_2 , Te_2 , SnTe_2 molecules and Te atoms. Both with SnSe and SnTe, when the samples were completely vaporized, small quantities (approximately 1% of the initial sample) of metallic Sn were left in the evaporation cell.

B. Pressure Data.

In order to obtain absolute values of the pressures, vaporizations were carried out quantitatively. Weighted samples of either SnSe or SnTe (about 100 mgrs) were therefore vaporized completely and the ion intensity of the main component (SnSe or SnTe) of the vapor integrated with time. The contribution of the minor species to the weight-loss is negligible in both cases. Partial pressures of the minor species were derived from the relation⁽¹⁵⁾

$$\frac{P_1}{P_2} = \frac{I_1^+ \sigma_2 \gamma_2 T_1}{I_2^+ \sigma_1 \gamma_1 T_2} \quad (1)$$

where P is the partial pressure, I^+ the ion intensity, σ the ionization cross section, γ the secondary electron multiplier efficiency and T the

absolute temperature.

Table I gives the σ and γ values used. For atomic species the σ values used were those calculated by Otvos and Stevenson⁽²¹⁾. For symmetric diatomic molecules the ionization cross section was taken as 1.6 times the value for the corresponding atom as shown to hold for Se_2 and Te_2 ^(22, 23) and other dimers^(24, 25). For other molecules the sum of 0.8 times the ionization cross section of the constituent atoms was used. The secondary multiplier efficiency γ was estimated from the calibration curve of a multiplier analogous to the one used in this work⁽²⁶⁾ and molecular effects on the first dynode of the electron multiplier were taken into account as suggested by Stanton, Chupka and Inghram⁽²⁷⁾.

The vapor pressure of SnSe and SnTe are summarized in Fig. 1. and 2. and compared to vapor pressure determinations by Nesterova, Pashinkin and Novoselova⁽⁷⁾ and Hirayama, Ichikawa and DeRoo⁽⁸⁾

TABLE I. Relative ionization cross section and multiplier efficiencies.

Molecule or atom	Cross section	Multiplier efficiency
Se	29.6	0.48
SnSe	35.5	0.41
Sn ₂ Se ₂	56.8	0.32
Te	25.6	0.51
Te ₂	41.0	0.37
SnTe	41.1	0.38
SnTe ₂	53.4	0.25
Sn ₂ Te ₂	65.8	0.27

C. Enthalpy of Sublimation and Formation.

1. SnSe

A second law treatment of the various experiments shown in fig. 1 led to an average value for the heat of sublimation:

$\Delta H_{900, \text{subl}}^{\circ}(\text{SnSe}) = 48.6 \pm 5.0$ kcal/mole, compared with the literature values 42.0⁽⁷⁾ and 48.0⁽⁸⁾ kcal/mole at similar temperatures. An

estimate of the difference in heat content $H_{900}^{\circ} - H_{298}^{\circ}$ was made for solid SnSe by using approximation methods described by Kubaschewski and Evans⁽²⁸⁾, while the corresponding quantity for gaseous SnSe is known⁽²⁹⁾ from spectroscopic data⁽⁵⁾. Whence

$$\Delta H_{298, \text{subl.}}^{\circ} (\text{SnSe}) = 50.3 \pm 6.0 \text{ kcal/mole}$$

Since absolute values of the pressure of SnSe were determined, a third law treatment could be applied provided an estimate of the free energy function - $\left(\frac{G_T^{\circ} - H_{298}^{\circ}}{T} \right)$ of solid SnSe be made. By comparison with other IV-VI compounds a value of the entropy $S_{298}^{\circ} (\text{SnSe(s)}) = 22.5 \text{ e. u.}$ was derived. This leads to the estimated free energy function values given in Table II which gives also literature values^(29, 31) for the other gaseous and solid species encountered in this study. In Table III, the third law values of $\Delta H_{298, \text{subl.}}^{\circ} (\text{SnSe})$ are given; the mean value $51.0 \pm 2.5 \text{ kcal/mole}$ is in agreement with the second law value.

A similar third law treatment of the pressure data of Nexterova, Pashinkin and Novoselova⁽⁷⁾ leads to a value of $51.5 \pm 2.5 \text{ kcal/mole}$, and of the pressure data of Hirayama, Ichikawa and De Roo⁽⁸⁾ to $51.0 \pm 2.5 \text{ kcal/mole}$.

From the Se_2 partial pressures, the enthalpy change for the reaction

was calculated. The values obtained are given in Table IV.

TABLE II. Free energy functions $-\left(\frac{G_T^\circ - H_{298}^\circ}{T}\right)$ in cal/degree/mole

	800°K	900°K	1000°K	ref.
Sn(s, l)	16.1	16.8	17.6	29

2. SnTe.

The enthalpy of sublimation $\Delta H_{900, \text{subl.}}^\circ (\text{SnTe})$ obtained by a second law treatment is: $\Delta H_{900, \text{subl.}}^\circ (\text{SnTe}) = 46.4 \pm 5.0$ kcal/mole, compared to the literature values $44.9^{(7)}$ and $51.4^{(8)}$ kcal/mole at similar temperatures. Estimating as for SnSe the heat content, $H_{900}^\circ - H_{298}^\circ$ for solid SnTe, a value $\Delta H_{298, \text{subl.}}^\circ (\text{SnTe}) = 48.1 \pm 6.0$ kcal/mole was obtained. The value obtained by a third law treatment (Table V) is $\Delta H_{298, \text{subl.}}^\circ (\text{SnTe}) = 52.1 \pm 2.0$ kcal/mole. Preference is given to the third law value on account of the fact that the entropy of solid SnTe is known⁽³⁰⁾ $S_{298}^\circ = 24.2 \pm 0.1$ e. u. and that the estimate of the free energy function of SnTe(s) is therefore reduced to that of the heat capacity between 900° and 298°K. A similar third law treatment of the pressure data of Nesterova, Pashinkin and Novoselova⁽⁷⁾ and Hiriyama, Ichikawa and De Roo⁽⁸⁾ leads respectively to a values of 52.6 ± 2.0 and 52.8 ± 2.0 kcal/mole.

The enthalpy change for the reaction

were also calculated and is given in Table VI. Using the enthalpy of sublimation $\Delta H_{298, \text{subl.}}^\circ (\text{Te}_2) = 39.6 \pm 2.0 \text{ kcal/mole}^{(33)}$, the heat of formation $\Delta H_{298, f}^\circ (\text{SnTe})$ was computed to be $\Delta H_{298, f}^\circ (\text{SnTe}) = -14.5 \pm 2.0 \text{ kcal/mole}$, in agreement with the value obtained by McAteer and Seltz⁽¹⁰⁾, $\Delta H_{298, f}^\circ (\text{SnTe}) = -14.6 \pm 0.3 \text{ kcal/mole}$. This agreement is a confirmation of the free energy function used for SnTe(s).

D. Dissociation Energy of Gaseous SnSe and SnTe.

Dissociation energies D_{298}° of both SnSe and SnTe derived from the thermochemical cycles given in Table VII, using the heats of formation and sublimation obtained in this work and the previously mentioned values for the heats of sublimation of Se_2 and Te_2 and $D_{298}^\circ(\text{Te}_2) = 52.5 \pm 2.0 \text{ kcal/mole}^{(3, 22)}$. The dissociation energy of Se_2 , $D_{298}^\circ(\text{Se}_2) = 75.4 \pm 2.0 \text{ kcal/mole}$ was obtained in a recent mass spectrometric study⁽³²⁾ by a third law procedure.

D_0° value are:

$$D_0^\circ(\text{SnSe}) = 95.0 \pm 3.0 \text{ kcal/mole or } 4.12 \pm 0.13 \text{ eV.}$$

$$D_0^\circ(\text{SnTe}) = 79.8 \pm 3.0 \text{ kcal/mole or } 3.46 \pm 0.13 \text{ eV.}$$

E. Stability of gaseous dimers Sn_2Se_2 and Sn_2Te_2 and of gaseous SnTe_2

In order to obtain values for the enthalpy of dimerization of SnSe and SnTe, values of the free energy function of these dimers were taken from an interpolation vs molecular weight of the free energy functions of the isoelectronic molecules As_4 and Sb_4 ⁽³¹⁾. This implies that the moments of inertia are roughly the same and that the decrease in symmetry number for Me_2X_2 compensates for an increase in the vibration frequencies. The values used are given in Table II.

The enthalpy of dimerization of SnSe was calculated from various experiments as shown in Table VIII. The mean value 46.5 ± 5.0 kcal/mole combined with $D_{298}^\circ(\text{SnSe})$ leads to an atomization energy of Sn_2Se_2 :

$$\Delta H_{298, \text{at}}^\circ(\text{Sn}_2\text{Se}_2) = 237.9 \pm 10 \text{ kcal/mole}$$

The dimerization enthalpy of Sn_2Te_2 was obtained from the reaction

whence $\Delta H_{298, \text{at}}^{\circ}(\text{Sn}_2\text{Te}_2) = 217.8 \pm 11 \text{ kcal/mole}$

$$\Delta H_{298, \text{dim}}^{\circ}(\text{SnTe}) = 46.8 \pm 6.0 \text{ kcal/mole}$$

The free energy function of SnTe_2 was calculated assuming a linear Te-Sn-Te structure by analogy with CS_2 and CO_2 ⁽³³⁾. The vibrational frequencies of the three normal vibrations, one of which is doubly degenerate (ω_2) were calculated to be $\omega_1 = 180 \text{ cm}^{-1}$, $\omega_2 = 89 \text{ cm}^{-1}$ and $\omega_3 = 335 \text{ cm}^{-1}$ assuming the stretching force constant k_1 of the Sn-Te to be identical to the one on the diatomic SnTe molecule; the bending force constant k_δ was estimated on the basis that

$$\frac{k_\delta}{l^2 k_1} = (3.5 \pm 0.3) 10^{-2} \text{ cm}^{-2} \text{ which holds for } \text{CS}_2 \text{ and } \text{CO}_2^{(33)}$$

l is the internuclear distance). The ground state was also assumed to be nondegenerate as for CO_2 and CS_2 . The free energy function calculated in this manner at 1000°K is given in Table II. Table IX gives the enthalpy change for the reaction

leading to an atomization enthalpy

$$\Delta H_{298, \text{at}}^{\circ}(\text{SnTe}_2) = 124.1 \pm 4.0 \text{ kcal/mole.}$$

DISCUSSION

SnSe and SnTe molecules.

The thermochemical values of the dissociation energy of SnSe and SnTe can be compared to the spectroscopically determined convergence limit of the excited E state of the molecules. It has been postulated^(34, 35) that the E state of all the group IV-group VI MeX molecules are analogous and correlate with the same atomic products. It has already been concluded⁽³⁵⁾, on the basis of the agreement between the convergence limits for this state and the Birge-Sponer value for the dissociation energy of the ground state, that this state correlates with $\text{Me}(^3\text{P}) + \text{X}(^3\text{P})$. Recent rotational analysis showed for $\text{PbO}^{(36)}$, $\text{PbS}^{(37)}$ and $\text{SnO}^{(38)}$ that for E state of these molecules the most probable correlation is $\text{Me}(^3\text{P}_1) + \text{O}(^3\text{P}_1)$. Likewise the comparison of thermochemical and spectroscopic data showed⁽⁴⁾ that for SnS and PbS the most likely correlations are $\text{Me}(^3\text{P}_1) + \text{S}(^3\text{P}_{1,0})$, the accuracy of the thermochemical data making it impossible to distinguish between $\text{S}(^3\text{P}_1)$ and $\text{S}(^3\text{P}_0)$ sublevels of sulfur, the separation of which is only of 0.02 eV. The rotational analyses for $\text{PbO}^{(36)}$ and $\text{PbS}^{(37)}$ favor however the $\text{Me}(^3\text{P}_1) + \text{O}(^3\text{P}_1)$ correlation. For SnSe the subtraction of several combinations of the excitation energies of the ^3P sublevels of Sn and Se from the well established convergence limit of the E state at 4.54 ± 0.06 eV would yield a value of the dissociation energy which is in agreement within the error limits with the thermochemical value $D^\circ(\text{SnSe}) = 4.12 \pm 0.13$ eV. These combinations include the $\text{Sn}(^3\text{P}_1) + \text{Se}(^3\text{P}_1)$ combination which leads to a value of $D^\circ(\text{SnSe}) = 4.08$ eV. This agreement may be used to suggest a selected dissociation energy $D^\circ(\text{SnSe}) = 4.10 \pm 0.10$ eV. Using for SnTe the "assumed" convergence limit of the E state at 4.07 eV, the $\text{Sn}(^3\text{P}_1) + \text{Te}(^3\text{P}_1)$ correlation yields a value of $D^\circ(\text{SnTe}) = 3.28$ eV compared to the thermochemical value $D^\circ(\text{SnTe}) = 3.46 \pm 0.13$ eV.

SnTe₂ molecule.

The SnTe₂ molecule is analogous to the well known CO₂ molecule of which two analogous were already known: CS₂ and SiO₂⁽¹⁾. Until now

TABLE X. Stability of group IV-group VI molecules (kcal/mole)

	$\Delta H_{\text{at}}^{\circ}(\text{MeX}_2)$	ref	$D_{\text{e}}^{\circ}(\text{MeX})$	ref	$\Delta H_{\text{at}}^{\circ}(\text{MeX}_2)/D_{\text{e}}^{\circ}(\text{MeX})$
CO/CO ₂	381.5	28	256.2	40	1.49
CS ₂ /CS	272.0	39	173.6	39	1.57
SiO ₂ /SiO	302.8	1	191.9	28 41	1.58
SiS ₂ /SiS	230.4	20	147.0	42	1.57
GeTe ₂ /GeTe	137.1	20	92.7	20	1.48
SnTe ₂ /SnTe	123.2	-	79.8	-	1.55

other molecules of this type, observed in mass spectrometric investigations⁽²⁰⁾ similar to the one reported here are: SiS₂, SiSe₂, SiTe₂ and GeTe₂. The stabilities of these molecules were estimated by assuming again that they are analogous in structure as well as in nature of the electronic state to CO₂. The values of the enthalpies of atomization $\Delta H_{\text{at}}^{\circ}(\text{MeS}_2)$ are given in Table X as well as the dissociation energy of the corresponding MeX molecules. It is interesting to observe that for these molecules the ratio $\Delta H_{\text{at}}^{\circ}(\text{MeX}_2)/D_{\text{e}}^{\circ}(\text{MeX})$ is reasonably constant for all the molecules detected to this day. The mean value 1.54 permits to predict with a good approximation the stability of the not yet observed group IV-group VI MeX₂ molecules.

Sn₂Se₂ and Sn₂Te₂ molecules

The dimerization energies of SnSe and SnTe, 46.5 and 46.8 kcal/mole

respectively are very close to those of the analogous molecules $\text{SnS}^{(4)}$ 48.7 and $\text{PbS}^{(4)}$, 44.8 kcal/mole. This approximate constancy of the dimerization energy, as well as the fact that the group IV-group VI dimers, and the homonuclear group V tetratomic molecules are isoelectronic had already been used⁽⁴⁾ to propose a close (tetragonal or tetrahedral) rather than a linear structure for the dimeric group IV-group VI molecules.

It is further to be noted that the dimerization energies are for these, as for several other molecules of this type, quite close to the heat of sublimation of the monomer from the lattice, implying that similar types of interaction are responsible for the stability of the polymeric molecules and of the lattice.
