WEIGHT DISTRIBUTION FORMULA FOR SOME CLASS
OF CYCLIC CODES

Tadao Kasami

Abstract

Let $h_1(X)$ and $h_2(X)$ be different irreducible polynomials such that $h_1(\alpha^{-2^h-1}) = 0$ for some $h(0 < h < m)$ and $h_2(\alpha^{-1}) = 0$, α being a primitive element of $GF(2^m)$. This paper presents the weight distribution formula of the code of length 2^m-1 generated by $(X^{2^m-1} - 1)/(h_1(X)h_2(X))$ for any m and h . Some applications to the cross-correlation problem between two different maximum length sequences are presented.

1. Introduction

W. W. Peterson [1] calculated a number of weight distributions for BCH codes of lengths 63 to 1023 and their dual codes by digital computation. He observed that some BCH codes with large t for a given m ($5 \leq m \leq 10$) have a very simple structure of weight distribution. The result presented here is a theoretical development of his observation.

Let C be a cyclic code of length $2^m - 1$. The extended code of C is the code with an overall parity check added to C as the first digit. The first symbol in a code vector is numbered 0, and for $i > 1$ the i -th digit is numbered α^{i-2} , α being a primitive element of $GF(2^m)$. Now for $a (\neq 0)$ and $b \in GF(2^m)$ and for a code vector v of the extended code, permute the symbol in position X to position $aX + b$. Then, the resulting vector is denoted by $\pi_{ab}v$. W. W. Peterson [1] proved that the extended codes of BCH codes are invariant under doubly transitive group of permutations $\pi = \{\pi_{ab} | a (\neq 0), b \in GF(2^m)\}$. This paper presents the weight distribution formula for a class of cyclic codes of length $2^m - 1$ whose extended codes are invariant under π .

Let $g_1(X)$ and $g_2(X)$ be different irreducible polynomials such that

$$(1) \quad g_1(\alpha^{2^h+1}) = 0 \quad \text{for some } h \ (0 < h < m),$$

$$(2) \quad g_2(\alpha) = 0$$

The degree of $g_1(X)$ is a factor m' of m and the degree of $g_2(X)$ is m . Let

$$h_1(X) = X^{m'} g_1(X^{-1}), \quad h_2(X) = X^m g_2(X^{-1}).$$

Let C_0 , C and C' denote binary cyclic codes with length $2^m - 1$ generated by $g_1(X)g_2(X)$, $(X^{2^m-1}-1)/(h_1(X)h_2(X))$ and $(X^{2^m-1}-1)/[(X-1)h_1(X)h_2(X)]$ respectively. Then C is the dual code of C_0 and a subcode of C' . If $h = 1$, then C_0 is a double error correcting BCH code, and if m is odd and $h = (m-1)/2$, then C is

a BCH code with the second largest t for given m .

In what follows, the weight distribution formula of code C for any m and h will be derived. This problem is closely related to the cross-correlation problem between two different maximum length sequences.* Some applications to the problem will be presented in section 6.

2. Preliminary Lemmas

Lemma 1: The extended code of C' or C_0 is invariant under π .

This lemma follows from the definition of C' or C_0 and a general theorem [2]. Let

$$m = m' m'' . \quad (1)$$

Since $\alpha^{2^{m-h}+1}$ is a root of $g_1(X)$, it can be assumed that

$$2h \leq m. \quad (2)$$

Since $(2^{m'}-1)(2^h+1)$ is divisible by $(2^m-1) = (2^{m'}-1)(2^{m'(m''-1)} + 2^{m'(m''-2)} + \dots + 1)$,

$$h \geq m'(m''-1) .$$

From (1) and (2),

$$m' m'' \geq 2h \geq 2m'(m''-1) . \quad (3)$$

Hence,

$$m'' = 1 \text{ or } 2.$$

If $m'' = 2$, then it follows from (3) that

$$m' = h.$$

That is, there are only two cases:

$$m' = m$$

and

$$m' = m/2 = h.$$

* Dr. B. Elspas pointed out this relation.

The following well-known lemmas will be used later.

Lemma 2: Let $u(\ell)$ denote the smallest positive integer u such that $2^u \equiv 1 \pmod{\ell}$. Then, $2^{u'} \equiv 1 \pmod{\ell}$ if and only if $u' \equiv 0 \pmod{u(\ell)}$.

Let (ℓ, ℓ') denote the greatest common divisor of ℓ and ℓ' .

Corollary 3: Let $u = (u_1, u_2)$. Then,

$$2^u - 1 = (2^{u_1} - 1, 2^{u_2} - 1).$$

Lemma 4: $2^u + 1$ (or $2^u - 1$) is divisible by $2^{u'} + 1$, if and only if u is divisible by u' and u/u' is odd (or even).

Let $c' = (m, h)$, $c = (m, 2h)$ and $v = (2^m - 1, 2^h + 1)$. By Corollary 3,

$$2^{c'} - 1 = (2^m - 1, 2^h - 1), \quad (4)$$

$$2^c - 1 = (2^m - 1, 2^{2h} - 1). \quad (5)$$

Since $(2^h + 1, 2^h - 1) = 1$,

$$(2^m - 1, 2^{2h} - 1) = (2^m - 1, 2^h + 1)(2^m - 1, 2^h - 1).$$

Thus,

$$(2^c - 1)/v = 2^{c'} - 1.$$

By definition, $c = c'$ or $2c'$. Therefore, we have:

Lemma 5: If $c = c'$, then $v = 1$. Otherwise,

$$v = 2^{c'} + 1 = 2^{c/2} + 1. \quad (6)$$

The next lemma is due to Pless [3].

Lemma 6: Let a_j and b_j denote the number of code vectors of weight j in a code A and the number of code vectors of weight j in the dual code of A respectively. If $b_1 = b_2 = 0$, then the following power moment identities hold:

$$\sum a_j = 2^k$$

$$\sum j a_j = 2^{k-1} n$$

$$\sum j^2 a_j = 2^{k-2} n(n+1)$$

$$\sum j^3 a_j = 2^{k-3} (n^3 + 3n^2) - 3! 2^{k-3} b_3$$

$$\sum j^4 a_j = 2^{k-4} (n^4 + 6n^3 + 3n^2 - 2n) - 4! 2^{k-4} n b_3 + 4! 2^{k-4} b_4,$$

where k denotes the number of information digits.

Let C_1 and C_2 denote binary cyclic codes with length $2^m - 1$ generated by $(X^{2^m - 1} - 1)/h_1(X)$ and $(X^{2^m - 1} - 1)/h_2(X)$ respectively. Codes C_1 and C_2 are subcodes of C and C' . If the degree of $g_1(X)$ is m , then the roots of $h_1(X) = X^m g_1(X^{-1})$ are:

$$\alpha^{-(2^h + 1)} = \alpha^{2^m - 2^h - 2}, \alpha^{-2(2^h + 1)} = \alpha^{2^m - 2^{h+1} - 2 - 1}, \dots,$$

$$\alpha^{-2^{m-h-1}(2^h + 1)} = \alpha^{2^{m-1} - 2^{m-h-1} - 1}, \alpha^{-2^{(m-h)}(2^h + 1)} = \alpha^{2^m - 2^{m-h} - 2},$$

$$\dots, \alpha^{-2^{m-1}(2^h + 1)} = \alpha^{2^{m-1} - 2^{h-1} - 1}.$$

There is no i ($0 \leq i < 2^{m-1}$) with $h_1(\alpha^i) = 0$ except for

$$i_1 = 2^{m-1} - 2^{m-h-1} - 1$$

and

$$i_1' = 2^{m-1} - 2^{h-1} - 1.$$

By (2), $i_1 < i_1'$.

If $m' = m/2$, then the roots of $h_1(X)$ are:

$$\alpha^{-(2^{m'} + 1)} = \alpha^{2^m - 2^{m'} - 2}, \alpha^{-2(2^{m'} + 1)} = \alpha^{2^m - 2^{m'+1} - 2 - 1}, \dots$$

$$\alpha^{-2^{m'-1}(2^{m'} + 1)} = \alpha^{2^{m-1} - 2^{m'-1} - 1}.$$

there is no i ($0 \leq i < 2^{m-1}$) with $h_1(\alpha^i) = 0$ except for

$$i_1 = 2^{m-1} - 2^{m'-1} - 1.$$

The roots of $h_2(X)$ are $\alpha^{-1} = \alpha^{2^m-2}, \alpha^{-2} = \alpha^{2^m-3}, \dots, \alpha^{-2^{m-1}} = \alpha^{2^{m-1}-1}$.

As it is done above, here we let

$$i_2 = 2^{m-1} - 1.$$

Let $X_1, X_2, \dots, X_w$ be the location numbers of code vector* $v(x)$ of C' .

Then,

$$v(\alpha^i) = \sum_{f=1}^w X_f^i, \quad 0 \leq i < 2^m - 1$$

For any $B_0 \in GF(2)$, any $B_1 \in GF(2^{m'})$ and any $B_2 \in GF(2^m)$, there exists a unique code vector $v(x)$ of C' such that $v(1) = B_0$, $v(\alpha^{i_1}) = B_1$ and $v(\alpha^{i_2}) = B_2$ (Mattson, Solomon [5]). Let $v(B_0, B_1, B_2; x)$ denote the code vector specified by B_0, B_1 and B_2 . By definition,

$$x^{i_1} v(B_0, B_1, B_2; x) = v(B_0, \alpha^{i_1} B_1, \alpha^{i_2} B_2; x)$$

If and only if $B_0 = 0$, $v(B_0, B_1, B_2; x) \in C$. If and only if $B_0 = B_1 = 0$ (or $B_0 = B_2 = 0$), then $v(B_0, B_1, B_2; x) \in C_2$ (or C_1). The cyclic permutations on code word symbols induce a permutation group on the code vectors of C' , which divides $C-C_2$ into disjoint sets of transitivity. Since $v = (i_1, 2^m - 1)$, each set consists of $(2^m - 1)/v$ code vectors. In case of $m' = m$, let $v(0, \alpha^i, B_2; x)$ ($0 \leq i < v$, $B_2 \in GF(2^m)$) represent each set. In case of $m' = m/2$, let $v(0, 1, B_2; x)$ represent each set.

*A polynomial representation will be used for a code vector [4].

Now, consider the extended code C_{ex} of code C' . Let $\bar{v}(\beta_0, \beta_1, \beta_2)$ denote the vector with an overall parity check added to $v(\beta_0, \beta_1, \beta_2; x)$ as the first digit. By definition $C_{ex} = \{\bar{v}(\beta_0, \beta_1, \beta_2) | v(\beta_0, \beta_1, \beta_2; x) \in C'\}$. Let $X_1, X_2, \dots, X_w$ be the location numbers of $\bar{v}(\beta_0, \beta_1, \beta_2)$ and let

$$S_i = \sum_{f=1}^w X_f^i, \quad 0 \leq i < 2^m - 1 \quad (7)$$

then, by definition

$$S_{i_1} = \beta_1, \quad (8)$$

$$S_{i_2} = \beta_2, \quad (9)$$

$$S_i = 0 \quad (i \neq i_1 2^l, i_2 2^l \pmod{2^m - 1}, \quad 0 \leq l < m)$$

Therefore,

$$S_i = 0 \quad (i \neq i_1, i_1', \quad 1 \leq i < 2^{m-1} - 1) \quad (10)$$

By Lemma 1, $\tau_{1b} \bar{v}(\beta_0, \beta_1, \beta_2) \in C_{ex}$ for any $b \in GF(2^m)$. Let

$$\tau_{1b} \bar{v}(\beta_0, \beta_1, \beta_2) = \bar{v}(\beta'_0, \beta'_1, \beta'_2). \quad (11)$$

The weights of $\bar{v}(\beta_0, \beta_1, \beta_2)$ and $\bar{v}(\beta'_0, \beta'_1, \beta'_2)$ are the same. By the definition of τ_{1b} ,

$$\begin{aligned} \beta'_1 &= \sum_{f=1}^w (X_f + b)^{i_1} \\ \beta'_2 &= \sum_{f=1}^w (X_f + b)^{i_2} \end{aligned}$$

Hence

$$\beta'_1 = \sum_{f=1}^w \sum_{i=0}^{i_1} \binom{i_1}{i} X_f^i b^{i_1-i} = \sum_{i=0}^{i_1} \binom{i_1}{i} S_i b^{i_1-i}.$$

From (8) and (10),

$$\beta'_1 = \beta_i \quad (12)$$

Note that $(X_f + b)^{2^{m-1}-1} = (X_f^{2^{m-1}} + b^{2^{m-1}}) / (X_f + b) = X_f^{2^{m-1}-1} + X_f^{2^{m-1}-2}b + \dots + b^{2^{m-1}-1}$. Then,

$$\beta'_2 = \sum_{f=1}^w \sum_{i=0}^{2^{m-1}-1} X_f^i b^{2^{m-1}-1-i} = \sum_{i=0}^{2^{m-1}-1} S_i b^{2^{m-1}-1-i} \quad (13)$$

Consider the case of $m' = m$. Since $i'_1 \equiv 2^h i_1 \pmod{2^{m-1}}$, $S_{i'_1} = S_{i_1}^{2^h}$. From (8), (9), (10) and (13),

$$\begin{aligned} \beta'_2 &= \beta_1 b^{2^{m-1}-1-i_1} + \beta_1^{2^h} b^{2^{m-1}-1-i'_1} + \beta_2 = \beta_1 b^{2^{m-h}-1} \\ &\quad + \beta_1^{2^h} b^{2^{h-1}} + \beta_2. \end{aligned} \quad (14)$$

For the case of $m' = m/2$, it follows from (8), (9), (10) and (13) that

$$\beta'_2 = \beta_1 b^{2^{h-1}} + \beta_2. \quad (15)$$

Hereafter we shall consider the case of $m' = m$ except for section 5.

For each i ($0 \leq i < v$), $V_i = \{\alpha^i b^{2^{m-h}-1} + \alpha^{i2^h} b^{2^{h-1}} \mid b \in \text{GF}(2^m)\}$ forms a subspace of $\text{GF}(2^m)$. Let

$$\begin{aligned} F_i(X) &= \alpha^i X^{2^{m-h}-1} + \alpha^{i2^h} X^{2^{h-1}} \\ &= \alpha^i X^{2^{h-1}} (X^{2^{m-2h}-1} + \alpha^{i(2^h-1)}), \end{aligned}$$

If $i = 0$, the order of a nonzero root in $\text{GF}(2^m)$ of $F_0(X)$ is a factor of $2^{m-2h}-1$. Since $c = (m, 2h) = (m, m-2h)$, $2^c - 1 = (2^{m-1}-1, 2^{m-2h}-1)$. This implies

that the roots in $GF(2^m)$ of $F_0(X)$ are in subfield $GF(2^c)$. Conversely, any element in this subfield is a root of $F_0(X)$. Hence, the dimension of V_0 is $m-c$. Let $v_{00} (=V_0), v_{01}, v_{02}, \dots, v_{0, 2^c-1}$ be the cosets of $GF(2^m)$ with respect to V_0 . Each coset has 2^{m-c} elements.

For $i \neq 0$, assume that α^j is a root of $F_i(X)$. Then,

$$2^{h \cdot i} (2^{m-2h}-1)j = i(2^h-1) \pmod{2^m-1}$$

$$(1-2^{2h})j \equiv i2^{h+1}(2^h-1) \pmod{2^m-1}$$

$$-(2^h+1)j \equiv i2^{h+1} \pmod{2^m-1}$$

Since v divides both 2^h+1 and 2^m-1 , v must divide i . However, $0 < i < v$.

Therefore, there is no root in $GF(2^m)$ of $F_i(X)$ except for zero. Consequently,

$$V_i = GF(2^m).$$

Let $B_{0j} = \{(\alpha^{2^{\ell i_1}}, \alpha^{2^{\ell i_2}} \beta) \mid 0 \leq \ell < 2^{m-1}, \beta \in V_{0j}\} \quad (0 \leq j \leq 2^c-1)$ and

$B_i = \{(\alpha^{i+2^{\ell i_1}}, \beta) \mid 0 \leq \ell < 2^{m-1}, \beta \in GF(2^m)\} \quad (0 < i < v)$. Then,

$$|B_{0j}| = (2^m-1)2^{m-c}/v \quad (0 \leq j < 2^c), \quad (16)$$

$$|B_i| = (2^m-1)2^m/v \quad (0 < i < v)^*. \quad (17)$$

It follows from the definition of B_{0j} or B_i that for any (β_1, β_2) and (β'_1, β'_2) in the same B_{0j} or B_i and for any $\beta_0 \in GF(2)$, there exists permutation π_{ab} such that $\pi_{ab} \bar{v}(\beta_0, \beta_1, \beta_2) = \bar{v}(\beta'_0, \beta'_1, \beta'_2)$ and $\beta'_0 \in GF(2)$. Therefore, $\bar{v}(\beta_0, \beta_1, \beta_2)$ and $\bar{v}(\beta'_0, \beta'_1, \beta'_2)$ have the same weight w . If β_0 (or β'_0) is zero,

* $|B|$ means the number of elements of B .

then $v(0, \beta_1, \beta_2; x)$ (or $v(0, \beta'_1, \beta'_2; x)$) has weight w . If β_0 (or β'_0) is one, then $v(1, \beta_1, \beta_2; x)$ (or $v(1, \beta'_1, \beta'_2; x)$) has weight $w-1$ by definition. Since C' contains all one vector $e = (1, 1, \dots, 1)$ and $e(\alpha^i) = \sum_{f=0}^{2^m-2} \alpha^{if} = [(\alpha^i)^{2^m-1} - 1] / (\alpha^i - 1) = 0$ ($0 < i < 2^m - 1$),

$$v(1, \beta_1, \beta_2; x) = v(0, \beta_1, \beta_2; x) + e(x).$$

Hence, if β_0 (or β'_0) is one, then $v(0, \beta_1, \beta_2; x)$ (or $v(0, \beta'_1, \beta'_2; x)$) has weight $2^m - w$. Therefore, we have Lemma 8.

Lemma 8: For each j (or i) ($0 \leq j < 2^c$, $0 < i < v$), there is w_{0j} (or w_i) such that for any $(\beta_1, \beta_2) \in B_{0j}$ (or B_i) the weight of $v(0, \beta_1, \beta_2; x)$ is either w_{0j} (or w_i) or $2^m - w_{0j}$ (or $2^m - w_i$).

3. Case I: $(m, h) = (m, 2h)$

Hereafter a_w will denote the number of code vectors of weight w in C and b_w will denote the number of code vectors of weight w in C_0 .

Lemma 9: For any w ,

$$wa_w = (2^m - w) a_{2^m - w},$$

$$wb_w = (2^m - w) b_{2^m - w}.$$

This lemma follows from a theorem due to Peterson [1] and Lemma 1. Consequently, if the values of w_{0j} 's ($0 \leq j < 2^c$) and w_i 's ($0 < i < v$) are known, the weight distribution of $C - C_2$ is completely determined. Furthermore, any nonzero vector of C_2 has weight 2^{m-1} , because C_2 is a maximum length sequence code.

Lemma 10: $b_1 = b_2 = 0$, $b_3 = (2^{c'-1} - 1)(2^m - 1)/3$.

Proof: Since C_0 is a subcode of Hamming code,

$$b_1 = b_2 = 0.$$

Assume that α^{j_1} , α^{j_2} and α^{j_3} are the location numbers of a code vector of weight 3 in C_0 . Then,

$$\alpha^{j_1} + \alpha^{j_2} = \alpha^{j_3} \quad (18)$$

$$\alpha^{j_1(2^h+1)} + \alpha^{j_2(2^h+1)} = \alpha^{j_3(2^h+1)} \quad (19)$$

From (18),

$$\begin{aligned} \alpha^{j_3(2^h+1)} &= (\alpha^{j_1} + \alpha^{j_2})^{2^h+1} = (\alpha^{j_1 2^h} + \alpha^{j_2 2^h})(\alpha^{j_1} + \alpha^{j_2}) \\ &= \alpha^{j_1(2^h+1)} + \alpha^{j_1 2^h} \alpha^{j_2} + \alpha^{j_1} \alpha^{j_2 2^h} + \alpha^{j_2(2^h+1)} \end{aligned}$$

By combining with (19),

$$\begin{aligned} \alpha^{j_1 2^h} \alpha^{j_2} + \alpha^{j_1} \alpha^{j_2 2^h} &= 0, \\ \alpha^{(j_1-j_2)(2^h-1)} &= 1. \end{aligned} \quad (20)$$

Thus,

$$(j_1 - j_2)(2^h - 1) \equiv 0 \pmod{2^m - 1}.$$

If $c' = (m, h) = 1$, then $(2^h - 1, 2^m - 1) = 1$. Therefore

$$j_1 = j_2.$$

This is a contradiction, which leads to the conclusion that $b_3 = 0$. If

$c' \neq 1$, then $(2^m - 1, 2^h - 1) = 2^c - 1$. Let

$$\mu = (2^m - 1) / (2^c - 1). \quad (21)$$

Then,

$$j_1 \equiv j_2 \pmod{\mu}.$$

Let $j_1 = l_1\mu + i$ and $j_2 = l_2\mu + i$ ($0 \leq i < \mu$). Since $\alpha^{l_1\mu} + \alpha^{l_2\mu} = \alpha^{l_3\mu}$ for some l_3 , it follows from (18) that $j_3 = l_3\mu + i$. Conversely, for any i ($0 \leq i < \mu$) and for l_1, l_2 , and l_3 such that

$$\alpha^{l_1\mu} + \alpha^{l_2\mu} = \alpha^{l_3\mu} \quad (22)$$

$$0 \leq l_1, l_2, l_3 < 2^{c'} - 1, \quad (23)$$

$\alpha^{l_1\mu+i}$, $\alpha^{l_2\mu+i}$, and $\alpha^{l_3\mu+i}$ satisfy (18) and (19). The number of unordered triplets (l_1, l_2, l_3) 's satisfying (22) and (23) is equal to $\binom{2^{c'}-1}{2}/3$.

Consequently,

$$b_3 = \mu \binom{2^{c'}-1}{2}/3 = (2^m-1)(2^{c'}-1)/3. \quad \text{Q.E.D.}$$

Lemma 11: Let I_2 and I_4 denote $\sum_{j \neq 0} (j-2^{m-1})^2 a_j$ and $\sum_{j \neq 0} (j-2^{m-1})^4 a_j$ respectively. Then,

$$I_2 = 2^{2m-2}(2^m-1),$$

$$I_4 = 2^{3m+c'-4}(2^m-1).$$

Proof: Note that $k = 2m$. By using the power moment identities of Lemma 6,

$$\begin{aligned} I_2 &= \sum j^2 a_j - 2^m \sum j a_j + 2^{2m-2} \sum_{j \neq 0} a_j \\ &= 2^{2m-2} n(n+1) - 2^{3m-1} n + 2^{2m-2} (2^{2m}-1) \\ &= (2^m-1) (2^{3m-2} - 2^{3m-1} + 2^{3m-2} + 2^{2m-2}) \\ &= (2^m-1) 2^{2m-2} \end{aligned}$$

$$\begin{aligned}
I_4 &= \sum j^4 a_j - 2^{m+1} \sum j^3 a_j + 3 \cdot 2^{2m-1} \sum j^2 a_j - 2^{3m-1} \sum j a_j \\
&\quad + 2^{4m-4} \sum_{j \neq 0} a_j \\
&= 2^{2m-4} (n^4 + 6n^3 + 3n^2 - 2n) - 2^{3m-2} (n^3 + 3n^2) \\
&\quad + 3 \cdot 2^{4m-3} n(n+1) - 2^{5m-2} n + 2^{4m-4} (2^{2m-1}) \\
&\quad + 3(2^{3m-1} - 2^{2m-1} n) b_3 + 3 \cdot 2^{2m-2} b_4 \\
&= n \{ 2^{2m-4} [(n+1)^3 + 3(n+1)(n-1)] - 2^{3m-2} [(n+1)^2 + \\
&\quad n-1] + 3 \cdot 2^{4m-3} (n+1) - 2^{5m-2} + 2^{4m-4} (2^m + 1) \} \\
&\quad + 3 \cdot 2^{2m-1} (b_3 + b_4) \\
&= n \{ 2^{5m-4} - 2^{5m-2} + 3 \cdot 2^{5m-3} - 2^{5m-2} + 2^{5m-4} \\
&\quad + 3 \cdot 2^{3m-4} (2^m - 2) - 2^{3m-2} (2^m - 2) + 2^{4m-4} \} \\
&\quad + 3 \cdot 2^{2m-1} (b_3 + b_4) \\
&= (2^m - 1) 2^{3m-3} + 3 \cdot 2^{2m-1} (b_3 + b_4)
\end{aligned} \tag{24}$$

Since all one vector $(1, 1, \dots, 1)$ is in C_0 ,

$$b_{2^m-4} = b_3.$$

By Lemmas 9 and 10,

$$\begin{aligned}
b_3 + b_4 &= b_{2^m-4} + b_4 = 2^{m-2} b_{2^m-4} = 2^{m-2} b_3 \\
&= 2^{m-2} (2^{c'-1} - 1) (2^m - 1) / 3.
\end{aligned} \tag{25}$$

By substituting the right hand side of (25) into (24),

$$I_4 = (2^m - 1) 2^{3m+c'-4}. \quad \text{Q.E.D.}$$

Let j_M be the smallest nonzero integer such that

$$a_{j_M} + a_{2^m - j_M} \neq 0.$$

By the definition of I_2 and I_4 ,

$$(j_M - 2^{m-1})^2 \geq I_4 / I_2 = 2^{m+c'-2} \quad (26)$$

Consider the case where $c = c'$. Then, $v = 1$ by Lemma 5. Since all nonzero vectors in C_2 are of weight 2^{m-1} , it follows from Lemma 8 and (16) that $a_j + a_{2^m - j}$ ($j \neq 0, 2^{m-1}$) must be divisible by $2^{m-c'}(2^m - 1) = 2^{m-c}(2^m - 1)$.

Therefore, from (26)

$$I_2 \geq (j_M - 2^{m-1})^2 (a_{j_M} + a_{2^m - j_M}) \geq 2^{2m-2} (2^m - 1) \quad (27)$$

By Lemma 11 and (27),

$$I_2 = (j_M - 2^{m-1})^2 (a_{j_M} + a_{2^m - j_M}) = 2^{2m-2} (2^m - 1).$$

Consequently,

$$(j_M - 2^{m-1})^2 = 2^{m+c'-2} = 2^{m+c-2} \quad (28)$$

$$a_{j_M} + a_{2^m - j_M} = 2^{m-c} (2^m - 1) \quad (29)$$

$$a_j = 0 \quad (j \neq 0, j_M, 2^{m-1}, 2^m - j_M).$$

Hence,

$$\begin{aligned}
 j_M &= 2^{m-1} - 2^{(m+c)/2-1} \\
 a_{2^{m-1}} &= 2^{2^{m-1}} - (a_{j_M} + a_{2^m - j_M}) \\
 &= (2^m - 2^{m-c} + 1) (2^m - 1)
 \end{aligned} \tag{30}$$

By Lemma 9, (29) and (30),

$$\begin{aligned}
 a_{j_M} &= (2^{m-c-1} + 2^{(m-c)/2-1}) (2^m - 1) \\
 a_{2^m - j_M} &= (2^{m-c-1} - 2^{(m-c)/2-1}) (2^m - 1)
 \end{aligned}$$

Thus, we have the following theorem.

Theorem 1: If $(m, h) = (m, 2h) = c$, then

$$\begin{aligned}
 a_0 &= 1 \\
 a_{2^{m-1} - 2^{(m+c)/2-1}} &= (2^{m-c-1} + 2^{(m-c)/2-1}) (2^m - 1) \\
 a_{2^{m-1}} &= (2^m - 2^{m-c} + 1) (2^m - 1) \\
 a_{2^{m-1} + 2^{(m+c)/2-1}} &= (2^{m-c-1} - 2^{(m-c)/2-1}) (2^m - 1) \\
 a_j &= 0 \text{ for other } j.
 \end{aligned}$$

4. Case II: $2(m, h) = (m, 2h) \nmid m$

Consider the case in which $2(m, h) = (m, 2h)$. Then, $v = 2^{c'} + 1$ by Lemma 5. Since $v(0, B_1, 0, x)$ is in C_1 , $w_{00} = w_0, w_1, \dots, w_{v-1}$ can be found from the weight distribution of C_1 . Each code vector of C_1 is a v concatenation of a code vector in cyclic code C'_1 of length $(2^m - 1)/v$ which is generated by $(x^{(2^m - 1)/v} - 1)/h_1(x)$. Let $v'(B; x)$ denote a code vector $v'(x)$

in C_1^i such that $v'(\alpha^{i_1}) = \beta$. With the same argument as the one of section 3, set $C_{1i}^i = \{v(\alpha^{i+\ell v}; x) \mid 0 \leq \ell < (2^m-1)/v\}$ ($0 \leq i < v$) consists of $(2^m-1)/v$ vectors of the same weight w_i' . Since $v(0, \beta, 0; x) = (v'(\beta; x), \underbrace{v'(\beta; x), \dots, v'(\beta; x)}_v)$, w_i can be given by the following equation:

$$w_i = vw_i' \quad (0 \leq i < v)$$

Therefore, by applying Lemma 6 to code C_1^i , we have

$$\begin{aligned} (2^m-1)/v \sum_{i=0}^{v-1} w_i/v &= 2^{m-1} (2^m-1)/v, \\ (2^m-1)/v \sum_{i=0}^{v-1} (w_i/v)^2 &= 2^{m-2} (2^m-1) (2^m-1+v)/v^2. \end{aligned}$$

Thus,

$$\sum_{i=0}^{v-1} w_i = v2^{m-1} \quad (31)$$

$$\sum_{i=0}^{v-1} w_i^2 = v2^{m-2} (2^m-1+v) = v2^{m-2} (2^m + 2^{c'}) \quad (32)$$

Therefore,

$$\begin{aligned} \sum_{i=0}^{v-1} (w_i - 2^{m-1})^2 &= v2^{m-2} (2^m-1+v) - 2^m v 2^{m-1} + 2^{2m-2} v \\ &= v2^{m-2} (v-1) = v2^{m+c'-2} \end{aligned} \quad (33)$$

On the other hand, it follows from Lemma 8, (16), (17) and the definition of I_2 that

$$\begin{aligned} I_2 &= I_{20} + I_{21}, \\ I_{20} &= 2^{m-c} (2^m-1) \sum_{j=1}^{2^{c-1}} (w_{0j} - 2^{m-1})^2/v, \\ I_{21} &= 2^{m-c} (2^m-1) (w_0 - 2^{m-1})^2/v + 2^m (2^m-1) \sum_{i=1}^{v-1} (w_i - 2^{m-1})^2/v. \end{aligned} \quad (34)$$

By Lemma 11 and (33),

$$\begin{aligned} I_2 &= 2^{2m-2}(2^m-1) \\ &\geq I_{21} = 2^{2m+c'-2}(2^m-1) - (2^m-1)(2^m-2^{m-c})(w_0-2^{m-1})^2/v. \end{aligned} \quad (35)$$

By a simple calculation,

$$\begin{aligned} (w_0-2^{m-1})^2 &\geq 2^{2m-2}(2^{c'}-1)v/(2^m-2^{m-c}) \\ &= 2^{m+c-2} \quad (\text{by (6)}). \end{aligned}$$

Hence,

$$w_0 = 2^{m-1} \pm (2^{(m+c)/2-1} + \delta), \quad \delta \geq 0 \quad (36)$$

Now, by (31) and (32)

$$\begin{aligned} I'_2 &= \sum_{i=0}^{v-1} (w_i - (2^{m-1} \mp 2^{m/2-1}))^2 \\ &= v2^{m-2}(2^{m-1+v} - 2(2^{m-1} \mp 2^{m/2-1})v2^{m-1} + (2^{m-1} \mp 2^{m/2-1})^2v) \\ &= v\{2^{2m-2} + 2^{m+c'-2} - 2^{2m-1} \pm 2^{3m/2-1} + 2^{2m-2} \mp 2^{3m/2-1} + 2^{m-2}\} \\ &= 2^{m-2}(2^{c'}+1)^2 \end{aligned} \quad (37)$$

On the other hand,

$$\begin{aligned} I'_2 &\geq (w_0 - (2^{m-1} \mp 2^{m/2-1}))^2 = [2^{m-1} \pm (2^{(m+c)/2-1} + \delta) - 2^{m-1} \mp 2^{m/2-1}]^2 \\ &= 2^{m-2}(2^{c'}+1+\delta 2^{1-m/2})^2 \end{aligned} \quad (38)$$

From (35), (36), and (37), we have that

$$\delta = 0$$

$$w_0 = 2^{m-1} \pm 2^{(m+c)/2-1} \quad (39)$$

$$w_i = 2^{m-1} \mp 2^{m/2-1} \quad (0 < i < v) \quad (40)$$

Since w_i ($0 \leq i < v$) is divisible by v , the $\pm$ sign is determined by Lemma 4.

Thus, we have:

Theorem 2: Let a'_{jv} denote the number of code vectors of weight j in C'_1 .

If m/c is odd (or even), then

$$a'_0 = 1$$

$$a'_{2^{m-1}-2^{(m+c)/2-1}} \text{ (or } a'_{2^{m-1}+2^{(m+c)/2-1}}) = (2^m-1)/(2^{c/2}+1)$$

$$a'_{2^{m-1}+2^{m/2-1}} \text{ (or } a'_{2^{m-1}-2^{m/2-1}}) = 2^{c/2}(2^m-1)/(2^{c/2}+1).$$

$$a'_j = 0 \text{ for other } j.$$

From (35) and (39) it follows that

$$\begin{aligned} I_{21} &= 2^{2m+c'-2}(2^m-1) - (2^m-1)(2^m-2^{m-c})2^{m+c-2}/v \\ &= 2^{2m-2}(2^m-1)(2^{c'}-(2^c-1)/v) \\ &= 2^{2m-2}(2^m-1) \\ &= I_2 \end{aligned} \quad (\text{by (35)}).$$

By (34),

$$I_{20} = (2^m-1)2^{m-c}/v \sum_{j=1}^{2^c-1} (w_{0j}-2^{m-1})^2 = 0$$

Hence,

$$w_{0j} = 2^{m-1} \quad (1 \leq j < 2^c). \quad (41)$$

By (16), (17), Lemma 8, (39), (40) and (41), we have:

$$\begin{aligned} a'_{2^{m-1}-2^{m/2-1}} + a'_{2^{m-1}+2^{m/2-1}} &= (2^m-1)2^{m+c/2}/(2^{c/2}+1) \\ a'_{2^{m-1}} &= (2^m-1)2^{m-c}(2^c-1)/(2^{c/2}+1) + 2^{m-1} \end{aligned}$$

$$a_{2^{m-1}-2^{(m+c)/2-1}} + a_{2^{m-1}+2^{(m+c)/2-1}} = (2^m-1)2^{m-c}/(2^{c/2}+1)$$

Thus, the next theorem follows from Lemma 9.

Theorem 3: If $2(m,h) = (m,2h) = c$ and $c \nmid m$, then

$$a_0 = 1$$

$$a_{2^{m-1}-2^{(m+c)/2-1}} = (2^m-1)(2^{(m-c)/2}+1)2^{(m-c)/2-1}/(2^{c/2}+1)$$

$$a_{2^{m-1}-2^{m/2}} = (2^m-1)(2^{m/2}+1)2^{(m+c)/2-1}/(2^{c/2}+1)$$

$$a_{2^{m-1}} = (2^m-1)((2^{c/2}-1)2^{m-c}+1)$$

$$a_{2^{m-1}+2^{m/2}} = (2^m-1)(2^{m/2}-1)2^{(m+c)/2-1}/(2^{c/2}+1)$$

$$a_{2^{m-1}+2^{(m+c)/2-1}} = (2^m-1)(2^{(m-c)/2}-1)2^{(m-c)/2-1}/(2^{c/2}+1)$$

$$a_j = 0 \quad \text{for other } j.$$

5. Case III: $2(m,h) = (m,2h) = m$

Consider the case of $m = 2h$. For any $B_1 \neq 0, B_2$ in $GF(2^m)$, there exists $b \in GF(2^m)$ such that

$$B_1 b^{2^{h-1}} + B_2 = 0,$$

because $(2^{h-1}, 2^m-1) = 1$. From (15) and a similar argument to the one for the case of $m = m'$, it follows that there exists w such that the weight of any code vector in $C-C_2$ is either w or 2^m-w . Since C_1' , the cyclic code of length $2^{m/2}-1$ generated by $(x^{2^{m/2}-1}-1)/g_1(x)$, is a maximum length sequence code, C_1 consists of one zero vector and $2^{m/2}-1$ vectors of weight $2^{m/2}-1$ ($2^{m/2}+1$). Therefore,

$$w = (2^{m/2} + 1) 2^{m/2-1}.$$

On the other hand, C_2 is a maximum length sequence code of length $2^m - 1$.

Hence,

$$a_{2^{m-1}} = 2^{m-1}.$$

According to Lemma 9, we have:

Theorem 4: If $m = 2h$, then

$$a_0 = 1$$

$$a_{2^{m-1}-2^{m/2-1}} = (2^{m/2}-1)(2^{m-1}+2^{m/2-1})$$

$$a_{2^{m-1}} = 2^{m-1}$$

$$a_{2^{m-1}+2^{m/2-1}} = (2^{m/2}-1)(2^{m-1}-2^{m/2-1})$$

$$a_j = 0 \quad \text{for other } j.$$

6. Crosscorrelation Functions of Two Maximum Length Sequences

It follows from Lemma 5 that $\alpha^{2^{h+1}}$ is a primitive element if and only if $c = c'$. Assume that $c = c'$. Let

$$v(0,1,0;x) = \sum_{f=0}^{2^m-2} v_{1f} x^f$$

$$v(0,0,1;x) = \sum_{f=0}^{2^m-2} v_{2f} x^f.$$

Then, $v_1 = v_{10}, v_{11}, \dots, v_{1,2^m-2}$ and $v_2 = v_{20}, v_{21}, \dots, v_{2,2^m-2}$ are maximum length sequences of length $2^m - 1$. In v_1 and v_2 , replace 0 by -1. Let

$u_1 = u_{10}, u_{11}, \dots, u_{1,2^m-2}$ and $u_2 = u_{20}, u_{21}, \dots, u_{2,2^m-2}$ be the resulting

sequences of real numbers 1 and -1. Correlation function $\theta(j)$ of u_1 and u_2 is defined by

$$\theta(j) = \sum_{f=0}^{2^m-2} u_{1f} u_{2f-j},$$

where suffix $f - j$ is to be taken mod 2^m-1 . Note that

$$v(0,1,0;x) + x^j v(0,0,1;x) = v(0,1,\alpha^{ji_2};x).$$

If $v(0,1,\alpha^{ji_2};x)$ has weight w , then

$$\theta(j) = 2^{m-1-2w}. \quad (42)$$

Let s_i denote the number of j 's ($0 \leq j < 2^m-1$) with $\theta(j) = i$. Then, s_i is the number of vectors $v(0,1,\beta;x)$ with weight $(2^{m-1}-i)/2$. From sections 2 and 3, we have theorem 5.

Theorem 5:

$$s_{-2^{(m+c)/2-1}} = 2^{m-c-1} - 2^{(m-c)/2-1},$$

$$s_{-1} = 2^m - 2^{m-c},$$

$$s_{2^{(m+c)/2-1}} = 2^{m-c-1} + 2^{(m-c)/2-1},$$

$$s_i = 0 \quad \text{for other } i.$$

For $0 \leq j < 2^m-1$, let

$$\theta_j = 1 \text{ if } \theta(j) = -2^{(m+c)/2-1} \text{ or } 2^{(m+c)/2-1},$$

$$\theta_j = 0 \text{ if } \theta(j) = -1.$$

Sequence $\theta = \theta_0, \theta_1, \dots, \theta_{2^m-2}$ will be called the correlation sequence of

u_1 and u_2 . We shall characterize the correlation sequence below. Recall that

$$V_0 = V_{00} = \{b^{2^{m-h-1}} + b^{2^{h-1}} \mid b \in GF(2^m)\}$$

Since $(2^{h-1}, 2^m - 1) = 1$,

$$V_{00} = \{b^{2^{m-2h}} + b \mid b \in GF(2^m)\}$$

Since $(m-2h, m) = c$, the Galois group of $GF(2^m)$ over $GF(2^c)$ is generated by the automorphism $X \rightarrow X^{2^{m-2h}}$ (by Theorem 9, p. 127 of [6]). Therefore, from the trace theorem (p. 121 of [6]) it follows that

$$V_{00} = \{b \mid \sigma(b) = 0, b \in GF(2^m)\},$$

where $\sigma(b)$ denotes the trace of b in $GF(2^m)$ over $GF(2^c)$, and

$$\sigma(b) = b + b^{2^c} + b^{2^{2c}} + \dots + b^{2^{m-c}}.$$

Hence, any element of each coset V_{0j} has the same trace $t_j \in GF(2^c)$, and if $j \neq j'$, $t_j \neq t_{j'}$.

Note that $v^2(0, \beta_1, \beta_2; x) = v(0, \beta_1, \beta_2; x^2) = v(0, \beta_1^2, \beta_2^2; x) \in C$ and that $v(0, \beta_1, \beta_2; x)$ and $v(0, \beta_1, \beta_2; x^2)$ have the same weight. Consequently, if $t_{j'} = t_j^2$, then $w_{0j'} = w_{0j}$. From the proof of Theorem 1 it follows that there is only one j_0 such that

$$w_{0j_0} = 2^{m-1} - 2^{(m+c)/2-1}$$

$$w_{0j} = 2^{m-1}, j \neq j_0.$$

Since $t_{j_0} = t_{j_0}^2$, $t_{j_0} = 0$ or 1 . Since C_1 is a maximum length sequence code, w_{00} must be 2^{m-1} . Therefore, $t_{j_0} = 1$. This implies that the weight of $v(0, 1, \beta; x)$ is not equal to 2^{m-1} if and only if $\beta + \beta^{2^c} + \beta^{2^{2c}} + \dots + \beta^{2^{m-c}} = 1$. From (42), $\theta(j) \neq -1$, if and only if $\alpha^{j i_2} + \alpha^{j i_2 2^c} + \alpha^{j i_2 2^{2c}} + \dots + \alpha^{j i_2 2^{m-c}} = 1$. Since $\alpha^{2 i_2} = \alpha^{2^{m-2}} = \alpha^{-1}$ and $\alpha^{-2^{m-1}} = \alpha^{i_2}$, we have

Theorem 6.

Theorem 6: $\theta_j = 1$ if and only if $\alpha^{-j} + \alpha^{-j2^c} + \alpha^{-j2^{2c}} + \dots + \alpha^{-j2^{m-c}} = 1$.

Now consider the case of $c = 1$. By definition, $v(0,0,1;\alpha^j) = 1$.

Therefore,

$$v(0,0,1;\alpha^{-2^l}) = 1 \quad (0 \leq l < m).$$

On the other hand, for any $\alpha^j \neq \alpha^{-2^l}$ ($0 \leq l < m$),

$$v(0,0,1;\alpha^j) = 0.$$

By the formula due to Reed and Solomon [7],

$$\begin{aligned} v_{2f} &= \sum_{j=0}^{2^m-2} v(0,0,1;\alpha^j) \alpha^{-jf} \\ &= \alpha^f + \alpha^{2f} + \alpha^{2^2f} + \dots + \alpha^{2^{m-1}f}. \end{aligned}$$

Hence, by Theorem 6

$$\theta_j = v_{2^{m-1}-j}.$$

This implies the following corollary.

Corollary 7: If $(m,h) = (m,2h) = 1$, then the correlation sequence of the maximum length sequence generated by $h_1(X)$ and the one generated by $h_2(X)$ is the maximum length sequence generated by $g_2(X) = X^m h_2(X^{-1})$.

R. Gold and E. Kopitzka [8] observed that for some pairs of maximum length sequences the correlation sequences are also maximum length sequences and they listed all such pairs of sequences of length 8191 or less. Among 28 listed pairs, 25 cases are covered by Corollary 7.

13. ABSTRACT Let $h_1(X)$ and $h_2(X)$ be different irreducible polynomials such that $h_1(\alpha^{2^h-1}) = 0$ for some $h(0 < h < m)$ and $h_2(\alpha^{-1}) = 0$, α being a primitive element of $GF(2^m)$. This paper presents the weight distribution formula of the code of length 2^m-1 generated by $(X^{2^m-1} - 1)/(h_1(X)h_2(X))$ for any m and h . Some applications to the cross-correlation problem between two different maximum length sequences are presented.
