SUMMARY PAGE

The Problem

To evaluate models of the two-piece submarine rescue and escape suits which have incorporated seven alterations recommended on the basis of previous field trials.

Findings

For submarine rescue and escape, the garment considered more satisfactory is the two-piece suit of two-way stretch material dyed International Orange, fitted with a neck gasket, head straps and two relief valves, one at the back of the head and one between the shoulder

Indications

Further investigation is needed to determine preferred operational characteristics such as: Diaphragm relief valve compared with flutter valve; cotton waffle weave underwear compared with wool divers underwear; and rubber gasket at the face opening compared with fabric gasket.

Published by the Naval Medical Research Laboratory
For Official Use

ADMINISTRATIVE INFORMATION

This investigation was conducted under Project NM 00 in cooperation with the Naval Clothing Supply Office, Brooklyn, which had requested an evaluation of improved models of experimental submarine rescue and escape suits by letter from Commanding Officer, Naval Clothing Supply Office, USNSA, N.Y., 1D42-1:mb of 8 December 1942.

REPORT OF INVESTIGATION

INTRODUCTION

The purpose of this study was to evaluate seven variables recommended as a result of a previous field evaluation (1) for the two-piece submarine rescue and escape suits furnished by the Naval Clothing Supply Office, Brooklyn, N.Y.

MATERIALS RECEIVED FOR TESTING

The garments were of a single basic type consisting of a one-piece suit of double laminated stretchable cotton with a layer of rubber between. The seven features recommended for incorporation in the test garments, included: (1) Built-in rubber neck gasket; (2) rubber face opening; (3) attached or detachable rubber gloves; (4) built-in life preserver; (5) draw-string or strap adjustment at the back of the neck; (6) variously located flutter valves; and (7) elbow and knee reinforcements.

Twelve suits were supplied; however, each incorporated a different combination of the above features.

METHOD AND RESULTS

The suits were tested by the instructor personnel and other officers attached to the Submarine Escape Training Tank under the following conditions: (1) Simulated submarine escapes from the lock using the Submarine Escape Appliance, the free or the restricted technique, with the standard submarine life jacket; (2) swimming distances with and without the life jacket, either with or without

lung (3) simulated rescue of a drowning man; and (4) skin diving and aqua lung diving to various depths.

These various tests were performed in three situations: (1) in the Training Tank in warm water (82-92°F); (2) in the Base swimming pool in cool water (76-82°F); and (3) in the Thames River in cold water (34-38°F).

After the cold water tests the length of time in the water and the water and air temperatures were recorded. Each individual was instructed to come out of the water whenever he began to feel uncomfortable. Oral temperature for each subject was recorded pre-and-post test, a physical examination was made for any evidence of hypothermia and each subject was asked the reason for his discontinuing the test. He was then asked to fill out an evaluation sheet.

Each man made a test using each suit and his opinion regarding the best features of each was determined. These evaluations were based primarily upon subjective responses and personal opinions of the individual. However, all personnel used in these tests have had considerable background of experience in underwater swimming and/or underwater physiology. Also, all the individuals used as subjects in these tests had had some experience with the prototype suits used in the previous evaluations.

The results of the tests and the consensus of opinion regarding each feature evaluated are included as Appendix A.

DISCUSSION

Basically, these suits are the same as the two-piece suits used in previous evaluations with the additions of the seven modifications:

The material has been dyed International Orange to increase visibility at sea, (see reference 2).

Leakage: Although the previous tests reported a minimum and number of leaks, considerable difficulty was encountered because of leakage in the seams. This caused wetting and chill to the body and resulted in the termination of most cold water trials to 12 minutes.

Face Opening: The rubber face opening was considered more comfortable than the fabric type and caused less leakage of the face mask. Slight alterations in the fabric opening proposed by observers from the Clothing Supply Office may eliminate these leaks and thus replace the rubber face opening which deteriorates more rapidly on stowage.

Relief Valves: Relief valves were located in the back of the chest and in suits having a neck gasket in either the chest or the back. Relief valves reduced or eliminated the leakage around the face mask even on rapid venting of the suit. It was found that the relief valve below the neck gasket worked best when located high on the back near the scapulae. All relief valves were of the flutter valve type and in one case did not vent properly when the life jacket or aqua lung was used. It was suggested that the diaphragm type of relief valve might solve this problem.

Neck Gasket: The neck gasket definitely reduces the leakage reaching the chest and back even in the suits which have a relief valve in the head. The gasket was comfortable and caused no neck restriction. It did not appreciably increase the difficulties in removing the suit. A relief valve below the neck gasket is used to vent off the air trapped in the body of the suit.

Buoyancy: On the suits with relief valves no excessive buoyancy was encountered. Free dives and aqua lung dives to 100 feet were made with no increased difficulty and no tendency toward squeeze in the arms or legs was noted. Escapes using the escape appliance or the frog technique revealed no increased buoyancy. Buoyant escapes with a life jacket revealed that gas in the suit was rapidly vented off.

Gloves: The detachable gloves were objectionable in many trials because of leakage and also because of restriction to circulation. The attached gloves are cumbersome and reduce manual dexterity. For submarine escapes this is no factor, however. Admittedly, detachable gloves are preferable if these two objectionable features can be eliminated, especially if the suit is to be used for underwater work as well as submarine escapes.

Elbow and Knee Patches: The need for elbow and knee patches could not be ascertained on these trials since insufficient time was available for tests of climbing in and out of small boats and working on the bottom. It was found that elbow and knee patches did not interfere with maneuverability or cause any discomfort. It therefore seems advisable to incorporate them in all models of suits.

Built-in Life Jacket: The built-in life jacket provided adequate buoyancy on the surface. It was possible, however, for a man to float face down in the water with the life jacket inflated. There were no relief valves in the life jacket and, therefore, it could not be used in buoyancy escape. Since the floating characteristics of this jacket are not as good as the present submarine life jacket, and since submarine life jackets must be maintained, there is no good reason for incorporating one in the exposure suit.

Comfort and Maneuverability: No areas of excessive restriction were noted in any of the suits. All were equally comfortable and maneuverable with either the submarine life jacket, the aqua lung,

Ease of Dressing: At the beginning of the trial, it took an average of ten minutes to don a suit with the aid of another person. After repeated attempts, however, the time was reduced to less than five minutes. The detachable gloves reduce the amount of time needed to don the suit as well as the need of an assistant.

Head Straps: The head straps were considered superior to those in use because they allow the individual to adjust them more easily for comfort.

CONCLUSIONS

The addition of relief valves to vent off trapped air and a gasket around the neck are a definite improvement to the two-piece submarine and rescue suit. The use of International Orange colored fabric increases detectability at sea (2). It is immaterial whether oxygen or fabric face openings, elbow and knee reinforcements and detachable gloves are incorporated in the garment when used in submarine situations.

Since the requirements of a good submarine escape suit and a good underwater rescue suit are essentially the same as those for a good underwater rescue suit, these additional features should be evaluated with this consideration in mind so that a single type suit suitable to both purposes can be obtained.

Further consideration is considered to be needed concerning the following items:

1. The development of a watertight, comfortable, detachable glove.
2. Further comparison of the fabric vs. rubber face opening.
3. Comparison of the diaphragm and the flutter relief valve.
4. Determining the necessity of elbow and knee reinforcement.

It is felt that investigation should be made of the advantages this type of suit as a substitute for the foul weather clothing now supplied for use by personnel exposed to constant wetting. It is felt that this escape and rescue suit might also prove valuable for personnel engaged in any other work in which there is exposure to cold and wetting, for example the torpedo retrievers.

APPENDIX A

A questionnaire was given each individual after each test. This questionnaire contained the following 12 questions concerning opinions. The findings on each feature evaluated appear in the opposite the questions.

<u>Question</u>	<u>Answer</u>
1. Did the neck gasket prevent water which may enter at the face opening from spreading down to the chest?	1. Unanimously <u>yes</u> with exception of one individual whose neck was larger than the opening.
2. Did you encounter any difficulty in passing your head through the neck gasket while donning and removing the suit?	2. Majority <u>yes</u> ; approximately 20% felt there was an increase in difficulty.
3. While wearing the suit was the neck gasket comfortable?	3. Majority <u>yes</u> ; approximately 20% felt slightly uncomfortable.
4. Which face opening was better suited to keep out water? (a) Which was more comfortable? (b) Which would you recommend?	4. 60% preferred the fabric face opening, 40% preferred the rubber face opening. (a) Rubber unanimously preferred. (b) 60% recommended rubber; 40% recommended fabric opening.
5. Was there excessive restriction at the wrists while wearing cuffs and detachable gloves? (a) Degree of discomfort?	5. Majority <u>yes</u> ; one individual felt there was no restriction. (a) Of those who felt there was restriction, half felt it was very objectionable, and half felt it was slightly objectionable.
(b) Did water enter at the wrist junction?	(b) Unanimously <u>yes</u> .

6. Did attached gloves allow sufficient manual dexterity?
 (a) Reasons?
 (b) Which style would you recommend at this time?
7. Which type of head adjustment did you prefer?
 (a) Which formed the tighter seal?
 (b) Which would you recommend for adoption?
8. Do you feel that flutter valves are necessary?
 (a) Number and location?
9. Do the reinforcements at the knees and elbows interfere with movement?
 (a) Do you recommend them?
10. What was the maximum length of time required to don the suits?
 (a) The minimum length of time?
11. In cold water tests, what were the existing conditions?
 (a) How long did you remain in the water?
 (b) Why did you come out?
6. Unanimously no.
 (a) Too large; too clumsy.
 (b) 60% preferred the detachable gloves.
7. Majority preferred strap; less than 20% preferred the drawstring.
 (a) One-half felt they were equally effective; the other half were equally divided as to which was the better.
 (b) Almost unanimously favor of the straps.
8. Over 90% felt they were necessary.
 (a) It was unanimously agreed by those favoring flutter valves to have one at the back of head and one between the scapulae.
9. Unanimously no.
 (a) Unanimously yes.
10. Average 11 minutes.
 (a) 4 minutes.
11. Water temperature 34-38°
 Air temperature 32-40°
 (a) Average 12 minutes.
 (b) Chilled from leakage water at the seams.

12. Physical findings resulting from cold exposure?

12. (a) Oral temperature
Average 1°F
Minimum of .4°F
Minimum of 1.6°F
(b) Hyperemia of
of the body
through leak.
