ABSTRACT

The feasibility of making an illuminating candle which produces a luminous intensity of 25 million candles is demonstrated. The goal is achieved by igniting all surfaces of a star shaped cavity which is formed through the center of the candle. Two horizontally opposed flames are generated by this candle.

The relationship between candle diameter and the ability of that candle to generate light efficiently is reported. This study includes data for both pressed and cast candles and shows the effect of different binder types. A general degradation of efficiency is observed as the cast candle diameter increases from 4 inches to 24 inches. The pressed candle series shows a maximum near the 4 inch diameter with degradation to either side.

Silicone, epoxy-polyglycol, polyester, polysulfide, and various combinations of these binders are described as they are used to make candles for the diameter study and the 25 million candle flare. A study of flare compositions consisting of magnesium and sodium perchlorate, the latter being partially dissolved in various methacrylate monomers is reported. A limited environmental program for a 4.5 inch diameter candle cast in an aluminum candle case and the development of a liner system for that candle is described. A polyester-epoxy

binder is used successfully to make a cast candle whose luminous efficiency is comparable to a candle made by the conventional pressed method.

Flame orientation and flame size effects are described. Contrary to common opinion, it is shown that a small flame size rather than a large flame from a given candle diameter is associated with candles which produce light with high efficiency. The binder is shown to be a major factor in the generation of various flame sizes and thus strongly influences the candle efficiency.

INTRODUCTION

This exploratory development program was conducted between June 1966 and June 1967 for the Air Force Armament Laboratory, Eglin Air Force Base, Florida, under MIPR-PG-6-58. The main objectives of the program were twofold. One goal was to demonstrate the feasibility of making an illuminating candle which has a luminous intensity of 25 million candles. This is a five-fold increase over the intensity delivered by the BRITEYE candle. The second goal was to conduct a study of the relationships between the diameter of a candle and the efficiency of light production from that candle. Both goals were attained during the contract period.

To assist the reader, the report is divided into four parts. Part I deals with the 25 million candle flare, Part II with the diameter studies, Part III with binder studies, and Part IV with flame orientation and flame size effects. Although the report is divided for convenience, it is noteworthy that all phases of this work are interrelated; that is, information generated in any one part is also utilized in the other phases in

an effort to extract the maximum amount of data from a minimum amount of work and hardware expenditure. With these remarks, the reader is encouraged to view this work as an integrated program instead of four distinct tasks.

The report is bound in two volumes. The main body of the report is in Volume I. The Appendices are in Volume II. A Table of Contents, Abstract, and Introduction for the entire report has been inserted at the beginning of each volume for convenience.

APPENDIX I

FLARE FABRICATION PROCESS

Magnesium and sodium nitrate have been used extensively for making illuminating flare compositions. Their granular size is often varied to cause changes in the burning rate of the composition. Also, the ratio of these ingredients causes changes in the burning rate as well as the efficiency (cd-sec/g). A third ingredient is normally added to the system. That ingredient, the binder, is normally a plastic in monomeric form which later can be polymerized to bond the composition to itself and to its container. In compositions prepared for casting, the binder content normally ranges from 9 - 15% by weight.

Generally, in preparing the composition, the binder and magnesium are preblended in a mixer. This preblending process desensitizes the magnesium, reduces the dust hazard, and inhibits surface oxidation of the magnesium particles. The sodium nitrate is later added to the preblend. This mass is then mixed until a homogeneous blend is obtained. When the binder content is about 12%, the composition has physical properties analogous to freshly ground hamburger. The material doesn't flow nor seek its own level. It can be molded, formed, and packed - under mild pressure.

The general procedure for making a candle consists of tamping the composition in place under pressure of about 50 - 60 psi. The star cavity is formed by means of a mold which is later removed. After polymerization of the binder system, the composition is

rigid and strong. The composition must also adhere in some manner to the flare container. This is necessary to prevent premature burning in the composition-case interface. A good bond between these two surfaces can be achieved by various techniques. One technique is to bond the composition directly to the case. Another is to introduce a liner between the case and the composition. That liner is bonded to both the case and the composition. The case bond must usually be able to withstand severe changes of temperature such as -65°F to $+160^{\circ}\text{F}$ and be sufficiently strong to withstand the normal safety and durability tests. Accordingly, the bond system must be developed in conjunction with the candle hardware.

APPENDIX II
STAR CONFIGURATION COMPUTATIONS

by Ralph Chipman

The configuration of an internal burning cavity was investigated. The problem was to determine the configuration of a star shaped cavity put in the center of a 16 inch flare that would produce a constant burning as the flare burned internally from the center outward. Since the burning surface is the product of the length of the flare and the perimeter of the cross section of the burning area, the problem reduces to obtaining a configuration that produces a constant cavity perimeter during burning. Equations to compute the perimeter were developed assuming the burning rate perpendicular to the burning surface was constant in all directions. Using these equations, a computer program was written to compute perimeter versus linear displacement of the burning surface for various shaped stars. Since five inches of linear burning was desired, the diameter of the star was fixed at six inches.

Although the goal of constant perimeter was not achieved, the best results came from a six-pointed star with the dimensions shown in Figure 1. Figure 2 shows a cross section of the theoretical burning surface at various burning distances for this configuration and a graph of the perimeter versus diameter is shown in Figure 3. As can be seen from the graph, the perimeter is nearly constant for the first two inches of burning and then

PERIMETER=30.59 IN.
AREA = 7.85 SQ. IN.

Figure 1-Cross Section of Configuration Which Gave Best Results

Figure 2-Cross Section of Theoretical Burning Surface at Various Burning Distances for Best Configuration.

Figure 3-Perimeter Versus Diameter of Cross Section of Best Configuration.

approaches a straight line with a positive slope. The slope of this line, which is the graph one would obtain if the star shaped cavity were replaced by a cylindrical hole, is equal to π .

Other shaped stars that were tried include various shaped four-, five-, and eight-pointed stars and six-pointed star with other combinations of star point widths and sizes of angle between the sides of the points. In all of the other cases of four-, five-, and six-pointed stars, the graph of perimeter versus diameter came closer to the line representing the case of the cylindrical hole. For the eight-pointed star, the perimeter first decreased to a minimum and then increased. The graph of a typical case of a few of these combinations are shown in Figure 4.

Figure 4-Perimeter Versus Diameter of Cross Section of Various Configurations.

Mathematical Derivation of Perimeter Equations

The following is the derivation of the equations for the perimeter of a burning star cavity assuming the burning rate perpendicular to the burning surface is constant in all directions. The final equations of the derivation are listed on page 151 of "Solid Propellant Rockets".⁽¹⁾ However, there is an error in the equation for initial perimeter given there.

Let N equal the number of star points. The star is then completely defined by the radius, R , and the angles A , B , and C . See Figure 5. The value of C is found by the expression

$$C = \frac{2\pi}{N}$$

and B is determined by the width of the end of the star points. A is free to vary over a range of values. The initial perimeter, P_0 , is equal to (see Figure 5)

$$P_0 = 2N(a+x). \quad (1)$$

The value of a is given by

$$a = R(C-B). \quad (2)$$

From the law of sines we have

$$\frac{x}{\sin B} = \frac{R}{\sin(\pi-A)}$$

By substituting $\sin A = \sin(\pi-A)$, we get

$$\frac{x}{\sin B} = \frac{R}{\sin A}$$

and solving for x we obtain

$$x = \frac{R \sin B}{\sin A}. \quad (3)$$

Figure 5A-Dimensions Used in Caloulations of Perimeter

Figure 5B-Perimeter of One-half of a Star Point Before and After Straight Sides Disappear

by substituting Eq (2) and Eq (3) in Eq (1) we get

$$P_0 = 2NR \left(C-B + \frac{\sin B}{\sin A} \right) \quad (4)$$

Let W equal the linear displacement of the burning surface from its original position. To find the perimeter during burning, two cases must be considered. One case is the period that the straight sides of the star points exist and the other is the period after the straight sides disappear. Let W' be the value of W at the point where the straight sides of the star points first disappear.

$$W' = X \tan A = R \frac{\sin B}{\sin A} \tan A = R \frac{\sin B}{\cos A}$$

Case 1

$W < \frac{R \sin B}{\cos A}$, straight sides of star points exist.

From Figure 5 we see that for this case the perimeter is

$$P = 2N(b + s + y). \quad (5)$$

The value of b is

$$b = (R+W)(C-B) = R(C-B) + W(C-B) \quad (6)$$

$$\text{and} \quad s = W(\pi/2 - A + B). \quad (7)$$

$$\text{Since} \quad y = X - Z \text{ and } Z = W \cot A$$

We have by substitution

$$y = R \frac{\sin B}{\sin A} - W \cot A. \quad (8)$$

By substituting Eq. 6, 7, and 8 in Eq. 5 and simplifying we obtain

$$P = 2NR \left(C-B + \frac{\sin B}{\sin A} \right) + 2NW(\pi/2 + C - A - \cot A)$$

$$\text{or} \quad P = P_0 + 2NW(\pi/2 + C - A - \cot A) \quad (9)$$

Case 2

$W > \frac{R \sin B}{\cos A}$, after straight sides of star points disappear.

The perimeter for the second case in Figure 5 is

$$P = 2N (b' + s') \quad (10)$$

where the value of b' is

$$b' = (R+W) (C-B) = R(C-B) + W(C-B). \quad (11)$$

From the law of sines we have

$$\frac{R}{\sin E} = \frac{W}{\sin B}$$

therefore

$$\sin E = \frac{R \sin B}{W}$$

and
$$E = \sin^{-1} \frac{R \sin B}{W}.$$

Since $s' = WD$ and $D = B+E$

we have
$$s' = W(B + \sin^{-1} \frac{R \sin B}{W}) \quad (12)$$

By substituting Eq. 11 and Eq. 12 in Eq. 10 and simplifying, we get

$$P = 2N \left[R (C-B) + W \left(C + \sin^{-1} \frac{R \sin B}{W} \right) \right] \quad (13)$$

Equations 4, 9 and 13 are the necessary equations for finding the perimeter in all cases.

APPENDIX III
COMPUTER PRINTOUT OF TEST DATA

This appendix contains the computer printout of the test data for MAPI flares 300, 342, 343, 394, 426, 427, 463, 464, and 556.

For each of the test flares, the printout presents the data in both numerical and graphical forms. In the numerical printouts various values are tabulated against instantaneous time during the burning period. The second column is the average luminous intensity of the high 29 photocells. The third column is the integrated candle-seconds from time zero. The fourth column is the running mean luminous intensity in units of candles taken from time zero. The fifth column is the running mean luminous intensity taken from time ten seconds. The sixth column is the standard deviation of the high 29 photocells and the seventh column is a uniformity factor which is defined as the high 29 average photocell reading minus the low 29 average photocell reading divided by the average photocell reading of all cells where the average is equal to the high average plus the low average divided by two. Thus, the uniformity factor can range from zero to 2.0 and is a measure of the uniformity of the light distributed in a spherical pattern. For example, when the light is perfectly distributed, the uniformity factor is zero. Thus, the closer this number is to zero the more uniform is the light distribution.

One graph shows the photocell intensity data plotted as a function of time. In that graphical presentation the photocells

are not sorted. Each photocell is plotted against time to show the variation of intensity on that photocell. These plots frequently overlap because the cell may be high at one instant in time whereas it may be low at another instant in time depending upon smoke conditions and other factors. In contrast to this, another graphical presentation is presented wherein the photocell data is sorted and plotted against time. In that presentation, the uppermost plot, for example, is the plot of the highest reading vs. time regardless of which cell is sensing this value. The second highest plot is a graph of the second highest reading vs. time regardless of which cell is sensing that value, etc. In this presentation, the plots do not overlap.

Another graph is presented which is a plot of intensity against time of the high 29, the low 29, and the average of all 58 cells. Since more than 56 cells are never used and often times less than 56 cells are used, the average of the low 29 is biased in the low direction by the number of cells which are not in use. The cells not in use are read by the computer as having an intensity of zero. On the other hand, the high 29 which are selected by the computer are representative of the intensity of the unit in the direction which is the most free from smoke and other light interferences. The plot of the average candlepower of all of the photocells is also biased in the low direction depending once again upon the number of cells that are not in use.

Another graph is presented which shows the integral candle-seconds against time. The linearity of this plot is a measure of the constancy of light output.

Another presentation is a plot of average luminous intensity against time starting with instantaneous time zero and time ten seconds. Graphical presentations are also included to show the standard deviation of the luminous intensity of the high 29 and low 29 photocells and to show the uniformity factor versus time.

13. ABSTRACT		
The feasibility of making an illuminating candle which produces a luminous intensity of 25 million candles is demonstrated. The goal is achieved by igniting all surfaces of a star shaped cavity which is formed through the center of the candle. The relationship between candle diameter and the ability of that candle to generate light efficiently is reported. A general degradation of efficiency is observed as the cast candle diameter increases from 4 inches to 24 inches. Silicone, epoxy-polyglycol, polyester, polysulfide, epoxy-polyester, sodium perchlorate-methyl methacrylate, and various combinations of these binders are described as they are used to make candles for the diameter study, the binder study, and the 25 million candle flare. Flame orientation and flame size effects are described. Contrary to common opinion, it is shown that a small flame size rather than a large flame from a given candle diameter is associated with candles which produce light with high efficiency. The binder is shown to be a major factor in the generation of various flame sizes and thus strongly influences the candle efficiency.

INSTRUCTIONS

1. **ORIGINATING ACTIVITY:** Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (*corporate author*) issuing the report.

2a. **REPORT SECURITY CLASSIFICATION:** Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.

2b. **GROUP:** Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.

3. **REPORT TITLE:** Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.

4. **DESCRIPTIVE NOTES:** If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.

5. **AUTHOR(S):** Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.

6. **REPORT DATE:** Enter the date of the report as day, month, year, or month, year. If more than one date appears on the report, use date of publication.

7a. **TOTAL NUMBER OF PAGES:** The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.

7b. **NUMBER OF REFERENCES:** Enter the total number of references cited in the report.

8a. **CONTRACT OR GRANT NUMBER:** If appropriate, enter the applicable number of the contract or grant under which the report was written.

8b, 8c, & 8d. **PROJECT NUMBER:** Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.

9a. **ORIGINATOR'S REPORT NUMBER(S):** Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.

9b. **OTHER REPORT NUMBER(S):** If the report has been assigned any other report numbers (*either by the originator or by the sponsor*), also enter this number(s).

10. **AVAILABILITY/LIMITATION NOTICES:** Enter any limitations on further dissemination of the report, other than those

imposed by security classification, using standard statements such as:

- (1) "Qualified requesters may obtain copies of this report from DDC."
- (2) "Foreign announcement and dissemination of this report by DDC is not authorized."
- (3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through _____."
- (4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through _____."
- (5) "All distribution of this report is controlled. Qualified DDC users shall request through _____."

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. **SUPPLEMENTARY NOTES:** Use for additional explanatory notes.

12. **SPONSORING MILITARY ACTIVITY:** Enter the name of the departmental project office or laboratory sponsoring (*paying for*) the research and development. Include address.

13. **ABSTRACT:** Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. **KEY WORDS:** Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, roles, and weights is optional.

Security Classification
