Introduction

This collection of abstracts provides information on Malaria, Japanese B Encephalitis and Melioidosis in the Soviet Union, China and Vietnam obtained from publications dated 1 January 1964 to date.

Our searches concentrated on resistance to therapy, drug resistant forms, incidence, clinical treatment and chemotherapeutics of the diseases. Although primary stress in our malaria search was on *Falciparum* malaria, there was so little material obtained that it was thought necessary to include items of peripheral interest for their potential value.

A MEDLARS search for references on melioidosis yielded no Soviet-bloc material. As a safeguard, a further search with no restrictions on area or language turned up the brief bibliography given in the appendix. In the other bibliographies items in Russian or Chinese or those of potential primary interest are indicated by a check (✓).

Appended are bibliographies obtained by a MEDLARS search in response to an ATD request.

TITLE: "Observation of the Effect of Pyrimethaminum and Sulfadiazinum on Tertian Malaria"

SOURCE: Peking, Chung-hua Nei-k'o- Tsa-chih (Chinese Journal of Internal Medicine), Vol 12, No 5, May 64, pp 425-426

ABSTRACT: Pyrimethaminum is the most popular antimalaria drug in China in recent years. In 1959, Hurly reported that Sulfadiazinum has an obvious effect of improving the action of this drug; therefore, the authors conduct a study with the method of combining the two drugs. The area of experimentation was a simple tertian malaria region, and the 171 cases were all verified by blood examinations. The patients were divided into 6 groups.

SOURCE: Peking, Chung-hua Nei-k'o- Tsa-chih (Chinese Journal of Internal Medicine), Vol 12, No 5, May 64, pp 418-422

ABSTRACT: Attacks of subertian malaria or malignant malaria are critical clinical expressions caused by the malaria protozoans. The attacks may be induced by a cold, over fatigue, over eating, or other diseases. The symptoms are not typical and may last one to three days until the patient falls into a coma. If malaria is not positively identified

in the blood, the symptoms may lead to a diagnosis of upper respiratory infection, septicemia, typhus, or acute schistosomiasis, and the treatment will be unduly delayed. This paper reviews the various different symptoms observed by the authors in the 56 cases hospitalized from July, 1962, to October, 1963.

TITLE: "Clinical Symptoms in 31 Cases of Malignant Malaria"

SOURCE: Peking, Chung-hua Nei-k'o- Tsa-chih (Chinese Journal of Internal Medicine), Vol 12, No. 5, May 64, pp 415-417

ABSTRACT: The clinical expressions of malignant malaria are rather complicated. The toxic symptoms are extremely severe, and these symptoms may occur at any time. From 1951 to 1961, a total of 115 cases were verified to be malignant malaria in Kuei-yang First People's Hospital through blood or bone marrow tests. The toxic symptoms of these cases were analyzed in the paper.

TITLE: Screening test of anti-Japanese B encephalitis virus drugs

SOURCE: Yao hsueh hsueh pao (Acta pharmaceutica sinica), v. 11, no. 6, 1964, 375-381

TOPIC TAGS: encephalitis, chemotherapy, drug effect, virus

ABSTRACT: Out of forty-seven kinds of drugs experimentally tested in mice infected with Japanese B encephalitis virus, 9 were shown to possess certain therapeutic effects; they are phenelzine, funacillin, 8-azaguanine, thiosemicarbazide, propadrine, deoxyephedrine, phenylhydrazine, isonicotinylhydrazide, 6-MP. Of particular interest was the observation that phenelzine and funacillin inhibited the multiplication of Japanese B encephalitis virus in mouse brain. By analyzing the relationship between chemical structures and therapeutic actions of such effective substances as hydrazine benzyl compounds, cyclo semicarbazide, ephedrine analogues, anti-purine compounds, it is reasonably expected that those compounds may be used as tools for further studies to throw additional light on the chemotherapeutic mechanism of action against Japanese B encephalitis virus. The authors express thanks to Prof. CHU Heng-pi (2612/1854/3880) for reading the manuscript. Orig. art. has: 4 tables. [FDD]

SOURCE: Peking, Chung-hua Nei-k'o- Tsa-chih (Chinese Journal of Internal Medicine), Vol 12, No 5, May 64, pp 466-468

ABSTRACT: This paper reviews the accomplishments in malaria studies in China since the inclusion of the elimination of the five parasites of China in an Outline for National Development of Agriculture (draft) by the party and the central government in 1956. The major achievements discussed in the paper include: 1. The study concerning the division of malaria regions and the respective control policy of each region; 2. The study on permanent cure for tertian malaria; 3. The study on mediums and carriers of malaria.

TITLE: "Cure of Tertiary Malaria in Children with 210 mg, 180 mg, and 120 mg of Primaquine During Latency"

SOURCE: Peking, Chung-hua Nei-k'o- Tsa-chih (Chinese Journal of Internal Medicine), Vol 12, No. 5, May 64, pp 407-410

ABSTRACT: Tertiary malaria has a wide distribution, and its elimination is an important problem. In foreign countries, the method of small doses and long duration of treatment is generally used for tertiary malaria. This method is not very effective for the tertiary malaria of the Southwest Pacific area, however, the rate of recurrence is as high as 30%. From October, 1961, to May, 1962, during a period of latency, a study was conducted with 210 mg of primaquine (divided into 7 days), 180 mg (divided into 80 days), and 120 mg (divided into 4 days). Other methods were used as control. The result showed that this method is the most satisfactory for tertiary malaria in children.

TITLE: Certain Special Clinical Expressions of Tertiary Malaria

SOURCE: Peking, Chung-hua Nei-k'o- Tsa-chih (Chinese Journal of Internal Medicine), Vol 12, No 5, May 64, pp 411-414

ABSTRACT: Certain special clinical expressions such as cornea, jaundice, and abdominal pain are frequently reported in malignant malaria, but seldom mentioned in tertiary malaria. Of the clinical data for tertiary malaria in the hospital of Shanghai First College of Medicine, there are some obvious symptoms of central nervous system, liver, lung, and kidney involvement. These symptoms, if not understood, may lead to mistakes in diagnosis. This paper reports these symptoms observed in 329 cases of adult tertiary malaria from January, 1958, to October, 1963.

TITLE: A Preliminary Observation of the Effect of Cyclochin on Tertian Malaria in Shanghai

SOURCE: Peking, Chung-hua Nei-k'o Tsa-chih (Chinese Journal of Internal Medicine), Vol 12, No 5, May 64, pp 423-424

ABSTRACT: Cyclochin is the 4-chloroquinum type antimalaria drug. It is not as easily accumulated as atabrin. Cyclochin is currently one of the common drugs for malaria in the Soviet Union. Its synthesis was accomplished by Shanghai Chung-hsi Pharmaceutical Plant in 1962. For the purpose of clarifying its effects as an antimalaria drug, the authors treated 34 children with tertian malaria in latency. Follow-ups in 10 weeks after the treatment was completed revealed protozoans in 93.9% of the cases, but none of the patients developed malaria symptom during the period observed.

TITLE: "Current Studies on Malaria"

SOURCE: Peking, Chung-hua Nei-k'o- Tsa-chih (Chinese Journal of Internal Medicine), Vol 12, No 5, May 64, pp 405-406

ABSTRACT: Great advancements have been made in studies on malaria in recent years. Through extensive surveys and large scale experimentation, the regional distribution of malaria is basically clarified. The species of mosquitoes, their ecological habits, and their relation to the prevalence of malaria are better understood. For the purpose of thorough elimination of malaria, the following key problems are listed in the paper as being in need of concentrated effort: 1. A permanent cure for tertiary malaria must be found. 2. The techniques of fluorescent antibody tracing and others, reported in foreign countries for determining the malaria antibody in the blood of inhabitants of an epidemic area, should be introduced and developed in this country. 3. Although chloroquinum, cyclochloroguanidum, pyrimethaminum, and primaquinum are all being mass produced in China and have become common antimalaria drugs, each has its defects and none is ideal. A more effective and safer drug remains an important problem for future study.

II. JAPANESE B ENCEPHALITIS

STUDIES ON THE PLAQUE-FORMING CHARACTERISTICS OF THREE STRAINS OF JAPANESE B ENCEPHALITIS VIRUS

Ch'en Po-ch'uan (7115/0130/2938), Hsu Chao-hsiang (6079/0340/4382), and Liu Yuan-yuan (2692/0337/0337). *Wei sheng wu hsiieh pao* (*Acta microbiologica sinica*), v. 10, no. 3, 1964, 333-338.

The difference between plaque-forming titer and the mouse-brain LD₅₀ titer, the plaque-forming rate, the rate of development of plaque, and the distribution of different plaque sizes of 3 strains (the A₂ strain, the chick embryo adapted A₂ strain and the Nakayama strain) of J. B. E. virus were studied. Concerning the rate of development in number and in size of the plaques formed by these strains during incubation, it was seen that the rate was evidently greater in A₂ strain than those observed in the other two. Finally, the possible reasons for the differences in plaque-forming characteristics and the relation of the plaque sizes to certain biological properties of these strains of J. B. E. virus, especially in respect to A₂ strain and the chick embryo adapted A₂ strain, were discussed.

INTERFERON FORMATION IN CHICK EMBRYO

Ivanova, M. A. Interferon formation conditions in a chick embryo fibroblast tissue culture infected with Japanese B encephalitis virus. *Bulleten' eksperimental'noy biologii i meditsiny*, no. 2, 1966, 75-77.

Only biologically active Japanese B encephalitis virus induced interferon formation in a chick embryo fibroblast tissue culture monolayer. Interferon formed in infected chick fibroblast cells quickly passed into the surrounding

fluid medium and did not accumulate in the cells. Large doses of heat-inactivated virus did not induce interferon formation in the cells. Preliminary interferon treatment of tissue culture before infection decreased rather than increased fresh interferon production.

EXPERIMENTAL STUDIES ON ACTIVE IMMUNIZATION AGAINST JAPANESE B ENCEPHALITIS; II. THE RELATION BETWEEN THE INDEX OF PROTECTION IN MICE AND THE ROUTE OF CHALLENGE

Hsu Chao-hsiang (6079/0340/4382), Chou Ming-hsien (0719/2494/0341), and Ch'en Li-ts. *Wei sheng wu hsueh pao (Acta microbiologica sinica)*, v. 10, no. 1, 1964, 9-16.

In an attempt to explore the mechanism of immunization of the activated encephalitis B vaccine, the authors compared the protective effects of immunization by brain and subcutaneous inoculation. The relationship between protective action and antibody level was also studied. It was found that mice immunized only once acquired no or only a very weak protection against virus attack through the brain, but very strong protection against subcutaneous attack. Furthermore, protection against small amounts of subcutaneous virus was observed one or two days after immunization. Mice immunized twice acquired a very high protection against subcutaneous attack, and also some protection against brain attack. The protective index was related not only to the amount of vaccine, but also to the interval of infections. In general, lower protection was obtained by injection at shorter intervals than by injection at longer intervals. Protection by immunization persisted for a short time only, even though neutralizing antibodies in the blood stream persisted longer. The relation between the index of protection and the route of infection was also discussed.

STUDIES ON THE VARIATION OF PERIPHERAL PATHOGENICITY OF
JAPANESE B ENCEPHALITIS IN WHITE MICE

Huang Chen-hsiang (7806/4384/4382). *Wei sheng wu hsueh pao*
(*Acta microbiologica sinica*), v. 10, no. 1, 1964, 1-6.

Variation in the toxicity of Japanese B encephalitis virus was studied in mice of different ages. Both intracerebral and subcutaneous inoculation were used, with virus material in all cases taken from the brain. The virulence of virus subcultured intracerebrally decreases over successive generations when injected subcutaneously. Conversely, subcutaneous virulence does not decrease when transmission is by the subcutaneous route. Strains with already lowered virulence regain their virulence when once again transmitted subcutaneously. The incubation period and variation in the decrease of subcutaneous virulence in successive generations of virus transmitted via the intracerebral route were related to age, incubation periods being longer and variation smaller in young mice. It was concluded that there are three stages in virus virulence of cerebrally transmitted strains, a latent period, in which progressive decrease in virulence occurs, and a static period, during which the decrease in virulence becomes stabilized.

STUDIES ON INFECTIOUS RIBONUCLEIC ACID OF JAPANESE B ENCEPHALITIS VIRUS;
IV. THE EFFECTS OF THE VIRUS WITH INFECTED RIBONUCLEIC ACID ON BRAIN
TISSUE RIBONUCLEASE ACTIVITY IN THE MOUSE

Liu Yuan-yuan (2692/0337/0337), and Liu Hua-ch'en (2692/5363/2525).
Wei sheng wu hsueh pao (*Acta microbiologica sinica*), v. 10, no. 1, 1964,
24-30.

Mice were infected with B encephalitis viruses with infective ribonucleic acid, and observations on the changes in ribonuclease activity in brain tissues were made. Ribonuclease activity in the brain tissues of in-

infected mice first increased and then decreased. Injection of virus ribonucleic acid or a large amount of virus material resulted in a more rapid increase in ribonuclease activity. Inoculation of small amounts of viruses caused a slow increase. When the multiplication of viruses in the infected mouse brain reached a certain degree, ribonuclease activity started to decrease. As virus concentration in the brain increased, ribonuclease activity continued to decrease until death, by which time it had fallen below the normal level. If a very small amount or sublethal dose of infective material was inoculated, some or all animals recovered easily within a short time and ribonuclease activity in the brain tissues returned to normal. On the basis of the experimental data, it is believed that the increase in ribonuclease activity in infected brain tissues may be the result of preliminary resistant action of cells against the infection. The decrease of ribonuclease activity in the later stages was probably due to intoxication and impairment of tissue mechanisms by the virus. The relationship between the formation of ribonuclease in cells and the low infectivity in virus ribonucleic acid was discussed.

PRODUCTION OF AN INTERFERON-LIKE SUBSTANCE FROM CHICK EMBRYO CELL CULTURES INFECTED WITH JAPANESE B ENCEPHALITIS VIRUS

Mao Chiang-shen (3029/3068/2773), Hsu Ch'ang-shou (2635/7022/1108), and Huang Chen-hsiang (7806/4394/4382). Wei sheng wu hsueh pao (*Acta microbiologica sinica*), v. 10, no. 3, 1964, 339-343.

An interfering substance with properties similar to interferon was demonstrated in Japanese B Encephalitis virus-infected chick embryo cell cultures. The titer of this substance, as estimated according to the plaque inhibition method with WEE as a challenge virus, varied from 1:32 to 1:128. The dynamics of its production from the infected cell cultures was studied. The results indicated that the maximum inhibitory activity was observed in the cell culture fluid at 48-72 hours after virus inoculation, which was later than the maximum titer of virus multiplication. The maintenance

level of the inhibiting substance in the infected cell was found to be related to the amount of virus inoculated. After the maximum titer of substance had been attained, some lowering of the level was observed when large doses of the virus were inoculated, while it showed no marked decrease for a period of 5 days when small inoculum was used. A comparison of the production of this substance between high (Peking strain) and low (Nakayama strain) peripheral pathogenic strains in cell cultures showed no difference in titer.

DYNAMICS OF INTERFERON PRODUCTION IN CHICK EMBRYO CELL CULTURE INFECTED WITH INFECTIVE RNA OF JAPANESE B ENCEPHALITIS VIRUS

Mao Chiang-sen (3029/3068/2773), and Huang Cher-hsiang (7806/4394/4382). *Wei sheng wu hsueh pao (Acta microbiologica sinica)*, v. 11, no. 3, 1965, 326-329.

Infective RNA of Japanese B encephalitis virus, Peking strain, was extracted from infective mouse brain suspension by the cold phenol method. Dynamics of interferon production and virus multiplication in chick embryo cell culture after infection with infective viral RNA were compared with those infected with complete virus. The results indicate that the interferon production in the viral RNA infected group was always lower and appeared 24 hours later than those infected with complete virus during 120 hours observation. This difference holds true even when the infective dose of viral RNA used is 1 log higher than that of complete virus. No difference in the virus multiplication curve pattern was found between the 2 groups. A possible explanation of the above phenomenon was discussed.

ENHANCEMENT OF JAPANESE B ENCEPHALITIS VIRUS TITER

Mao, Chiang-sen, and Huang, Chen-hsiang. Enhancement of the virus titer of Japanese B encephalitis virus propagated in chick embryo cells by D₂O. *Wei sheng wu hsueh pao* (*Acta microbiologica sinica*), v. 12, no. 1, 1966, 34-38.

Japanese B encephalitis virus when grown in D₂O-treated cells was found to have a higher titer than the control. The difference was found to be greater in the heat-labile Nakayama strain than the more heat-stable Peking strain.

ELECTRON MICROSCOPIC STUDIES ON JAPANESE B ENCEPHALITIS IN TISSUE CULTURE CELLS

P'ang Ch'i-fang (7894/0366/2455), and Chang Li-pi (1728/4409/3880). *Wei sheng wu hsueh pao* (*Acta microbiologica sinica*), v. 10, no. 3, 1964, 294-301.

This paper reports electron microscopic observations concerning the development of JEV in chick embryo fibroblasts and hamster kidney cells. In the early stage of the infection, "dark cells" (cells with marked metabolic activities) appeared among the "bright cells" (cells with less metabolic activity). One of the most distinct changes of the infected cells in the moderate and advanced stages was the formation of "multiple vesicles" in all parts of the cytoplasm, accompanied by the appearance of JEV. The development of JEV could be seen in almost all parts, especially in the vacuoles and matrix substance of the cytoplasm, but not in the nucleus. JEV measured approximately 26-32mu in diameter and appeared round in shape. No intracellular crystal formation could be found in the authors' studies. The release of JEV from the cells was found to be mainly through the vacuoles, which usually contained large numbers of virus particles. The relationship between JEV and the vesicles was discussed.

CONCENTED CAMPAIGN AGAINST JAPANESE ENCEPHALITIS IN THE PRIMORSKIY KRAY
(MARITIME TERRITORY)

Shestakov, V. I., A. I. Mikhayeva, I. N. Plenova, and V. S. Dorokhova.
Zhurnal mikrobiologii, epidemiologii i immunobiologii, no. 5, 1966, 8-14.

An intensive campaign against endemic Japanese encephalitis in the Khasanok region of the Primorskiy Kray involving control of mosquito vectors and protection of the people from insect bites has been in progress since 1960. The tables show results of attempts to eliminate mosquitoes by spraying their breeding places with chemicals. Spraying in early spring produced the best results. Mosquito vectors of Japanese encephalitis in this region are: *C. tritaeniorhynchus* G., *C. bitaeniorhynchus* G., *C. pipiens* L., *A. togol* and *A. esoenis*, Jam. Diethyltoluamide was the most effective mosquito repellent.

TITLE: Study of Japanese encephalitis carriers in the Primorskiy Kray (Maritime Territory)

SOURCE: Meditsinskaya parazitologiya i parazitarnyye bolezni, v. 35, no. 5, 1966, 545-550

TOPIC TAGS: disease vector, animal disease, mosquito, virus disease, encephalitis

ABSTRACT: More than twenty mosquito species were identified in Japanese encephalitis foci in the Primorskiy Kray (both coastal and meadow regions) in 1957-1961. The potential vectors of Japanese encephalitis

among the identified species were: *Culex pipiens* (5% of mosquito collection), *C. bitaeniorhynchus* (1%), *C. tritaeniorhynchus* (0.5%), *A. togoi* (78%), *A. koreicus* (1%), and *A. esoenis* (2%). The population of *C. tritaeniorhynchus*, the chief vector of Japanese encephalitis in meadow foci, has decreased 30—40 times in recent years due to elimination of rice fields. In the coastal area, the chief species attacking man was *A. togoi*, and in fishing villages, *A. togoi* and *Culex pipiens*. In the meadow areas the following species commonly attacked man: *A. dorsalis*, *A. vexans nipponi*, *A. esoenis*, *Anopheles hyrcanus*, and sometimes *Culiseta silvestris amurensis*. Effective mosquito control consisted of treating ponds with insecticides (coastal regions) and serial spraying (meadow foci). Orig. art. has: 1 table and 2 figures.

[W.A. 50]

Shestakov, V. I., and I. N. Polanova. Wintering places of bloodsucking mosquitoes in Japanese encephalitis foci in Primorskiy kray. *Zoologicheskii zhurnal*, v. 44, no. 12, 1966, 1871-1873. AP7001071

Wintering places of adult *Culex* and *Anopheles* mosquitoes in Japanese encephalitis foci in the southern Primorskiy kray were studied in 1962—1963. Vegetable storehouses, inspection wells of water supply lines, caves, cellars, etc., with humidity levels of 80—100%, were most often chosen. Mosquitoes were found in hill sites 150 m above their breeding places. Mass flight of *Culex* mosquitoes to wintering sites occurred in late September—early October (mean temperature 9—16°C). Mean temperature in the wintering places rarely dropped below 0°C. In the spring *Anopheles hyrcanus* mosquitoes left the wintering sites first, in March. *Culex modestus* and *Culex pipiens* mosquitoes became active somewhat later, when the temperature inside the wintering places reached 8—10°C. Most mosquitoes had left the sites by late May—early June. The following species of mosquitoes were found in the wintering places: *Culex pipiens pipiens* (up to 90% of population), *C. vagans*, *C. modestus*, *C. apicalis*, *C. orientalis*, *C. bitaeniorhynchus*, and *Anopheles hyrcanus*.

JAPANESE B ENCEPHALITIS VIRUS AND THE PRODUCTION OF INTERFERON

Wang Shu-sheng (3769/2885/5116), and Huang Chen-hsiang (7806/4394/4382).
Wei sheng wu hsueh pao (*Acta microbiologica sinica*), v. 10, no. 3, 1964,
363-368.

This paper deals with the studies of different methods and degree of inactivation of Japanese B encephalitis virus, Peking strain, on interferon production. Studies on the ability of different degrees of heat inactivated virus to interfere with the homologous virus multiplication also showed that complete inactivation of virus did not interfere with virus multiplication nor with the production of interferon. This further confirms the fact that complete inactivation of virus caused it to lose its power to elicit interferon production.

The fact that interferon is heat stable and Japanese B encephalitis virus can be completely inactivated at 56°C for 45-60 min, together with the finding that completely inactivated material does not influence the virus multiplication nor interferon production, suggest that such a simple method as inactivation may be preferable to the acid dialysis method usually employed for this purpose.

EFFECT OF HIBERNATION ON THE COURSE OF JAPANESE B ENCEPHALITIS VIRUS
INFECTION IN GROUND SQUIRRELS

Wang Yen-kuei (3769/0056/6311). Wei sheng wu hsueh pao (*Acta microbiologica sinica*), 11, no. 3, 1965, 330-334.

These experiments were carried out during winter with hibernating ground squirrels, *Citellus mongolicus ramosus* Thomas. Lethal doses of Japanese B encephalitis virus (Nakayama strain) were inoculated into the brain of soundly torpid squirrels and observations made during and after hibernation. None of the squirrels exhibited signs of illness and no deaths could be attributable to the virus infection.

during 59 days of hibernation. Virus was found in the brain of individual squirrels from the seventh to the 44th day, and the LD₅₀ titers (in mice per 0.03 ml intracerebrally) of the virus varied between 10^{-2.37} and 10^{-3.25}. No virus was isolated from the liver or spleen. After the squirrels were brought to room temperature from the cold cabinet on the seventh to 59th day, all squirrels succumbed after one to three days. Japanese B encephalitis virus was isolated from the brain of these squirrels and LD₅₀ reached values of 10^{-6.25} to 10^{-8.25}. No virus was isolated from the liver and spleen.

JAPANESE B ENCEPHALITIS VACCINE PREPARED FROM MONOLAYER TISSUE CULTURE; 1. VIRUS CULTIVATION AND VACCINE PREPARATION

Wang Yung-chi (3762/3938/2813), Chou Ning-chen (0719/1380/3791), Ku P'ei-wei (7367/0160/7279), Sun Mien (1327/0517), Ma Wen-hsin (7456/2429/0207), Sun Shang-hao (1327/2141/6275), and Li Mei-jung (2621/5919/1369). *Wei sheng wu k'ueh pao (Acta microbiologica sinica)*, v. 10, no. 1, 1964, 31-38.

In 1958, the preparation of a B encephalitis vaccine was begun using chick embryo cells as a culture medium. By 1960, a considerable amount of encephalitis vaccine had been prepared and had begun to be used as a prophylactic agent for encephalitis in man. The authors investigated virus culture and preparation of vaccine. Both chick embryo and mouse brain strain of B encephalitis virus multiplied easily on single-layer chick embryo cells and could be serially passaged for many generations. The toxicity (LD₅₀) of serially passaged viruses did not increase. The growth curve pattern of various strains of the virus was studied and found to be identical with a maximum titer (LD₅₀) ranging from 10^{-5.0} to 10^{-6.0}. Parallel titrations of the virus content both in infected cells and in the corresponding maintenance fluids gave comparable LD₅₀ titers. A culture medium containing seven amino acids may be used as a substitute for No. 199 culture medium in culturing the viruses of B encephalitis. The toxicity of viruses obtained from the two culture media was almost the same, but varied at different culture intervals. In the seven amino acids culture medium, it attained its maximum concentration at 48 hours or somewhat later after inoculation. In No. 199

culture medium, however, it attained its maximum at about 36 hours. For preparing tissue culture vaccines, it is suggested to use mouse brain strain or chick embryo strain as the parent strain, and to maintain the culture temperature of cells and virus strains at 33-37C. When 0.1% formalin was added to the culture media, it was activated within a short time and maintained its antigenicity.

TWO CASES OF SUCCESS IN CHICK EMBRYO ISOLATION OF B ENCEPHALITIS VIRUS FROM BLOOD

Wang Yung-chi (3769/3938/2813), and Li Mei-jung (2621/5019/1369). Wei sheng wu hauch pao (Acta microbiologica sinica), v. 10, no. 1, 1964, 121-123.

Encephalitis viruses from the pathological materials of B encephalitis patients were isolated using chick embryo and mice. Among twenty-one blood samples, there were two positive cases. Two virus strains thus obtained were isolated successfully from the chick embryo but not from mice. From twenty-one spinal fluid samples, there was one positive case, and there were two positive cases from three brain tissue samples. All three positive cases were successfully isolated from the chick embryo and from the mouse and six virus strains obtained. The above eight virus strains have been proved to be B encephalitis viruses by means of the neutralization test, the complement fixation test, and the blood coagulation inhibiting test.

IV. VECTORS

MOSQUITO FOOD SOURCES IN THE LAKE ZAISAN--BLACK IRTYSH
DELTA AREA

Anufriyeva, V. N., and A. A. Yagil'tsev. Food sources of bloodsucking mosquitoes in a focus of ARBO virus infections in the southeast part of the shore of Lake Zaisan and in the Black Irtysh delta (East Kazakhstan oblast, Kazakh SSSR). *Meditsinskaya parazitologiya i parazitarnyye bolezni*, v. 36, no. 1, 1967, 22-32. AP7007782

The food sources of bloodsucking mosquitoes were studied in the summers of 1963 and 1964 in the Zaisan region of East Kazakhstan oblast by the standard methods of analyzing the blood in mosquito stomachs and using baited traps. The following species of mosquitoes were most common in the area investigated: *Anopheles hyrcanus*, *A. maculipennis*, *Aedes caspius*, *Ae. vexans*, *Ae. flavescens*, *Culex modestus*, *C. pipiens*, and *Mansonia richiardii*. It was found that on the shore of Lake Zaisan and in the Black Irtysh delta area (including nearby populated areas), food sources for mosquitoes were cattle, horses, sheep, goats, people, and birds (chiefly migratory birds). Tests of the blood in 626 mosquito stomachs using the precipitation reaction showed that in uninhabited territory and around populated areas in the Black Irtysh delta and floodplain, mosquitoes fed more on wild birds (41%) than on cattle (17%), horses (13%), or humans (20%). In settlements, the chief source of food was cattle (50%). It is probable that the role of birds as mosquito hosts is even more important in wilderness areas. Use of traps containing muskrats or wild birds showed that the greatest number and variety of bloodsucking females were attracted to common pochards (*Authya ferina*), gadwalls (*Anas strepera*), red-necked grebes (*Podiceps grisegena*), carrion crows (*Corvus corone*), and moor buzzards (*Circus aeruginosus*). Tables with a detailed breakdown of the number of mosquitoes of each species in different areas or traps are provided. Traps fixed in the windows and chimneys of houses contained only *Anopheles hyrcanus* mosquitoes, although *A. maculipennis* and *Ae. caspius* also are known to invade houses in this area. The existence of a natural focus of ARBO viruses (equine encephalitis group) in this area was established by the presence of antibodies and viruses in the blood of six species of wild birds and

four species of bloodsucking mosquitoes, and by the demonstration of parasitic connections between mosquitoes and a number of wild bird species, humans, and agricultural animals.

MOSQUITO CONTROL IN CHINA

Ho, Ch'i (0149/3823). Recent progress in study of mosquito control in China. *Chung-kuo k'ung ch'ung hsueh hui erh shih ch'ou nien hsueh shu t'ao lun hui hui k'an*, 1966, 67-69.

AT6030759

The author reviews the progress of studies made on mosquito control in China since 1952, based on discussion at the Medical Insects Group. A total of 99 papers on medical insects were submitted, and only one paper, presented by Professor Li Hui-han (2621/6540/3352) of the Shantung Medical College (Shan-tung i hsueh yuan), was on mosquito control. This indicated that studies on mosquito control had not been adequate, although a nationwide insect control program was well underway. A 1960--1961 study by Li Hui-han and Sun Wen-hsiu (1327/2429/0208) of the Shantung Province Parasitic Disease Control Institute (Shan-tung chi sheng ch'ung ping fang chih so) showed that *Culex pipiens pallens* in Tsou-hsien, Shantung had been controlled with DDT and benzene hexachloride. *Anopheles minimus* was controlled in South China, particularly on Hainan in 1963. Control of *Anopheles hyra-*

Cannus sinensis and *Anopheles ludlowii* began in the Ch'ing-p'u County near Shanghai under the supervision of the East China Entomology Institute (Hua-tung k'un ch'ung yen chiu so) and in Wu-hsing County, Chekiang, under the auspices of the Parasitology Institute of the Chinese Academy of Medical Sciences (Chung-kuo i hsueh k'o hsueh yuan Chi sheng ch'ung ping yen chiu so). Preliminary results were to be available at the end of 1966. Since paddy borers and *Anopheles* species are bred in rice fields, the author proposes that study must be made in order to develop an effective method for simultaneous control of both insects.

MITES AND TICKS OF THE SUBTROPICAL ZONE IN ABKHAZ ASSR
(ACARINA, TYROGLYPHOIDEA)

Kadzhaya, G. Sh. IN: *Akademiya nauk Gruzinskoy SSR. Soobshcheniya*, v. 39, no. 1, 1965, 191-196.

Twenty-five species of Acarina and Tyroglyphoidea comprising $\pm$ 45% of the species of the Georgian SSR and 20% of SSSR fauna were found in the subtropical zone of Abkhaz ASSR during a study conducted mainly in 1961-62. This pest population is serious to agriculture and horticulture. Species registered in Abkhaz SSR are classified as follows: family Tyroglyphidae, 10 genera and 16 species; family Saprotyroglyphidae, 2 genera and 2 species; family Glycyphagidae, 4 genera and 7 species. They are divided into 2 groups according to their adaptation to specific habitats: the synanthropic forms include 13 species found mainly in grain and seeds, tobacco, tea, bulbs, tubers, fruits, cellars of storehouses and granaries, and in wet debris in storehouses, mills, and wine barrels. The field forms include 12 species found in natural surroundings: forest floor, plant refuse, decomposing wood, leaves, and ant hills. The synanthropic population was heaviest where optimal moisture

conditions were maintained. Thus, several thousands of *Aleuroglyphus ovatus* were found per 150-200 ml of flour residues from a water-powered mill. The population density of the field form depended on moisture conditions and on food supply, hay stacks being most heavily infested.

ZOOLOGICAL FACTORS IN THE EXISTENCE OF SEVERAL NATURAL TULAREMIA FOCI

Kucheruk, V. V., I. L. Kulik, N. A. Nikitina, P. A. Panteleyev, M. A. Rubina, and N. V. Tupikova. *Zhurnal mikrobiologii, epidemiologii i immunobiologii*, no. 6, 1965, 80-86.

A July 1956 outbreak of tularemia among water rats (*Arvicola terrestris* L.) living along a brook in the Altai foothills (Krasnogorsk Rayon) was described. Affected animals constituted 27% of the water rat population of the section of the brook where the epizootic occurred and 12% of the total rat population of the brook. The vector was the *Ixodes* tick which in its larval and nymphal stages parasitized chiefly the adult animals. Water was a less common source of infection, for after removal of the sick rats, no other animals became diseased although the brook remained infected. The epizootic was confined to the summer, coinciding with the period of mass infestation of *Ixodes* nymphs. It was also concentrated within a small area. Epizootics in the subalpine brook foci do not spread too far because the individual brook populations have little contact with each other during the summer. All the tularemia foci of the floodplain and subalpine brook types studied shared the following characteristics: the water rat is the universal source of infection, while *Ixodes* ticks serve as a reservoir of the pathogen during the periods between epizootics;

the epizootics occur during periods of peak infestation by the tick nymphs.

MOSQUITOES IN ROCKY AREAS OF THE ILI RIVER BASIN

Isimbekov, Zh. M. IN: Akademiya nauk Kazakhskoy SSR. Izvestiya. no.3, 1966, 71-76.

Mosquitoes are the main component of the blood-sucking insect population of the Ili river basin. Collections were made from May to September 1963 as part of a larger study of virus-carrying insects. At the time of the study no investigation for infection of mosquitoes was carried out because the aim of the study was ecological rather than epidemiological since little was known about species composition and habitat of these insects in this area. The collection area was varied, with clear vertical zonation in ecological areas ranging from desert to forest. Fourteen species and one subspecies were collected from heights between 2000 and 2700 m above sea level. The table shows results of collections.

Table 1. Species Composition and Relative Number of Mosquitoes in Rocky Areas of the Ili River Basin

MEDICAL INSECT CULTURE

Lu, Pao-lin (7120/1405/7792). Chung-kuo k'un ch'ung hsueh hui erh shih chou nien hsueh shi 'ao lun hui hui k'an, 1966, 50-51. AT6030754

The author reviews the progress and discusses major problems in medical insect culture. Problems encountered in development of insect strains in laboratories include difficulties

in mating and ovary development, overcome by Prof. Ho Ch'i (0149/3823) in fertilization of Chinese mosquitoes (*A. sinensis*) by forced mating; conditions for oviposition, including the prevention of retardation in growth and hatching by the use of fermented culture media to stimulate hatching by Hu Neng (5170/5) 74) in 1963; and homogeneity of insect quality, with emphasis on control of culture conditions and population densities to increase breeding efficiency. The author urges extensive studies in order to keep abreast of foreign developments in insect culture. This paper was prepared during discussion by the Insect Bionomics Group on 14 July.

CONTROL OF BITING INSECTS

Mirsayeva, A. G. Conference on the problem of control of bloodsucking insects. AN SSSR. Sibirskoye otdeleniye. Investiya. Seriya biologo-meditsinskikh nauk, no. 2, 1966, 147.

From 25 to 28 January 1966 a meeting was held in Novosibirsk at the Biological Institute of the Siberian Branch of the Soviet Academy of Sciences on control of bloodsucking insects. One hundred and fifty representatives of 69 organizations heard 42 papers. The conference emphasized the biological basis of control of these pests. A number of papers were devoted to the ecology of bloodsucking insects in various regions of the Soviet Union, and related subjects. It was noted that when cattle are massively infested with these pests, milk production declines by 11.5%, and weight gain in calves, by 34%. The results of testing new insecticides and repellents were presented. The most effective was found to be diethyltoluamide. Good results were also obtained with benzinino. The use of protective clothing was discussed, as was the application of aerosols. Areas for further investigation were pointed out, and, in

conclusion, the following recommendations were made:
developing the production of possible insecticides, estab-
lishing a system of territorial stations for pest control,
and further study of the newest methods of controlling
these pests.

TITLE: Studies of the fauna and ecology of bloodsucking mosquitoes in
the Gomel' oblast of the Byelorussian SSR

SOURCE: Meditsinskaya parazitologiya i parazitarnyye bolezni, v. 35,
no. 5, 1966, 607-609

TOPIC TAGS: animal disease, disease vector, mosquito, population study

ABSTRACT: Twenty species of mosquitoes were identified in the Svetlo-
gorak rayon, including 18 bloodsucking species (subfamily Culicoidae)
belonging to the genera *Anopheles*, *Aedes*, *Culex*, and *Theobaldia*, and
two non-bloodsucking species (subfamily Chaoborinae) belonging to the
genera *Chaoborus* and *Nochlonyx*. The most numerous and widespread
species of bloodsucking mosquitoes were *Aedes communis*, *Aedes exorua-*
cians, *Aedes punctor*, and *Aedes maculatus*. The chief breeding places
for *Aedes* mosquitoes were forest and meadow bogs, sinkholes, trenches,
and ditches. The seasonal population of *Aedes* mosquitoes (late April
to early September) varied depending on the biotope. The average
number of mosquitoes collected in 10 minutes was highest in areas of
nettle and *Spiraea* (meadowsweet, etc.) growths. Orig. art. has: 1 fig-
ure.

ABSTRACT:

Aedes rusticus was first observed in the Soviet Union in the Krasnodar region in 1956. Since then, after a cold winter, the insect appears in the early spring and is most common in lightly wooded areas.

SIMULIIDAE OF THE LOWER KAN RIVER

Murav'yeva, T. V. *Simuliidae of the lower Kan River in the Krasnoyarsk region. Meditsinskaya parazitologiya i parazitarnyye bolezni*, no. 1, 1966, 15-19.

In this area 25 species of simuliidae imago and larvae were found. During the entire season, 99.2% of adults consisted of *Simulium galaratum*, *S. morsitans longipalpe*, *Gnus jacuticum* and *Gnus cholodkovski*. The Kan River and the Rybnaya, its largest tributary, are the main breeding places of these bloodsucking black flies. Water temperature is the most important factor determining simuliidae species composition in streams while current speed mainly influences habitat distribution of larvae in the river. *P. alpestre*, *P. tridentatum*, *E. longipalpe*, *E. bicornis*, and *E. shevjakovi* preferred stony bottom areas with a temperature no higher than 10°C. Only one species, *E. aurum*, was collected where current speed was less than 0.5 m/sec.

MOSQUITOES IN THE VICINITY OF NORILSK

Polyakova, P. Ye. IN: *Sibirskoe otdeleniye Akademii nauk SSSR. Izvestiya*, v. 4, no. 1, 1966, 151-153.

Data resulting from collections of flies made in 1963 in the vicinity of Norilsk are summarized in Table 1. As shown, the Talnakh community is dominated by *A. communis* and in Labytnanga, *A. ezoruians*, *A. punctor* and *A. hexodontus* predominate. As shown by Figs. 1 and 2, the mosquito population reaches a peak in July and the mosquitoes themselves are most active during the night hours.

pine forests along the Ob' River. Maximum numbers of mosquitoes were recorded from late May to mid-July. Peak populations varied with the species, however. *Aedes communis* was most numerous in early June and *Aedes punctator* in late June; *Aedes communis* mosquitoes made up 48.0% of the population, and *Aedes punctator* 40.0%. Mosquitoes were most active in the morning and evening hours. It was established that the most favorable temperatures for mosquito activity are between 20°C and 25°C.

MOSQUITO ECOLOGY IN THE TOMSK REGION

Polyakova, P. Ye., and A. G. Hirsayeva. *Meditinskaya parazitologiya i parazitarnyye bolezni*, no. 1, 1966, 35-38.

In 1960, 7624 female mosquitoes from the Asino district of the Tomsk region were captured and examined, and 14 species were found, dominated by *Aedes punctor*, *Ae. communis* and *Ae. cinereus*. Phenology and percentage ratios of individual species, and effects of temperature and light on flight activity were studied in order to plan mosquito control in Western Siberia.

ASSOCIATION: Laboratoriya parazitologii Biologicheskogo instituta SO AN SSSR, Novosibirsk (Parasitology Laboratory, Biological Institute, SO AN SSSR) 23: 246, 36. [LP]

DIPTERA IN THE ANGARA RIVER DISTRICT

Rasnitsin, S. P., S. I. Makarova, and G. A. Shevelova. *Distribution of Diptera, Simuliidae in streams of the Angara River District. Meditsinskaya parazitologiya i parazitarnyye bolezni*, no. 1, 1966, 3-5.

In streams of the Angara River District water temperature is the main influence on the distribution of blackfly larvae. Where the water temperature is 3—10°C *Prosimulium alpestre* predominate; from 11—16°, *Simulium vulgare*; at 21° and above, *Eusimulium aureum*, *E. latipes* and *Hellicha baffinensis*. *P. alpestre*, *S. vulgare*, and *Cnephia edwardsiana* are most numerous. In streams, bloodsucking species seldom occur both in the larval and imago stages and have little practical importance.

tute of Medical Parasitology and Tropical Medicine, Minis-
try of Health SSSR) *COE 116,37* [LP]

BLOODSUCKING DIPTERA IN THE CHERNIZOV REGION OF THE UKRAINE

Shevchenko, A. K. *Meditinskaya parazitologiya i parazitarnyye bolezni*, no. 1, 1966, 28-32.

Forty-nine Dipteran species falling into three families were found in the middle part of the Resna River in the Chernizov region. Species composition, breeding places, and seasonal prevalence were studied. *Anopheles* breeds near the shores of the Seyma and Ubed Rivers. The greatest numbers were found in the Ubed delta. In spring *Sch. matthiesseni* are found principally near the Desna and Seyma. Culicidae were found in greatest numbers in the middle of June in quiet waters and in cisterns. Many *Aedes* species inhabit peat bogs and swamps. In spring *Aedes behningi* and *Ae. intrudens* were prevalent; in early summer, *Ae. excrucians*—in damper places *Ae. maculatus* and *Ae. flavescens*; in July, *Ae. dianteus* and *Ae. cinereus*; and in August, *Ae. vexans*. The land and climate conditions of this area are favorable to this type of insect.

FORECAST OF CHANGES IN THE BLOOD SUCKING INSECT POPULATION NEAR AN ILI RIVER RESERVOIR

Forecast of components of the blood sucking insect population in the Kapchagay'skiy reservoir area

Shumkov, M. A., and A. M. Dubitskiy. AN KazSSR. Vestnik,
no. 1, 1967, 72-73. AP7007179

A forecast of anticipated changes in the population of blood-sucking insects (biting midges, horseflies, mosquitoes, and gnats) when the Kapchagayskiy reservoir is completed is discussed. This desert basin of the Ili River is densely populated with a total of 79 species of bloodsucking insects. The insect population is expected to decrease below the dam as overflow reservoirs dry up and periodic flooding ceases. The population of *Aedes* mosquitoes in this area will drop sharply. Above the dam, the insect population will drop sharply in the first year but recover in 3-4 years, depending on the time of year and rate of filling of the reservoir. *Culex*, *Anopheles*, and *Culiseta* mosquitoes and common species of horseflies and biting midges should find numerous good breeding places around the new reservoir, especially in the shallow waters at the southern end. However, the new conditions will be unfavorable for the malaria mosquitoes *Anopheles maculipennis* and *Anopheles hyrcanus*, especially in the western and northern areas of the reservoir. There is a potential hazard of leishmaniasis if future settlements are created on the relatively pest-free northwest shore of the reservoir, since this area adjoins a natural habitat of sandflies and gerbils. Appropriate measures must be taken in the first year of existence of the reservoir to keep the population of blood-sucking insects under control. [JS]

TITLE: Methods of detecting AEDES mosquito eggs in soil

SOURCE: Meditsinskaya parazitologiya i parazitarnyye bolezni, v. 35, no. 5, 1966, 615-617

TOPIC TAGS: insect, insect control, ~~Aedes~~ mosquito, 30%

ABSTRACT: Soil samples were taken from the Northern Donets River and Lower Don (Lestov oblast) flood plains in September-October, before the autumn rains, and were examined for eggs of six *Aedes* species (*As. caspius*, *As. vexans*, *As. cinereus*, *As. keningi*, *As. flavescens*, and *As. exornotans*). During laboratory examination, air temperature was 24.5—26.5°C, and water temperature, 19—21.5°C. Multiple rehydration and drying of soil specimens showed that mass emergence from diapause in *Aedes* mosquitoes was in February in the steppe zone. In analysis of the soil specimens, hatched larvae were counted, and species was determined for those reaching age III—IV. The number of hatched larvae of a given species served as an index of soil infestation with that species. Orig. art. has: 1 figure

PROTECTION OF DOMESTIC ANIMALS AGAINST BLOOD-SUCKING INSECTS

Teivunin, V. S., I. A. Zakamyrdin, V. V. Kormachov, and G. Kh. Kamay. Class 45, No. 188213. Izobreteniya, promyshlennyye obrabztsy, tovarnyye znaki, no. 21, 1966, 181. AP7001443

Aqueous emulsions of insecticides are usually applied to the skin of domestic animals to protect them against blood-sucking insects (e.g., mosquitos). To increase the effectiveness and to decrease the toxicity of the insecticides, in the proposed method, diethylmercapto-n-butylmethylphosphine thioxide is used as the insecticide.

EFFECT OF VOLGOGRAD RESERVOIR CONDITIONS ON BREEDING OF MOSQUITOES

Viktorov, V. F. The effect of hydrological conditions at the Volgograd reservoir on breeding of bloodsucking mosquitoes in the Volga floodplain. *Meditinskaya parazitologiya i para itarnyye bolezni*, v. 36, no. 1, 1967, 17-22.
AP7007781

The effect on the mosquito population of changing hydrological conditions in the Volga floodplain of Saratov oblast due to creation of the Volgograd reservoir was studied in 1961-1964. Seasonal fluctuations in the mosquito population are determined to a large extent by the amount of water consumed by the Volgograd and Kuybyshev hydroelectric power stations. In the completely flooded lower part of the reservoir, of course, mass breeding of mosquitoes does not occur. In the Saratov-Engels area, most favorable conditions for the development of *Aedes* mosquitoes are created in years of moderate floods in early spring, followed by considerable variations in the water level in spring and summer (as occurred in 1961 and 1962). Under these conditions, mass flights of mosquitoes occur in late May and again in late June. In the Marx-Volsk wooded floodplain, high floods covering large areas with shallow water promote mass breeding of mosquitoes (as in 1960). In the Balakovo-Khvalynsk floodplain, also, higher floods create larger breeding areas (as in 1963). The species composition of mosquitoes in the Engels area is approximately: 63-75% *Aedes vexans*, 11% *A. cantans*, 13% *A. excrucians*, 14% *A. caspius* and *A. dorsalis* and a few examples of *A. geniculatus*, *A. flavescens*, *A. cyprinus*, *A. cataphylla*, *A. pulchritarsis*, *A. detritus*, and *A. leucomelas*. Mass breeding of *Culex modestus* in favorable conditions occurs in July and August. The population of *Anopheles maculipennis* around Saratov-Engels has dropped considerably since the creation of the reservoir. Control of *Aedes* mosquitoes in this area is best attempted when larvae are developing in late April and early May.

INSECTICIDE TRIALS ON PREIMAGINAL AND IMAGINAL Aedes MOSQUITOES

Vinogradskaya, O. N. Tests of insecticides on preimaginal and imago stages of *Aedes* mosquitoes. *Meditsinskaya parazitologiya i parazitarnyye bolezni*, v. 36, no. 1, 1967, 54-60. AP7007784

Laboratory tests of four organophosphorus insecticides were conducted with preimaginal *Aedes* mosquitoes in water from natural biotopes (swamps adjoining the Ob in Tyumen oblast) under temperature conditions simulating the natural environment. Adult mosquitoes were also tested with lindane. Experiments showed that methylnitrophos (0,0-dimethyl 0-3-methyl-4-nitrophenyl thiophosphate) and trichlormetaphos-3 (0-methyl 0-ethyl 0-2,4,5-trichlorophenyl thiophosphate) were most toxic for *Aedes* larvae. The minimum dose of methylnitrophos causing 100% mortality of first- and second-stage larvae was 0.001—0.002 g of commercial preparation per m^2 , or 0.016 g/ m^2 for larvae of stages III and IV, or 0.7 g/ m^2 for pupae. For trichlormetaphos-3, the minimum doses were 0.0032 g/ m^2 for first- and second-stage larvae, 0.032 g/ m^2 for third- and fourth-stage larvae, and 4 g/ m^2 for pupae. DDVP and methylacetophos (0-dimethyl S-carbethoxy-methyl thiophosphate) were less effective against larvae. The doses for larval stages should be considered approximate, since the insecticidal activity of organophosphorus compounds in water varies with the temperature and pH of the medium, the character of bottom sediment, the vegetation, and other factors. For adult *Aedes* mosquitoes, the most toxic preparations were DDVP (0,0-dimethyl 0-2,2-dichlorovinyl phosphate) with a minimum dose causing 100% mortality of 0.0007 g/ m^2 , and 10% lindane dust, with a minimum dose of approximately 0.005 g/ m^2 . Smaller doses of insecticides were effective for smaller mosquitoes. All the above doses must be verified under natural conditions.

Vladimirova, V. V. Experience of mass breeding of *Aedes aegypti* L. *Meditinskaya parazitologiya i parazitarnyye bolezni*, v. 35, no. 6, 1966, 719-723. AP7001494

A method of mass breeding of *Aedes aegypti* mosquitoes using wall cabinets with special tanks for raising larvae was described. This method, which can produce 2000—3000 mosquitoes in three to six days, has been in use since 1962. Good results are obtained with infusions of guinea pig excrement and brewer's yeast in the larval tanks. The infusion is partially replenished each week, and completely every two to three months. Temperature in the cabinets is kept at 26—28°C, and humidity at 70—80%. Adult mosquitoes intended for insecticide testing are kept in breeding places with tanks containing cotton moistened with glucose. Mosquitoes destined for egg-laying are allowed in addition to feed on guinea pigs or mice for three to four hr a day. This method of mass breeding of mosquitoes requires minimal time and attention, since larvae are automatically fed into tanks, and imagoes fly out of the tanks into the breeding places. V. RELATED ATMOSPHERIC AND
ENVIRONMENTAL ASPECTS

SETTLING OF COARSELY DISPERSED AEROSOLS IN THE ATMOSPHERIC BOUNDARY LAYER

Dunakiy, V. F., I. F. Yevdokimov, V. H. Krasil'nikov, K. P. Mikulin, Yu. S. Khol'kin, and Z. M. Yuzhnyy. *Settling of coarsely dispersed aerosols on the underlying surface of the ground. Leningrad. Glavnaya geofizicheskaya observatoriya. Trudy, no. 106, 1966. Voprosy atmosferynoy diffuzii i zagryazneniya vozdukh (Problems of atmospheric diffusion and air pollution), 148-161.* AT6035526

Results are presented for field experiments investigating the diffusion of coarsely dispersed aerosols ejected from linear sources into the surface boundary layer of the atmosphere and the settling of the dispersed phase on the surface of the ground. The investigations (June-July 1960 and 1961) involved flights of an AN-2 airplane (170 km/hr speed) fitted with spraying equipment, at heights of 100-600 m above a flat area measuring 10 x 20 km covered with rather homogeneous but not dense vegetation averaging 20-30 cm in height. The spray was a water-glycerin (60% technical grade) mixture. The airplane was flown along the windward side of the test field at a given height approximately perpendicular to the wind direction. A total of 200-400 check points were spaced 500 m apart in transverse rows, 500 or 1000 m apart. Two flat troughs (0.125 m²) and one glass plate (9 x 12 cm) were used to determine by fluorescence analysis the amount of settled liquid; coated glass plates were used to make a microscopic analysis of the precipitate. After the experiment, the liquid in the troughs was washed off with a specific amount of 0.1% NaOH and 0.1% OP-7 solutions in distilled water. The fluorescein concentration in the wash was measured with an EF-3 fluorometer and the dispersed phase settled in each trough was calculated. The droplets settled on the glass plates were examined in transmitted light under a microscope equipped with an eyepiece and reticle.

Curves were constructed of the total droplet density versus the distance from the source. Subsequent analysis showed that the observed systematically higher values obtained with the fluorescence analysis were due to failure to take account of the natural background effect. However, the agreement was good enough to indicate that both methods were valid.

Meteorological conditions existing during each experiment were checked by taking gradient measurements of the mean wind speed, temperature, and humidity at two points on opposite ends of the field at heights of 0.4 and 1.6 m, and at heights of from 25 to 600 m at one of these points. Twelve experiments were selected for quantitative comparisons; they had been conducted with uniform spraying during steady and favorable (in respect to wind direction) winds and uniform temperature stratification in the surface boundary layer of the atmosphere.

The most important fact determined during the experiments was that such aerosols may settle over areas as large as hundreds of square kilometers in periods measured in tens of minutes or hours, i.e., under conditions when meteorological conditions are functions not only of height, as is usually assumed in the theory of atmospheric diffusion, but of all three spatial coordinates and time. [ER]

FILTRATION OF AEROSOLS BY LAYERS OF FIBROUS MATERIALS

Kolganov, V. A., L. V. Radushkevich, and V. G. Sazanova. Experimental investigation of the process of filtering aerosols with layers of fibrous materials. Zhurnal prikladnoy khimii, v. 39, no. 12, 1966, 2725-2730. AP7003142

The first results obtained in an experimental investigation of aerosol filtration using layers of fibers are presented as a continuation of an earlier study of the precipitation of aerosols on single isolated fibers of various diameters. The experiments were conducted with three-dimensional layers of increasing porosity. The following materials were employed in the experiments: 1) staple fibers of industrial grade nitron with an average diameter of 16 μ , 2) FPP-15 fibrous material with an average fiber diameter of 1.5 μ , and 3) fiberglass with an average diameter of 0.8--0.9 μ . Procedures for preparing the filters from each type of fiber are described. The experiments were conducted with polydispersed polystyrene and vegetable oil aerosols having

known particle-diameter distribution. Aerosol particles first were counted with a continuous flow VDK-4 ultramicroscope to determine initial concentrations, passed through test filters at a constant flow speed, and then redetermined after filtration.

The effectiveness of precipitation η is determined from the filtration coefficient K with the following assumptions: the layers of filter material have uniform porosity, identical diameter, and play the same role in the precipitation of aerosol particles (illustrated in text). Characteristic features of the precipitation of aerosol particles in the three types of filter material are discussed in detail.

The results of these experiments showed that in making the transition from isolated single fibers to layers of the same fibers, the filtration process is complicated by the effects of various factors caused by the structural characteristics of the layers. The following conclusions were drawn: 1) Comparative experiments showed that the nature of the dependence of effectiveness of precipitation on particle sizes for fibers in a layer differed from that for isolated fibers of the same diameter at identical flow speeds. 2) The change from isolated fibers to single fibers in a layer usually decreases the selectivity of aerosol particle sizes. 3) These peculiarities associated with precipitation on fiber layers can be explained by the effect of their structure, the arrangement of fibers, and packing irregularities.

BACTERIOLOGICAL WEAPONS

Myasnenko, A. Injurious factors. Bacteriological weapons. Voyennyye znaniya, no. 2, 1967, 27-28. AP7009494

Bacteriological weapons are discussed as part of a new series of popularized civil-defense articles, designed to supplement the 21-hr civil-defense course. Material for bacteriological weapons should meet the following require-

ments: it should grow on artificial nutrient media, remain viable and infectious for long periods under adverse conditions, resist drying, infect rapidly and in small doses, and cause severe diseases which are difficult to cure. Diseases which are rare and little studied are preferred. The microorganisms causing plague, anthrax, tularemia, brucellosis, glanders, melioidosis, scrub typhus, smallpox, ornithosis, and yellow fever are considered suitable for these purposes. American military specialists in bacteriological weapons consider aerosols the most effective means of dispersing these agents. Clouds or fogs containing microorganisms can be created over several thousand square kilometers of territory. Furthermore, man can be infected by aerosols of diseases not normally spread by this route, such as scrub typhus or yellow fever. Carriers of the chosen microorganisms, such as infected ticks, can also be airdropped in special containers. [JS]
