SUMMARY

There is frequent need to obtain information as to the attributes, characteristics, reliabilities, and capabilities of production items. Such information is required for logistic planning, tactical operations, and alternative uses and to determine that the supplier has met contractual specifications. The normal procedure involves the testing of a number of items that have been randomly chosen from a production lot.

In one type of acceptance sample testing, it is assumed that each item will be either a success or a failure, and no allowance is made for varying degrees of success. Upon completion of the testing, it is desired to determine, at a certain level of confidence, limits on the reliability of the entire lot from which the sample was selected.

Graphs are given here that may be used to determine either one-sided or two-sided reliability limits at any desired confidence level, based on the success ratio for the tested items. The sample is assumed to have been drawn from a population with unknown reliability p (percentage of good items). The graphs are for sample sizes from 1 to 100 and also from 100 to 1,000 in multiples of 10.

Two basic assumptions are possible in random sample testing: that of the binomial distribution and that of the hypergeometric distribution. The theory and the graphs of this report are based upon the binomial distribution. The binomial distribution is usually sufficiently accurate, but formulas for approximating the hypergeometric distribution from the binomial distribution values are given in the appendix.

INTRODUCTION

A common contract provision for acceptance of production items is a given probability of successful performance under specified conditions. An associated confidence level is usually either implied or stated. An accepted factor in any estimate of the quality of the produced item is this performance probability, often called reliability.

In 100-percent testing, how many units passed and how many failed is known, and thus the reliability is known. In sample testing, only the success and failure ratios for that sample and that test are known. This success ratio for a given test is the best estimate of the probability of successful performance on that test of an individual item of the remainder of the group of items. The probability of a randomly selected item of the untested items passing or failing the test is between 0 and 1, but any value between these limits has an associated upper and lower confidence level based on the sample test results. Correspondingly, for a given confidence level, there is an associated one-sided or two-sided population reliability limit. The definition of these confidence levels, as used here, together with their adequacy, is discussed in the section entitled "Theory."

This report presents graphs of the entire spectrum of confidence levels and the associated reliabilities determined by the sample testing results. The graphs are based on the binomial distribution theory. There are 190 graphs given, one for each sample size from 1 to 100, and from 100 to 1,000 in multiples of 10.

From these graphs and the actual number of successes, upper reliability bounds and associated confidence levels, and lower reliability bounds and associated confidence levels can be read. Reliability intervals for given levels of confidence can also be read. Conversely, the number of successes required for a particular sample to meet a stated reliability at stated confidence levels can be determined. The graphs can also be used to determine whether the sample falls within predetermined risk levels.

The binomial distribution theory assumes that the reliability of the items in the population remains unchanged as the sample is selected. For a finite population or a nonreplacement sampling plan, the exact theory is that of the hypergeometric distribution. Since the population size is usually large compared to the sample size, the binomial result is a good approximation to the hypergeometric. Hypergeometric distribution tables are given in reference 1. Formulas for approximating the hypergeometric distribution from binomial distribution values are discussed in the appendix.

SYMBOLS

n	Sample size
s	Number of items in a sample that pass a given test
p	Population reliability
p_ℓ	Lower reliability limit
$C_\ell(p_\ell; s,n)$	Confidence level that $p \geq p_\ell$, given s and n
p_u	Upper reliability limit
$C_u(p_u; s,n)$	Confidence level that $p \leq p_u$, given s and n
$1 - C_\ell(p_\ell; s,n)$	Risk that $p < p_\ell$
$1 - C_u(p_u; s,n)$	Risk that $p > p_u$

THEORY

Consider the determination of an unknown population reliability p, based on the testing of a sample of n items randomly drawn from the population. The probability $\phi(j)$ of obtaining exactly j successes within the n items tested is given by the binomial distribution

$$\phi(j) = \frac{n!}{j!(n-j)!} p^j (1-p)^{n-j} \tag{1}$$

The probability of obtaining at most s - 1 successes in the sample of n is $\sum_{j=0}^{s-1} \phi(j)$. This probability is used by many authors as the definition of the confidence level that the reliability is at least p_ℓ, given s and n (see references 2 and 3); that is,

$$C_\ell(p_\ell; s,n) = \sum_{j=0}^{s-1} \phi(j) = 1 - \sum_{j=s}^{n} \phi(j) \tag{2}$$

It should be noted that, because of the discrete nature of the distribution, the probability that the reliability is at least p_ℓ is, in general, greater than $C_\ell(p_\ell; s,n)$. This is also pointed out in reference 3. In other words, the definition used for the level of confidence is conservative, and is most conservative when the size of the sample is small.

Conversely, the confidence level that the reliability is at most p_u, given s and n, is defined by

$$C_u(p_u; s,n) = \sum_{j=s+1}^{n} \phi(j) = 1 - \sum_{j=0}^{s} \phi(j) \tag{3}$$

Again, $C_u(p_u; s,n)$ is conservative.

Note that, for s = 0, $C_\ell(p_\ell; s,n) = 0$ for any p_ℓ greater than 0. For s = n, $C_u(p_u; s,n) = 0$ for any p_u less than 1. Note also that, if $p_u = p_\ell$, $C_u(p_u; s-1,n) = 1 - C_\ell(p_\ell; s,n)$. This fact makes it possible to combine graphs for p_ℓ and p_u.

THE GRAPHS

The graphs are given in figures 1 through 190. A separate graph is given for each sample size, n, from 1 to 100 and from 100 to 1,000 in multiples of 10. The vertical scale on the left side of each graph is for $C_\ell(p_\ell; s,n)$ and that on the right side is for $C_u(p_u; s,n)$. The graphs for n from 1 to 50 give separate curves for all possible number of successes, s, from 1 to n for p_ℓ, and from 0 to n - 1 for p_u. For n > 50, the values of s for which curves are actually plotted are entered on the appropriate curves. These values were chosen so that linear interpolation in the horizontal direction will give three-decimal accuracy. In most cases, if the graphs are plotted and read precisely, the error in linear interpolation in the horizontal direction will be considerably less than 0.001.

EXAMPLES

For the following examples, assume that n = 10 and s = 5. Then the graph of figure 10 is used, the fifth curve being used for p_ℓ and the sixth curve for p_u.

Example 1

Determine a 90-percent confidence interval for the population reliability.

In general, to determine the C% confidence level (two-sided symmetric interval) use $C_u = (1 + C)/2$ to determine p_u and $C_\ell = (1 + C)/2$ to determine p_ℓ. The reliability interval for the C% confidence level is then

$$p_\ell \leq p \leq p_u$$

For this problem,

$$C_\ell = \frac{1 + 0.9}{2} = 0.95$$

and

$$C_u = \frac{1 + 0.9}{2} = 0.95$$

Then from the graph of figure 10, p_ℓ is determined to be 0.22, and p_u is determined to be 0.78. Thus at the 90-percent confidence level, the required reliability interval is given by $0.22 \leq p \leq 0.78$.

Example 2

For

$$C_\ell(p_\ell; 5,10) = 0.8, \; p_\ell \approx 0.33$$

For

$$C_u(p_u; 5,10) = 0.8, \; p_u \approx 0.675$$

Thus for a 60-percent confidence interval,

$$0.33 \leq p \leq 0.675$$

Example 3

For

$$C_\ell(p_\ell; 5,10) = 0.9, \; p_\ell \approx 0.265$$

For

$$C_u(p_u; 5,10) = 0.9, \; p_u \approx 0.735$$

Thus for an 80-percent confidence interval,

$$0.265 \leq p \leq 0.735$$

NUMERICAL ANALYSIS

For computational purposes, using equation (1), it is convenient to write equation (2) in the form

$$C_\ell(p_\ell;\, s,n) = \frac{n!}{(s-1)!\,(n-s)!} \int_{p_\ell}^{1} x^{s-1}\,(1-x)^{n-s}\,dx \tag{4}$$

Then

$$\frac{\partial C_\ell(p_\ell;\, s,n)}{\partial p_\ell} = -\frac{n!}{(s-1)!\,(n-s)!}\; p_\ell^{s-1}\,(1-p_\ell)^{n-s} \tag{5}$$

and

$$\frac{\partial^2 C_\ell(p_\ell;\, s,n)}{\partial p_\ell^2} = -\frac{\partial C_\ell(p_\ell;\, s,n)}{\partial p_\ell} \times \frac{(n-1)\left(p_\ell - \dfrac{s-1}{n-1}\right)}{p_\ell(1-p_\ell)} \tag{6}$$

For $0 < p_\ell < 1$, the only point of inflection is at $p_\ell = (s-1)/(n-1)$. Equations (1), (2), and (5) in logarithmic form were used to evaluate $C_\ell(p_\ell;\, s,n)$ and $[\partial C_\ell(p_\ell;\, s,n)]/(\partial p_\ell)$ at $p_\ell = (s-1)/(n-1)$.

For $(s-1)/(n-1) < p_\ell < 1$, $C_\ell(p_\ell;\, s,n)$ was evaluated by numerical integration. The formula that was used is

$$C_\ell(p_\ell + h;\, s,n) = C_\ell(p_\ell;\, s,n)$$

$$+\frac{h}{2}\left[\frac{\partial C_\ell(p_\ell + h;\, s,n)}{\partial p_\ell} + \frac{\partial C_\ell(p_\ell;\, s,n)}{\partial p_\ell}\right]$$

$$-\frac{h}{12}\left[\frac{\partial^2 C_\ell(p_\ell + h;\, s,n)}{\partial p_\ell^2} + \frac{\partial^2 C_\ell(p_\ell;\, s,n)}{\partial p_\ell^2}\right]$$

The first derivative was calculated by the equation (derived from equation (5))

$$\frac{\partial C_\ell(p_\ell;\, s,n)}{\partial p_\ell} = \frac{\partial C_\ell(p_{\ell_0};\, s,n)}{\partial p_\ell} \left(\frac{p_\ell}{p_{\ell_0}}\right)^{s-1} \left(\frac{1-p_\ell}{1-p_{\ell_0}}\right)^{n-s}$$

The second derivative was calculated by equation (6).

For $0 < p_\ell < (s - 1)/(n - 1)$, $C_\ell(p_\ell; s,n)$ was calculated by the equation (derived from equations (1) and (2))

$$C_\ell(p_\ell; s,n) = 1 - C_\ell(1 - p_\ell; n + 1 - s,n)$$

For $s = 1$, $C_\ell(p_\ell; 1,n)$ was calculated by the equation (derived from equations (1) and (2))

$$C_\ell(p_\ell; 1,n) = (1 - p_\ell)^n$$

An estimate of the error in the method can be obtained at $p_\ell = 1$, since

$$C_\ell(1; s,n) = 0$$

The maximum deviation of the calculated value of $C_\ell(1; s,n)$ from 0 was less than 2×10^{-6}.

APPENDIX

CONVERSION FROM BINOMIAL TO HYPERGEOMETRIC DISTRIBUTION

Reference 1, page 19, gives formulas for approximating the hypergeometric distribution if results for the binomial distribution (such as the graphs of the present report) are given.

Let

N = lot size

n = sample size

s = number of "successful" items in sample

$C_\ell(p_\ell, s,n)$ = confidence level

p_{ℓ_0} = lower reliability for the binomial distribution (provided by the graphs)

p_ℓ = lower reliability for the hypergeometric distribution

Then, from reference 1,

$$p_\ell \approx \frac{1}{N}\left[Mp_{\ell_0} + \frac{1}{2}(s-1) - \frac{\delta}{24M}\right]$$

where

$$M = N - \frac{1}{2}(n-1) - \frac{1}{2}$$

and

$$\delta = \left(\frac{1}{1-p_{\ell_0}} - 1 + p_{\ell_0}\right)(n-s+1)^2 + \left(p_{\ell_0} - \frac{1}{p_{\ell_0}}\right)s^2$$

$$+ \left(2p_{\ell_0} - 1\right)\left[(s-1)(n-s) - 1\right] + \frac{1}{p_{\ell_0}} - \frac{1}{1-p_{\ell_0}}$$

As an example, consider $N = 25$, $n = 20$, $s = 13$, and $C_\ell(p_\ell; s,n) = 0.7$. From figure 20, $p_{\ell_0} \approx 0.565$. Then

$$\delta = \left(\frac{1}{0.435} - 0.435\right)(64) + \left(0.565 - \frac{1}{0.565}\right)(169) + (0.13)(83) + \frac{1}{0.565} - \frac{1}{0.435}$$

and

$$p_\ell \approx \frac{1}{25}\left[(15.5)(0.565) + 6 - \frac{\delta}{(24)(15.5)}\right] = 0.598$$

If δ is taken as zero, calculations give $p_\ell = 0.590$. From the tables of reference 1, the true value of p_ℓ is 0.600.

Again, consider N 25, n 10, s 8, and $C_\ell(p_\ell, s,n) = 0.6$. From figure 10, $p_{\ell_0} \approx 0.705$. Then

$$\delta = \left(\frac{1}{0\ 295} - 0\ 295\right)(9) + \left(0.705 - \frac{1}{0.705}\right)(64) + (0\ 41)(13) - \frac{1}{0.705} - \frac{1}{0.295}$$

and

$$p_\ell \approx \frac{1}{25}\left[(20.5)(0.705) + 3.5 - \frac{\delta}{(24)(20.5)}\right] = 0.719$$

If δ is taken as zero, calculations give $p_\ell = 0.718$. From the tables of reference 1, the true value of p_ℓ is 0.720.

According to reference 1, δ can usually be taken as zero if $n < 0.4N$.

The corresponding formula for p_u is

$$p_u \approx \frac{1}{N}\left(Mp_{u_0} + \frac{1}{2}s - \frac{\delta}{24M}\right)$$

where

$$M = N - \frac{1}{2}n + \frac{1}{2}$$

and

$$\delta = \left(\frac{1}{1 - p_{u_0}} - 1 + p_{u_0}\right)(n - s)^2 + \left(p_{u_0} - \frac{1}{p_{u_0}}\right)(s + 1)^2$$

$$+ (2p_{u_0} - 1)\left[s(n - s - 1) - 1\right] + \frac{1}{p_{u_0}} - \frac{1}{1 - p_{u_0}}$$

Consider N = 25, n = 20, s = 14, and $C_u(p_u; s,n) = 0.78$. Figure 20 gives $p_{u_0} \approx 0.792$. Then

$$\delta = \left(\frac{1}{0.208} - 0.208\right)(36) + \left(0.792 - \frac{1}{0.792}\right)(225) + (0.584)(69) + \frac{1}{0.792} - \frac{1}{0\ 208}$$

and

$$p_u \approx \frac{1}{25}\left[(15.5)(0.792) + 7 - \frac{\delta}{(24)(15.5)}\right] = 0\ 761$$

If δ is taken as zero, calculations give $p_u = 0.771$. From the tables of reference 1, the true value of p_u is 0.760.

Again, consider N = 25, n = 10, s = 6, and $C_u(p_u; s,n) = 0.74$. Figure 10 gives $p_{u_0} = 0.735$. Then

$$\delta = \left(\frac{1}{0.265} - 0.265\right)(16) + \left(0.735 - \frac{1}{0.735}\right)(49) + (0.47)(17) + \frac{1}{0\ 735} - \frac{1}{0.265}$$

and

$$p_u \approx \frac{1}{25}\left[(20\ 5)(0\ 735) + 3 - \frac{\delta}{(24)(20\ 5)}\right] - 0\ 720$$

If δ is taken as zero, calculations give $p_u = 0\ 723$ From the tables of reference 1, the true value of p_u is 0 720.

ABSTRACT

Graphs are given for the determination of the upper and lower reliability confidence limits as defined by the number of successes in a random sample test. The graphs are for sample sizes from 1 to 100, and also from 100 to 1,000 in multiples of 10, and any number of successes. Two reliability results can be read directly from the graphs: the probability confidence that the reliability is at least p_ℓ, and that it is at most p_u.

The number of successes required for a particular sample to meet stated reliability confidence levels can be read. The graphs can also be used in determining whether the sample falls within predetermined risk levels.
