Preface

One of the primary functions of the Technical Information Section of the USAF Environmental Technical Applications Center (ETAC) is to locate reference material requested by the various governmental agencies and those civilian organizations completing government contracts. The requests are generally initiated to aid in the solution of specific problems. However, many of these bibliographies represent a substantial listing of pertinent sources which, having been compiled, could prove very beneficial to other researchers with similar interests in subject matter or area of coverage. It is with this in mind that USAF ETAC publishes certain reference listings such as this bibliography. It is believed that, by publication and distribution of these consolidated reference lists, much of the time-consuming reference-searching of the researcher can be eliminated.

Inclusion of an item in this listing does not constitute an endorsement of the information included therein by the DOD, USAF, Air Weather Service, or USAF ETAC. It also must be noted that references selected for this bibliography should not be construed as being the best or only references available as many excellent papers, reports, etc. were no doubt overlooked during the limited search period allotted the author for this project.

Introduction

This bibliography was compiled as a by-product of the regular reference-searching that characterizes the normal workload of the Technical Information Section, USAF ETAC. Many of the abstracts herein were taken from the publications themselves, many from Meteorological and Geostrophysical Abstracts (Amer. Met. Soc.), and others were prepared by members of the Technical Information Section of USAF ETAC. The individuals identified below are credited with the preparation of one or more abstracts shown in this publication.

Since only a limited time was available to the authors to compile this reference listing, it is very possible that, in some cases, an author's best work is not the item we have included. Furthermore, some important papers, reports, summaries, etc., undoubtedly have been completely overlooked in our search and we offer our apologies for such unintentional oversights.

It will be noted that references in this bibliography are listed alphabetically by author for the four segments (General references, Belgium, Luxembourg, and Netherlands) but the items are numbered consecutively without a break for the segments. For convenience, a subject index is furnished on pages vii and viii. A locator map of the country precedes each section. Stations shown are only a sampling and are not meant to be an official station list of the country. In the left margin opposite each item, the publication date and the language(s) of the reference are shown. Each item lists a source at which the article can be located either by library accession number, AD number, or other indicator. Generally, most references were

located within the Washington, D.C. area. Abbreviations denoting the various libraries are identified under Index to Source Symbols below.

Index to Source Symbols

Census	Census Bureau Library, FOB 3 Suitland, Md.
DAS	Atmospheric Sciences Library, ESSA, Silver Spring, Md.
DAS P Col	Periodical Collection, Atmospheric Sciences Library, Silver Spring, Md.
DLC	Library of Congress
DLC Gov. Pub. R. Rm.	Library of Congress, Government Publications Reading Room
DNAL	National Agricultural Library, Dept. of Agriculture, Beltsville, Md.
IPB	Information and Publications Branch, USAF ETAC

Bibliographies. During the reference search to accomplish this listing, the bibliographies entered below were noted and are considered excellent compilations of pertinent references:

Roman, Simon J. An Annotated Bibliography of Climatic Maps for Belgium and Luxembourg, F.A.S., Office of Climatology, Weather Bureau, Wash., D.C., Apr 1961. DAS M(016) U587be Maps, and AD 660849.

Wallace, J.A. An Annotated Bibliography on the Climate of Luxembourg. U.S. Dept. of Commerce, Weather Bureau, WB/BC-53, Wash., D.C., Jun 1962, 12 p. AD 660673.

Grimes, Annie S. and Weight, Marie L. Annotated Bibliography on Climate Maps of the Netherlands. Wash., D.C., U.S. Weather Bureau, Jan 1961. 7 p, 24 titles, annotated. DAS M(016) U587ne.

Netherlands Royal Meteorological Institute. Report of the Netherlands on National Climatological Activities 1955-1969, Rept. to WMO Secretariat, De Bilt, 1969, 3 p. 1PB Files.

The author wishes to thank Mrs. Edna G. Robinson, USAF ETAC for her excellent work in arranging and typing the numerous references in this bibliography.

The valuable assistance obtained from personnel of the various libraries in the Washington, D.C. area is gratefully acknowledged; their efforts facilitated the task of reference searching for this publication.

...Numerous studies, dating from 1783, have been conducted on cyclone and anticyclone paths. This study discusses movement and generation of pressure centers, both cyclones and anticyclones, from a theoretical and climatological point of view. It discusses, by month, the pressure system paths over Europe; areas of genesis; and the relationship of paths to 500-mb circulation. Cyclogenesis on the lee side of a terrain barrier is discussed in the light of the conservation of potential vorticity. Pettersen's development formula is used to show the effect of landlocked bodies of water on the genesis of pressure systems. Cyclone and anticyclone tracks vary from season to season, month to month. The tracks, shown on charts, are discussed in the light of these variations. There are favored latitudes for cyclogenesis (40, 49-57, and 70N), as well as favored areas. The areas and factors affecting genesis are discussed. There is a striking similarity between the axis of maximum cyclone frequency and maximum west wind. There is also a similar tendency for anticyclone tracks. The mean wind features correlate with pressure system paths. The correlations and other features of the 500-mb circulation are discussed. ...The 3 types of water balances occurring in Belgium and the Grand Duchy of Luxembourg are illustrated by means of graphs for 3 characteristic stations (Leper, Stavelot, Baraque Michel). The water balance is calculated for each station with the aid of nomograms and auxiliary tables. Most elements calculated in the water balance are mapped (annual and 4 seasonal maps); seventeen numerical tables illustrate some seasonal and geographical textures. The published maps show the distribution of: a) annual and seasonal observed mean temperature; b) annual and seasonal calculated potential evapotranspiration; c) annual and seasonal observed mean precipitation; d) annual and seasonal calculated actual evapotranspiration; e) annual accumulated potential water loss; f) period and duration of accumulated potential water loss; g) annual and seasonal calculated water deficit; h) period and duration of water deficit; and i) annual and seasonal calculated water surplus. ...This study is based on data and tables of measurements from the meteorological network of the Dept. of the Air Routes, for 1945-1961. The authors deal principally with data from 4 stations: Ostend (lower Belgium), Melsbroek (middle Belgium), Saint Hubert (upper Belgium) and Luxembourg (Grand Duchy). Rawinsonde measurements made at the Royal Met. Inst., Uccle-Brussels for the period 1952-1959 are included. General consideration is given to surface and upper air winds; turbulence, variation with altitude, representation, and measurement. Figures and tables include data on: mean wind, relative frequency of strong winds, relative

6. (cont)

frequency of calms, resultant direction of wind, persistence and wind regime, monthly and seasonal variations, diurnal variations, and variation with the height. (AV)

[Statistical Characteristics of Upper Air Winds for the North Atlantic-European-Near Eastern Area], Berichte des Deutschen Wetterdienstes, No. 105, Band 14, Offenbach a.M., 1967, 8 p, 44 maps. DAS M(055) G373 ba.

1967

German

...The circulation conditions of the lower stratosphere in the North Atlantic-European-Near Eastern Region and upper wind conditions at 225 mb and 96 mb have been examined. Radiowind measurements mainly were taken as a base. To obtain a network of points of intersection of coordinates these measurement results were completed from synoptic upper-air charts -- for the above mentioned levels -- in using cyclostrophic wind and by interpolation to a universe of wind values free of gaps. On the basis of such homogeneous material some statistical characteristics of upper wind have been computed and represented on regional maps for the North Atlantic-European Region with windroses, isotachs, mean vector wind, persistence as well as zonal and meridional standard deviation. In doing so the representativeness of the basic material was checked. Considerations based on the comparisons of these results yielded some essential features of the regional distribution of these upper wind parameters which appear interesting in relation to atmospheric circulation. Statistics for the 55°N 10°E area are applicable to the Benelux nations. (Pt. Author Abs.)

...Deterioration of grassland by the exceptional drought of 1959 has been evaluated thru estimation percentage of green grass 4-6 days after the rain began. Based on a study of the relation between grass vegetation, soil conditions, and climate, the authors test their conclusions upon grassland on known soils. The results show some lack of consistency, mainly due to nonpedological factors (maintenance and use of grassland). The salient pedological factor seems to be the moisture degree of the soil. Soil-texture is important on dry soils. Depth and character of the subsoil are of some importance, especially within critical moisture limits. (Author)

...This study deals with the following: a brief description of the physical geographic characteristics of the basin; monthly, seasonal, and annual amounts of precipitation, including probability of dry and wet months, seasons and years; monthly, seasonal and annual normals, etc.; daily precipitation including distribution of seasonal and annual frequencies of daily precipitation, probability of the annual and seasonal daily precipitation of at least 20, 25, 30 and 35 mm, etc.; precipitation in the course of periods of varying duration; dry and wet periods; nonhomogeneity of precipitation over the basin; spatial distribution of precipitation over the basin; and snow cover. Extensive data are presented in the text and an appendix. (ILD)

...The author emphasizes the importance of the "water problem" in Belgium and summarizes the cooperation of the Royal Meteor. Inst. in hydrological research work, namely in the International Hydrological Decade. The program of the Belgian hydrometeorological network and the utilization of the data are analyzed. The program includes the statistical study of the daily water amount collected over 7 basins for the period 1954-64, the installation of a basic hydrometeorological network, and the collection, statistical processing, and regular publication of its observations. French

...A survey of the microclimate of a poplar planting during a year and chiefly deals with the phenomena related to heat transfer within a poplar. The winter conditions are investigated in order to obtain data on the freezing of the sap. In order to investigate the frost-cracks of poplars, a microclimatic station was installed in a poplar planting at Léau (northeastern Hesbaye) equipped with platinum resistance thermometers placed within and in the neighborhood of the planting and with a Honeywell-Brown recorder. A Campbell-Stokes heliograph supplied data on sunshine duration in the planting. Pt. A deals with the temperature data obtained during the critical days of winter 1954-55. Graphs and plates show the temperature distribution for the critical winter days. On clear days, pronounced horizontal gradients and rapid variations are noted by reason of the alternation of severe night frost and daytime sunshine. Special attention is given to the rapidity of the variation in thermal conditions on these clear days and on the rapid alternation of the freezing and thawing of the sap in the wood rings which cause internal tensions and frost-cracks. Pt. 3 gives a climatological survey for the northeastern Hesbaye where the poplar planting of Zoutleeuw (Léau) is located and where the microclimatic station was erected. (AV)

...A survey of the present state of the aerological station of the Royal Met. Inst. of Belgium. It contains a concise description of the main instruments and of the measurements made, together with a brief comment on the usefulness of these observations. The Royal Met. Inst. makes every day, at 0h and 12h (U.T.), 2 radio-soundings of pressure, temp, and humidity. The British Kew MDII, the German Graw H50, and the American AMT sondes are used for this purpose; the calibration technique of these radio-sondes is briefly described. Since 1958 some 30 special soundings are made every year in order to determine the vertical distribution of atmospheric ozone. Atmospheric electricity soundings are also made, using a triode fitted on a Kew MKII radiosonde. Upper-wind radar measurements are made 4 times a day. Part II of the publication deals with the radiometeorological appliances installed at Uccle for precipitation and thundery sector detection. The last part is devoted to tropospheric propagation of radio waves, statistics, and the publication of aerological observations. (AV)

...This study was conducted by a section called CEBEDAIR of the Belgian Center for Study and Documentation of Water. The author explains the meaning of general investigation of air pollution, defines the purposes, and surveys the method used. The possibilities and restrictions of such investigations are shown by analyzing the great economic interest involved as concerned the industrial and demographic development of a given region. Inquiries have been made in various regions of the Belgian provinces. In order to determine probable development of air pollution, basic scales were established. For example, for dust, a distinction was made between the surroundings of the country, the region neighboring on a town, the town, and the industrial region. The results of the first observations seem to reveal that air pollution intensity in Belgium is one of the highest in Europe. (AV)

...Frequencies of daily rainfall amounts generally have a J-shaped distribution. The observations made at the Observatory of Ghent University during the period 1901-50 are first analyzed to obtain the annual distribution. Different kinds of frequency curves are adjusted to the empirical distribution; a Polya curve, an exponential, and a Pearson-curve type VI. The annual distribution is fitted best by a transformed exponential distribution, abstraction being made of the representative point for rainless days and of the points corresponding to extreme and exceptional rainfall amounts. For a given daily rainfall amount one obtains the probability θ_1 and the corresponding number of days Δ_1 in a mean year. The same frequency curve then used to study the seasonal and the monthly distribution. A table gives the obtained results. (Author)

...The daily observed values of the mean atmospheric pressure, reduced to 0°C and to sea-level, during the period 1921-1960 at the Observatory of the Ghent University, were analyzed per pentad.

1965

Flemish

Each of these 73 pentads leads to a mean value and a dispersion for the corresponding 200 observations. The variation of the dispersion is very pronounced and shows a shift of 1 month as compared with the annual motion of the sun. In winter, the dispersion is more than twice the summer value. These facts are correlated with the seasonal variability of the thermal structure of the atmosphere. The frequency distribution of the pressures is studied for each season and, while the normal distribution does not seem to be applicable, the observations are very well fitted by a type I Pearson-curve. For each season the characteristics of this distribution are established and the graphical representation of the data is given. (Author)

...The instrumentation used to pick up the microbes is described. In investigating the relationships between microbial concentrations and weather conditions, air masses were considered in the four following groups: 1) maritime polar; 2) returning polar; 3) maritime tropical, and 4) maritime and continental air. Microbe countings in samples of unstable air masses amount on the average to twice those in stable air masses. Within stable air, microbe values seem to be unaffected by temperature, humidity, or wind velocity conditions. Within unstable air, on the contrary, high values are associated with high temperatures, low relative humidities, and strong or moderate winds; whereas low countings occur for lower temperatures, high humidities, and feeble to zero wind. ...The method of investigating the effect of meteorological conditions upon the contamination of the atmosphere by radioactive substances involves the classification of the results of daily measurements of the pollutants. The mean daily values of atmospheric pressure (p) and temperature (t) are calculated. Each pair of daily values of t and p corresponds to a plane of a system of coordinates (t, p) at a point. The mean daily values of wind speed and direction, cloud cover and type, atmospheric precipitation (amount and type), etc. are plotted at each of these points. Two characteristic lines, namely $p = \bar{p}$ and $t = \bar{t}$ are drawn; $\bar{p}$ and $\bar{t}$ represent the mean long-period

41. (cont)

values of atmosphere pressure and temperature at each station for an appropriate time interval. These lines separate the plane into 4 quadrants. The variation of pollution is made separately for each quadrant. The results of the application of this method to measurements made in Feb 1952, 1962, and 1963 at Uccle (Belgium) and Warsaw (Poland) are presented. (ILD)

...On account of the rapid evolution in geophysical sciences, the aerological station of the Royal Met. Inst. of Belgium has recently been re-organized and equipped with latest up-to-date instrumentation. The paper gives a summary dealing with equipment, measurements, and observations at Uccle, which constitutes a restatement of a similar report published in 1961 (Belgium, I.R.M., Pub. Ser. A, No. 16). Radio soundings are now made using the improved German Graw M60 (PTU) sonde and the American AMT4 sonde (principally for ozone and electric field measurements). These instruments, their calibration, and the technique of radio soundings are described. Upper wind measurements are made using various radar facilities, an automatic tracking radar which also serves for precipitation detection was installed in 1963. A cooperative program for ozone soundings during the IQSY is succinctly considered, together with the now regularly made soundings of the vertical gradient of the electric field. Short paragraphs deal with the thunderstorm detectors now in use, and with measurements of the tropospheric propagation of radio waves. (AV)

...Description of statistical distribution of two radio-meteorological parameters: the co-index of the air refraction and the average gradient of this co-index between the ground surface and the 850-mb level. Both values were computed twice a day at the aerological station of the Royal Meteor. Inst. (Uccle) from April 1, 1957 to March 31, 1962. The cumulative distribution of the co-index and its gradient computed from the meteorological observations at 00h and 12h UT for a 5-yr period (April 1957-March 1962) are represented in 8 graphs showing the time percentage during which the value in ordinates is not exceeded. Some characteristic data of these distributions are represented in 4 tables. Another table gives the scattering of the values of co-index at surface and of co-index gradient around their median value. It is shown that this scattering is more important at 12h than at 00h and in both cases it is higher in summer than in winter. (AV)

...The propagation of radio waves with frequencies of more than 30 Mc/s and influenced by the thermodynamic conditions of the atmosphere are dealt with. The knowledge of this propagation depends on some physical properties of the medium within which the waves propagate and, on the refractive index. Three tables give the mean values of the refractive index at the surface and at a few standard levels. These mean values were computed on the basis of observations made from Jan 1, 1956 to Dec 31, 1960 at the Royal Met. Inst. in Uccle. The author points out that the radio waves undergo a deflection due to decrease of the refractive index with height and emphasizes the importance of this deflection for very high frequency radio communication as well as in the field of space communication. ...Daily measurements of the artificial beta-radio activity at ground level, are carried out at the Belgium Nuclear Research Center at Mol. These measurements include the concentration in air (C_a), the concentration in collected rainwater (C_r), the rainfall (n), and the related deposition rate for rain per unit area ($A_d = nC_r$).

1303

English

Data collected during Sep-Dec 1961 and May-Sep 1962 were used for regression analysis. Data collected Jul-Dec 1957 in Germany are used in illustration. A combination of 3 mechanisms for determining the radioactivity collected in rainwater is given. Rainfall is a determining parameter for describing the relationship between the fall-out in rain and in air. The C_r/C_a value averaged over a longer time than 1 day tends to be unaffected by the amount of rainfall. (2/3)

49. Nanson, Alphonse. Enquete sur la resistance de diverses provenances de Douglas vert a l'hiver, 1962-63 en Belgique. [Investigation on the Resistance of Douglas Fir of Various Origins during the Winter 1962-63 in Belgium], Societe Royale Forestiere de Belgique, Bulletin 71(1):pp 1-11, Jan 1964, 5 tables, 6 refs. DNAL 99.9 B85.

...In Belgium the winter of 1962-63 caused a lot of damage to Douglas fir plantations. That winter was the most severe since observations started in Belgium. The mean air temperature was the lowest recorded since 1833. Sunshine duration was significant and easterlies prevailed. The soil was frozen until the beginning of April. The damage was less important in upper Belgium than in the rest of the country. The plantations with southern exposure suffered

49. (cont)

more damage than those exposed to the north. The investigation of the damage, in relation to the climatic factors, suggests that the cause of the damage is connected with 3 main factors; a) the depth of the frost in the soil, b) the root distribution in depth, and c) the rapidity and the intensity of the diurnal or periodic heating accompanied by intense sunshine and dry winds. (AV)

French

...In order to study the planning of eastern Belgium, a committee was faced with the water problem. A working group of this committee undertook the study of this question in the region Verviers-Eupen. The article gives the first results of a study concerning the inundation hazard in this region. The first part is devoted to the description and examination of the floods which occurred during the last 20 years. Of 3 local floods, 4 had most severe consequences. The data show that these devastating floods were due to: a) the occurrence of pouring rain storms. The thunderstorm on May 13, 1960 yielded 140 mm of rain within 45 min; b) the steep slope of the hillsides; c) the important extent of pastures; d) the convergence of several rivers at certain points; and e) the steep longitudinal slope of the lower part of the valley. The second part deals with the theoretical study of the different basins in the region. The computation of the flow in the basin was made by means of the Inhoff formula. The influences of the topographical conditions, of the slope gradient of the form of the basins, and of the plant cover are discussed. (AV)

...There are numerous applications in various fields of meteorology for the theory of probability. In this article, the author examines some meteorological problems in which the application of the random theory has largely stood the test of time. Notions of chance, of games of chance and of aleatory events, are briefly recalled. In the first part, after having explained the notions of probability, of random variable and of the law of probability, the author develops the adjustment of a law of probability. The adjustment of a law of probability comprises 3 distinct stages; the choice of the law of probability, the properly so-called adjustment and a criterion permitting the appraisal of the quality of the adjustment obtained. All these notions are illustrated by well chosen examples. These laws of probability make it possible to elaborate statistical forecasts and, more particularly, to estimate the return periods of certain determined climatic conditions. As an example, the author applies these laws to the determination of the return periods at Uccle of annual mean temperatures, of winter mean temperatures, of water amounts gathered in Dec, etc.. The 2nd part concerns the laws of probability when several variables are implicated; emphasis being on some particular applications. (AV)

...Study of the statistical properties of the days with thunderstorm over Belgium. This study is based on a homogeneous series of observations made from 1930 through 1939 and 1946-1960. The author considers the probability laws which determine the frequency of thunderstorms and attempts to work out the possible existence of a regional variation about this probability. The existence of a seasonal regional variation in the frequency of thunderstorms is explained on the basis of the proximity of the sea. In the coastal region, thunderstorms are somewhat less frequent in spring, but more frequent in autumn. Thunderstorms seem, however, to be generally more prevalent over the central regions of the country. (ALS)

...A detailed report on the weather of Belgium for each year including data and descriptions of general atmospheric conditions, winds, precipitation, temperatures, humidity, and cloudiness, plus month-by-month summaries of weather conditions, are given. In addition, the most distinctive element in each year is noted, i.e., 1965 had the highest annual rainfall recorded in Brussels since 1833; 1966 had higher than normal temperatures and little sunshine, and abundant rainfall, about 143% of the normal. ...For certain climatological phenomena, the dates of the first and last days of occurrence are taken into account, for example, the dates of the first and last frost or those of the first and last snow. Due to the frequent departures in the dates of beginning and end of a period, these dates might practically be considered as independent variables and, consequently, the law of two variables might be deduced directly by combining the laws of probability governing the dates of beginning and end of the period, respectively. However, the author reveals the inconsistency of this method and, on account of the distribution of these phenomena, he investigated the laws of truncated normal distribution. He first considers the effect of any linear truncation on a normal population with several variables by computing first of all the function generator of the momenta of the truncated distribution and by deducing from this function the momenta of the 1st and 2nd order of the distribution considered. The formulas required to make the adjustment of such a distribution on the basis of the momenta provided by the series of observations are established. The application of this method is illustrated by an example: the distribution of beginning and end of the period the soil at Uccle is covered with snow at least 1 cm deep. (AV)

...Six variates, chosen to characterize the snow cover at Bruxelles-Uccle, have been submitted to statistical analysis: the date of the first snow cover, the date of the last snow cover, the duration of the snow-cover season, the number of days with snow cover, the longest period of consecutive days with snow cover, and the maximum depth of the snow cover. Each variate has been tested against trend, probability functions have been adjusted, and their fit to the series of observations tested. Ordinary, and modified, normal and double exponential laws have been used and the fact that the absence of a snow-cover season must have the same probability as a number of days or a longest period of consecutive days with snow cover, both equal to zero, and has been taken into account. Owing to its length, the series of observations at Bruxelles-Uccle constitutes the basic reference for extrapolation of snow-cover conditions in Belgium. (Author)

62. Sneyers, R. Les Proprietes Statistiques De L'enneigement Du Sol En Belgique [Statistical Properties on the Snow Cover of Belgium], Pub. Series A, No. 63, Institut Royal Meteorologique De Belgique, Brussels, 18, 1967, 34 p. DAS M(055) B429p.

...The snow cover in Belgium has been characterized by 6 variates: the date of the first snow cover, the date of the last snow cover, the duration of the snow lying season, the number of days with snow lying, the longest period of consecutive days with snow lying and the maximum depth of the snow cover.

The data gathered at the Belgian airports have been investigated and probability functions have been adjusted. Moreover the accuracy of the estimation of the parameters of these probability functions has been improved by taking into account:

1967

French

- (1) the correlation between regional data and the corresponding observations of Bruxelles-Uccle for which the considered distributions are well-known
- (2) the existence of linear relationships between the values of these parameters and the variation of altitude in Belgium

...The principal reefs on which the description of climate on a regional scale founder is the shortness of the series of observations one has at his disposal in studying it, and the effect that this shortness has on limiting the accuracy with which the necessary parameters can be estimated. The inconvenience can, however,

63. (cont)

be notably reduced if one possesses a long series of observations for one central station, and if the considered region behaves in a sufficiently homogeneous manner with regard to the meteorological conditions that determine its climate. Under these two conditions, one can predict that a good correlation exists between the observations of the central station and those at the regional stations, and that, moreover, the regional variations of the climatological parameters are closely related to geographical coordinates, such as altitude, distance from the sea, or variations in latitude. Thus, one has a double means of reducing the error of estimating the considered parameters. For example, results are given of a study on snow cover in Belgium and on the effectiveness of the method. In this particular case, it was possible to obtain good results for the regional study of precipitation. (Author/DBK)

...The classical extreme-value theory does not give a good account of the distribution of maximum rainfall intensities in Belgium. Reasons are given for the use, in this case, of a probability function defined by a double exponential whose argument is a function represented by a curve with 2 asymptotes. The application of such a probability function, when the curve is a branch of a hyperbola, to the maximum rainfall in 1 min at Uccle, leads to a good fit. (Author)

...A summary of the observations and knowledge so far acquired of the features of the water-bearing strata and ground waters of the Hautes-Fagnes plateau of Belgium. This high region, strewn with peat bogs and marshes, has a rainy and moist climate. The rainfall supplies the surface layers; the sphagnum contributes to the preservation of underground moisture and promotes percolation towards the deep layers. In summer the sphagnum evaporates its water and the peat dries up; in this season the influence of dew is noticeable. The peat bogs constitute a perfect regulator of the hydrologic regime in two respects: 1) on the regime of the brooks which rise in the bog and 2) on the water-bearing strata. The supersession of peat bogs by conifer plantations modifies the water regime of the surface layers and is prejudicial to the feeding of underground water. Through the increase in water requirements, the necessity of a permanent supply of underground water arises. (AV)

...The investigation into the behavior of squalls and thunderstorms in connection with the repartition of land and sea in the southwest of the Netherlands is still in an initial stage. Owing to the voluntary collaboration of a large number of observers, all the possibilities for obtaining a precise insight in this matter are present. The intensity variation of thunderstorms is continually recorded at Woensdrecht and Wolphaartsdijk. It is not yet quite certain whether squalls are influenced by estuaries or not. But there is an evidence that squalls occur by preference in some special regions, e.g., in a zone just behind the coast line from Zeeuws - Flanders via Walcheren to Schouwen and along a line going from Hulst via Rilland-Bath and South Beveland to Willemstad. The observation network, program, and treatment of observations are described. (AV)

...Where the soil is cultivated, the amount of moisture in it which is normally available for the plants diminishes quickly in periods of summer drought. The course of the decrease and its limit in extreme cases depend on many factors such as the nature of the soil, vegetation, the duration of the drought, etc. Therefore, its effect on water control and on crops varies widely. Practical data on the decrease in the moisture content of good, well-treated soils in extremely dry periods may be of importance when solving certain problems of water control. (Author)

February 1970

53. (cont)

1969

Dutch

...On July 14, 1968, a shower-line extended from the southwest to the northeast over the Netherlands. In Bolsward a waterspout passed over a rain gauge which recorded 25 mm of precipitation in 6 minutes. This amounted to an intensity of 4.2 mm/min. The highest precipitation intensity in the Netherlands hitherto recorded was between 3.1 and 4.7 mm/min over a period of $1\frac{1}{2}$ minutes. An actual tornado was reported by an observer as having travelled from Afsluitdijk to Bolsward. The author considers the questions of whether a tornado actually passed over the rain gauge at Bolsward and whether the registered rainfall intensity actually indicates a record. The possibility that waterspouts retain water following their formation over a water surface is considered; such water is not rainwater. Since the distance between Cape Afsluitdijk and Bolsward is about 10 km, it is not likely that the tornado could have retained its water over this distance. The intense rainfall reported on July 14 should be regarded as the result of a cloud burst. (ILD)

1964

Dutch

...The annual sunshine average of 1500 h for the Netherlands is small in comparison with the 3000 h for the Mediterranean borders. Nevertheless, marked differences in solar climate are stated for the various regions of the Netherlands. These differences have been proved by continuous sunshine recordings made at about 25 stations since 1953. These 10-yr recordings showed that sunshine prevailed in the coastal regions with a maximum for the islands of Zeeland and South Holland and in the Den Helder region. A figure shows that the largest measured annual difference of 235 h was reached between Flushing and Winterswijk. The sunshine duration decreases towards the east. Considering winter and summer half-years, it is stated that during the winter half-year, the sunshine duration was most important in the southwestern part of the Netherlands, with markedly less sunshine in the Wadden Zee islands; the causes of these variations are discussed from the point of view of location and weather. As concerns the summer half-year, the sunshine duration decreased from west to east with a maximum for the delta area, the western Wadden Zee islands, and North Holland. The causes of this sunshine distribution are dealt with. (AV)

85. de Wiljes, H.C. and J.C.A. Zaat. The Influence of Climate upon the Number of Weather-Working Hours in Combine Harvesting in the Netherlands. Arch. Met. Geoph. Biokl., Ser. B, 16, 1966, pp 105-114. DAS P Col.

1966

English

...Over the years 1964, 1965, and 1966, the relationship between the possibility to combine harvest and the rainfall has been summarized in a linear regression equation: $y = a + b_1x_1 + b_2x_2$, with y = mean number of weather-working hours per day per half-monthly period, x_1 = mean daily rainfall per half-monthly period, x_2 = number of dry days per half-monthly period.

For chosen percentiles of the frequency distribution of y , the corresponding number of weather-working hours in the same period can be estimated for future years. Taking the (two dimensional) frequency distribution of x_1 and x_2 , as fixed, confidence intervals for the estimated number of weather-working hours can be calculated. (Pt. Author Abs.)

86. Dorrestein, R. Wind and Wave Data of Netherlands Lightvessels since 1949. Netherlands. Meteorologische Instituut, Mededelingen en Verhandelingen, No. 90, 1967. 123 p, tables, refs. English and Dutch summaries pp 121-122. DAS M(055) N469m No. 90 Ser. A.

1967

English

...Wind and wave data collected every 3 hours since 1949 by Netherlands lightvessels are listed in frequency and other tables. The method of preparation of these tables is given and a summary of them can be found in par 1.6 of the text. An interpretation of some of the data is given. Relative frequencies (percentages of observations) of winds of force 4 and more, 6 and more and 8 and more, respectively, for the years 1949-1957 were compared with those recorded by the Netherlands lightvessels during 1910-1939 and with wind data from other sources (par 2.2.2). An increase in the frequency of wind forces 4 and more in all seasons, and an increase in the frequency of wind forces 6 and more in autumn and winter is indicated. The comparison supports the idea that some of the (mostly small) differences between frequencies of different lightvessels are real, that is, caused by the differences in ship positions: the lightvessel "Texel" may have a little higher frequency of gales than "Goeree" and "Terschellingerbank", especially in autumn and winter;

36. (cont)

"Goeree" shows a lower annual variation in the wind frequencies than the northern lightvessels. Other differences are probably due to slight systematic differences between the observers on board the different lightvessels. A similar statement can be made for the frequencies of wave heights in excess of various values (par 2.3.2 and par 2.5.2). The highest wind force reported during the 15 years 1949-1963 inclusive was 11 (violent storm) for "Goeree" (on 6 occasions) and for "Texel" (on 9 occasions), and 12 (hurricane) for "Terschellingerbank" (on 2 occasions). The maximum significant wave height experienced by any of the 3 lightvessels in these years was probably 7 to 8 m. (Author)

...Records from a network of volunteer thunderstorm observers in the Netherlands are used with routine synoptic and upper-air data to investigate relations between storm severity and almost simultaneous (just prior) meteorological parameters. The latter are derived from fields of the meteorological variables. The X^2 test and screening regression show that the ratio of storms associated with lightning damage to the total number of storms increases significantly with the surface wet-bulb potential temperature (θ_{SW}) and the instability index (ΔT), but the relations are rather weak. Hail frequency increases monotonically with the instability index, but is bimodally distributed with respect to the potential temperature. Hail-size-windshear relations are barely significant. Additional information provided by parameter combination over that in a single best predictor is limited by fairly strong correlations between wind velocities at 700 and 500 mb as well as by correlation

88. (cont)

among the surface wet-bulb potential temperature, the stability index, and the saturation deficit (D). Stratification of the data according to synoptic situation and the use of nonlinear functions of the variable improve some of the relations. (Author)

1965

English

...An objective method has been developed for forecasting the occurrence of thunderstorms. Four parameters have been selected, one of which has been derived from the 500-mb contour pattern. The other 3 parameters (atmospheric pressure, stability, and humidity) are related to the center of the forecast area. The method, which is based on many observations (~1000), can readily be applied for the day following the 0000 GMT aerological sounding if the 500-mb flow pattern is sufficiently known. From this 500-mb flow a parameter has been derived that is combined with atmospheric pressure at De Bilt defining a parameter X. By combination of a stability parameter and a moisture variable - both of which have been derived from the aerological sounding at De Bilt - a 2nd parameter, Y, has been defined. Finally, the probability of the occurrence of thunderstorms can be obtained as a function of X and Y. The system has been designed for the summer season and is based on 11 years (1949-1959, inclusive) of dependent data. It was tested for 3 years (1960-1962, inclusive) of independent data yielding a skill factor $I = 0.48$. The method shows more than 2.5 times the skill factor of the persistence forecast. (Author)

...A relation between the frequency of rain and various meteorological parameters has been investigated with the aid of surface data of the period 1901-1951 and aerological data of the period 1945-1952. Owing to a necessary restriction of the number of parameters, a selection has been made on the basis of a quantitative criterion which has been developed for this purpose. Three parameters, viz., persistence, atmospheric pressure, and direction of surface wind are related to the local frequency of rain. By combining this frequency with a humidity parameter referring to the 850- and 700-mb levels, the areal distribution of the occurrence of rain can be determined. (Pt. Author Abs.)

...A description of a heavy rainfall at De Bilt on June 6, 1961. The pluviograph recorded 49.8 mm of water in 422 min or an average intensity of 0.118 mm/min for the total duration. The device used for rainfall intensity measurement recorded a max of 2.4 mm/min (record: 4-5 mm). The heavy rain continued during 40 min (avg intensity: 1 mm/sec) and gave 40.8 mm of water. The max value between 1926 and 1961 was 28.5 mm in 28 min. The wind velocity was only 2 m/sec and the trajectory of the drops was nearly vertical. The De Bilt meteorological park contains 15 rain gages. The lowest value recorded was 54.3 mm and the highest value 56.9 mm for this rain. (AV)

...Practical questions as to the interdiurnal variations of temperature and humidity forced us to make a thorough study of the interdiurnal variability (I.V.). First of all, we examined which quantity could represent the I.V. best. The I.V. proved to depend on the situation of the station and to possess a highly-pronounced annual variation. Considerations of reliability required numerical knowledge of the autocorrelation of the time series of the daily values of temperature and humidity. Coefficients of autocorrelation of orders 1, up to and including 6, were computed. The time series of the I.V. shows negative autocorrelation. In order to facilitate answering practical problems, a nomogram was constructed. A second nomogram makes it possible to estimate, for instance, the minimum length of the basic period required in order that the answer found with the help of the first nomogram possesses a prescribed reliability. ...The choice of the 24 stations, the daily rainfalls of which were to be punched, was not easy. The basic period should be sufficiently long and homogeneous; the daily measurements should be reliable; the number of missing figures should be small; the stations should be distributed fairly regularly all over the country; they should be representative. There were no stations, which were ideal in all respects. Table 2 presents a survey (which holds for the end of 1953) of the stations with basic periods of at least 40 years. We see, for instance, that there were 24 stations with basic periods of 80 years and more, 17 of which present uninterrupted and 7 of which present interrupted basic series (see Fig. 3). The 24 stations which were ultimately selected are indicated in Fig. 5. Example: station Helmond; frequency book No. 6; basic period, 78 years; two uninterrupted sub-periods; 2.2% of the daily falls were missing. Part A of the study goes into the theory involved and Part B presents tabulated data. There are many figures, graphs, tables included in these volumes. (Pt. Author Abs.)

...Two types of pluviographs have been used during the basic period 1931-1960, De Bilt, the records of which have been analyzed hour for hour: the balance and the float type (1931-1953 and 1954-1960). The rims of both self-recording rain-gauges were at 40 cm above the ground; the circular openings of the gauges were 400 cm². The opening of the ordinary, non-recording rain-gauge, with which the total quantity of rain was measured three times per day, also was 400 cm², but the height of the rim above the ground

106. (cont.)

was 150 cm up to 1 Jan 1946 and 40 cm since then. The readings of the records of the pluviograph were not adjusted for the wind influence, since this was impracticable. Snow has been measured as rain since the self-recording rain-gauge was equipped with a heating device which came automatically into action as soon as the temperature of the collecting funnel fell below zero. Dew, fog, hoarfrost, and hail also have been measured as rain. Falling hourly values were estimated as well as possible in order to obtain uninterrupted series of data so that troubles of mechanical nature when constructing and punching the quantities and durations of rain in periods of successive hours could easily be overcome. ...The Delta works, which are carried out in the south-western part of the Netherlands in order to improve the protection of the low-lying country against storm floods, make it possible to improve also the water conservancy in this region. At present, damage is caused by high salinities of the surface and ground water on one hand, and by desiccation on the other. The enclosed estuaries and tidal rivers will act in future as fresh water arteries, whereas the southern part will be transformed into a lake, which will make it possible to store water. In this article the water requirements for several purposes and the water management, which is being designed to meet these needs as much as possible, are discussed. (Author)

113. Scharringa, H. Beoordeling van zomers [Classification of Summers], Hemel en Dampkring, The Hague, 58(10):227-230, Oct 1960, 4 tables. DAS M(05) N469h.

1960

Dutch

...It is not easy to give a summer its rightful place in a series of summers; the economic significance of a summer and the impression it makes on man depend on many factors. Temperature is an important factor, but the norm to be adopted may be chosen from mean temperature, mean daily maximum temperature, or number of summer days. Precipitation amount and sunshine duration are very important; rainfall amount and duration can also be considered. The author gives a table with the ten warmest and the ten coldest summers (1926-1960) classified according to: the mean temperature of De Bilt, the number of summer days, the days with temperature $\geq 20^{\circ}\text{C}$, and the mean maximum

113. (cont)

temperature. The correlation coefficient between number of summer days and mean temperature is + 0.75. There is a relation between: 1) the number of days with temperature $\geq 20^\circ$ and the number of official summer days ($> 25^\circ$); correlation coefficient: + 0.79. 2) mean temperature and number of days with $\geq 20^\circ$ temperature; correlation coefficient: + 0.64. Another table gives the ten rainiest and the ten driest summers. The correlation coefficient between rain duration and precipitation amounts is + 0.60. Also the ten most sunny and the ten most cloudy summers are given. To end the article, all summers between 1900-1960 are rated from 1 to 35 according to: mean temperature, number of summer days, number of days with maximum $\geq 20^\circ$, mean maximum temperature, sunshine duration, rainfall amount, and rainfall duration. This method gives a group of seven classification numbers from which a mean index is deduced for final classification. (AV)

1963

Dutch

...It is often claimed that a cold winter involves a great chance that the next summer will be warm; the year 1947 is cited as an example. This study investigates the accuracy of this assertion. Cold summer and Warm summer are defined. The investigation is based on data collected at De Bilt from 1856 to 1955. The results of this investigation reveal that the occurrence of a warm summer should not be linked with the fact that the preceding winter was cold. Moreover, it appears that the occurrence of a warm summer is also independent of the fact that the preceding winter was mild or not. The author calculated the correlation between two series of 100 winter and summer temperatures covering a period of 100 years. The correlation coefficient was found to be: $r = 0.013$. Since this value is nearly equal to 0, it may be concluded that the summer temperatures are by no means related to the temperatures of the preceding winter. Warm summers occur independently of a preceding cold or mild winter. (AV)

1964

Dutch

...The investigation of 227 years of data showed that Sep was the warmest month of the year 1961; this phenomenon occurred only once. Jul was, on an average, the warmest month; however, this was actually only the case in 51.5% of the years considered. In 40.7% of the cases, Aug was the warmest month, whereas Jun was only in a good 7% of the cases the warmest one. May was never the warmest month. This investigation, moreover, showed that Jan was the coldest month of the winter half-year in 47.7% of the cases. Nov and Mar were the coldest months in 3% of the cases. Precipitation means for the whole country over a period of 100 years revealed that Aug was the wettest month of the year, whereas Feb was the driest one. For the May-Sep period, Jul was mostly the wettest month. Oct was, in the majority of cases, the wettest or the driest month of the year. (AV)

1969

English

...In this investigation, the area considered extends from the eastern and northern extremities of the Baltic across the British Isles to include the ocean weather station (OWS) 'I' and 'J'. A selection of observations for 13 stations spanning this region are examined to show how precipitation varies in type and intensity across it and,

117. (cont)

using the observations nearest midday, how visibility varies in precipitation. Interest is mainly confined to coastal and sea areas rather than to inland stations (data for Schiphol, Netherlands is included). (Author)

118. Ten Kate, H. 1959 was zeer zonnig en droog [1959 was Very Sunny and Dry], Hemel en Dampkring, The Hague, 58 (3):76-79, Mar 1960, table. DAS M(05) N469h.

1960

Dutch

...The year 1959, with $5\frac{1}{2}$ months of summertime, was very sunny, dry, and warm and was the opposite of the year 1958. Dryness was remarkable (536 mm rain for normally 719 mm); only 1901 was dryer. Only the month of Jan presented a precipitation surplus. Jan showed 13 snow days, it was exceptional. Temperature was above normal value: 10.1° (norm: 9.2°); 37 summerdays (norm: 24), 55 frost days (norm: 67). Jul 9th was the warmest day (30.6°); Feb was the coldest month. Sunshine was most abundant: from 1869 hours at Eelde to 1906 hours at Helder. High pressure was very frequent over the North Sea, blocking the arrival of low pressure and winds from the West. Winds were mostly between N and E. (AV)

1961

Dutch

...A climatological survey of the winter season in the Netherlands. Two facts are to be noticed; mean temp above the normal and excessive precip. Dec and Jan were mild months with a mean temp of 3.8°C (norm: 2.3°) and only 11 frost days (norm: 41); a lower number of frost days has been recorded during the winter 1897/1898 when it reached 21. Feb had the largest thermal excess. The precip. amounted to 264 mm for a normal of 174 mm; this value of the winter (1960-61) was exceeded only in 1914/15 (mean for the territory -- 267 mm) and in 1947/48 (mean -- 263 mm). The author comments on the depth of precip. for different provinces of the country. Sunshine duration was the lowest in the North, in other regions it was almost normal. Winds from SW predominated and fog occurred frequently. (AV)

120. Ten Kate, H. De Zomer Van 1961 [Summer, 1961], Hemel en Dampkring. The Hague, 59(10):234-235, Oct 1961. DAS M(055) J469h.

1961

Dutch

...After the bad summer of 1960, great hope was set on the summer of 1961. A survey of the 3 summer months (Jun, Jul, Aug) 1961 does not indicate a fine summer. The temperature was nearly normal but there was a shortage of warm days and sunshine; it was a rather wet summer. The mean temperature at De Bilt was 15.7° C. (normal 16.4°C); there were 10 fine days during this period; whereas, there were 6 in Sep. The largest number of fine days was counted in the southeastern half of the Netherlands. The sunshine duration varied very much, the average for the entire country was 537 h (normal: 615 h). Regarding precipitation, important variations were also noted, the average for the entire country was 240 mm (normal: 214 mm), Zeeland was the driest region with 188 mm (normal: 196 mm), and Actertock, the wettest one with 285 mm (normal: 230 mm). At De Bilt the rainfall duration was 136 h (normal: 108 h). Summer 1960 was characterized by a higher amount of rainfall in comparison with 1961; the period Aug 29-30, 1961 was very sunny and at the end of the summer, a few tropical temperatures were noted such as on Sep 16. (AV)

1962

Dutch

...Climatological survey of the winter 1961-62 (Dec, Jan, Feb) in the Netherlands. The temperature of the 3 winter months in De Bilt was 2.6°C against 2.3°C. normal. Dec was the coldest and Jan. the warmest month. Throughout the country 255 mm precipitation was an average against 175 mm, normal. The largest quantity reached 307 mm and was measured at Veluwe; the smallest, 200 mm, in the northern half of Limburg. It rained during 228 hours against 117 hours normal at De Bilt. The large quantity of rain caused great difficulties. The storms of Feb 12-13 and Feb 16-17 caused damage on the coast. The average of the number of sunshine hours of the country amounted to 189 against 240, normal; 214 hours sunshine were recorded at Woensdrecht and only 155 hours at Winterswijk. (AV)

11. Ten Kate, H. De zomer van 1963 [Summer, 1963], Hemel en Dampkring, The Hague, 61(12):306-308, Dec 1965, 2 figs. DAS M(05) N469h.

1963

Dutch

...General survey of the main climatic elements during summer 1963 in the Netherlands. Like the 3 preceding summers, that of 1963 was too cold, too wet, and too dull; the few fair days during this period did not make up for the deficiency of sunshine, heat, and dry weather. Aug was rather cold and in the coastal region, there were only 5 summery days; while in the northernmost part of the Netherlands, there was no summery day. There was a marked sunshine deficit in the southeast. For the whole country the average rainfall reached 266 mm for 214 mm normal. The excess was most important in Zeeland, southern Holland, and central Holland; it was smaller in the far southeast. (AV)

12. Ten Kate, H. Het weer in 1964 [Weather in 1964], Hemel en Dampkring, The Hague, 63(4):94-96, 1965. 2 figs. DAS M(05) N469h.

1965

Dutch

...Survey of the weather in the Netherlands in 1964. In general, temperature, precipitation, and sunshine deviated little from normal. The winter was cold, very dry, and rather sunny; spring had normal temperature and precipitation but a very high number of days without sunshine; the summer was normal; and autumn rather cold. The mean temperature at De Bilt was 9.1°C against 9.3° normal; 201 days were too cold. Coldest month was Jan; warmest, Jul. De Bilt had 23 summer days (normal -- 23) and 71 frost days against 64 normal. The highest temperature was 37°C at Venlo and the lowest -13°C in the east. Amount of precipitation in the 15 districts of the Netherlands, normal amount, and deviation from normal are shown on a chart. Wettest was southern Holland with an average amount of 768 mm against 752 mm normal; driest was Drenthe with 610 mm against 752 mm normal. The average amount for the country was 697 mm (normal 740 mm). Jan and Feb were driest, Oct wettest. The distribution of sunshine duration is also shown on a chart. Hellevoetsluis had most sunshine with 1687 hr. Kootwijk least with 1503 hr. De Bilt had 38 days without sunshine (normal - 69 days). There were five days with severe storms or heavy thunderstorms. (AV)

124. Ten Kate, H. De zomer van 1965 [The Summer of 1965], Hemel en Dampkring, The Hague, 63(12):338-340, 1965. Figs. DAS M(05) N469h.

1965

Dutch

...Climatologically seen, the summer of 1965 and, especially, Jul in the Netherlands, was wet, somber, and cold. During Jun, Jul, and Aug, 308 mm rain fell on the average against 214 mm, normal. Since the beginning of the observations in 1850, only 4 summers were wetter: 1882 (328 mm), 1894 (333 mm), 1927 (323 mm) and 1954 (321 mm). The deficits in sunshine duration varied from 21% in South Limburg to 6% in Eelde. The mean temperature at De Bilt was 15.0°C against 16.4°C, normal. During the last 50 years only the summers of 1956 (14.4°C) and 1962 (14.6°C) were colder. The absolute maximum at De Bilt was 27.6°C; except for 1962 (27.0°C), this is the lowest maximum ever observed since 1850. Charts are presented of the distribution of precipitation, sunshine duration, number of summer days, and mean temperature in the Netherlands. (AV)

1963

English

...The influence of the topography and the orography on the precipitation pattern in a certain area, such as the Netherlands, depends to a very high extent on the wind direction. It is, of course, well known that, in addition, precipitation patterns are also affected by other factors, as there are the distribution of convective cells, the presence of condensation nuclei, etc. The influence of the latter factors makes it difficult to draw conclusions about the influence of the topography and orography by studying the patterns originating from individual days. However, by grouping cases according to wind direction, the influence of the wind direction will dominate over that of the other factors, which, in this way, will be more or less eliminated.

The present study describes the distribution over the Netherlands of the number of rainy days and of the then-observed precipitation amounts for various wind directions. As the number of days with rain in the various wind direction groups were too small, no attempt was made with respect to the differentiation of the wind speed. (Author)

...Potentiality of radiocarbon dating of ground water in the indication of recharge rates of aquifers. Relationship between the age at a point in the water body and the recharge depends on whether or not the aquifer is confined. For an unconfined aquifer receiving recharge over the whole surface area, a simple relationship is deduced. Such an aquifer can be characterized by its age at half depth. Natural radiocarbon has been used to study flow patterns and flow rates of subterranean water bodies in different regions in the Netherlands. Deep ground water in the southeast region of the IJsselmeer presents a complicated situation caused by the inhomogeneity of the strata. Flow rates are not readily deduced, but the different aquifers can be distinguished by using the isotopes C-14 , C-13 and C-12 as natural tracers. In the province of Friesland, deep ground water shows a more consistent picture with flow-times of several thousand years.

130. (cont)

corresponding to a quite acceptable flow rate of ~ 10 m/yr. A much faster turnover time is observed in the unconfined, fresh water aquifer on the island of Schiermonnikoog. Hydrological parameters, as deduced from C-14 and H₃ measurements, compare reasonably well with other methods. (Author)

...This paper gives the results of the investigations into the risk of damage to crops caused by ground frost in spring. The author's records of temperatures 10 cm above the ground show that the differences between simultaneous readings from a shielded and an unshielded thermometer on a clear calm night was at least 0.8°C. Temperature measurements were taken at 10 cm above ground with a protected thermometer. Intensities of frost are also covered. (ALS)
