I. Preface.

Recent investigation of the effects of ionospheric retardation and refraction on satellite tracking radars has generated a need for a means to predict the errors and correct for them. This paper describes a project undertaken by 4th Weather Wing to produce a realistic electron density profile based upon parameters which can be forecast reasonably accurately. The authors wish to acknowledge the help provided them in this project. Lt Colonel Hansrote provided the impetus for producing such a model. Capt Jack Wrobel solved our initial problems of scale height by providing "Wrobel's Equation." MSgt Birch and TSgt Myster analyzed and evaluated the model against actual observations. Mrs. Green accomplished the manuscript typing. Thanks, also to Lt Bo Eross for his system analysis suggestions.

11. Introduction.

The development of a computer program for predicting electron density profiles was prompted by the realization that ionospheric retardation and refraction produced errors in range and azimuth of satellite tracking radars. These errors are of the same order of magnitude as those produced by tropospheric effects when the UHF radars are operating above a few degrees elevation. Since the effects are rather small, it was assumed that a simple model from 100 km to 1000 km would be sufficient. However, as development work began, other requirements for electron density profiles became apparent. A three-dimensional ionosphere for HF ray tracing, which requires considerably more accuracy in the lower ionosphere, was requested. In addition, total electron content for correcting for Faraday rotation in some navigational satellites requires a model extending higher than 1000 km.

The program described in this report has been used routinely for about eight months to predict electron density profiles for the FPS-85 radar at Eglin AFB, Fla. Results are encouraging enough to warrant publication. It should be considered an interim report, however, as improvements are sure to be required as its accuracy is evaluated for different purposes.

III. Development.

The ionospheric electron density profile model presented in this paper consists of the sum of three Chapman layers (E, F1, and F2). Each layer is of the form

$$N_h = N_{\max} \exp a[1-Z-\exp(-Z)]$$

$$\text{where } Z = (h-h_{\max})/h_s$$

N_h = electron density at height h

$N_{\max}$ = electron density at the peak of the Chapman layer $h_{\max}$

h_s = scale height at the peak (except for the topside of the F2 region)

The value of the constant, a , depends upon whether electrons are lost by attachment or by recombination. While neither process is unique in any layer, a is assumed to be 0.5 for the E-layer and 1.0 for the F1 and F2 layers.

Electron densities in the topside ionosphere are controlled by complex motions rather than a production-loss balance and cannot be successfully described strictly by a Chapman layer. An effort was made to keep from over-complicating the model and still obtain the best topside profile. After some experimentation a fit was obtained by simply using the Chapman equation for the topside ionosphere, but computing the electron densities by using a variable scale height throughout the region.

The scale height profile is calculated from the equation

$$h_s = \frac{\log h}{2.186 \times 10^{-2}} - 203.447$$

This equation describes the scale height of a simple standard atmosphere and was derived by Capt J. Wrobel (private communication).

Critical frequencies for the E and F1 regions are determined from regression equations [1], [2].

$$f_{oE} = 0.9[(180 + 1.44R) \cos x]^{0.25}$$

$$f_{oF1} = 1.26f_{oE} + 0.5$$

where R = the twelve-month running mean sunspot number

x = the solar zenith angle

When x exceeds 90° , f_{oE} is set to 0.7 MHz. When x exceeds 135° , f_{oE} is set to 0.3 MHz.

The F2 region critical frequency may be predicted from the ITS (ESSA) coefficients by predicting a sunspot number (R) [1]. It may also be predicted manually on a short-term basis by the Air Force Aerospace Environmental Support Center. For post analysis purposes, an observed value may be used.

The height of the peak of the E region is assumed to be 120 km. After some experimentation, the F1 peak was placed halfway between the E and F2 peaks.

The height of the F2 peak is calculated by using Shimazaki's equation [3]:

$$h_{\max} = \frac{1490}{M} - 176$$

where the $M(3000)$ factor, M , may be predicted in a manner similar to the prediction of f_oF2 , or observed. Computations of $h_{\max}$ using $M(3000)$ were found to be accurate within 20 km at mid latitudes. If a more accurate measure of $h_{\max}$ is available,

such as $h_p F2$, an artificial $M(3000)$ may be calculated from the Shimazaki equation and used as an input into the computer program.

IV. Description of the Computer Program.

A copy of the computer program used to compute an electron density profile is listed in Appendix A. The program is written in IBM 7090 FORTRAN IV. There are three input options (all of which are concerned with the method of obtaining $foF2$ and $M(3000)$). Two output options are available, depending upon the representation of the profile required.

The program computes electron densities independently for each of three regions (E , $F1$ and $F2$). The base of the profile is 100 km and computations are made at 5 km increments to 1000 km. The three regions are added together to give the total electron density at each increment of altitude. Electron density is not permitted to decrease with altitude, but is held constant across "valleys" in the profile.

Total electron content in a one square meter cross section up to a given altitude is also computed. An initial electron content is established at 95 km, to represent the total content below 100 km. A calculation of plasma frequency is made from the electron density for each 5 km interval.

Input parameters are read from data cards. The first data card indicates output options (Table 1). The second data card contains information pertaining to the geographic location of the profile. The format of the card is the same for all input options (Table 2).

As previously mentioned, there are three input options which determine the method by which $foF2$ and $M(3000)$ are introduced into the program. Data card number 3 contains information pertinent to the profile, including the input option variable IOPT. Table 3 lists the input parameters on the third data card and indicates which of them are used by the program under each of the three input options. If $IOPT = 1$, $foF2$ and $M(3000)$ are computed from a card deck of ITS Prediction Coefficients. (Subroutines used to compute $foF2$ and $M(3000)$ from ITS coefficients were extracted from a program published in [4].) If $IOPT = 2$, a long-term data tape containing sunspot dependent coefficients of $foF2$ and $M(3000)$ is read to determine $foF2$ and $M(3000)$. Finally, if $IOPT = 3$, $foF2$ and $M(3000)$ are read explicitly from the data card.

TABLE 1

<u>Card Column</u>	<u>Variable</u>	<u>Explanation</u>
1	IPLOT	If IPLOT = 1, a profile of plasma frequency vs height is plotted. If IPLOT = 0, plot is suppressed.
2	IPNCH	If IPNCH = 1, the 17 most significant points depicting the profile are punched onto data cards. If IPNCH = 0, the punch routine is suppressed.

TABLE 2

7	NORS	Hemisphere (N, S)
8-13	CLONG	Longitude
14	IHEM	Hemisphere (E, W)
15-38	NAME	Name of Station

TABLE 3

<u>Card Column</u>	<u>Variable</u>	<u>Required Under Option</u>	<u>Explanation</u>
1-2	IYR	1, 2, 3	Year
3-4	MNTH1	1, 2, 3	Month
5-6	MNTH2	1, 2	Used if mean of two months coefficients are required.
7-8	IDA	3	Day
9-12	IBHR	1, 2, 3	Beginning time of set of consecutive profiles (GMT).
13-16	IEHR	1, 2, 3	Ending time of set of consecutive profiles (GMT).
17-18	INC	1, 2, 3	Increment of time step (hours).
19-21	JDAY	1, 2, 3	Julian Day
22	IOPT	1, 2, 3	Option
26-30	SSN	1, 2, 3	Sunspot Number
31-40	FOF2	3	foF2 (explicit) MHz and tenths
41-50	EM3000	3	M(3000) (explicit) hundredths
51-56	IVB	1, 2	Beginning of valid time (i.e., 10 May).
57-62	IVE	1, 2	Ending of valid time (i.e., 20 May).

NOTE: All numbers are integers except SSN, FOF2, and EM3000. These three are floating point, punched with a decimal point, anywhere in the field.

V. Description of the Computer Produced Profile.

Appendix 2 is a sample profile produced by computer. The profile is in four sections. The first section provides a summary of input data and pertinent information for each of the three regions. The second section is the profile itself, listing values of height, E-region density, F1-region density, F2-region density, total density, cumulative electron content, plasma frequency and scale height for each 5 km increment of the model. Output of the third section depends upon the value of the output option IPLOT (see Table 1), and plots a graph of plasma frequency vs height for the model. The fourth and final section depends upon the value of the output option IPNCH. If selected, the 17 most significant values of plasma frequency describing the profile are chosen objectively and written onto magnetic tape for punching onto data cards. In addition, a checklist of the points selected is printed.

VI. Evaluation of the Model.

An evaluation of this model was made by comparing with observed electron density profiles and with total electron content measurements.

Figures 1 to 8 show model monthly median profiles for Wallops Island, Va., during 1968, compared with the observed profiles available from World Data Center A, Boulder, Colorado. Excellent results are obtained during winter and at night. The July 1800Z (mid-day) is the worst case among several dozen such comparisons at various locations and times.

In Table 4, the total electron content calculated to 1000 km is compared with observations of total content from Bedford, Mass., to geostationary satellites, a path which passes through the F2 peak near Wallops Island. These observations, courtesy of Jack Klobuchar, Air Force Cambridge Research Laboratories, are converted to vertical incidence by assuming a cosine correction factor. As expected, the model is generally lower than the observations since it cuts off at 1000 km. It is interesting to note that in the summer daytime, when the model overestimates the bottomside content (Figure 6), it underestimates the total content. This implies that more electrons are present in the topside than the model predicts.

A third comparison is shown in Figure 9. Here, total content to 1000 km from the model is compared with the total content on near vertical incidence paths to synchronous satellites in the vicinity of Hawaii [5]. The shape of the diurnal curve is good and the results are again excellent at night but are underestimated at midday.

VII. Summary and Conclusion.

The electron density profile model came about as an attempt to produce a reasonably simple method of predicting electron densities in the 100-1000 km range. This model should not be considered final, by any means, even for the current applications. The scale height profile should be improved to include diurnal and seasonal variations. The model should be extended from its upper limit of 1000 km to the plasmopause. Variations of electron density with geomagnetic activity should be included. Improved prediction or specification of any of the input parameters will, of course, improve the accuracy of the profile model. The height of the F2 maximum is probably the most important of these.

13. ABSTRACT		
This paper describes a project undertaken by 4th Weather Wing to produce a realistic electron density profile based upon parameters which can be forecast with reasonable accuracy. The ionospheric electron density profile model presented in this paper consists of the sum of three Chapman layers (E, F1, F2). Electron densities in the topside ionosphere are controlled by complex motions rather than a production-loss balance and cannot be successfully described strictly by a Chapman layer. After some experimentation a best fit was obtained by simply using the Chapman equation for the topside ionosphere, but computing the electron densities by using a variable scale height throughout the region. The program described in this report has been used routinely for eight months to predict profiles for radar refraction. This report should be considered interim as improvements in accuracy are sure to be required as the model is evaluated for different purposes.
