## ABSTRACT

---

Theoretical studies concerning the mechanics of penetration and perforation of a snow covered Arctic sea ice sheet subjected to projectile impact were performed.

Penetration problems were treated by a deep penetration theory based on dynamic spherical cavity expansion analysis. In particular, finite compactibility and permanent deformation of both the snow and sea ice target materials were taken into account by assuming a locking approximation for behavior under hydrostatic stress, and response as an elastic-plastic, linear strain hardening solid under shear stress.

Perforation problems were treated with the aid of a two-dimensional, large deformation, dynamic, elastic-plastic computer code (CANDIA CODE) which was developed in a previous investigation. Specifically, axisymmetric, dynamic stress distributions were studied under conditions of impact at normal incidence for a cylindrical blunt end projectile and a sea ice target slab. A capability for considering perforation problems where fracture in the sea ice target material occurs was developed. In this connection, the redistributions of both tensile and shear stresses that accompany propagating fracture surfaces were acknowledged. The program was also modified to provide projectile deceleration loads during the perforation process, and subroutines were created to treat multilayer ice slabs and thereby accommodate effects contributed by overlying snow cover and the underlying mushy sea ice skeleton layer.

## PREFACE

---

The investigation reported here was sponsored by the U.S. Naval Ordnance Laboratory (NOL, White Oak), Silver Spring, Maryland, under ONR Contracts Nonr-2332(00) and N00014-68-A-0243 (SRI Project No. 7000-452). The work was performed between 1 July 1969 - 31 December 1969 and 15 April 1970 - 31 June 1970 and is designated, unofficially, Phase IV Study. Results of the <sup>(1969-1970)</sup> Phase I, <sup>(1969-1970)</sup> Phase II, and <sup>(1969-1970)</sup> Phase III studies were published in separate Stanford Research Institute reports under a similar title and dated November 1965, May 1967, and September 1969.

The contract was monitored for the Naval Ordnance Laboratory by Mr. M. M. Kleinerman. Project leader for Stanford Research Institute was Dr. Bernard Ross, and principal investigators were Dr. Sathya Hanagud, Dr. Bernard Ross, and Mr. Gursharan Sidhu.

## SYMBOLS

- $A$  - cross-section area of projectile
- $a$  - radius of spherical cavity, see Fig. 3
- $B_1, B_2$  - constants related to dynamic pressure, see Eq. III-34
- $b$  - radius of spherical shock front, see Fig. 3
- $C_0$  - constant of integration
- $C_1, C_2$  - constants related to dynamic pressure, see Eq. III-77
- $D$  - diameter of projectile
- $E$  - modulus of elasticity (Young's modulus)
- $E_t$  - tangent modulus for linear strain-hardening
- $\bar{f}$  - limit of integration, see Eqs. III-8, III-41
- $f(t), g(t)$  - functions of integration
- $k$  - radius of elastic-plastic spherical shock front, see Fig. 5
- $M$  - mass of projectile
- $n$  - summation exponent
- $P_I$  - static pressure term given by Eq. III-52
- $P_{II}$  - static pressure term given by Eq. III-72
- $p_s$  - static pressure term given by Eq. III-34
- $p(t)$  - dynamic pressure applied to spherical cavity surface as a function of time

$q, \dot{q}, \ddot{q}$  - depth, velocity, and acceleration, respectively, of projectile in target material

$q_{os}$  - depth of projectile penetration at transition point,  $q_{os} = R$

$q_t$  - final penetration depth of projectile

$R$  - depth of snow-ice interface at transition point of projectile penetration process, see Fig. 2

$R_o$  - depth of snow cover, see Fig. 1

$r$  - radial coordinate

$r'$  - dummy variable of integration

$t$  - time

$V_o$  - velocity of projectile after completion of shallow penetration phase, assumed equal to impact velocity

$v$  - outward particle velocity in radial direction

$v_{os}$  - projectile velocity at transition point, equal to impact velocity for second phase of penetration

$x$  - nondimensional quantity,  $x = \xi^2$

$Y$  - yield stress

$y$  - nondimensional quantity,  $y = 1/x$

$\alpha_p$  - ice parameter given by  $\alpha_p = \left(1 - \frac{\rho_o}{\rho_{lp}}\right)$

$\bar{\alpha}_p$  - parameter given by  $\bar{\alpha}_p = \left(1 - e^{-3\beta \frac{\rho_o}{\rho_{lp}}}\right)$

$$\alpha_s - \text{snow parameter given by } \alpha_s = \left(1 - \frac{\rho_{os}}{\rho_{ls}}\right)$$

$$\bar{\alpha}_s - \text{parameter given by } \bar{\alpha}_s = \left(1 - e^{-3\beta_s \frac{\rho_{os}}{\rho_{lp}}}\right)$$

$$\alpha_{ls} - \text{parameter given by } \alpha_{ls} = \left(1 - \frac{\rho_{lp}}{\rho_{ls}}\right)$$

$$\beta - \text{material parameter for ice given by } \beta = \frac{Y}{2E} - \frac{\bar{\epsilon}_l p}{3}$$

$$\beta_s - \text{material parameter for snow given by } \beta_s = \frac{Y_s}{2E_s} - \frac{\bar{\epsilon}_{ls}}{3}$$

$\epsilon$  - small quantity in the mathematical sense

$\epsilon_l, \bar{\epsilon}_l$  - locking strain,  $\bar{\epsilon}_l = -\epsilon_l$

$\epsilon_r, \epsilon_\theta$  - normal strains in radial and circumferential directions, respectively

$\dot{\epsilon}_r, \dot{\epsilon}_\theta$  - normal strain rates in radial and circumferential directions, respectively

$$\eta - \text{series expression given by } \eta = \sum_{n=1}^{\infty} \frac{1}{n^2} \left(1 - e^{-3\beta \frac{\rho_o}{\rho_{lp}}}\right)^n$$

$\theta$  - equatorial spherical coordinate

$\xi$  - nondimensional quantity,  $\xi = r/a$

- $\rho$  - density of target material
- $\rho_l$  - locking density of target material
- $\sigma_r, \sigma_\theta$  - normal stresses in radial and circumferential directions, respectively

#### Subscripts

- p - refers to locked plastic region in sea ice
- o - refers to initial values and/or stress-free region
- s - refers to snow region
- I - refers to ice region
- 1, 2 - initial and final states, respectively, of a hydrostatic compression process

## I INTRODUCTION

This report presents the final results of a comprehensive, long term investigation concerning the penetration and perforation\* behavior of Arctic sea ice subjected to impact by inert projectiles. The importance of these engineering problems to the Arctic Antisubmarine Warfare Program has been described in three reports under the present title issued during November 1965,<sup>1\*\*</sup> May 1967,<sup>2</sup> and September 1969.<sup>3</sup> The last report contained a complete summary of work performed and progress achieved up to that date; therefore, the topic is not considered anew.

However, it is noted briefly that two important analytical procedures for treating projectile-sea ice interaction problems were developed after completion of the second study. As described in the last report, these efforts included the realization of a large deformation, elastic-plastic, artificial viscosity type computer program (CANDIA CODE) which could be used to solve a wide variety of axisymmetric, two-dimensional, dynamic, and/or impact problems,<sup>4,5,6,7,8</sup> and a large deformation deep penetration theory for analyzing projectile motion in compactible media.<sup>9,10,11,12</sup>

Even though it was possible to derive a substantial body of information by applying these procedures to Arctic sea ice perforation

---

\* For the purpose of this study, penetration can be defined as the entrance of a projectile into a target or ice cover without completing its passage through the body, whereas perforation implies the complete piercing of the target slab or ice cover by the projectile.

\*\* Superscript numbers refer to references which are collected at the end of this report.

and penetration problems, it was recognized that further improvements were still required for practical application of the theoretical work.

For example, perforation of an Arctic sea ice cover by an impacting projectile creates fracture surfaces in the target material, and it is the resultant geometry of this process that describes both the mode of perforation and the associated value of critical impact velocity.\* Moreover, important redistributions of stresses occur when fracture surfaces develop, and these changes affect both the failure phenomenon itself and the magnitudes of stress experienced by the impacting projectile. In this connection, the previous version of the code was capable of providing complete descriptions of both stress and deformation fields in the impacting bodies. It remained to postulate suitable failure criteria and expected crack propagation paths to define the global fracture pattern and the mechanism of projectile transit through the sea ice cover.

In consequence of the present work, it is possible now to track the actual failure configuration as a function of time after initial impact, and to acknowledge that the complement of both shear and cleavage fracture surface propagation paths is being influenced continuously by the developing fracture process.

On the other hand, the previous deep penetration theory was limited in application to homogeneous, isotropic media and thus was not suitable for cases involving a snow covered Arctic ice sheet. To correct this shortcoming, present research efforts were directed toward realization of a multilayer deep penetration theory to treat the practical projectile

---

\* Critical velocity is defined as the minimum or threshold impact velocity for complete penetration, i.e., perforation.

penetration problem characterized by a two-layer, snow-ice target material. This work can be employed to obtain penetration performance curves for projectiles deployed in a typical Arctic environment.

In sum, these connected analyses (namely, direct treatment of the dynamic fracture problem and synthesis of a multilayer, large deformation, deep penetration theory) constitute the basis of this investigation. However, in addition to these studies a subsidiary effort concerning the determination of maximum deceleration loads experienced by a projectile during the sea ice perforation process was carried out. Unfortunately, numerical calculations for both of these problems could not be carried out due to a lack of funds for computer runs. Therefore, the significance of present developments as applied to the design and development of naval weapons for Arctic application could not be examined.

## II MECHANICS OF FRACTURE

The work accomplished was concentrated on modifying and restructuring the CANDIA CODE to enable theoretical analysis of problems where fracture of the ice slab occurs. This phenomenon engenders redistributions of stresses in the target material, and accompanying effects in the magnitude and distributions of loads sustained by the impacting projectile. Thus, from an overall viewpoint, these efforts were directed toward the transformation of a computer code employed previously as a research tool to a working code which can be utilized to perform engineering design and development calculations.

To sustain these particular goals and to treat the fracture problem in sea ice, per se, it was necessary to recast the code so that problems characterized by greater numbers of variables and finer finite-difference calculation mesh networks could be accommodated. For example, in initial format the code considered sea ice to be homogeneous and isotropic, whereas, in fact, this material is strongly anisotropic and inhomogeneous. Consequently, introduction of this more advanced description of material composition would furnish a demand for increase in the number of input variables that are needed for numerical calculation. Moreover, greater machine storage and capability were also required because a developing fracture surface submits many more mesh points of importance into the calculation process. To overcome these difficulties, the entire CANDIA CODE, as listed and flow-charted in the last comprehensive report,<sup>3</sup> was restructured to eliminate its dependence on high speed core memory storage. As a result, the code in its present format can be employed to take advantage of random access disc storage.

**Preceding page blank**

At this time, the entire code exists on disc in precompiled form which is compatible with all electronic data processing equipment based on the FORTRAN language. As such, the code gains advantage in capability and versatility by employing fixed or consistent amounts of high speed core storage with a random access interface.

Briefly, advantages of the new disc format are:

- Capacity increased; that is, problems characterized by greater numbers of intrinsic variables and requiring finer mesh works for calculation purposes can be treated. The fracture problem in sea ice falls within this definition.
- Convenience increased; that is, ease of working with the code has been considered. For instance, the code is transcribed presently on one disc pack in lieu of multiple racks of perforated cards.
- Versatility increased; that is, interrupted calculations can be performed so that when a computation procedure is stopped intermittently it is no longer necessary to resume calculations from the initial, or zero, input state. Instead, numerical treatment can be restarted from the previous termination point. In this manner, and with particular relevance to the fracture problem, an analysis can be intercepted to focus attention on the development of a propagating fracture surface and the attendant stresses in plastic zones surrounding a crack tip.
- Information display possibilities increased; that is, direct computer readout is feasible to furnish continuing computer code output by means of cathode ray terminals. Thus, it becomes practical to take movies of progressive display patterns and thereby indicate visually the continuing propagation of fracture surfaces and ancillary stress redistributions in both target material and impacting projectile.

With restructuring and modification of the computer code effected, it was possible to attack the fracture problem directly. However, in

this case it was acknowledged first that the treatment of stress redistributions due to developing fracture surfaces would be closely coupled to the states of stress existing on free surface boundaries such that the proper numerical treatment of boundary conditions themselves would be an utmost necessity. In this connection, it was pointed out in Ref. 3 that many large deformation elastic-plastic computer codes currently in existence were founded on incorrect boundary condition formulations. Thus, an appendix was included in the report containing a lengthy derivation for the true treatment of these boundary conditions. Because this development was somewhat unwieldy in the form presented, considerable effort was expended during the current period in rewriting a more concise and simplified algorithm for this aspect of the problem.

Once this task was completed, it was possible to create an additional algorithm to treat the fracture problem itself. In this case, the algorithm was founded on the development of a point condition code which enabled integer point condition values to be associated with different characteristic free surface points on nodal intersections in the finite difference network. For example, individual point values were ascribed with concomitant subroutines to represent lateral and transverse free surface points, interior fracture surface points, and corner points on both target and projectile. As a result, point condition changes could be related to responsive subroutines in correspondence with physical transformations of both impacting bodies. Consequently, it is possible now to track in the computer both current boundary states and conditions, as well as emerging and propagating fracture surfaces.

Use was then made of the modified boundary condition and fracture algorithms to treat the shear fracture problem encountered when a blunt or hemispherical nose projectile experiences initial penetration in a target material. In this case, it was known from previous experimental,

field test, and theoretical studies that, due to the anisotropic nature of a sea ice target material, initial fracture under these impact conditions would occur in the shear mode along  $\sigma_{zz}$ -normal stress planes in the vertical direction.\*

With the shear fracture phase of the overall perforation process accounted for, work progressed toward realization of a fracture algorithm to describe failure surface propagation under tensile principal stresses. The important difficulty overcome in treating this problem was that fracture does not occur necessarily along a mesh direction.\*\* Therefore, there remained the burden of outlining and defining not only the stress redistributions at incipient fracture but the directions of the fracture planes themselves.

In this context, a method of approach was devised and implemented in the present version of the code. Specifically, all components of the  $\sigma_{ij}$

---

\* Fracture configurations in the shear mode are initiated upon projectile impact at normal incidence because, for a blunt penetrator, regions of intense shear stress are generated around the projectile periphery. Moreover, laboratory experiments and field test results, as well as theoretical calculations (CANDIA CODE), indicate that continued shear penetration and concomitant fracture patterns are engendered in the sea ice slab until penetration depths of the order of 70-80% sea ice sheet thickness are achieved. At this point, it is recognized that shear stress magnitudes fall off and that further fracture and ultimate perforation are the result of sea ice failure under tensile stress. In sum, complete penetration is obtained through a composite process characterized by initial failure due to shear and terminal failure as a result of tensile or cleavage fracture. Consequently, ultimate perforation results in the ejection of a cylindrical-conical shear plug of target material by the impacting body.

\*\* In this connection, the orientations of component segments of a developing tensile fracture surface are related directly to the magnitudes and directions of local principal stresses, which themselves are dependent variables of the problem in question. Thus, developing cleavage fracture surfaces do not correspond necessarily in spatial alignment and configuration to the postulated geometry of the mesh network employed for finite-difference calculations.

stress tensor are determined at the center point of a given area segment in a mesh network. Knowing these quantities enables the three principal stresses to be determined, whereupon a test is performed to isolate any possibility that the shear stress component of the total stress tensor violates the allowable shear failure stress of the target material. Assuming this is not the case and that shear fracture does not develop, then the calculation sequence is pursued further by comparing the maximum principal stress value with the allowable failure stress in uniaxial tension. If the former quantity exceeds the latter, it can be assumed (i.e., at least for an elastic brittle material such as freshwater ice) that fracture occurs over the mesh section of interest. Then, spatial orientation of the fracture surface segment is obtained by considering the cleavage plane to be orthogonal to the direction of the maximum principal stress component.

Thus, knowledge of the magnitudes and directions of principal stress quantities at a central point in the mesh section enables the prediction of fracture likelihood and resultant local failure surface geometry to be made. Once fracture occurs over a mesh section, it is necessary to postulate free surface boundary conditions which provide a zero traction state over the developing area of material separation. Then, the physical situation at the failed mesh section must be rechecked at each and every time step of succeeding numerical calculation to determine whether changes in external loading and/or internal stress state have resulted in subjecting the mutual fracture surfaces to closure and compressive pressure. If this turns out to be the case, free surface boundary conditions are stricken and appropriate interface conditions substituted in their place. Finally, at the conclusion of each calculation time step, a locus or contour is passed through all of the individual fracture surface segments to indicate instantaneous states of the composite failure pattern developed in the target material subjected to projectile impact.

### III MECHANICS OF PENETRATION

In addition to continuing research in the fracture problem, efforts were devoted to realizing a theory for the deep penetration of projectiles in multilayered media such as a snow covered Arctic sea ice sheet.<sup>13,14,15</sup> Solutions of the deep penetration problem for a single layer, homogeneous, isotropic sea ice cover have been obtained already, and their formulation and development were presented in a recently issued comprehensive report.<sup>3</sup> Fortunately, most of this previous work was applicable directly to the multilayered penetration problem; thus, the compounding of a tractable theory applicable to projectile-sea ice interaction problems for a more complicated target material did not offer substantial difficulty.

In this case, continued use was made of the two most important conceptual fundamentals upon which the previous theory was based. These are: first, that transformation of the deep penetration problem itself can be effected successfully to yield a problem concerned with dynamic stress distributions in an infinite solid that contains a spherical cavity subjected to step input in pressure\*, and, second, that the dynamic constitutive behavior of compactible materials such as Arctic sea ice and snow can be represented satisfactorily by assuming an idealized locking approximation for Rankine-Hugoniot material behavior under hydrostatic compressive stress.

---

\* This metamorphosis is founded specifically on the assumption that dynamic pressure experienced by a penetrating projectile at its stagnation point is comparable by reason of symmetry to the similar pressure quantity which exists at the surface of a dynamic expanding spherical cavity. A corollary assumption enables an expression for the complete force resisting continued penetration to be established by postulating that the spatial variation of pressure over the frontal portion of the projectile can be represented by a simple cosine relationship.<sup>17</sup>

Both of these arguments were invoked to resolve the multilayer penetration problem. In particular, a systematic approach was devised to recast the two-layer target configuration into the form of an idealized infinite body that included a spherical cavity surrounded by two concentric spherical regions of material having the relevant physical and mechanical properties of Arctic snow and sea ice. Then, the dynamic spherical expansion problem was worked through again for the composite material configuration. This task demanded relatively more complicated algebraic formulations but did not require an increase in mathematical generality or important theoretical innovation. The problem was made somewhat easier by the fact that reflected stress waves in a locked material travel at infinite speeds, so that introduction of limiting conditions into the mathematical process resulted in well-defined simplifications.

The problem considered is depicted schematically in Figs. 1 and 2. Attention is directed first to the ideal locked-rigid plastic material in Region 1<sub>s</sub> (Figs. 3 and 4) which is behind the advancing shock front at  $r = b(t)$ . The locking condition on strain is

$$\epsilon_r + 2\epsilon_\theta = \epsilon_{l_s} \quad (\text{III-1})$$

where  $\epsilon_{l_s}$  the ideal locking strain for snow is a time-invariant material property. Differentiating with respect to time results in

$$\dot{\epsilon}_r + 2\dot{\epsilon}_\theta = 0 \quad (\text{III-2})$$

These strain rate quantities can be expressed in terms of radial outward particle velocity,  $v(r,t)$ , by the kinematic relations

$$\dot{\epsilon}_r = \frac{\partial v}{\partial r} \quad \dot{\epsilon}_\theta = \frac{v}{r} \quad (\text{III-3})$$

FIGURE 1 SCHEMATIC REPRESENTATION OF PROJECTILE PENETRATION PROCESS IN SNOW COVERED ICE SHEET. INITIAL ENTRY AND FIRST PHASE MOTION

FIGURE 2 SCHEMATIC REPRESENTATION OF PROJECTILE PENETRATION PROCESS IN SNOW COVERED ICE SHEET. TRANSITION AND SECOND PHASE MOTION

FIGURE 3 DYNAMIC CAVITY EXPANSION PROBLEM FOR A RIGID PLASTIC, IDEAL LOCKING MATERIAL

FIGURE 4 IDEALIZED STRESS-STRAIN CURVES FOR A RIGID PLASTIC, IDEAL LOCKING MATERIAL WITH LINEAR STRAIN HARDENING AFTER YIELD

Substitution and integration yield

$$v_s = \frac{f_s(t)}{r^2} \quad (\text{III-4})$$

where subscript  $s$  denotes quantities in the locked-plastic snow region. The stress-strain relationship in shear for a rigid-plastic material with linear strain hardening is<sup>3</sup>

$$\sigma_\theta - \sigma_r = Y_s + \frac{2}{3} E_{ts} (\epsilon_\theta - \epsilon_r) \quad (\text{III-5})$$

Under conditions of spherical symmetry, the equation of motion becomes

$$\frac{\partial \sigma_r}{\partial r} + \frac{2}{r} (\sigma_r - \sigma_\theta) = \rho_{ls} \left( \frac{\partial v_s}{\partial t} + v_s \frac{\partial v_s}{\partial r} \right) \quad (\text{III-6})$$

Finally, the large deformation circumferential strain is given by

$$\epsilon_\theta = \ln \frac{r}{r_o} \quad (\text{III-7})$$

Combining these relationships into Eq. III-6 and integrating provides the following expression.

$$\begin{aligned} \sigma_{rs} = & 2Y_s \ln r + 2 \int_{\bar{f}_s}^r \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_o} + \frac{2\bar{\epsilon}_{ls}}{3} \right) dr' \\ & - \rho_{ls} \frac{\dot{f}_s}{r} + \frac{1}{2} \rho_{ls} \frac{\dot{f}_s^2}{r^4} + g_s(t) \end{aligned} \quad (\text{III-8})$$

Conservation of mass across the shock front at the stress free-locked plastic interface yields

$$\rho_{os} \dot{b} = \rho_{ls} (\dot{b} - v_s) \quad @ \quad r = b(t) \quad (\text{III-9})$$

or upon reduction

$$f_s(t) = \alpha_s b^2 \dot{b} \quad (\text{III-10})$$

where

$$\alpha_s = 1 - \rho_{0s}/\rho_{ls} \quad (\text{III-11})$$

Similarly, conservation of momentum yields

$$\sigma_{rs} = -\rho_{ls}(\dot{b} - v_s)v_s \quad @ \quad r = b(t) \quad (\text{III-12})$$

or upon reduction

$$\sigma_{rs} \Big|_{r=b} = -\rho_{0s} \alpha_s \dot{b}^2 \quad (\text{III-13})$$

The boundary condition on stress at the cavity surface is

$$\sigma_{rs} = -p(t) \quad @ \quad r = a(t) \quad (\text{III-14})$$

Then, from Eq. III-8 evaluated at  $r = a(t)$

$$\begin{aligned} g_s(t) = & -p(t) - 2Y_s \ln a - 2 \int_{\bar{r}_s}^a \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_o} + \frac{2\bar{\epsilon}_{ls}}{3} \right) dr' \\ & + \rho_{ls} \frac{\dot{f}_s}{a} - \frac{1}{2} \rho_{ls} \frac{f_s^2}{a^4} \end{aligned} \quad (\text{III-15})$$

so that the equation for radial stress becomes

$$\begin{aligned}\sigma_{r_s} = & -p(t) + 2Y_s \ln \frac{r}{a} + 2 \int_a^r \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_o} + \frac{2\bar{\epsilon}_s}{3} \right) dr' \\ & + \rho_{ls} \alpha_s \left( b^2 \ddot{b} + 2b\dot{b}^2 \right) \left( \frac{1}{a} - \frac{1}{r} \right) \\ & - \frac{1}{2} \rho_{ls} \alpha_s^2 b^4 \dot{b}^2 \left( \frac{1}{a^4} - \frac{1}{r^4} \right)\end{aligned}\quad (\text{III-16})$$

Using Eq. III-13, an expression is obtained for the pressure variation with time at the cavity surface

$$\begin{aligned}p(t) = & 2Y_s \ln \frac{b}{a} + 2 \int_a^b \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_o} + \frac{2\bar{\epsilon}_s}{3} \right) dr' \\ & + \alpha_s \rho_{ls} \left( b^2 \ddot{b} + 2b\dot{b}^2 \right) \left( \frac{1}{a} - \frac{1}{b} \right) \\ & - \frac{1}{2} \alpha_s^2 \rho_{ls} b^4 \dot{b}^2 \left( \frac{1}{a^4} - \frac{1}{b^4} \right) + \rho_{os} \alpha_s \dot{b}^2\end{aligned}\quad (\text{III-17})$$

Equation III-17 can be reduced further by application of the boundary condition on particle velocity at the cavity surface

$$v_s = \dot{a} \quad @ \quad r = a(t) \quad (\text{III-18})$$

Using Eqs. III-4, III-10 results in

$$\alpha_s b^2 \dot{b} = a^2 \dot{a} \quad (\text{III-19})$$

Differentiation of both sides of Eq. III-19 with respect to time yields

$$\alpha_s (b^2 \ddot{b} + 2b\dot{b}^2) = a^2 \ddot{a} + 2a\dot{a}^2 \quad (\text{III-20})$$

Substitution of these results into Eq. III-17 gives

$$\begin{aligned} p(t) = & 2Y_s \ln \frac{b}{a} + 2 \int_a^b \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_o} + \frac{2\bar{\epsilon}_{ls}}{3} \right) dr' \\ & + \rho_{ls} (a^2 \ddot{a} + 2a\dot{a}^2) \left( \frac{1}{a} - \frac{1}{b} \right) \\ & - \frac{1}{2} \rho_{ls} a^4 \dot{a}^2 \left( \frac{1}{a^4} - \frac{1}{b^4} \right) + \rho_{os} \frac{a^2}{b^2} \dot{a} \dot{b} \end{aligned} \quad (\text{III-21})$$

Surfaces of discontinuity in displacement and particle velocity cannot exist if fracture at the shock front is omitted from consideration. Thus,  $v_s(t)$  is zero on the shock front since the stress free material ahead of the locked plastic zone is quiescent. As a consequence, no material moves through the shock front and the following compressibility relationship can be applied at successive times over the volume of locked plastic material bounded by the cavity surface and an arbitrary spherical surface at the present shock front location

$$(b^3 - a^3) \rho_{ls} = (b^3 - a_o^3) \rho_{os} \quad (\text{III-22})$$

Upon reduction

$$\alpha_s \frac{b^3}{a^3} = 1 - \frac{a_o^3}{a^3} \frac{\rho_{os}}{\rho_{ls}} \quad (\text{III-23})$$

But, it has been shown by Goodier<sup>16,17,18</sup> that, for the deep penetration problem, the following assumption can be made

$$a^3 \gg a_o^3$$

In addition,  $\rho_l > \rho_o$ , so that

$$b^3 \approx \frac{1}{\alpha_s} a^3 \quad (\text{III-24})$$

Equation III-21 becomes

$$\begin{aligned} p(t) = & -\frac{2}{3} Y_s \ln \alpha_s + 2 \int_a^b \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_o} + \frac{2\bar{\epsilon}_s}{3} \right) dr' \\ & + \rho_{ls} \left( a\ddot{a} + 2\dot{a}^2 \right) \left( 1 - \alpha_s^{1/3} \right) \\ & - \frac{1}{2} \rho_{ls} \dot{a}^2 \left( 1 - \alpha_s^{4/3} \right) + \rho_{os} \dot{a}^2 \alpha_s^{1/3} \end{aligned} \quad (\text{III-25})$$

The remaining integral must be evaluated. Application of an appropriate compressibility relationship at an arbitrary location,  $r$ , within the locked plastic region yields

$$(r^3 - a^3) \rho_{ls} = (r_o^3 - a_o^3) \rho_{os} \quad (\text{III-26})$$

Using the deep penetration assumption (i.e.,  $a^3 \gg a_0^3$ ), Eq. III-26 becomes\*

$$\frac{r}{r_0} = \left[ \frac{\rho_{os}}{\rho_{ls}} \frac{r^3/a^3}{r^3/a^3 - 1} \right]^{1/3} \quad (\text{III-27})$$

Letting

$$x = \xi^3 = r^3/a^3$$

and employing Eq. III-27 enables the integral expression in Eq. III-25 to be written as follows

$$\begin{aligned} & 2 \int_{a(t)}^{b(t)} \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_0} + \frac{2\bar{\epsilon}_{ls}}{3} \right) dr' \\ &= \frac{4}{9} E_{ts} \left\{ \int_1^{b^3/a^3} \ln \frac{\rho_{os}}{\rho_{ls}} \frac{dx}{x} + \int_1^{b^3/a^3} \bar{\epsilon}_{ls} \frac{dx}{x} + \int_1^{b^3/a^3} \ln \frac{x}{x-1} \frac{dx}{x} \right\} \quad (\text{III-28}) \end{aligned}$$

---

\*

$$(r^3 - a^3) \rho_{ls} = (r_0^3 - a_0^3) \rho_{os}$$

$$r^3 - a^3 = (r_0^3 - a_0^3) \rho_{os}/\rho_{ls}$$

$$r^3 - a^3 = r_0^3 \frac{\rho_{os}}{\rho_{ls}} - a_0^3 \frac{\rho_{os}}{\rho_{ls}}$$

$$\frac{r^3}{r_0^3} - \frac{a^3}{r_0^3} = \frac{\rho_{os}}{\rho_{ls}} - \frac{a_0^3}{r_0^3} \frac{\rho_{os}}{\rho_{ls}}$$

(footnote continued on next page)

Evaluation of the first two integrals in the second member of Eq. III-28 is straightforward.<sup>3</sup> The remaining integral is attacked by letting  $y = 1/x$  and changing the lower limit of integration to  $1-\epsilon$  where  $\epsilon \ll 1$ . There results

$$\int_1^{b^3/a^3} \ln \frac{x}{x-1} \frac{dx}{x} \rightarrow \int_{1-\epsilon}^{a^3/b^3} \ln (1-y) \frac{dy}{y} \quad (\text{III-29})$$

Since  $b > a$  always and  $1-\epsilon < 1$ , the range of values over which integration takes place (i.e.,  $1-\epsilon \geq y \geq b^3/a^3$ ) ensures that  $y < 1$  so that the integrand can be expanded in series form. Step by step integration yields

$$\int_1^{b^3/a^3} \ln \frac{x}{x-1} \frac{dx}{x} = \left[ y + \frac{y^2}{4} + \frac{y^3}{9} + \dots \right]_{a^3/b^3}^{1-\epsilon} \quad (\text{III-30})$$

---

\* (footnote continued)

but  $\rho_{ls} > \rho_{os}$  and  $r_o^3 \gg a_o^3$

$$\therefore \frac{(\rho_{os}/\rho_{ls})}{r^3/r_o^3 - a^3/r_o^3} = 1$$

$$\frac{(\rho_{os}/\rho_{ls}) r^3}{r^3/r_o^3 - a^3/r_o^3} = r^3$$

$$\frac{(\rho_{os}/\rho_{ls}) r^3 r_o^3}{r^3 - a^3} = r^3$$

$$\therefore \frac{r^3}{r_o^3} = \frac{(\rho_{os}/\rho_{ls}) r^3/a^3}{r^3/a^3 - 1}$$

Allowing  $\epsilon \rightarrow 0$  and introducing Eq. III-24 results in

$$\int_1^{b^3/a^3} \ln \frac{x}{x-1} \frac{dx}{x} = \frac{\pi^2}{6} - \sum_{n=1}^{\infty} \frac{1}{n^2} \alpha_s^n \quad (\text{III-31})$$

Finally, Eq. III-25 becomes

$$\begin{aligned} p(t) = & -\frac{2}{3} Y_s \ln \alpha_s + \frac{4}{9} E_{ts} \left( \frac{\pi^2}{6} - \sum_{n=1}^{\infty} \frac{1}{n^2} \alpha_s^n \right) \\ & + \rho_{ls} (a\ddot{a} + 2\dot{a}^2) (1 - \alpha_s^{1/3}) \\ & - \frac{1}{2} \rho_{ls} \dot{a}^2 (1 - \alpha_s^{4/3}) + \rho_{os} \dot{a}^2 \alpha_s^{1/3} \end{aligned} \quad (\text{III-32})$$

The expression for pressure can be broken down into static and dynamic parts so that

$$p(t) = p_s + \rho_{ls} (B_1 a\ddot{a} + B_2 \dot{a}^2) \quad (\text{III-33})$$

where

$$p_s = \frac{2}{27} \pi^2 E_{ts} - \frac{2}{3} Y_s \ln \alpha_s - \frac{4}{9} E_{ts} \sum_{n=1}^{\infty} \frac{1}{n^2} \alpha_s^n$$

$$B_1 = 1 - \alpha_s^{1/3}$$

$$B_2 = \frac{3}{2} - (1 + \alpha_s) \alpha_s^{1/3} + \frac{1}{2} \alpha_s^{4/3}$$

or

$$B_2 = \frac{3}{2} - \alpha_s^{1/3} - \frac{1}{2} \alpha_s^{4/3} \quad (\text{III-34})$$

The relationship for pressure variation at the cavity surface given by Eq. III-33 is used in the Goodier deep penetration theory<sup>3,16</sup> to obtain an expression for resisting forces acting on the projectile. Then, an equation of motion for projectile transit in the target material can be written

$$M\ddot{q} = - \left\{ p_S + \frac{2}{3} \rho \ell_s \left( B_1 \frac{D}{2} \ddot{q} + B_2 \dot{q}^2 \right) \right\} \frac{\pi D^2}{4} \quad (\text{III-35})$$

After integration, Eq. III-35 becomes

$$\ln \left( p_S + \frac{2}{3} B_2 \rho \ell_s \dot{q}^2 \right) = - \frac{4}{3} B_2 \rho \ell_s \frac{q}{\frac{M}{A} + B_1 \frac{D}{3} \rho \ell_s} + C_0 \quad (\text{III-36})$$

Exact shallow penetration theory<sup>3,16</sup> is avoided in this consideration. Instead, it is assumed on balance that the onset of resistance to penetration in snow takes place at an indentation depth corresponding to the centroid of the nose hemisphere. That is, when  $q = 5D/16$ . Under these conditions, Eq. III-36 becomes

$$\ln \frac{p_S + \frac{2}{3} B_2 \rho \ell_s \dot{q}^2}{p_S + \frac{2}{3} B_2 \rho \ell_s V_o^2} = - \frac{4}{3} \frac{B_2 \rho \ell_s}{\frac{M}{A} + B_1 \frac{D}{3} \rho \ell_s} (q - 5D/16) \quad (\text{III-37})$$

The first phase of penetration is completed when the projectile encounters the snow-ice interface. Here,

$$q = q_{0s} = R \gtrsim R_o$$

Substitution of  $q = R$  into Eq. III-37 determines the projectile velocity,  $\dot{q}_{0s}$ , which characterizes initiation of the second penetration phase.

In the second phase of penetration, the projectile encounters an ice cover which is assumed in the present problem to behave as an elastic-plastic solid in shear, and incompressible under hydrostatic stress. Attention is directed to Figs. 5 and 6. Using expressions which have been developed in Ref. 3, the radial normal stress at the snow-ice interface is given by\*

$$\begin{aligned}
 -\sigma_{rI}\bigg|_{r=R} = & -\frac{2}{3} Y \ln\left(1 - e^{-3\beta} \frac{\rho_o}{\rho_{lp}}\right) + \frac{2}{27} \pi^2 E_t \\
 & - \frac{4}{9} E_{ts} \sum_{n=1}^{\infty} \frac{1}{n^2} \left(1 - e^{-3\beta} \frac{\rho_o}{\rho_{lp}}\right)^n \\
 & + \frac{4}{9} E \left(1 - e^{-3\beta}\right) + \alpha_p \rho_o \dot{b}^2 \\
 & + \alpha_p \rho_{lp} (b\ddot{b} + 2\dot{b}^2) \left(\frac{b}{R} - 1\right) \\
 & - \frac{1}{2} \alpha_p^2 \rho_{lp} \dot{b}^2 \left(\frac{b^4}{R^4} - 1\right)
 \end{aligned} \tag{III-38}$$

Again, from previous work

$$v_I\bigg|_{r=R} = \alpha_p \frac{b^2 \dot{b}}{R^2} = \frac{f_I(t)}{R^2} \tag{III-39}$$

$$\text{where} \quad f_I(t) = \alpha_p b^2 \dot{b} \tag{III-40}$$

---

\* The subscript, I, has been omitted from the quantities  $Y$ ,  $\rho_o$ ,  $\rho_{lp}$ ,  $E_t$ , and  $E$  for reasons of mathematical convenience.

FIGURE 5 DYNAMIC CAVITY EXPANSION PROBLEM FOR AN ELASTIC-PLASTIC, INCOMPRESSIBLE MATERIAL

FIGURE 6 IDEALIZED STRESS-STRAIN CURVES FOR AN ELASTIC-PLASTIC, INCOMPRESSIBLE MATERIAL WITH LINEAR STRAIN HARDENING AFTER YIELD

In the snow region, the general solution to the problem can be written as

$$\begin{aligned} \sigma_{r_s} = & 2Y_s \ln r + 2 \int_{\bar{f}_s}^r \frac{1}{r'} E_{t_s} \left( 2 \ln \frac{r'}{r_o} + \frac{2}{3} \bar{\epsilon}_{l_s} \right) dr' \\ & - \rho_{l_s} \frac{\dot{f}_s}{r} + \frac{1}{2} \rho_{l_s} \frac{r_s^2}{r^4} + g_s(t) \end{aligned} \quad (\text{III-41})$$

$$v_s = \frac{f_s(t)}{r^2} \quad (\text{III-42})$$

Boundary conditions are given by:

$$\begin{aligned} r &= a(t) \\ \sigma_{r_s} &= -p(t) \end{aligned} \quad (\text{III-43})$$

$$\begin{aligned} r &= R(t) \\ \rho_{l_s}(\dot{R} - v_s) &= \rho_{l_p}(\dot{R} - v_I) \end{aligned} \quad (\text{III-44})$$

$$\sigma_{r_s} - \sigma_{r_I} = -\rho_{l_p}(v_I - \dot{R})(v_I - v_s) \quad (\text{III-45})$$

The quantities  $\sigma_{r_I}$  and  $v_I$  at  $r = R$  are given by Eqs. III-38, III-39. Use of Eq. III-43 enables the quantity,  $g_s(t)$ , in Eq. III-41 to be expressed in terms of  $p(t)$ .

Then, the new relationship for  $\sigma_{rs}$  is given by

$$\begin{aligned} \sigma_{rs} = & -p(t) + 2Y_s \ln \frac{r}{a} + 2 \int_a^r \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_o} + \frac{2}{3} \bar{\epsilon}_{ls} \right) dr' \\ & + \rho_{ls} \dot{f}_s \left( \frac{1}{a} - \frac{1}{r} \right) - \frac{1}{2} \rho_{ls} f_s^2 \left( \frac{1}{a^4} - \frac{1}{r^4} \right) \end{aligned} \quad (\text{III-46})$$

From the boundary condition of Eq. III-44,

$$v_s \Big|_{r=R} = \left( 1 - \frac{\rho_{lp}}{\rho_{ls}} \right) \dot{R} + \frac{\rho_{lp}}{\rho_{ls}} v_I \quad (\text{III-47})$$

Then,

$$f_s(t) = \left( 1 - \frac{\rho_{lp}}{\rho_{ls}} \right) R^2 \dot{R} + \frac{\rho_{lp}}{\rho_{ls}} f_I(t) \quad (\text{III-48})$$

Substitution into the boundary condition given by Eq. III-45 yields

$$\sigma_{rs} - \sigma_{rI} \Big|_{r=R} = \rho_{lp} \left( \dot{R} - \alpha_p \frac{b^2 \dot{b}}{R^2} \right) \left( \alpha_p \frac{b^2 \dot{b}}{R^2} - \alpha_{ls} \dot{R} - (1 - \alpha_{ls}) \alpha_p \frac{b^2 \dot{b}}{R^2} \right) \quad (\text{III-49})$$

or

$$\sigma_{rs} - \sigma_{rI} \Big|_{r=R} = \rho_{lp} \left( -\alpha_{ls} \dot{R}^2 + 2\alpha_{ls} \alpha_p \frac{b^2 \dot{b} \dot{R}}{R^2} - \alpha_p^2 \alpha_{ls} \frac{b^4 \dot{b}^2}{R^4} \right) \quad (\text{III-50})$$

Substitution of Eqs. III-46, III-38 in Eq. III-50 gives

$$\begin{aligned}
 & - p(t) + 2Y_s \ln \frac{R}{a} + 2 \int_a^R \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_o} + \frac{2}{3} \epsilon_{ls} \right) dr' \\
 & + \rho_{ls} \left[ \alpha_{ls} (2R\dot{R}^2 + R^2\ddot{R}) + \frac{\rho_{lp}}{\rho_{ls}} \alpha_p (2b\dot{b}^2 + b^2\ddot{b}) \right] \left( \frac{1}{a} - \frac{1}{R} \right) \\
 & - \frac{1}{2} \rho_{ls} \left[ \left( 1 - \frac{\rho_{lp}}{\rho_{ls}} \right) R^2\dot{R} + \frac{\rho_{lp}}{\rho_{ls}} \alpha_p b^2\dot{b} \right]^2 \left( \frac{1}{a^4} - \frac{1}{R^4} \right) \\
 & + P_I + \alpha_p \rho_o \dot{b}^2 + \alpha_p \rho_{lp} (2b\dot{b}^2 + b^2\ddot{b}) \left( \frac{1}{R} - \frac{1}{b} \right) \\
 & + \frac{1}{2} \alpha_p^2 \rho_{lp} b^4 \dot{b}^2 \left( \frac{1}{R^4} - \frac{1}{b^4} \right) \\
 & = \rho_{lp} \left( - \alpha_{ls} \dot{R}^2 + 2\alpha_{ls} \alpha_p \frac{b^2 \dot{b} \ddot{R}}{R^2} - \alpha_p^2 \alpha_{ls} \frac{b^4 \dot{b}^2}{R^4} \right) \quad (III-51)
 \end{aligned}$$

where

$$\begin{aligned}
 P_I &= - \frac{2}{3} Y \ln \left( 1 - e^{-3\beta} \frac{\rho_o}{\rho_{lp}} \right) + \frac{2}{27} \pi^2 E_t \\
 & - \frac{4}{9} E_t \sum_{n=1}^{\infty} \frac{1}{n^2} \left( 1 - e^{-3\beta} \frac{\rho_o}{\rho_{lp}} \right) + \frac{4}{9} E \left( 1 - e^{-3\beta} \right) \quad (III-52)
 \end{aligned}$$

Solving Eq. III-51 for the dynamic pressure variation at the cavity surface and subsequent rearrangement yields

$$\begin{aligned}
 p(t) = & 2Y_s \ln \frac{R}{a} + 2 \int_a^R \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_o} + \frac{2}{3} \bar{\epsilon}_{ls} \right) dr' \\
 & + \alpha_{ls} \rho_{ls} (2R\dot{R}^2 + R^2\ddot{R}) \left( \frac{1}{a} - \frac{1}{R} \right) \\
 & + \alpha_p \rho_{lp} (2b\dot{b}^2 + b^2\ddot{b}) \left( \frac{1}{a} - \frac{1}{b} \right) \\
 & - \frac{1}{2} \rho_{ls} \left[ \alpha_{ls} R^2 \dot{R} + \frac{\rho_{lp}}{\rho_{ls}} \alpha_p b^2 \dot{b} \right]^2 \left( \frac{1}{a^4} - \frac{1}{R^4} \right) \\
 & + \frac{1}{2} \alpha_p^2 \rho_{lp} b^4 \dot{b}^2 \left( \frac{1}{R^4} - \frac{1}{b^4} \right) + P_I \\
 & + \alpha_p \rho_o \dot{b}^2 + \alpha_{ls} \rho_{lp} \dot{R}^2 - 2\rho_{lp} \alpha_{ls} \alpha_p \frac{b^2 \dot{b}}{R^2} \dot{R} \\
 & + \alpha_p^2 \alpha_{ls} \rho_{lp} \frac{b^4 \dot{b}^2}{R^4}
 \end{aligned} \tag{III-53}$$

The following relationships have been derived in Ref. 3 and are listed for convenience.

$$2 \int_a^R \frac{1}{r'} E_{ts} \left( 2 \ln \frac{r'}{r_o} + \frac{2}{3} \bar{\epsilon}_{ls} \right) dr' = \frac{2}{27} \pi^2 E_{ts} - \frac{4}{9} E_{ts} \eta \tag{III-54}$$

$$2Y_s \ln \frac{R}{a} = -\frac{2}{3} Y_s \ln \left( 1 - e^{-3\beta_s \frac{\rho_{os}}{\rho_{ls}}} \right) \tag{III-55}$$

where

$$\beta_s = \frac{Y_s}{2E_s} - \frac{\bar{\epsilon}_{ls}}{3} \quad (\text{III-56})$$

$$\alpha_{ls} (2R\dot{R}^2 + R^2\ddot{R}) = 2a\dot{a}^2 + a^2\ddot{a} \quad (\text{III-57})$$

$$\alpha_{ls} R^2 \dot{R} = a^2 \dot{a} \quad (\text{III-58})$$

$$\frac{b}{R} = \left( 1 - e^{-3\beta} \frac{\rho_o}{\rho_{lp}} \right)^{-1/3} \quad (\text{III-59})$$

where

$$\beta = \frac{Y}{2E} - \frac{\bar{\epsilon}_{lp}}{3} \quad (\text{III-60})$$

$$\frac{R}{a} = \left( 1 - e^{-3\beta_s} \frac{\rho_{os}}{\rho_{lp}} \right)^{-1/3} \quad (\text{III-61})$$

$$(b^3 - R^3) \rho_{lp} = (b_o^3 - R_o^3) \rho_o \quad (\text{III-62})$$

$$b_o = b e^{-\beta} \quad (\text{III-63})$$

Using Eqs. III-62, III-63

$$b^3 \left( 1 - e^{-3\beta} \frac{\rho_o}{\rho_{lp}} \right) = R^3 \left( 1 - \frac{R_o^3}{R^3} \frac{\rho_o}{\rho_{lp}} \right) \quad (\text{III-64})$$

or

$$b = R \left( 1 - e^{-3\beta} \frac{\rho_o}{\rho_{lp}} \right)^{-1/3} \left( 1 - \frac{R_o^3}{R^3} \frac{\rho_o}{\rho_{lp}} \right)^{1/3} \quad (\text{III-65})$$

Now  $\rho_{lp} > \rho_o$ , and for deep penetration depths of the order of several projectile diameters in ice,  $R^3 \gg R_o^3$ . Thus, Eq. III-65 becomes

$$b \cong R \bar{\alpha}_p^{-1/3} \quad (\text{III-66})$$

where

$$\bar{\alpha}_p = \left( 1 - e^{-3\beta} \frac{\rho_o}{\rho_{lp}} \right) \quad (\text{III-67})$$

It follows readily that

$$b = a \left( 1 - e^{-3\beta_s} \frac{\rho_{os}}{\rho_{lp}} \right)^{-1/3} \left( 1 - e^{-3\beta} \frac{\rho_o}{\rho_{lp}} \right)^{-1/3} \quad (\text{III-68})$$

or

$$b = a \bar{\alpha}_s^{-1/3} \bar{\alpha}_p^{-1/3} \quad (\text{III-69})$$

where

$$\bar{\alpha}_s = \left( 1 - e^{-3\beta_s} \frac{\rho_{os}}{\rho_{lp}} \right) \quad (\text{III-70})$$

Introduction of these relationships in Eq. III-53 yields

$$\begin{aligned}
 p(t) = & -\frac{2}{3} Y_s \ln \left( 1 - e^{-3\beta_s \frac{\rho_{os}}{\rho_{ls}}} \right) + \frac{2}{27} \pi^2 E_{ts} \\
 & - \frac{4}{9} E_{ts} \eta + \rho_{ls} (a^2 \ddot{a} + 2a \dot{a}^2) \left( \frac{1}{a} - \frac{1}{R} \right) \\
 & + \alpha_p \rho_{lp} (\bar{\alpha}_p)^{-1} (\bar{\alpha}_s)^{-1} (a^2 \ddot{a} + 2a \dot{a}^2) \left( \frac{1}{a} - \frac{1}{b} \right) \\
 & - \frac{1}{2} \rho_{ls} \left[ a^2 \dot{a} + \frac{\rho_{lp}}{\rho_{ls}} \alpha_p (\bar{\alpha}_p)^{-1} (\bar{\alpha}_s)^{-1} a^2 \dot{a} \right]^2 \left( \frac{1}{a^4} - \frac{1}{R^4} \right) \\
 & + \frac{1}{2} \alpha_p^2 \rho_{lp} (\bar{\alpha}_p)^{-2} (\bar{\alpha}_s)^{-2} a^4 \dot{a}^2 \left( \frac{1}{R^4} - \frac{1}{b^4} \right) \\
 & + P_I + \alpha_p \rho_o (\bar{\alpha}_p)^{-2/3} (\bar{\alpha}_s)^{-2/3} \dot{a}^2 + \rho_{lp} \alpha_{ls} (\bar{\alpha}_s)^{-2/3} \dot{a}^2 \\
 & - 2\rho_{lp} \alpha_{ls} \alpha_p (\bar{\alpha}_p)^{-1} (\bar{\alpha}_s)^{-2/3} \dot{a}^2 \\
 & + \rho_{lp} \alpha_p^2 \alpha_{ls} (\bar{\alpha}_p)^{-2} (\bar{\alpha}_s)^{-2/3} \dot{a}^2
 \end{aligned} \tag{III-71}$$

Now let

$$\begin{aligned}
 P_{II} = & P_I - \frac{2}{3} Y_s \ln \left( 1 - e^{-3\beta_s \frac{\rho_{os}}{\rho_{ls}}} \right) \\
 & + \frac{2}{27} \pi^2 E_{ts} - \frac{4}{9} E_{ts} \eta
 \end{aligned} \tag{III-72}$$

Then

$$\begin{aligned}
 p(t) = & P_{II} + (a\ddot{a} + 2\dot{a}^2) \left[ \rho l_s \left( 1 - \bar{\alpha}_s^{1/3} \right) \right. \\
 & \left. + \frac{\alpha_p \rho l_p}{\bar{\alpha}_p \bar{\alpha}_s} \left( 1 - \bar{\alpha}_s^{1/3} \bar{\alpha}_p^{1/3} \right) \right] \\
 & - \frac{1}{2} \rho l_s \dot{a}^2 \left[ 1 + \frac{\rho l_p}{\rho l_s} \frac{\alpha_p}{\bar{\alpha}_p \bar{\alpha}_s} \right]^2 \left( 1 - \bar{\alpha}_s^{4/3} \right) \\
 & + \frac{1}{2} \frac{\alpha_p^2 \rho l_p}{\bar{\alpha}_p^2 \bar{\alpha}_s^2} \left( 1 - \bar{\alpha}_s^{4/3} \right) \dot{a}^2 \\
 & + \dot{a}^2 \left[ \frac{\alpha_p \rho}{\bar{\alpha}_p^{2/3} \bar{\alpha}_s^{2/3}} + \frac{\alpha l_s \rho l_p}{\bar{\alpha}_s^{2/3}} - 2 \rho l_p \frac{\alpha l_s \alpha_p}{\bar{\alpha}_p \bar{\alpha}_s^{2/3}} + \frac{\alpha_p^2 \alpha l_s}{\bar{\alpha}_p^2 \bar{\alpha}_s^{2/3}} \rho l_p \right] \quad (III-73)
 \end{aligned}$$

Rearranging

$$\begin{aligned}
 p(t) = & P_{II} + a\ddot{a} \left[ \rho l_s \left( 1 - \bar{\alpha}_s^{1/3} \right) + \frac{\alpha_p \rho l_p}{\bar{\alpha}_p \bar{\alpha}_s} \left( 1 - \bar{\alpha}_s^{1/3} \bar{\alpha}_p^{1/3} \right) \right] \\
 & + \dot{a}^2 \left[ 2 \rho l_s \left( 1 - \bar{\alpha}_s^{1/3} \right) + \frac{2 \alpha_p \rho l_p}{\bar{\alpha}_p \bar{\alpha}_s} \left( 1 - \bar{\alpha}_s^{1/3} \bar{\alpha}_p^{1/3} \right) \right. \\
 & - \frac{1}{2} \rho l_s \left( 1 + \frac{\rho l_p}{\rho l_s} \frac{\alpha_p}{\bar{\alpha}_p \bar{\alpha}_s} \right)^2 \left( 1 - \bar{\alpha}_s^{4/3} \right) \\
 & + \frac{1}{2} \frac{\alpha_p^2 \rho l_p}{\bar{\alpha}_p^2 \bar{\alpha}_s^2} \left( 1 - \bar{\alpha}_s^{4/3} \right) + \frac{\alpha_p \rho}{\bar{\alpha}_p^{2/3} \bar{\alpha}_s^{2/3}} + \frac{\alpha l_s \rho l_p}{\bar{\alpha}_s^{2/3}} \\
 & \left. - 2 \rho l_p \frac{\alpha l_s \alpha_p}{\bar{\alpha}_p \bar{\alpha}_s^{2/3}} + \frac{\alpha_p^2 \alpha l_s}{\bar{\alpha}_p^2 \bar{\alpha}_s^{2/3}} \rho l_p \right] \quad (III-74)
 \end{aligned}$$

Equation III-74 can be rewritten as

$$p(t) = P_{II} + C_1 \ddot{a} + C_2 \dot{a}^2 \quad (\text{III-75})$$

where

$$C_1 = \rho l_s \left(1 - \alpha_s^{1/3}\right) + \frac{\alpha_p \rho l_p}{\bar{\alpha}_p \bar{\alpha}_s} \left(1 - \bar{\alpha}_s^{1/3} \bar{\alpha}_p^{1/3}\right) \quad (\text{III-76})$$

$$\begin{aligned} C_2 = & 2\rho l_s \left(1 - \bar{\alpha}_s^{1/3}\right) + 2 \frac{\alpha_p \rho l_p}{\bar{\alpha}_s \bar{\alpha}_p} \left(1 - \bar{\alpha}_s^{1/3} \bar{\alpha}_p^{1/3}\right) \\ & - \frac{1}{2} \rho l_s \left(1 + \frac{\rho l_p}{\rho l_s} \frac{\alpha_p}{\bar{\alpha}_p \bar{\alpha}_s}\right)^2 \left(1 - \bar{\alpha}_s^{4/3}\right) \\ & + \frac{1}{2} \frac{\rho l_p \alpha_p^2}{\bar{\alpha}_p^2 \bar{\alpha}_s^2} \left(1 - \bar{\alpha}_s^{4/3}\right) + \frac{\alpha_p \rho}{\bar{\alpha}_p^{2/3} \bar{\alpha}_s^{2/3}} + \frac{\alpha_s \rho l_p}{\bar{\alpha}_s^{2/3}} \\ & - 2\rho l_p \frac{\alpha_s \alpha_p}{\bar{\alpha}_p \bar{\alpha}_s^{2/3}} + \frac{\alpha_p^2 \alpha_s}{\bar{\alpha}_p^2 \bar{\alpha}_s^{2/3}} \rho l_p \end{aligned} \quad (\text{III-77})$$

It has been shown in Ref. 3 that an expression for dynamic pressure at the spherical cavity surface, such as the one given by Eq. III-75, can be employed to derive an equation of motion for projectile penetration. In the present case, the following relationship is obtained

$$M\ddot{q} = - \left[ P_{II} + \frac{2}{3} \left( C_1 \frac{D}{2} \ddot{q} + C_2 \dot{q}^2 \right) \right] \frac{\pi D^2}{4} \quad (\text{III-78})$$

The usual process of integration yields

$$\ln \frac{P_{II} + 2/3 C_1 \dot{q}^2}{P_{II} + 2/3 C_2 v_{0s}^2} = - \frac{4 C_2 (q - q_{0s})}{3 M/A + C_1 D/3} \quad (III-79)$$

Solving for the terminal penetration depth

$$q_t = q_{0s} + \frac{3}{4} \frac{M/A + C_1 D/3}{C_2} \ln \frac{P_{II} + 2/3 C_2 v_{0s}^2}{P_{II}} \quad (III-80)$$

Here,  $q_{0s}$  and  $v_{0s}$  refer to the penetration depth and exit velocity, respectively, characterizing projectile transit through the overlying snow cover. These quantities are obtained from solution of the first phase penetration problem.
