13. ABSTRACT A detailed analytical evaluation is made of a new rotor system with torsionally elastic blades and dual controls -the controllable twist rotor (CTR). The controls consist of conventional pitch horn linkages at the inboard end and an aerodynamic control flap at the outboard end. The analysis involves an aeroelastic loads digital computer program which was developed to account for the blade response modes and blade control modes on either single or dual control rotors. Six response modes are included. Blade flapping, blade feathering, blade lagging, blade flapwise bending, blade torsion, and control flap feathering. The two control modes are included separately, and incorporate control system stiffness so that control loads are calculated. The aeroelastic analysis includes nonlinear inertia distributions, nonlinear airfoil characteristics, and inertial and mechanical coupling among the modes. The analysis outputs transient responses for stability evaluation and steady-state blade load and angle-of-attack distributions, blade dynamics, and rotor performance for each trimmed flight condition. Comparisons are made between a CTR and a conventional direct control rotor (DCR), using the above nonlinear aeroelastic loads analysis. Both are sized to meet an assumed utility helicopter mission. Conclusions resulting from this comparison show that the CTR has the following capability as compared to the DCR: 30 percent decrease in solidity 15 percent reduction in power 18 percent increase in range 30 percent decrease in bending amplitudes (resulting in increased blade life) 15 percent lighter gross weight 10 percent smaller rotor diameter 25 percent lower installed power 15 percent less hover power (OGE, 4000 feet, 95°F)

EUSTIS DIRECTORATE
FORT EUSTIS, VIRGINIA 23604

This report has been reviewed by the Eustis Directorate, U. S. Army Air Mobility Research and Development Laboratory, and is considered to be technically sound.

The purpose of the program was to analyze the performance improvement obtainable with the controllable twist rotor concept. The analysis techniques which were used are fully described in this report. The techniques appear to be reasonable for the purposes intended. Although final conclusions relative to this concept can be reached only as a result of adequate experimentation, the predicted performance gains for the controllable twist rotor can be viewed with sufficient confidence to encourage further investigation. This report is published for the dissemination of this data and for the stimulation of ideas relative to the basic subject.

The program was conducted under the technical management of Mr. W. E. Nettles of the Aeromechanics Division of this Directorate.

SUMMARY

A detailed analytical evaluation is made of a new rotor system with torsionally elastic blades and dual controls - the controllable twist rotor (CTR). The controls consist of conventional pitch horn linkages at the inboard end and an aerodynamic control flap at the outboard end.

The analysis involves an aeroelastic loads digital computer program which was developed to account for the blade response modes and blade control modes on either single or dual control rotors. Six response modes are included: blade flapping, blade feathering, blade lagging, blade flapwise bending, blade torsion, and control flap feathering. The two control modes are included separately and incorporate control system stiffness so that control loads are calculated. The aeroelastic analysis includes nonlinear inertia distributions, nonlinear airfoil characteristics, and inertial and mechanical coupling among the modes. The analysis outputs transient responses for stability evaluation and steady-state blade load and angle-of-attack distributions, blade dynamics, and rotor performance for each trimmed flight condition.

Comparisons are made between a CTR and a conventional direct control rotor (DCR), using the above nonlinear aeroelastic loads analysis. Both are sized to meet an assumed utility helicopter mission. Conclusions resulting from this comparison show that the CTR has the following capability as compared to the DCR:

- 30 percent decrease in solidity;
- 15 percent reduction in power;
- 18 percent increase in range;
- 30 percent decrease in bending amplitudes (resulting in increased blade life);
- 15 percent lighter gross weight;
- 10 percent smaller rotor diameter;
- 25 percent lower installed power;
- 15 percent less hover power (OGE, 4000 feet, 95°F).

FOREWORD

This report presents the work that was accomplished during the contract effort to analytically evaluate the blade aeroelastic characteristics and rotor performance of the controllable twist rotor. The report presents a description of the rotor, a detailed discussion of the analytical techniques developed herein, an evaluation and comparison of the CTR with conventional rotor systems, and a schematic of the control system kinematics. The computer analysis and control system schematic are on file at the USAAMRDL Eustis Directorate.

The research program was conducted by Kaman Aerospace Corporation under Contract DAAJ02-67-C-0068 (Task 1F162203A14302) and was carried out under the technical cognizance of Mr. William E. Nettles of the Eustis Directorate.

The research program began in July 1967 and was completed in March 1971. Personnel associated with the contract in addition to the authors were Messrs. D. W. Robinson, Jr., R. Jones, A. Berman, E. Walcek, and J. Kennedy.

LIST OF SYMBOLS

[A]	linear operating matrix for multiplying with the acceleration matrix
a	blade section lift curve slope
A_0	collective pitch horn control input, deg
a_0	mean value of lift curve slope for use in Lock no. calculation
A_{1s}	lateral pitch horn control input, deg
$a_{11}, a_{12}, \text{ etc}$	coefficients of Equation (50)
B	geometrical flapping rotation matrix
b	number of rotor blades
b_0, b_1, b_2, b_3	coefficients of Equation (51)
B_{1s}	longitudinal pitch horn control input, deg
c	blade chord
c_d	two-dimensional airfoil drag coefficient
c_l	two-dimensional airfoil lift coefficient
$c_{m\delta}$	two-dimensional flap hinge moment. Trailing edge down is positive
$c_{m\theta}$	two-dimensional airfoil pitching moment coefficient about the 1/4 chord. Nose up is positive
c_q	damping coefficient for the dissipative function in elastic bending, in.-lb/in./sec
c_{tw}	damping coefficient for the dissipative function in elastic torsion, in.-lb/deg/sec
CTR	designation for the Controllable Twist Rotor
c_β	damping coefficient for the flapping motions, in.-lb/deg/sec

LIST OF SYMBOLS (Continued)

c_{ζ}	damping coefficient for the lag motions (lag damper), in.-lb/deg/sec
c_{θ}	damping coefficient for the feathering motions (pitch damper), in.-lb/deg/sec
Δc	distance from blade trailing edge to flap trailing edge, in.
c_o	mean blade chord used for Locke no. or solidity calculation, in.
c_o, c_1, c_2, c_3	coefficients of Equation (57)
$c_{11}, c_{12}, c_{13} \dots c_{nn}$	inertial coefficients of the linear equations of motion
D	blade section drag force parallel to the local relative air velocity, lb
DCR	designation for the Direct Control Rotor
d_o, d_1, d_2, d_3	coefficients of Equation (51)
E_1, E_2	geometrical transfer matrix for the flapping and lag offset hinges
e_1	flapping hinge offset distance, in.
e_2	lag hinge offset distance, in.
e_3	distance from feathering axis to flap hinge line, in.
$[F]$	forcing function matrix
f	helicopter equivalent drag area defined by $D = \frac{1}{2} \rho V^2 f, ft^2$
$[F_{NL}]$	nonlinear forcing function matrix
F_x	rotor force parallel to the flight path, lb
F_y	rotor lateral force normal to the flight path. Positive to the left

LIST OF SYMBOLS (Continued)

F_z	rotor force normal to flight path in the vertical direction. Often equivalent to the gross weight, lb
GW	helicopter gross weight, lb
HP	rotor shaft horsepower, horsepower
H_s	longitudinal force in the shaft plane. Positive aft
I	when subscripted numerically indicates one of the many inertial integrals as defined in the appendix
i	blade running feathering inertia, lb-in. ² /in.
$[I_L]$	linear inertial matrix
$[I_{NL}]$	nonlinear inertial matrix
$I_{\theta tw}$	integral of mass when multiplied by the square of the mode shape results in the torsional inertia, lb-in. ²
I_1	blade flapping inertia about the flapping hinge, lb-in. ²
K_β	flapping spring rate, in.-lb/deg
K_δ	spring rate for the flap, in.-lb/deg
$K_{\delta\beta}$	flapping to flap feedback coefficient
$K_{\delta\zeta}$	lag to flap feedback coefficient
$K_{\delta\theta}$	feathering to flap feedback coefficient
K_ζ	lag spring, in.-lb/deg
K_θ	feathering root spring, in.-lb/deg
$K_{\theta\beta}$	flapping to feathering feedback coefficient
$K_{\theta\zeta}$	lag to feathering feedback coefficient
k	iteration count for computer analysis

LIST OF SYMBOLS (Continued)

L	blade section lift force normal to the local relative air velocity, lb
L/D	blade section lift to drag ratio
$[L_L]$	linear airload matrix
$[L_{NL}]$	nonlinear airloads matrix
M	when subscripted numerically, indicates one of the many mass integrals as defined in the appendix
M_θ	aerodynamic pitching moment on blade section. Nose up is positive, in.-lb
M_δ	aerodynamic flap moment trailing edge down is positive about the flap hinge, in.-lb
N	number of iterations required for convergence
OGE	out-of-ground effect
P	geometrical transfer matrix from point on blade to flapping hinge
$[P]$	linear periodic response matrix
Q	geometrical transfer matrix for the elastic bending
q_M	maximum elastic bending amplitude at the blade tip. Peak-to-peak value, in.
Q_s	rotor torque, in.-lb
q_1	blade elastic bending response of the first bending mode measured up from the rigid blade at the tip, in.
R	rotor radius, in.
r	radial position along rotor blade, in.
S	when subscripted numerically, indicates one of the many static moment integrals as defined in the appendix

LIST OF SYMBOLS (Continued)

S_j	generalized coordinate tensor
T_s	rotor thrust, lb
$T_{\max}$	maximum thrust at rotor stall, lb
$T_{11}, T_{12},$ $T_{13} \dots T_{nn}$	aerodynamic coefficients of the linear equations of motion
U	resultant blade element relative air velocity, in./sec
$\bar{U}$	nondimensional blade element relative air velocity
U_p	component of total blade element relative air velocity normal to the shaft plane, in./sec
U_t	component of total blade element relative air velocity parallel to the shaft plane, in./sec
$\bar{U}_{t_0}$	nondimensional tangential relative air velocity in the shaft plane
U_1, U_2	strain energy for the blade and flap mass elements
V	forward speed, knots
V_t	velocity of generalized coordinate system in the earth reference, in./sec
V_x, V_y, V_z	components of helicopter forward speed, in./sec
w	blade running weight, lb/in.
x	rotor coordinate in shaft plane measured aft, in.
x	nondimensional radial station
x_{cg}	chordwise cg position from feathering axis positive forward, in.

LIST OF SYMBOLS (Continued)

Y	rotor coordinate in shaft plane measured to the right, in.
Y_s	lateral force in the shaft plane positive to the right, lb.
Z	geometrical lag rotation transfer matrix
z	rotor coordinate system in shaft plane measured up
α	angle of attack of blade element with relative air velocity, deg
α_{max}	maximum blade section angle of attack, deg
α_s	shaft forward inclination with respect to the vertical, deg
α_{tip}	tip angle of attack, deg
α_{0m}	airfoil angle of attack with zero pitching moment about the 1/4 chord, deg
α_{72}	angle of attack at the 72% radius, deg
β	flapping response measured up from the shaft plane, deg
β_o	zero position of the flapping spring, deg, rad
$\Gamma_1, \Gamma_2, \Gamma_3, \text{etc}$	inertial terms used in the nonlinear equations
γ	blade Lock number defined by $\frac{c_o \rho_o a_o R^4}{I_1}$
δ	response of the flap measured positive with the trailing edge down. deg
δ_c	collective flap input, deg
δ_{in}	net flap control input, deg
δ_o	zero position for the flap spring, deg

LIST OF SYMBOLS (Continued)

δ_{1c}	lateral flap control input
δ_{1s}	longitudinal flap input, deg
δ_{2s}, δ_{2c}	sine and cosine second-harmonic flap control input, deg
ζ	lag response positive counter-clockwise looking down on the rotor, deg
ζ_0	zero position for lag spring, deg
η_z	vertical load factor in steady flight
Ξ	geometrical transfer matrix for the feathering rotation
θ	rigid body feathering displacement measured leading edge up from the shaft plane, deg
θ_c	collective pitch horn control (equivalent of A_0 in pitch horn control input series), deg
θ_{in}	net pitch control input, deg
θ_{tw}	blade elastic twist displacement at blade tip, deg
x	geometrical transfer matrix for the built-in twist rotation
θ_x	built-in blade twist with wash-out having a negative sense, deg
θ_o	zero position for feathering spring, deg, rad
θ_{1c}	lateral pitch horn control (equivalent of A_{1s} in pitch horn control series), deg
θ_{1s}	longitudinal pitch horn control (equivalent of B_{1s} in pitch horn control input series), deg
θ_{2s}, θ_{2c}	sine and cosine components of the second harmonic pitch horn control input, deg

LIST OF SYMBOLS (Continued)

λ	mean value of rotor inflow normal to the shaft plane positive up through the rotor
μ	rotor advance ratio defined by $\mu = \frac{V\phi_{\alpha_s}}{\Omega R}$
ξ_a	distance from the feathering axis to the aerodynamic center, in.
ξ_δ	distance from flap hinge to center of pressure on the flap, in.
ξ_1	chordwise distance from the feathering axis to an element of blade mass, in.
ξ_2	chordwise distance from the flap hinge to an element of flap mass, in.
ρ	ambient air density, slugs/ft ³
ρ_o	sea level standard air density, slugs/ft ³
ρ/ρ_o	air density value divided by the sea level standard value
σ	rotor solidity value
ϕ_r	amplitude of the one-per-rev elastic twist response at the blade tip, deg
ϕ_{tw}	geometrical transfer matrix for the elastic twist rotation
ϕ_{tw}	elastic twist displacement mode shape generally having the value of unity at the blade tip
ϕ_v	angle of local relative blade element air velocity, deg
ϕ_o	collective elastic twist response of the blade tip, deg
ϕ_{lc}	cosine component of the one-per-rev elastic twist, tip deflection

LIST OF SYMBOLS (Continued)

ϕ_{1s}	sine component of the one-per-rev elastic twist tip deflection, deg
x_i	generalized coordinate of the i-th mass, in.
$\dot{x}_i$	velocity in the generalized coordinate system of the i-th mass, in./sec
$\ddot{x}_i$	acceleration in the generalized coordinate system of the i-th mass, in./sec ²
$[\ddot{x}]$	linear acceleration matrix
ψ	blade azimuth position, measured counter-clockwise from the aft position looking down on the rotor, deg
ψ_ϕ	azimuthal phase position of the one-per-rev elastic twist response, deg
Ω	rotor rotational speed, rad/sec
ω	nonrotating bending frequency for the first elastic flatwise mode, cycles/sec
ω_{tw}	nonrotating elastic torsional frequency, cycles/sec
ΩR	rotor tip speed, ft/sec, in./sec
dp_i	external force element for the evaluation of virtual work in the Lagrangian equations of motion
Δc	flap chord, in.
Δp	blade foreshortening term due to elastic bending, in.
$\partial U_1 / \partial s_j,$ $\partial U_2 / \partial \dot{s}_j$	derivative of the strain energy and the dissipative energy with respect to the generalized coordinate system

LIST OF SYMBOLS (Continued)

dm	mass element for blade and flap, slugs
$\partial x_i / \partial s_j$	derivative of the position tensor with respect to the generalized coordinate
dw_2/ds_j	expression for virtual work in the equations of motion
Q_j	expression for generalized forces in the Lagrangian equations of motion
E_1	geometrical transfer matrix for chordwise offset of blade mass element from elastic axis
E_2	geometrical transfer matrix for chordwise offset of flap mass element from flap hinge line
$\phi(\text{angle})$	symbol for the cosine of an angle
$\$(\text{angle})$	symbol for the sine of an angle
'	prime denotes derivative with azimuth
''	double prime indicates the second derivative with azimuth
.	dot indicates the first derivative with time
''	double dot indicates the second derivative with time
—	bar indicates division by $I_1 \Omega^2$

BACKGROUND

Helicopter rotors are sized to meet load factor and maneuverability (agility) requirements at various flight conditions specified by the user. Whether a rotor is designed for a small observation helicopter, a utility transport helicopter, an armed fire suppression helicopter, or a heavy-lift helicopter, rotor diameter and solidity are determined by the required operating extremes of the flight envelope that are specified. Rotors are not sized by cruise speed conditions of the vehicle.

Most of today's helicopters are constrained at their extreme flight conditions by two sets of problems. First are the basic aerodynamic problems associated with compressibility and blade stall. Rotor systems can tolerate only small portions of the disk operating near the maximum angle of attack on the retreating side and in supercritical flow on the advancing side. Second are the problems associated with the necessity to trim the helicopter and to provide stability and control. Because there is a unique set of control inputs required to trim conventional rotors at each flight condition, little can be done to alter the airload distribution for fixed-geometry rotors. As a result of these two sets of constraints, the greater portion of the disk is lightly loaded. Therefore, it is necessary to resort to high blade solidity in order to satisfy the requirements of the flight envelope.

The high solidity conventional rotor designed for the extreme conditions is overdesigned at hover where more nearly uniform load distributions are generated. The hover performance of the high solidity rotor is less than optimum because of the increased parasite drag resulting from unnecessary blade area and because the low blade section angles of attack are far from the maximum L/D angles.

In addition to the performance problem in sizing the rotor, there is the problem associated with dynamic loading and vibration. In conventional rotor design, alleviation of blade stresses, fuselage vibration and control loading can only be accomplished in the structural design of the blade itself. Even then, only limited improvements are possible and other constraints such as static droop, aerodynamic section characteristics, manufacturing processes, etc., limit the changes possible.

Having recognized that these problems exist in conventional rotor design, it is axiomatic that if blade stall and compressibility problems are alleviated, rotor solidity can be reduced. This reduction will decrease profile power, thereby improving the total rotor performance picture.

One viable approach to the alleviation of the blade stall and compressibility problems is through proper redistribution of blade airloads. This, in turn, may be accomplished by proper distribution of blade twist.

Fixed built-in twist is in common usage in helicopter design, and the effects of blade built-in twist on power requirements, vibratory loads, stall characteristics, and compressibility effects of fully articulated and hingeless rotor systems have been analyzed quite extensively for various helicopter configurations. Reference 1 contains the results of some of these analyses. One of the primary conclusions reported in Reference 1 states that blade twist is an extremely important parameter of rotor performance and blade stresses. A direct quote of this statement is presented in the following paragraph.

"Blade twist was found to be a significant variable for control of blade stresses and rotor performance. Increased negative twist acts to unload the retreating and load the advancing blade. Due to the helicopter's pitch-trim requirements, the advancing blade must carry the increased load on the inboard panels rather than the more efficient outboard panels. The resulting one-per-rev load dissymmetry is the aerodynamic cause of increased blade vibratory stress....Results of calculations for planform-twist variation indicate a rapid rise in vibratory bending moments with increase in blade twist for rigid and articulated rotor systems. Small values of negative twist resulted in minimum blade stress, while the optimum power-twist tradeoff required larger values of negative twist....For the aircraft considered, blade twist to minimize stress was found to be in the region of $+2^\circ$ to -2° . Optimum power for helicopters was found in the region of -8° twist....".

Other more recent analyses which have been performed as part of preliminary design studies have indicated that the twist for optimum figure of merit may be even higher than that reported in Reference 1. Although these studies have not been documented, values as high as -16° have been commonly discussed and are likely to represent the twist required for optimum efficiency in hover.

These results indicate that high negative blade twist yields minimum power requirements at hover and low speed, whereas low negative blade twist yields minimum vibratory loads at high forward speeds. Therefore, the built-in twist in conventional rotor design must be a compromise which will produce satisfactory performance and dynamic loads but which does not represent the optimum for either.

In addition to the benefits which can be derived from built-in twist, a qualitative evaluation of the Reference 1 results suggests that decreased negative twist on the advancing blade and increased negative twist on the retreating blade further decrease vibratory loads at high forward speeds. Consequently, this evaluation suggests a variable-geometry rotor blade which has the ability to collectively vary its twist with forward speed and to cyclically vary its twist with azimuth.

In order to investigate this hypothesis, wind tunnel tests were conducted with a torsionally-segmented model helicopter rotor. This rotor consisted of a two-panel blade with each panel controlled independently in order to simulate the desirable characteristics of a variable-geometry blade. The test results are reported in Reference 2. Despite the hardware problems encountered in designing the two-panel blade, and the drag penalties incurred by blade panel discontinuity, the maximum propulsive force measured for the segmented rotor was more than nine times that for the corresponding conventional rotor. In summary, the aerodynamic principle was established for a variable-geometry rotor with variable pitch schedules along the radius and around the azimuth.

A recent analysis has been made of the variable-geometry blade requirements which would redistribute airloads so as to yield minimum vibratory hub shears. This analysis, reported in Reference 3, shows that blade twist is a primary parameter in providing the proper airload distribution for minimizing shears. The conclusions state that a torsionally flexible blade with dual control inputs at the blade root and tip can provide significant improvements over existing conventional rotor systems.

THE CONTROLLABLE TWIST ROTOR

SYSTEM DESCRIPTION

The controllable twist rotor (CTR), as shown in Figure 1, was conceived as a practical system by which blade twist distribution can be controlled both cyclically and collectively. The system is intended to satisfy the twist requirements as stated in Reference 1 by allowing the selection of a high negative twist in hover and progressively lower negative twist as forward speed is increased. The CTR also satisfies the recommendations of Reference 2 for improving performance and Reference 3 for reducing hub shears by allowing the selection of a cyclic twist distribution.

CTR consists of an articulated torsionally flexible blade that is controlled by a conventional pitch horn (direct control) linkage at its root and an aerodynamic control flap at its tip. For this study, the pitch horn device is considered the primary trim control system for vectoring rotor thrust magnitude and direction. The flap generates the necessary external moments for elastically twisting the blade about its mean trim position in order to provide an efficient distribution of blade airloads. The flap also provides a means for varying the blade tip section camber line, thereby resulting in an uncambered airfoil section on the advancing side and a high lift airfoil section on the retreating side.

Figure 1 illustrates the dual control system independently actuated by two separate swashplates. Both the primary and secondary control systems can be varied collectively and/or cyclically. Each can also be scheduled to vary with forward speed. Design methodology for the linkage mechanisms of the dual control system and for the torsionally elastic blade utilizes existing technology from proven flightworthy hardware now in service use.

It is conjectured that a fixed relationship between the otherwise independent controls may provide optimum rotor performance and blade dynamics for a specific helicopter configuration. If such a relationship exists, the control system can be simplified through the use of a single swashplate.

Extremely large rotors operate in a reduced centrifugal force field. Consequently, a second alternative actuating system for large rotors would use a swashplate for the pitch horn and a fly-by-wire electromechanical actuator for the flap.

Figure 1. Control Arrangements for the Controllable Twist Rotor.

The electromechanical actuator would be installed in the blade and could be used as a tuning ballast weight. Because it would be driven electrically, the input signal waveform to the flap could be controlled to include various amplitudes and phasings of higher harmonics.

MODES OF OPERATION

If independent swashplates are used, the controllable twist rotor is anticipated to have the capability of generating the required trim forces for any flight condition through a continuous range of control input combinations. It can be flown with pure pitch horn control and no flap input or, at the opposite extreme, with pure flap control and no pitch horn input. Different combinations of the two inputs produce various steady and periodic twist distributions on the blade, and various combinations of radial and azimuthal variations in angles of attack. Thus, there is every reason to expect that it is possible, through control input alone, to redistribute the loading at forward speed so as to substantially increase the average blade loading at constant peak loads, thereby reducing the solidity, weight, and power requirements, compared to a direct control rotor.

In addition to reducing the required solidity, it is conjectured that the smoothing of the airload distribution achieved by the CTR increases aerodynamic efficiency and reduces the vibratory components, resulting in lower vibratory blade stresses, hub shears, and control loads. The lower blade stresses would provide increased blade life. Reduced vibratory hub shears, resulting in lower fuselage vibration levels and stresses, would reduce the weight of added structure required for fatigue reliability and would reduce the weight of vibration alleviation devices required for personnel efficiency and comfort and equipment reliability. Increased blade efficiency automatically would improve hover and lifting capability. The inboard and outboard controls of the CTR system will provide a degree of control over rotor vibration.

ANALYTICAL METHODS

EQUATIONS OF MOTION

The analysis used to evaluate the CTR and the direct controlled rotor is an extension of the analysis developed in Reference 4, where the method of solution and the coupled aeroelastic equations of motion are derived for five response modes and two control modes for a fully articulated rotor system. The CTR has an added degree of flexibility derived from the elastic twist displacements. Consequently, the elastic twist degree of freedom has been added to make the present analysis descriptive of six response modes and two input control modes. The response modes can be considered normal modes and are described as follows:

- Blade Pitching
- Blade Lagging
- Blade Flapping
- Blade Flapwise Bending (First Elastic Bending Mode)
- Blade Twisting (First Elastic Twisting Mode)
- Flap Pitching

Figure 2 shows the displacements associated with the response modes.

The derivation of the equations of motion and basic method of solution have been reported in detail in References 4 and 5. They are discussed in the present report only to the extent that a general understanding of the problem is developed.

The modal approach is used to evaluate the airloads on a fully articulated rotor by mathematically describing blade motions with the listed six degrees of freedom. The complete inertial and centrifugal terms for the equations of motion are derived through the use of matrix transformations. Potential strain energy and dissipative energy terms are included in the equations of motion by assuming concentrated springs and viscous dampers for the four rigid body modes, and by evaluating the fundamental bending and torsional frequencies of the rotating blade for the flapwise bending and torsion modes.

Generalized aerodynamic forces for each of the six modes are obtained from strip theory by calculating an instantaneous local airfoil section angle of attack and using this angle of attack to evaluate aerodynamic force coefficients from available wind tunnel data. Derivations of the equations of motion and of the generalized forces are presented in Appendix I.

Figure 2. Controllable Twist Rotor Displacements.

Because of the modes included in the analysis, these equations can be used to analyze articulated rotors controlled directly with pitch horns, articulated rotors controlled aerodynamically with flaps, articulated rotors with dual controls, hingeless rotors controlled by pitch horns, hingeless rotors controlled by flaps, or hingeless rotors with dual controls.

In their present form, the aeroelastic equations of motion include all nonlinear inertial coupling effects and nonlinear aerodynamic effects such as reverse flow, stall, Mach number variations and large induced flow angles. The present study used uniform inflow because of computer capacity and time limitations. However, the variable inflow calculations are treated as a subroutine in the overall aeroelastic loads computer program and, as such, can be modified to incorporate any of the published methods.

Additional features to the analysis are the inclusion of feedback mechanical coupling among the flap, blade feathering, blade flapping, and blade lagging motions and the inclusion of arbitrary spring rates and dampers for each mode. Any one or combination of these parameters can be eliminated easily from the analysis. Furthermore, spring rates for the two types of control systems are also included in order that accurate control loads can be calculated.

As previously mentioned, the flexible twist degree of freedom is necessary to properly describe the mathematical model of the CTR. It was found more convenient to add this new degree of freedom to the existing methods of solution described in Reference 4, rather than to rederive a complete new set of nonlinear equations. This is primarily due to similarities between the feathering equation and the twisting equation which allow the almost direct substitution, of new terms containing the twist parameter, into the feathering equation. Thus, a new equation is created for twist. The justification for this procedure lies in the fact that the radial integrations of the linear inertial terms for the feathering equations are identical to those of the twist degree of freedom when modified by the twist mode shape. However, before proceeding with further development of the equations, it is necessary to obtain an understanding of the mechanism of twist and how it is applied in a modal analysis.

The twist energy must satisfy a balance such that it may be applied to the Lagrangian equations of motion for the j th generalized coordinate as established in Reference 4.

$$\iint \ddot{x}_i (\partial x_i / \partial s_j) dm + \partial U_1 / \partial s_j + \partial U_2 / \partial \dot{s}_j = \iint (\partial x_i / \partial s_j) dp_i \quad (1)$$

where the strain energy

$$U_1 = U_1(s_j) \quad (2)$$

and the dissipative energy

$$U_2 = U_2(\dot{s}_j) \quad (3)$$

As in Reference 4, a point on the flap is given by

$$\chi_2 = V_t + \Psi E_1 + Z\{E_2 + B[P + \phi_{tw}^{\theta} \theta_x(Q + E_3 + \Delta E_2)]\} \quad (4)$$

and a point on the blade is given by

$$\chi_1 = V_t + \Psi[E_1 + Z\{E_2 + B[P + \phi_{tw}^{\theta} \theta_x(Q + E_1)]\}] \quad (5)$$

where the transformation matrices are defined in Appendix I. The evaluation of $\ddot{\chi}_i(\partial\chi_i/\partial s_j)$ and $(\partial\chi_i/\partial s_j)dp_i$ will produce terms in twist that are similar to the terms in pitch since twist terms appear everywhere that pitch terms appear, and derivatives with respect to twist are similar to the derivatives with respect to pitch. The twist rotation as defined in Appendix I is

$$\phi_{tw} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \phi_{\phi_{tw}\theta_{tw}} & -\phi_{\phi_{tw}\theta_{tw}} \\ 0 & \phi_{\phi_{tw}\theta_{tw}} & \phi_{\phi_{tw}\theta_{tw}} \end{bmatrix} \quad (6)$$

where ϕ_{tw} is the elastic twist mode shape and θ_{tw} is the twist tip deflection.

In linear form, using small angle assumptions, Equation (6) becomes

$$\phi_{tw} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & -\phi_{tw}\theta_{tw} \\ 0 & \phi_{tw}\theta_{tw} & 1 \end{bmatrix} \quad (7)$$

As in Reference 4, the linear pitch rotation is given as

$$\theta = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & -\theta \\ 0 & \theta & 1 \end{bmatrix} \quad (8)$$

Evaluating Equation (1) for the pitch degree of freedom and for the twist degree of freedom using Equations (4) through (8), the integrated inertial terms in twist are identical to those in pitch except that twist is modified by the twist mode shape. The twist acceleration, velocity, and displacement terms in the twist equation are modified by the square of the mode shape because these terms result from second derivatives of twist and/or products of derivatives and twist. Similar results are obtained for the linear aerodynamic forcing functions.

Direct substitution of the twist tip deflection mode shape into the feathering equation produces the twist equation to be added to the five-degree-of-freedom system reported in Reference 4. The matrix transformations, the six nonlinear response equations, and the corresponding radial and chordwise inertial integrations of masses, first moments, and second moments of inertia are listed in Appendix I.

The portion of potential or strain energy, U_1 , that is attributed to elastic twist can be defined as

$$(U_1)_{\text{twist}} = 1/2 I_{\theta_{\text{tw}}} \omega_{\text{tw}}^2 \phi_{\text{tw}}^2 \theta_{\text{tw}}^2 \quad (9)$$

Equation (9) is the torsional response equation for a bar of uniform torsional stiffness (Reference 4), the assumption being made that the rotor blade has a uniform torsional stiffness. This strain energy is derived in a nonrotating system; therefore, the natural response frequency, ω_{tw} , is the natural frequency of the blade for the first nonrotational mode; ϕ_{tw} is the associated mode shape. $I_{\theta_{\text{tw}}} \phi_{\text{tw}}^2$ is the torsional inertia of the blade, and since the mass of the flap contributes to this inertia, it is defined as follows:

$$\phi_{\text{tw}}^2 I_{\theta_{\text{tw}}} = e_3^2 M_{33} + I_{18} - 2e_3 S_{52} + I_{41} \quad (10)$$

where the various terms are defined in Appendix I. From Equations (9) and (10) and Reference 4, the total strain energy becomes

$$\begin{aligned}
 U_1 = & 1/2 K_\beta (\beta - \beta_0)^2 + 1/2 K_\theta (\theta - \theta_0)^2 + 1/2 K_\zeta (\zeta - \zeta_0)^2 \\
 & + 1/2 K_\delta (\delta - \delta_0)^2 + 1/2 (M_4 + M_{20}) \omega^2 q_1^2 + 1/2 K_{\theta_{in}} (\theta - \theta_{in})^2 \\
 & + 1/2 K_{\delta_{in}} (\delta - \delta_{in})^2 + 1/2 (e_3^2 M_{33} + I_{18} - 2e_3 S_{52} \\
 & + I_{41}) \omega_{tw}^2 \theta_{tw}^2
 \end{aligned} \tag{11}$$

The dissipative function due to elastic twist results from structural damping and can be described approximately as

$$(U_2)_{\text{twist}} = 1/2 C_{tw} (\theta'_{tw})^2 \tag{12}$$

where the prime denotes the derivate with azimuth. From Reference 4 and Equation (12), the total dissipative function is

$$\begin{aligned}
 U_2 = & 1/2 C_\beta (\beta')^2 + 1/2 C_\zeta (\zeta')^2 + 1/2 C_\theta (\theta')^2 \\
 & + 1/2 C_q (q_1')^2 + 1/2 C_\delta (\delta')^2 + 1/2 C_{tw} (\theta'_{tw})^2
 \end{aligned} \tag{13}$$

In Equations (11) and (13), K_ζ , K_β , K_θ , K_δ and C_ζ , C_β , C_θ , C_δ represent the spring stiffness constants and the viscous damping constants, respectively. Initial tension in the springs is removed by indexing the angular deflections through the angles ζ_0 , β_0 , θ_0 , δ_0 . The first flapwise bending mode, its natural frequency, and the effective mass associated with this mode are denoted by q_1 , ω , and $(M_4 + M_{20})$ in Equation (11). The derivatives of the strain function and the derivatives of the dissipative function with respect to the various degrees of freedom, $\partial U_1 / \partial s_j$ and $\partial U_2 / \partial \dot{s}_j$, have been evaluated and are combined with the proper inertia coefficients in Appendix I.

The surface forces acting on the rotor blade and flap consist of the aerodynamic forces and moments which can be separated into steady and unsteady components. As mentioned previously, Equation (1) represents the condition of dynamic equilibrium of the moments for each degree of freedom. Consequently, the generalized forces for these equations will be given by moments which account for the appropriate boundary conditions in each mode. The generalized forces that appear in Equation (1) can be written in terms of the virtual work done by the external forces.

$$Q_j = \iint \frac{\partial X_i}{\partial s_j} dp_i = \frac{dw_2}{ds_j} \quad (14)$$

Equation (14) is not in a convenient form for use with the equilibrium equations, because it is written in terms of pressures rather than the more common aerodynamic lift, drag, and pitching moment distributions along the blade.

The generalized forces can be expressed in terms of these aerodynamic parameters by applying the distributed loads along the blade and allowing the blade to undergo a virtual displacement in each mode. When this is done, expressions for each Q_j can be written as follows:

$$\begin{aligned} Q_\zeta &= \int [L\phi_v + D\phi_v](r - e_1) dr \\ Q_\beta &= \int [L\phi_v - D\phi_v](r - e_2) dr \\ Q_\theta &= \int M_\theta dr \\ Q_{q_1} &= \int [L\phi(\theta + \theta_x - \phi_v) + D\phi(\theta + \theta_x - \phi_v)]\phi dr \\ Q_{\theta_{tw}} &= \int M_\theta \phi_{tw} dr \\ Q_\delta &= \int M_\delta dr \end{aligned} \quad (15)$$

Detailed expressions for the generalized forces are given in Appendix I. Figures 3, 4, and 5 illustrate the blade airfoil cross-section geometry, the section aerodynamic force, moment, and velocity vectors, and the blade generalized forces.

The present analysis describes the behavior of articulated rotors with pitch control input, with flap control input, or with dual control input. The feathering input is given by

$$\theta_{in} = \theta_c - \theta_{1s}\$ \psi - \theta_{1c}\$ \psi - \theta_{2s}\$ 2\psi - \theta_{2c}\$ 2\psi + K_{\theta\beta}\beta + K_{\theta\zeta}\zeta \quad (16)$$

The flap input is given by

$$\delta_{in} = \delta_c + \delta_{1s}\$ \psi + \delta_{1c}\$ \psi + \delta_{2s}\$ 2\psi + \delta_{2c}\$ 2\psi + K_{\delta\beta}\beta + K_{\delta\theta}\theta + K_{\delta\zeta}\zeta \quad (17)$$

In Equations (16) and (17), the various azimuthal coefficients correspond to collective, cyclic, and second harmonic inputs; the constants correspond to the mechanical feedback couplings among the modes.

METHOD OF SOLUTION

Generally, nonlinear response equations are solved by numerical methods for computer adaptation. Most often, these solutions use a forward integration approach, which requires a knowledge of initial conditions in order to precipitate the solution (initial value problem). Experience has shown, however, that an estimate of the initial conditions can be so far from the steady-state solution of a multi-mode analysis that it is not possible to achieve stability or that it takes many iterations to get to the stable solution.

The method used for solving the above nonlinear equations is an expanded version of the method described by Berman for a two-degree-of-freedom system (Reference 5). This method is generally applicable to sets of nonlinear differential equations with coefficients that are arbitrary functions of a single independent variable; in this case, the variable is time. A brief description of the procedures is outlined below.

Figure 3. Blade and Flap Geometry.

Figure 4. Airfoil Section Indicating Aerodynamic Force and Velocity Vectors.

Initially, the set of nonlinear equations is linearized by making the usual small angle assumptions and neglecting terms higher than first order. The aerodynamic forcing functions are linearized only with respect to local angle of attack. Linearized aerodynamic force and moment derivatives are tabulated versus Mach number for the normal flow region, for the reverse-flow region, and for a narrow band around the reverse-flow circle corresponding to low dynamic pressures. The linearized differential equations are then written as a set of finite difference equations; they are summarized in Appendix II. The finite difference equations are solved via the integrating matrix operator developed by Berman.

The direct application of an integrating matrix operator to the linearized equations written in matrix form yields two important results. First, the completely coupled transient response of the linearized system to an initial disturbance is calculated. The initial disturbance can be a displacement or a velocity step input in any single mode or any combination of modes. Transient responses are calculated for a pre-specified time interval (usually 20 rotor revolutions) in order to evaluate the stability characteristics of the coupled system. Second, the response matrices of the system are obtained which depend only on the coefficients of the linearized equations. When the coefficients and the forcing functions are periodic, the response matrices are modified by the end conditions to yield periodic responses directly, without carrying the calculations through more than one cycle.

Thus, the initial value approach for obtaining linearized transient solutions is transformed into a boundary value approach for obtaining nonlinearized periodic (steady-state) solutions.

The response to the complete nonlinear equations is obtained through the use of the above-mentioned periodic response matrices. The methodology is better understood by beginning with the general description of the linear solutions. The left-hand side of the equation is composed of the linear inertia matrix $[I_L]$ and the linear airload matrix $[L_L]$, the sum of which is set equal to a forcing function matrix $[F]$. This leads to the following equation:

$$([I_L] + [L_L]) = [F] \quad (18)$$

The left-hand side of Equation (18) includes functions of the displacements, velocities, and accelerations of the various response modes. Through the techniques reported in Reference 4 and the integrating matrix operators of Reference 5, the left-hand side can be made functions of accelerations only such that Equation (18) can be rewritten in terms of the acceleration matrix $[\ddot{X}]$, as shown in Equation (19).

$$[A][\ddot{X}] = [F] \quad (19)$$

The periodic response matrix is defined by

$$[P] \equiv [A^{-1}] \quad (20)$$

where the matrices $[A]$ and $[P]$ are matrix operators. Equation (19) becomes

$$[\ddot{X}] = [P][F] \quad (21)$$

These matrices are integrated by the methods in Reference 5 to give velocities and displacements providing the linear solutions. These linear solutions are subsequently used as initial inputs for the iterative procedures in order to obtain nonlinear solutions.

The nonlinear equations can be similarly represented with nonlinear inertias $[I_{NL}]$, and nonlinear airloads $[L_{NL}]$, and set equal to the nonlinear forcing function $[F_{NL}]$ as in the following equation:

$$([I_{NL}] + [L_{NL}]) = [F_{NL}] \quad (22)$$

This equation can be rewritten

$$0 = [F_{NL}] - ([I_{NL}] + [L_{NL}]) \quad (23)$$

If the linear inertias and loads are added to both sides, we get Equation (24):

$$([I_L] + [L_L]) = ([I_L] + [L_L]) - ([I_{NL}] + [L_{NL}]) + [F_{NL}] \quad (24)$$

Using the definitions in Equations (18) through (21), we can write the accelerations as follows:

$$[\ddot{X}] = [P]\{([I_L] + [L_L]) - ([I_{NL}] + [L_{NL}]) + [F_{NL}]\} \quad (25)$$

Equation (25) represents a complete set of nonlinear equations operated on by linear response matrices. The included linear effects are self cancelling by definition from Equation (24). The numerical solutions of the acceleration matrix $[\ddot{X}]$ represent solutions for each response mode at every azimuth position.

Because the right-hand side of Equation (25) has terms which include modal velocities, displacements, and accelerations, it is solved by iterative methods. Subscripts are added to Equation (25) to indicate the successive iterations. The iterative nonlinear response equation is defined as

$$[\ddot{X}]_k = [P]\{([I_L] + [L_L])_{k-1} - ([I_{NL}] + [L_{NL}])_{k-1} + [F_{NL}]_{k-1}\} \quad (26)$$

where

k = present iteration count

$k-1$ = previous iteration count

and k has the range $(1 \leq k \leq N)$, with N being the number of iterations required for convergence.

The initial responses, i.e., displacements, velocities, and accelerations, are determined from the linear solution of Equation (21). These are substituted into the right-hand side of Equation (25) to generate the nonlinear matrices which are used to determine the second set of accelerations. In general, these new accelerations are not identical to those that were input on the right-hand side because the linear solution does not have the same accelerations as the nonlinear solutions. Therefore, these accelerations are integrated to obtain new displacements and velocities which are reinserted into the right-hand side to obtain a third solution to the accelerations. These substitutions are repeated until the k th responses coincide with the $(k-1)$ th responses to within specified tolerances. The last set is the converged responses.

COMPUTER PROGRAM

A computer program for the aeroelastic analysis was written in FORTRAN IV language for an IBM 360/40 digital computer with a Disk Operating System, and a 132,000 word storage capacity. (USAAMRDL will provide copies of the program upon receipt of a blank tape and a letter of request on organization letterhead stationary). The computer program can handle a rotor blade with 16 radial stations which are used to describe nonuniform radial distributions of chord, twist, airfoil section, mass, moment of inertia, chordwise center of gravity, bending mode, twisting mode, elastic axis, and aerodynamic center. Sixty azimuth positions can be evaluated for each of the six response modes. Aerodynamic force and moment coefficient data are tabulated for each of 3 airfoil sections at 5 Mach numbers and 49 angles of attack; one of the airfoil sections has coefficient data tabulated for 5 flap settings in addition to the Mach number and angle-of-attack ranges. Unsteady airfoil characteristics are estimated by force and moment derivatives based on Theodorsen theory.

Figure 6 illustrates schematically the basic program logic for computation of the rotor airloads and responses. Data for the specific rotor are input, and rotor inertias and linear aerodynamic terms are calculated. Pertinent information is stored on the disk for intermediate storage. The coefficients of the linearized equations are calculated and integrated to form the [A] matrix. This matrix is inverted to form the periodic response matrix which is stored on the disk for use in all subsequent solutions. The initial value matrix is determined, and the transient responses are obtained as a user option. The boundary conditions are generated and also stored on the disk.

The above portion of the computer program is known as Part I and must be run for every flight condition or for any change in the physical properties of the rotor. Part II of the computer program contains the input requirements for the controls (i.e., pitch horn and/or flap controls) and calculates the steady-state responses of the fully coupled nonlinear equations. Therefore, it must be run for each new control setting. Using the data stored on the disk and the input for the controls, the linear forcing functions are now calculated, and the linear steady-state responses are determined. The local angles of attack are computed from these linear responses, and the local airloads are determined from blade element theory. The nonlinear forcing functions are obtained using these airloads, and new blade responses are computed. The iterative process of computing nonlinear airloads and nonlinear responses is cycled until convergence is reached between successive iterations.

Figure 6. Flow Chart of the Computer Program for the Controllable Twist Rotor (CTR) Theoretical Analysis.

Rotor performance is calculated from the converged airloads by integrating the various airload distributions radially and azimuthally over the disk. The expressions used to evaluate rotor thrust, torque, drag, and side force are given below.

$$T_s = \frac{b}{2\pi} \int_0^{2\pi} \int_{e_1}^R (L\phi_{\phi_v} - D\phi_{\phi_v}) \phi_{\beta} dr d\psi \quad (27)$$

$$Q_s = \frac{b}{2\pi} \int_0^{2\pi} \int_{e_1}^R (L\phi_{\phi_v} + D\phi_{\phi_v}) r dr d\psi \quad (28)$$

$$H_s = \frac{b}{2\pi} \int_0^{2\pi} \int_{e_1}^R [(L\phi_{\phi_v} + D\phi_{\phi_v}) \phi_{\psi} - (L\phi_{\phi_v} - D\phi_{\phi_v}) \phi_{\beta} \phi_{\psi}] dr d\psi \quad (29)$$

$$Y_s = - \frac{b}{2\pi} \int_0^{2\pi} \int_{e_1}^R [(L\phi_{\phi_v} + D\phi_{\phi_v}) \phi_{\psi} + (L\phi_{\phi_v} - D\phi_{\phi_v}) \phi_{\beta} \phi_{\psi}] dr d\psi \quad (30)$$

Blade responses are printed in the form of radial and azimuthal distributions of angles of attack, airloads normal to the shaft plane, airloads in the shaft plane, feathering moments, torques, Mach numbers, and critical Mach number ratios. Time histories of the six coupled blade responses, pitch horn control loads, and flap rod control loads are also output. Standard harmonic analysis techniques automatically resolve the waveforms of angles of attack, airloads, moments, and blade responses to yield the harmonic content of each parameter. Angle-of-attack distributions are also interpolated automatically to locate radial stations corresponding to integer values in angle of attack. These latter results are used to generate angle-of-attack contour plots.

AERODYNAMIC FORCE AND MOMENT DATA

Unlike many pitch horn configurations which have a constant airfoil section over the length of the blade, the CTR has a section of the blade which contains a control flap. The presence of the flap and its concurrent deflections modify the pitching moments, the lift, and the drag of these blade sections. The present computer analysis has the capability of including at any radial stations a choice of aerodynamic data for any of three airfoil sections, one of which may include data for various flap deflections. The input for

the analysis requires the lift coefficient, drag coefficient, blade pitching moment coefficient, and flap hinge moment coefficient. The aforementioned section characteristics are based on the total chord of the blade and flap.

The aerodynamic characteristics for the airfoil sections used in this study are tabulated in Appendix IV. The section coefficients are presented for 49 angles of attack ranging from 0 to 360 degrees, for four Mach numbers, and for five flap deflections. Table XXXI contains the data for the modified Kaman 23012 airfoil. For the direct control rotor, these data are used over the whole rotor blade; for the CTR, they are used in the nonflapped regions only. The data for this airfoil were synthesized for the reverse-flow regions using data from Reference 9. Mach number effects were included by means of the Prandtl-Glauert correction factor as described in References 10 and 11.

The Kaman external flap has a NACA 63-015 airfoil section, and is placed directly aft of the Kaman modified 23012 blade section. The test data available for this combination are meager for high Mach numbers and large flap deflections. However, some wind tunnel data were available in Reference 11, which, when combined with extrapolations and the Prandtl-Glauert effects in Reference 10, were used to synthesize Table XXXII in Appendix IV.

The external trailing flap configuration described above carries some penalty in profile drag due to flap and blade interference and due to the gap between the flap and the blade. A faired flap modifies the airfoil section such that there is no gap; the flap combines with the blade to form a single airfoil section with a smooth surface running from the blade leading edge to the flap trailing edge. Data for the trailing flap mentioned above was modified in Reference 10 to account for the effects of fairing the surfaces; the resulting data for the faired flap airfoil are found in Table XXXIII in Appendix IV. The modifications include effects on lift coefficients, pitching moment coefficients, hinge moment coefficients, and profile drag coefficients.

ROTOR TRIM

The CTR aeroelastic loads analysis produces a set of forces, blade responses, and rotor performance for a specific set of control inputs. However, the forces produced are not necessarily the forces required for trim at the particular flight condition. The method for achieving the proper control inputs to obtain the necessary trim forces is called the trim program. Figure 7 is a flow chart that shows how the trim program is used. Several initial cases are run, producing a set of forces for each initial case. These forces are compared to the control inputs in the trim program, and a new control prediction is made based on these comparisons.

For a rotor system with a single control input (either pitch horn or aerodynamic flap), there is a unique combination of collective and cyclic control inputs which will generate the required trim hub forces at a specified speed. Because of its dual control inputs, the CTR has many combinations of collective and cyclic inputs that produce the same trim forces. Thus, trimming the CTR involves an optimization procedure. These rotor characteristics are illustrated in Figure 8.

In order to optimize the CTR dual controls, one of the controls is fixed during the trim process. An iteration process is begun whereby the pitch horn control settings remain fixed and the trim program compares the resultant rotor forces with those required for trim, and modifies the flap controls to achieve trim. The airloads program is run again, and the process is repeated until the output rotor forces match the required trim forces. Performance is determined only for trimmed cases such that no effort in this analysis is spent on untrimmed cases.

TRIM ANALYSIS

Figure 8. Control Input Combinations for Rotor Trim.

EVALUATION OF ROTOR CHARACTERISTICS

CONFIGURATION OPTIMIZATION

In order to provide a proper basis for comparing the controllable twist rotor with conventional rotors, an extensive parametric study was conducted of many CTR configurations. Four different CTR planforms were considered in combination with configuration changes to determine the effects of built-in twist, the aerodynamic effects of a faired flap as opposed to an external flap, the effects of flap size and location, the effects of blade torsional stiffness, and the effects of control input. A detailed description of the geometrical and inertial characteristics for each configuration is presented in Appendix III. Results of the parametric evaluation are also discussed in Appendix III and are used to select an optimum CTR configuration for further evaluative comparisons with a direct control rotor. The geometry of the optimized CTR as selected from the parametric study is presented in Table I.

In addition to the CTR configuration study, a parametric investigation was conducted with a conventional direct control rotor. One DCR blade planform was selected and was used to evaluate the effects of built-in twist and solidity. The geometrical and inertial properties for the DCR are described in Appendix III as are the results of the parametric study for this rotor system. Table I summarizes the characteristics of the final DCR system which will be used as a basis for comparison in the present study.

COMPARISON WITH CONVENTIONAL ROTORS

To quantitatively analyze the effects discussed previously and further benefits of the CTR as opposed to a comparable direct control rotor (DCR), over 5000 computer cases have been run for the optimized rotor systems described under the section titled "Analytical Methods" in this report. This includes over 400 trimmed cases.

Table I indicates that both the CTR blade and the DCR blade have the same general planform. The CTR was studied using four blades while the DCR was studied with four, five, and six blades. Otherwise, the rotors are comparable in appearance, having identical values of radius and blade chord. Both rotor systems were evaluated at identical tip speeds. A summary of significant computer runs is presented in Table II for the CTR and DCR systems.

TABLE I. RESULTING CONFIGURATION		
	Optimum CTR Configuration	DCR Configuration
Number of Blades	4	6
Radius	264 In. (44' Dia)	264 In. (44' Dia)

Figure 9 shows contour plots of angle-of-attack distribution for both the CTR and DCR four-bladed rotors at a design condition of 180 knots at standard sea level. This design condition corresponds to a maximum speed of 150 knots for a 4000-ft, 95°F day. As seen from Table II, both rotors were trimmed out to the same forces at this condition. Experience obtained at Kaman with the computer analysis indicates that flight conditions resulting in calculated local angles of attack greater than 13.5 degrees correspond to stall onset in flight. Therefore, this value has arbitrarily been established as the maximum allowable angle of attack on the rotor disk. In situations where the angle of attack exceeds 13.5 degrees, the rotor system is considered stalled.

Obviously in Figure 9, the four-bladed direct control rotor is deep into stall and cannot fly at this speed whereas the four-bladed CTR is not stalled. Thus, in order to design a direct control rotor to operate up to this speed, it is necessary to increase the solidity of such a system. The solidity was increased by considering both five- and six-bladed rotors. The contour plot of a six-bladed direct control rotor is shown in Figure 9. The six-bladed DCR is trimmed to the same forces as the four-bladed rotors. The higher solidity DCR now shows an improved angle-of-attack distribution.

Figure 10 shows the time histories of the section angles of attack at the blade tip and the 72-percent radius for both the four-bladed CTR and the six-bladed DCR at a flight speed of $V = 180$ knots. These curves indicate that both rotors are operating below stall. Figure 11 shows the out-of-plane airloads for these angles of attack at the 89-percent radius for the four-bladed CTR and the six-bladed DCR, operating at 180 knots. The four-bladed CTR has higher blade loadings than the six-bladed DCR because of different solidities.

Although these figures show that the four-bladed CTR and the six-bladed DCR have similar performance characteristics at the selected flight condition, this clearly does not constitute an adequate comparison. In comparing these rotor systems, the performance must be evaluated over the entire flight range as well as at the design condition.

To accomplish this broader comparison, much data has been generated using the computer facilities for the optimum CTR configuration and for the four-, five-, and six-bladed DCR configurations. These data contain results obtained over a range of flight speeds. The main rotor power required for both the CTR and DCR systems is depicted in Figure 12 as a function of flight speed.

Figure 12. Main Rotor Power as a Function
 of Flight Speed for the CTR
 and DCR Systems.

As seen in Figure 12, there is an obvious reduction in the DCR power requirement due to reduced solidity in going from the six-bladed rotor to the four-bladed rotor. However, Figure 12 also shows that the four-bladed CTR requires less power than any of the DCR configurations. This reduced CTR power requirement indicates that the CTR not only makes use of lower solidity, it also has a more efficient twist schedule which results in less power than that of a geometrically similar DCR for the same flight conditions.

The maximum blade section angles of attack for the four rotor systems are plotted in Figure 13 as a function of forward speed. This plot indicates that the four-bladed DCR stalls at 159 knots, the five-bladed DCR stalls at 169 knots, and the six-bladed DCR stalls at 180 knots. The four-bladed CTR also stalls at 180 knots, a speed that is equivalent to that of the six-bladed DCR.

Over the flight speeds, shown in Figure 13, indicate that the CTR operates at lower angles of attack than the four-bladed DCR, whereas it operates at higher angles of attack than the five- or six-bladed DCR systems at the lower speeds. At the lower speeds, minimum angle of attack at the blade tip is not an objective for the CTR. Rather, the goal is to obtain more efficient blade loadings which result in lower rotor horsepower.

Horsepower and stall requirements are not the only important parameters in helicopter flight. Also of importance are vibration problems which result from elastic blade bending responses. It is conjectured that the magnitude of the elastic tip deflection is directly related to the magnitude of the blade vibratory forces which govern ship vibration levels and blade life. The elastic tip deflections due to flatwise bending are shown in Figure 14 for both the CTR and DCR systems and are plotted as a function of forward speed. As seen from this figure, the vibratory bending tip deflections for the four-bladed CTR are lower than those for the four-bladed, five-bladed, and six-bladed DCR over the complete flight spectrum. This comparison indicates further the benefits of a more uniform airload distribution.

Figure 13. Maximum Blade Section Angle of Attack as a Function of Forward Speed for the CTR and DCR Systems.

Figure 14. Elastic Flatwise Vibratory Tip Bending Deflection as a Function of Forward Speed for the CTR and DCR Systems.

The level flight conditions described above for a particular gross weight condition do not indicate the maximum thrust capability of the CTR and the DCR systems. For this study, maximum thrust at a specified forward speed is defined as the thrust generated by a rotor when it reaches a local angle of attack of 13.5 degrees at that speed. Computer runs were made specifically to evaluate this capability for both rotor systems. Results of a few maximum thrust cases are tabulated in Table II; many more cases are presented in Tables XII through XXX of Appendix III.

Few of the high thrust cases could be made to trim exactly at 13.5 degrees because of computer time limitations. Consequently, the calculated results from the high thrust cases were cross plotted and interpolated to generate maximum thrust boundaries which, in turn, were normalized on gross weight to define the load factor capability of each rotor.

Figure 15 presents load factor as a function of forward speed for the CTR and DCR configurations. The region between the load factor boundary and the level flight line ($n_z = 1.0$) represents the maneuverability margin for each rotor. As expected, the six-bladed DCR is capable of larger load factors than the five-bladed or the four-bladed DCR. The four-bladed CTR is equivalent to the six-bladed direct control rotor.

The CTR load factor is shown as a range of values within which the CTR can fly rather than as a unique boundary because the CTR can vary the maximum tip angle of attack through its elastic twist variations. The lower portion of this load factor range represents twist scheduling for minimum horsepower, whereas the upper portion represents twist scheduling for minimum tip angle of attack conditions.

The efficiency of the CTR is further demonstrated in Figure 16, where the maximum thrust-to-horsepower ratio is shown as a function of forward speed. In Figure 16, the load factor varies with forward speed and corresponds to the maximum attainable value for each point on these curves. The curves are intercepted by the stall boundary where the load factor is equal to 1.0. The CTR has a higher maximum thrust-to-horsepower ratio than the four-, five-, or six-bladed DCR over the speed range considered. Therefore, the CTR has sufficient thrust and horsepower reserve to handle any maneuver condition within the flight envelope, and surpasses conventional systems having 50 percent higher solidity.

$\alpha_{\text{MAX}} = 13.5 \text{ DEG}$

Figure 16. Maximum Thrust-to-Horsepower Ratio as a Function of Forward Speed.

Figures 17, 18, and 19 show how controllable twist can redistribute the angles of attack and airloads at the higher load factors. Figure 17 shows the angle-of-attack contours for the four-bladed CTR and the six-bladed DCR for a load factor of 1.35 operating at an airspeed of 160 knots. The CTR contour plot shows a substantial redistribution of angles of attack from that of the conventional rotor system while maintaining the same peak angles of attack; it has increased the average value of angle of attack over the advancing region of the rotor disk. Figure 18 shows the corresponding angle-of-attack time histories for the two rotors. These curves are plotted at the tip station and the 72-percent radial station. The CTR has increased angles of attack in the fore and aft azimuth positions and higher inboard angles of attack as compared to the conventional rotor system. This would be indicative of reduced loading on the advancing and retreating sides of the rotor, increased loading fore and aft, and increased loading over the inboard stations. Blade airload harmonics for the above flight conditions are depicted in Figure 19 in the form of bar charts. At the tip station and the 72-percent radial station, the 2-per-rev cosine airloading comparisons indicate that the CTR substantially increases the fore and aft airloading over the DCR. These redistributions improve the aerodynamic efficiency of the CTR system.

MISSION ANALYSIS

Up to this point, comparisons between CTR and DCR were made for a 11,500-pound utility helicopter with the flat plate drag area of 25 square feet. The comparisons show that in order to match CTR one g capability, the DCR requires a 50 percent increase in solidity at the limit design speed of 180 knots. This increased rotor solidity will increase significantly the DCR vehicle empty weight and installed power which, in turn, either will deteriorate the useful load at a fixed gross weight or will increase the vehicle gross weight to accommodate the same load. As was illustrated in Figure 12, the DCR requires 15 to 25 percent greater power than the CTR over all forward speeds for the same gross weight. Consequently, the range for a helicopter using a CTR will be 18 percent greater than that for the vehicle with reduced load using a DCR. As was shown in Figure 14, the DCR blade tip bending amplitudes are 40 percent higher than those of the CTR configuration at the cruise speed conditions of 120 to 140 knots. The increased bending will significantly decrease DCR blade life and increase ship vibration levels. This, in turn, will require greater weights for the various components subjected to these vibration levels.

A more valid comparison between the two rotor systems can be made by sizing the vehicle and rotor to hover OGE at 4000 ft, 95°F and to fly a 1000-pound load over a range of 200 nautical miles at a cruise speed of 140 knots at 4000 ft, 95°F. This latter mission requirement translates into a maximum airspeed of 175 knots (10 knots below stall) at standard sea level. Using trending data and a statistical weight breakdown, the performance parameters shown in Table III were developed for both CTR and DCR propelled helicopters. As seen in Table III, the direct control rotor helicopter has a 19-percent increase in takeoff gross weight to accomplish the specified mission. In order to accomplish this, the DCR vehicle requires 37 percent increase in fuel load and 30 percent higher installed power. The direct control rotor diameter is 10 percent greater than that of the CTR in order to maintain the same disk loading. These performance benefits accrue because CTR can carry a 50-percent higher blade loading than its DCR counterpart without stalling.

Takeoff Gross Weight	13700	11500
*Includes CTR Weight Penalties; 80 lb for Flaps and Mass Balance; 170 lb for Duplicate Control.		

CONCLUSIONS

The following conclusions are made as a result of the mission analysis comparing the controllable twist rotor (CTR) to a conventional direct control rotor (DCR) that is sized to perform the stated mission:

1. The CTR requires a 30-percent decrease in solidity to match the DCR 1.0 g capability.
2. The CTR requires 15 percent less power than the DCR over all forward speeds.
3. The CTR propelled helicopter has an 18 percent greater range than that of a DCR propelled helicopter.
4. Blade bending amplitudes on the CTR are 30 percent lower than the blade bending amplitudes on the DCR at cruise speeds.
5. The lower CTR blade bending amplitudes result in significantly increased blade life and reduced ship vibration levels.
6. The CTR helicopter gross weight is 15 percent lighter than the DCR helicopter gross weight.
7. The CTR diameter is 10 percent less than the DCR diameter.
8. Installed power on the CTR helicopter is 25 percent less than installed power on the DCR helicopter.
9. CTR hover power requirements (OGE, 4000 ft, 95°F) are 15 percent less than those of the DCR.

Note: The prefix "R" (on the above designations) indicates data used in the reverse flow region, and the prefix "S" indicates data used in the stall regions.

slopes and unsteady aerodynamic coefficients that are used in the normal flow region, in the reverse-flow region, and in an assumed stall flow region. The Mach number effects are considered only for the normal flow region on the rotor blades. The aerodynamic characteristics and data used in the nonlinear portion of the analysis are tabulated in Appendix IV.

All flight conditions throughout this analysis were considered at sea level and for a standard day. Speeds range from hover to 180 knots, and are listed in Table X, where the values for the trim variables used for level flight and the values of inflow used for various load factors are described.

ELASTIC TWIST AND CONTROL REQUIREMENTS

In the conventional rotor system, the relationships between the performance and the control requirements are complicated by the high degree of nonlinearity contained in the interaction effects. Neglecting the rotor control, we have three effects of the pitch horn, namely, longitudinal, lateral, and collective controls. These three controls all interact and affect the resolution of the rotor trim forces. On the other hand, the CTR having a dual control system has a more complex relationship with the performance parameters. We now have six control parameters: two longitudinal, two lateral, and two collective. These all interact in a highly nonlinear fashion making it difficult to find a relationship between performance parameters and controls. Thus, in order to understand some of the problems of optimization, it is necessary to learn some of the problems of the controls and twist and their effects on performance.

Control requirements were discussed in References 5 and 6, where the importance of control programming over the flight spectrum of the CTR was stressed. The CTR has two control systems, each one by itself capable of flying the ship in trim. It is necessary, therefore, to program the two control systems together, using some combination to give the desired elastic twist at all flight speeds. The desired twist is then the twist that gives either minimum horsepower, minimum vibration, little blade stall, or any combination thereof.

In order to achieve desired twist, a relationship between the controls and twist must be defined. The pitch horn and flap controls are input into the airloads analysis in series form as a first harmonic variation. The flap has a positive series,

$$\delta_{in} = \delta_0 + \delta_{ls} \sin \psi + \delta_{lc} \cos \psi \quad (46)$$

TABLE X. FLIGHT CONDITIONS AT SEA LEVEL AND STANDARD DAY					
Trim Factors for Level Flight					
	$\mu = 0.0$	$\mu = .20$	$\mu = .30$	$\mu = .40$	$\mu = .45$
V	0.0 kts	80 kts	120 kts	160 kts	180 kts
α_f	0.0	-0.5 deg	-3.4 deg	-8.5 deg	-11.5 deg
F_z	11,500 lb	11,500 lb	11,500 lb	11,500 lb	11,500 lb
F_x	0.0 lb	524 lb	1200 lb	2210 lb	2882 lb
F_y	-71 lb	288 lb	29 lb	-746 lb	-1318 lb
Values of Inflow, λ , for Various Load Factors					
η_z	$\mu = 0.0$	$\mu = .20$	$\mu = .30$	$\mu = .40$	$\mu = .45$
1.0	-.0603	-.0371	-.0615	-.1120	-.1460
1.2	-	-	-	-.1135	-
1.35	-	-	-.0663	-.1152	-
1.48	-	-	-.068	-.116	-
1.83	-	-.045	-.071	-	-

while the pitch horn has a negative series in order to comply with conventional standards,

$$\theta_{in} = A_0 - B_{1s} \sin \psi - A_{1s} \cos \psi \quad (47)$$

Blade twist is a response and is obtained from the airloads program as an output for the trim cases. The twist response is harmonically analyzed, and only the first harmonic is included for study in the present analysis. Twist is defined as a positive series given by Equation (48):

$$\theta_{tw} = \phi_0 + \phi_{1s} \sin \psi + \phi_{1c} \cos \psi \quad (48)$$

where ϕ_0 is the collective elastic twist and ϕ_{1s} and ϕ_{1c} , the longitudinal and lateral components of the one-per-rev cyclic twist. In this relation, cyclic twist can be expressed in vector form, which sometimes makes it easier to visualize. The vector magnitude and its angular phase relationship around the azimuth are defined by Equation (49):

$$\phi_r = \sqrt{\phi_{1s}^2 + \phi_{1c}^2}, \quad \psi_\phi = \tan^{-1} \frac{\phi_{1s}}{\phi_{1c}} \quad (49)$$

THE EFFECTS OF BUILT-IN TWIST ON THE DCR

For comparison purposes, a direct control rotor configuration was chosen with a similar geometry to the CTR configuration. The physical distributions of planform, mass, feathering inertia, and chordwise center of gravity have already been discussed, and the direct control rotor blade has been designated DCR-a, with planform I. Computer runs were made on the DCR-a for values of built-in twist of $\theta_x = 0.0, -4.0, -8.0,$ and -10.0 degrees. The results, presented in Figure 26, show the effects of built-in twist on maximum blade tip angle of attack, peak-to-peak tip bending deflection, and shaft horsepower for three different advance ratios. Results show that tip angle of attack and power can be reduced with increased negative twist but at the cost of higher tip bending deflections. Thus, according to these curves, a good compromise for all three of the blade parameters would be a built-in twist of $\theta_x = -8$ degrees. This is a value of built-in twist that is fairly well accepted throughout the helicopter industry for the conventional rotor system.

Figure 26. The Effect of Built-In Twist on the DCR-a Configuration.

THE EFFECTS OF BUILT-IN TWIST ON THE CONTROLLABLE TWIST ROTOR

Computer runs were also made on the CTR using built-in twist values of $\theta_x = -4.0$ and -8.0 degrees, designated as CTR-A2 and CTR-A3, respectively. These were conducted at flight speeds of $V = 120$ knots and 160 knots. After several initial runs, it was found that an almost linear relationship exists between the control inputs and the twist response and may be expressed by the following matrix relation:

$$\begin{bmatrix} A_o \\ B_{1s} \\ A_{1s} \\ \delta_o \\ \delta_{1s} \\ \delta_{1c} \end{bmatrix} = \begin{bmatrix} a_{1,1} & a_{1,2} & a_{1,3} & a_{1,4} \\ a_{2,1} & \cdot & \cdot & \cdot \\ a_{3,1} & \cdot & \cdot & \cdot \\ a_{4,1} & \cdot & \cdot & \cdot \\ a_{5,1} & \cdot & \cdot & \cdot \\ a_{6,1} & \cdot & \cdot & a_{6,4} \end{bmatrix} \begin{bmatrix} 1.0 \\ \phi_o \\ \phi_{1s} \\ \phi_{1c} \end{bmatrix} \quad (50)$$

A minimum of four trim cases are required to evaluate the coefficients of Equation (50). If more cases are available, an accurate evaluation of these coefficients is made through the use of the multiple linear regression computer program described in Reference 7. This program evaluates the coefficients with a least-squares fit.

The value of Equation (50) lies in the fact that the twist can be specified and the controls required to achieve this twist can be determined. The effects of variations in twist on performance, angle of attack, and blade bending can be observed directly by using a minimum of computer runs.

The coefficients of Equation (50) have been evaluated for the CTR at speeds of $V = 120$ knots and 160 knots, and are found in Table XI for two values of built-in twist. As expected, these tables show that the most significant changes occur in the intercepts (column 1 of each group) due to the speed differences and that relatively minor changes occur in the derivatives (columns 2 through 4).

Figures 27, 28, and 29 show the effect of elastic collective twist on the maximum tip angle of attack, peak-to-peak bending tip amplitude, and rotor shaft horsepower for the CTR system. These curves also reflect the one-per-rev cyclic twist vector magnitudes and phasing obtained for various points that were run on the computer. For these curves, the cases were chosen such that the phasing of cyclic twist was kept at approximately 60 degrees. Figure 27 shows the variations at an advance ratio of $\mu = 0.3$ and a built-in twist of $\theta_x = -8$ degrees. This curve indicates that minimum tip angle of attack, minimum bending, and minimum horsepower occur at values of collective twist of $\phi_0 = -3.5$, -6.0 and -3.0 degrees, respectively. Figure 28 presents the results generated for an advance ratio of $\mu = 0.4$ and a built-in twist of $\theta_x = -8$ degrees. In this figure, the tip angle of attack and the horsepower are a minimum at $\phi_0 = -5.5$ degrees. Figure 28 also shows that high values of collective twist, ϕ_0 , produce high values of peak-to-peak bending displacement, q_{tip} . Figure 29 summarizes results for an advance ratio of $\mu = 0.4$ and a built-in twist of $\theta_x = -4.0$ degrees. A comparison of Figures 28 and 29 shows that the minimum power and minimum bending displacements are lower for a built-in twist of $\theta_x = -4$ degrees than for a built-in twist of $\theta_x = -8$ degrees. The tip angles of attack, however, are higher for the built-in twist of $\theta_x = -4$ degrees than those for a built-in twist of $\theta_x = -8$ degrees.

A comparison between Figures 27 and 28 shows that an increase in forward speed tends to give an increase in curvature to the tip angle of attack and horsepower curves. The minima are therefore better defined at the higher speeds. These phenomena may be due to compressibility and stall effects.

Figures 30, 31, and 32 show the effect of one-per-rev cyclic phasing, ψ_ϕ , on maximum tip angle of attack, peak-to-peak bending tip deflection, and rotor shaft horsepower. Figure 30 is for the built-in twist configuration of $\theta_x = -8$ degrees at an advance ratio of $\mu = 0.3$. In this set of curves, a vector magnitude of $\phi_r = 6.0$ degrees and a collective elastic twist of $\phi_0 = -2.0$ degrees are held constant. As seen in this figure, the resulting curves are sinusoidal in character. Also at this speed, the lowest tip angle of attack occurs at $\psi_\phi = 180$ degrees, while minimum bending deflections and minimum horsepower occur at $\psi_\phi = 60$ degrees and 90 degrees, respectively. It should be noted that the angles of attack are well below stall for all cyclic twist phasing. Figure 31 is a similar set of curves for the CTR configuration with a built-in twist of $\theta_x = -8$ degrees at an advance ratio of $\mu = 0.4$. Values of collective twist and vector twist, ϕ_0 and ϕ_r , are constant at values of -2.0 and 6.0 degrees, respectively. In these curves it is seen that there is less of a sinusoidal character than in Figure 30. The bending tip deflections and

Figure 30. The Effect of Cyclic Twist Phasing on Shaft Horsepower, Elastic Bending, and Maximum Tip Angle of Attack for the CTR-A3 Configuration; $V = 120$ Kts; $\theta_x = -8$ Deg.

Figure 31. The Effect of Cyclic Twist Phasing on Shaft Horsepower, Elastic Bending, and Maximum Tip Angle of Attack for the CTR-A3 Configuration; $V = 160$ Kts; $\theta_x = -8$ Deg.

Figure 32. The Effect of Cyclic Twist Phasing on Shaft Horsepower, Elastic Bending, and Maximum Tip Angle of Attack for the CTR-A2 Configuration; $V = 160$ Kts; $\theta_x = -4$ Deg.

the tip angle of attack do not have a minimum at the same cyclic twist phase that occurs at minimum horsepower. Bending and tip angle are minimum at $\psi_\phi = 140$ degrees while horsepower is minimum at $\psi_\phi = 60$. Figure 32 shows the effect of cyclic twist phasing for the built-in twist configuration of $\theta_x = -4.0$ degrees at an advance ratio of $\mu = 0.4$. In this figure, ϕ_0 and ϕ_r are held at approximately -5.0 and 6.0 degrees, respectively. As in Figure 31, minimum bending and tip angle of attack do not occur at minimum horsepower. Minimum horsepower occurs at $\psi_\phi = 60$ degrees, whereas minimum bending occurs at $\psi_\phi = 140$ degrees.

The effects of built-in twist on the four-bladed CTR and DCR configurations are shown in Figure 33, where shaft horsepower is plotted as a function of built-in twist for both rotor systems, for forward flight speeds of $V = 120, 160,$ and 180 knots. These curves were developed for the CTR-A1, A2, and A3 configurations as well as the DCR-a1, a2, a3, and a4 configurations. As previously mentioned, the DCR had a best built-in twist of $\theta_x = -8$ degrees, and, as the curves indicate, the CTR had a best built-in twist of $\theta_x = -2.0$ degrees, at speeds of $V = 120$ and 160 knots. Data for these cases can be found in Tables XII through XVI. Table XVII summarizes data generated for the DCR-a configuration with five and six blades.

THE EFFECTS OF FAIRED FLAP

The CTR-B2 configuration consists of a faired flap rather than an external flap. The aerodynamic data for these airfoil sections was described previously. Computer cases were run on this configuration with a built-in twist of $\theta_x = -2$ degrees at a flight speed of $V = 160$ knots and are shown in Table XVIII. Figure 34 shows the effect of collective elastic twist, vector twist, and twist phasing on rotor horsepower. Here the minimum rotor power occurs at a collective elastic twist of $\phi_0 = -7.0$ degrees, a vector twist of $\phi_r = -4.0$ degrees, and a twist phasing of $\psi_\phi = 45$ degrees. The lowest value of horsepower on this curve is $P = 2231$ horsepower, which is approximately 100 horsepower lower at 160 knots than that of the CTR-A2 configuration having an external flap. This is as expected because of the reduced drag of the faired flap configuration. Consequently, faired flap data were used in all succeeding computer runs.

Figure 33. The Effect of Built-In Twist on the Minimum Horsepower for the 4-Bladed CTR-A and DCR-a.

Figure 34. The Minimum Power Required for the CTR-B2 Configuration Using a Faired Flap; $V = 160$ Kts; $\theta_x = -2$ Deg; Tip Flap.

INBOARD FLAP

The CTR-E configuration has a 42-inch faired flap located at the 75-percent radius. Data for the computer runs on this configuration are found in Table XIX. These runs were also made at a flight speed of $V = 160$ knots. Of all the cases run on this configuration, the lowest value of tip angle of attack achieved was $\alpha_{\max} = 19.4$ degrees. Although the power requirements for this configuration were low, the angles of attack are unacceptable because they are above stall. Thus, it was concluded that the tip flap was more beneficial.

TORSIONAL STIFFNESS

Computer cases were run on the CTR-B2, C1, and C2 configurations; the results are found in Tables XVIII, XXVIII, and XXIX. These cases represent runs using nonrotating torsional frequencies of $\omega_t = 6.76, 8.28, \text{ and } 9.43$ cycles per second. The CTR-B2 configuration has already been discussed but is presented here for comparison purposes. Figure 35 shows the effects of collective elastic twist, vector twist, and twist phasing on the rotor horsepower required for the three configurations of different torsional stiffnesses. In general, it is seen that the torsional stiffness effects are slight and the CTR-B2 configuration still has the lower power requirements. Thus, the torsional stiffness of the CTR-B2 configuration was used for the remainder of the analysis.

CONTROL FLAP SIZE

Computer cases were run for the CTR-F, B2, and G configurations the data for which may be found in Tables XXI, XVIII, and XXII. These cases represent, respectively, rotor blades with flaps that are 38, 48, and 58 inches long. The B2 configuration was discussed previously but is shown here for comparison purposes. Again, the evaluation was made at a flight speed of $V = 160$ knots. Figure 36 shows the effect of collective elastic twist, vector twist, and twist phasing on rotor horsepower. It is clearly seen that the longer flap has the lowest power requirements. The CTR-G configuration was chosen as the optimum configuration.

THE EFFECT OF FORWARD SPEED

The CTR-G configuration was sized and optimized at 160 knots. Additional computer runs were made on this configuration at $V = 0.0, 120, \text{ and } 180$ knots. The results of the cases at these speeds are found in Tables XXIV, XXV, and XXVI. Even though the basic configuration geometry has been optimized, it is still necessary to optimize the control requirements at the

Figure 35. The Effects of Torsional Frequency on the Shaft Horsepower Required for the CTR; $V = 160 \text{ Kts}$; $\phi_x = -2 \text{ Deg}$; Tip Flap.

Figure 36. The Effects of Servo-Flap Size on the Shaft Horsepower Required for the CTR; $V = 160$ Kts; $\theta_x = -2$ Deg; Tip Flap.

various speeds based on minimum horsepower or angle of attack limitations.

Figure 37 shows rotor power required as a function of collective elastic twist, ϕ_0 , for the CTR-G configuration at hover. For this condition, the one-per-rev cyclic flap motions were set to zero such that only the effects of collective flap are considered. It is therefore evident that the cyclic twist will also be zero. This curve indicates that minimum horsepower occurs at a collective elastic twist of $\phi_0 = -8$ degrees.

Figure 38 presents the rotor horsepower required for the CTR-G configuration at a forward speed of $V = 120$ knots as a function of collective elastic twist, vector twist, and cyclic twist phasing. Figure 38 shows that minimum power occurs at a collective elastic twist of $\phi_0 = -8$ degrees, vector twist $\phi_r = 1.5$ degrees, and cyclic twist phasing $\psi_\phi = 30$ degrees. The minimum horsepower obtained from any of these points is $P = 1145$ horsepower.

Figure 39 shows the results for the G configuration at $V = 180$ knots. Rotor horsepower and maximum tip angle of attack are shown as a function of collective elastic twist, vector twist, and cyclic elastic twist phasing. At this speed, power must be optimized with explicit consideration for tip angle of attack to avoid stall. Over the range of study on these curves, it is seen that angle of attack has little variation with collective twist and cyclic twist phasing. However, the slope of the power variation with vectored twist is negative, whereas the slope of maximum tip angle of attack with vector twist is positive. The choice of a value for vector twist should then be made where the maximum angle of attack is equal to the stall angle for the blade section. This will provide the minimum horsepower allowable before the rotor stalls. The unstalled case with the minimum power setting chosen for this run was with a collective elastic twist of $\phi_0 = -9.3$ degrees and a vector twist of $\phi_r = 2.2$ degrees at a cyclic twist phasing of $\psi_\phi = 88$ degrees.

In order to maintain trim with elastic twist, and to achieve minimum horsepower, certain relationships must exist between the servo flap controls and the pitch horn controls. Figure 40 shows how the elastic twist and the two controls relate to each other. Here the collective and cyclic elastic twist, the collective and cyclic flap, and the collective and cyclic pitch horn deflections are plotted as a function of forward speed. The results are as expected, with the collective values having a parabolic shape with forward speed and the cyclic values increasing with forward speed.

APPENDIX IV
AIRFOIL SECTION CHARACTERISTICS

The aerodynamic characteristics for the airfoil sections used in this study are presented for 49 angles of attack ($0^\circ < \alpha < 360^\circ$), 4 Mach numbers (0.30, 0.45, 0.65, 0.80), and for 5 flap deflections (-10° , -5° , 0° , 5° , 10°). Table XXXI contains aerodynamic data for the modified Kaman 23012 airfoil without a flap. Tables XXXII and XXXIII contain data for the Kaman 23012 airfoil with a trailing flap and a faired flap, respectively. Wind tunnel test data were used directly where available for these tables and were cross-plotted, interpolated, and modified using standard NASA techniques for thickness, camber, flap angle, and Mach number effects to synthesize the tabulated coefficients. All section characteristics tabulated herein are based on the total chord of the blade or of the blade and flap, as applicable.

TABLE XXXI. AERODYNAMIC COEFFICIENT DATA
FOR THE KAMAN 23012 AIRFOIL
SECTION

APPENDIX V
CONTROL SYSTEM KINEMATICS

As mentioned previously, the heart of the CTR system consists of a torsionally elastic blade with dual controls. A schematic illustrating the controls for this rotor system is shown in Figure 41. As seen in this schematic, little complexity is added to the rotating control system used typically in contemporary helicopters. Conventional pitch links control the blade angle at the inboard end of the rotor. The flap controls the outboard blade angle. The flap also controls the degree of twist along the rotor blade, thus increasing the uniformity of the airload over the rotor disk.

The control mechanisms for the dual system are based on existing technology. Control rods for the flap system are connected to a swashplate under the hollow rotor drive shaft, and runs up through the hollow drive to a walking beam on top of the rotor hub. Control action continues across the walking beam, down to an L-crank, across another walking beam, and out through the blade on a control rod connected to the flap near the tip of the blade. The pitch horns attached to the blade root are connected by control rods to a separate swashplate on the outside of the drive shaft. The two swashplates are actuated by linkages from the mixing box which is inserted between the pilot's collective and cyclic pitch controls and the swashplates. The mixing box is responsive to forward speeds and automatically determines optimum blade angles needed to carry out the pilot's directions. If a pilot wants to go faster, he generally will move his cyclic pitch stick forward, and the mixing box will translate cyclic stick motion into the proper control phasing to produce the most efficient blade twist for increasing aircraft speed.

The following list contains the components of the control system and also describes the functions of these components.

<u>ITEM</u>	<u>FUNCTION</u>
Flap swashplate	Actuates servo flap
Blade swashplate	Actuates blade root pitch
Collective control	Actuates both swashplates for collective control
Cyclic control	Actuates both swashplates for cyclic control

Figure 41. Schematic of the Complete Servo-Flap Actuator System.

<u>ITEM</u>	<u>FUNCTION</u>
Primary hydraulic boost	Provides hydraulic boost power to blade swashplate
Secondary hydraulic boost	Provides ASE control input to both servo flap and blade pitch
CTR input actuators	Provides differential control to both swashplates as programmed by the CTR differentiator
CTR differentiator	Converts airspeed signal into proper CTR requirement
Servo angular positioner	Positions the (6) CTR input cams angularly according to airspeed
CTR input cams	Profiled according to optimum CTR control requirements. Six cams are installed, three for each swashplate, controlling the longitudinal, lateral, and collective positioning of each swashplate
Linear potentiometers	Transfers cam motion into electrical signal to CTR input actuators
Airspeed pickup	Conventional pitot tube
Pressure transducer	Converts airspeed into an electrical signal

In order to properly design the CTR input actuators and differentiators, it is required to know how the flap and pitch horn controls relate to each other. In running the computer cases for the CTR G configuration, it was found that a linear relationship existed between the two control systems. This relationship is expressed by the following equation:

$$\begin{vmatrix} A_o \\ B_{1s} \\ A_{1s} \end{vmatrix} = \begin{vmatrix} b_o & b_1 & b_2 & b_3 \\ c_o & c_1 & c_2 & c_3 \\ d_o & d_1 & d_2 & d_3 \end{vmatrix} \begin{vmatrix} 1 \\ \delta_o \\ \delta_{1s} \\ \delta_{1c} \end{vmatrix} \quad (51)$$

The linear coefficients in Equation (51) are shown as a function of speed in Figure 42. Figure 42 shows the intercepts for the pitch horn requirements for zero servo flap inputs and the changes in pitch horn collective due to changes in servo flap collective and cyclic controls. Also shown are the effect of changes in servo longitudinal and lateral controls. These figures indicate a linear relationship with speed of b_1 , b_2 , b_3 , c_2 , c_3 , d_1 , d_2 , and d_3 . The linear relationship or constant relationships with speed are significant because they greatly simplify the design of the actuating systems.

APPENDIX VI TRIMMED FLIGHT CHARACTERISTICS

The effects of main rotor power, maximum blade section angle of attack, elastic flapwise tip bending deflection, and load factor have been previously discussed, using Figures 12 through 15. The cases chosen for these figures were obtained from the runs at the various speeds described in Appendix III. Only the minimum power cases were chosen at speeds below stall. At the high-speed condition, the optimum cases were chosen from unstalled cases only (not minimum power). The optimum cases have already been described in Table II for the CTR along with equivalent cases run on the DCR. Due to a large quantity of output contained with each fully trimmed computer run, it is considered impractical to present all of the data for these cases in this report. However, selected items were chosen from the output of each trimmed case in Table II and are plotted in Figures 43 through 146 as shown in this Appendix. For each case considered, the following curves are presented:

1. Angle-of-attack contour plots.
2. Time histories of the input control and response modes.
3. Harmonic analysis of the response modes.
4. Time histories of the blade section angles of attack.
5. Time histories of the out-of-plane airloads.
6. Harmonic analysis of the out-of-plane airloads.
7. Time histories of the in-plane airloads.
8. Harmonic analysis of the in-plane airloads.
