PREFACE

An important part of the Rand/ARPA research program on the dynamics of climate is the evaluation of the accuracy of simulations of the global climate given by numerical solutions of models of the general atmospheric circulation (in particular, the Mintz-Arakawa model). Systematic evaluation requires a knowledge of the global distribution of the common climatic variables. These include pressure, temperature, humidity, wind, and precipitation, together with the associated distributions of the elements of the global radiation and hydrologic balances. Such data, we have discovered, are not readily available, and even those that are obtainable are usually in a variety of forms and not immediately comparable to other climatic data.

The data presented in this report follow the pattern of our January reports R-915-ARPA and R-915/1-ARPA. These studies are the result of a continuing effort to gather in one place and in a common format the most representative global climatologies of selected seasonal meteorological variables. These July data represent the second part of a set of seasonal (quarterly) data being compiled for a Global Climatic Atlas.

SUMMARY

From selected climatological data sources the July global distribution of pressure, temperature, wind, and moisture is reconstructed for the surface, 800 mb, and 400 mb. These data are supplemented by presentations of the global distributions of albedo, cloudiness, evaporation, precipitation, and selected elements of the surface heat balance. All data are interpolated at the 4° latitude by 5° longitude global grid used in the Mintz-Arakawa model and are given in the form of both tabulated values and machine-analyzed maps.

ACKNOWLEDGMENTS

Sincere appreciation is extended to those at the National Climatic Center of the National Oceanic and Atmospheric Administration (NOAA), the National Center for Atmospheric Research (NCAR), and the Environmental Technical Applications Center (ETAC) of the Air Force, who cooperated in making available the latest magnetic tapes of surface and upper-air data for this special analysis. Appreciation is also extended to R. C. Alexander for his efforts in developing the data on sea-surface temperature and ice limits at high latitudes. Thanks are also due R. L. Mobley and A. B. Nelson for reducing these data to the desired format.

1. INTRODUCTION

The data presented in this report describe the global distribution of the primary climatic elements of pressure, temperature, wind, and moisture, together with the surface albedo and a number of components of the surface heat and water balances for July. The planetary albedo data included in R-915/1-ARPA (Schutz and Gates, 1972) are *not* available for July. Both smoothed and unsmoothed data were gathered and processed for use in the evaluation of climate simulation experiments made with numerical general circulation models. The present report, however, is a response to the recognition that these data may also be useful as a climatic summary in their own right.

A primary purpose of the present compilation of data is to present the "observed" July distribution of those meteorological variables simulated by the two-level atmospheric model of Mintz and Arakawa. This model simulates the wind, temperature, and geopotential at two tropospheric levels--which for our purposes may be regarded as the 400-mb and 800-mb levels--and also the moisture distribution at the lower (800-mb) level. At the earth's surface, the model simulates the pressure, the surface air temperature, and the ground temperature, together with the elements of the surface heat balance, including the net radiation flux, the latent heat flux associated with surface evaporation, and the surface flux of sensible heat. The model also simulates elements of the hydrologic balance, including cloudiness, precipitation, and ground wetness. The ocean temperature and surface albedo data also given here are input boundary conditions to the model.*

Despite a search for the best possible data, the July global distribution of each of these variables was not readily available in the climatic literature. Those variables that were available at the surface,

at 800 mb, and at 400 mb are summarized in Table 1.1, which also serves as a guide to the report's sources of information, maximum period of record, maps, and data tabulations. In most cases the 800-mb and 400-mb data had to be interpolated at the 4° latitude, 5° longitude grid of the Mintz-Arakawa model from unsmoothed, taped data in two NAVAIR publications, whereas most of the surface data were visually interpolated from analyses published in atlases.

A global analysis of each variable selected is given in Sec. 3, together with a tabulation of the associated grid-point data in Sec. 5. Exceptions are the observed clouds and winds, for which only northern-hemisphere data are presently available in adequate quantity. Geostrophic wind and satellite cloud analyses are included, however, for both the northern and southern hemispheres, in an effort to present an approximation to the global wind and cloud pattern for July.

For each of the data distributions shown in Sec. 3, the corresponding distribution of the zonal averages is given in Sec. 4, along with the global average value. Further details of the data selection and processing are given below. The asterisk (*) in the grid-point data tabulations of Sec. 5 denotes missing data. These regions correspond to the blank or "no data" areas on the analyzed maps and zonal averages of Secs. 3 and 4. An exception occurs in the sea-surface temperature data in Secs. 3 and 5, where the letter "I" is included to denote the locations of sea ice.

2. DATA SELECTION AND PROCESSING

The processing or manipulation of each primary source of the July mean data identified in Table 1.1 is briefly described below. After a careful review of all known sources of pertinent data, we concluded that the sources used here represent the best collection of "global" data possible at the present time, at least for the purpose of comparison with the model's global simulations. The observational content, special processing, and limitations of these data (including various record lengths) are discussed further in the data publications themselves. Although the discussion in this report refers primarily to the data of Figs. 3.1 through 3.24, it also applies to the corresponding zonally averaged data of Figs. 4.1 through 4.24, as well as to the supporting grid-point data presented in Tables 5.1 through 5.24.

SURFACE DATA

The surface and sea-level pressure, temperature, and relative humidity shown in Secs. 3, 4, and 5 are based on unsmoothed data for the July averages for the northern and southern hemispheres. These data were taped from two previous publications: NAVAIR 50-1C-52 (Crutcher and Meserve, 1970) and NAVAIR 50-1C-55 (Taljaard, et al., 1969). A linear interpolation was applied to the 5° latitude tabulated data to generate data for every 4° of latitude, beginning at the poles; the presentation of the 5° longitude data was left intact.

Pressure, Temperature, and Relative Humidity

The sea-level pressure (Fig. 3.1), the surface air temperature (Fig. 3.2), and the surface dew-point temperature were taken from the foregoing sources. The dew point was then converted to relative humidity (RH) (Fig. 3.4) by the formula

$$RH = \frac{e^A(p - 6.11 \text{ mb } e^B)}{e^B(p - 6.11 \text{ mb } e^A)} \quad (1)$$

where p is the (total) air pressure (in mb) and the parameters A and B are given by

$$A = 17.269 T_d (T_d + 237.3 \text{ deg C})^{-1} \quad (2)$$

$$B = 17.269 T (T + 237.3 \text{ deg C})^{-1} \quad (3)$$

with T_d the dew-point temperature (in deg C) and T the air temperature (in deg C). The resulting relative humidity distribution at the surface is shown in Fig. 3.4.

The global distribution of average July sea-surface temperatures shown in Fig. 3.3 is based largely on the data contained in the National Center for Atmospheric Research (NCAR) publication of monthly averages (Washington and Thiel, 1970). The NCAR data, which apply between latitudes of 66°N and 66°S, were linearly extrapolated by 2.5° of latitude and longitude in the direction of land or ice (interpolated for small islands or narrow peninsulas) and then transferred to the present 4° latitude, 5° longitude grid by interpolation. Poleward of 66°N and 66°S, sea temperature and the distribution of sea ice were obtained from U.S. Navy Hydrographic Office atlases (1944, 1957, 1958). The grid elements containing more than 50 percent sea ice are denoted by "I" in Fig. 3.3. This convention introduces a bias toward more severe ice conditions. (For example, if 60 percent of an area contains ice of 60 percent concentration, only 36 percent of the area is actually covered by ice.) This practice may partly compensate for the usual bias in the data toward calm, warm weather and ice-free conditions when ships can operate. In high northern latitudes, we used August sea temperatures, which are slightly warmer than those for July.*

Cloudiness

The distribution of total cloud cover shown in Fig. 3.5A was constructed from the digitized representation of both satellite and conventional observations compiled by the Global Weather Central for the

*The U.S. Navy Hydrographic Office atlases for 1957 and 1958 show sea temperatures only for February, May, August, and November.

Environmental Technical Applications Center (1971). These data were collected at 0000Z and 1200Z, and were compiled for this presentation in terms of the total cloud cover C from the formula

$$C = \sum_{N=0}^8 \frac{C_{00,N} + C_{12,N}}{2} \frac{N}{8} \quad (4)$$

where $C_{00,N}$ and $C_{12,N}$ are the percentages of the 00Z and 12Z observations that have N -eighths cloud cover. These digitized cloud data appear on the GWC (Global Weather Central) grid. This is a square grid with octagonal boundaries superimposed on a polar stereographic projection, with a southern boundary at approximately 15°N . Equations from Scientific Services Technical Note #1 (1962) were used to transform the latitude and longitude of each of the 46×72 points of the present grid to the coordinates in the GWC grid, followed by a bilinear interpolation using the four nearest GWC grid values.

Since the northern-hemisphere data of Fig. 3.5A contain all modern cloud observations, during both day and night hours, they are considered the best available representation of northern-hemisphere total cloud cover. In an effort to obtain global coverage, however, Fig. 3.5B was constructed from a digitized representation of the sun-oriented TIROS data of Miller (1970) and Miller et al. (1970). These computer-rectified data give the mean daytime cloudiness at approximately 1400 local sun time. Since they compare favorably with the gross features in Fig. 3.5A associated with storm tracks, anticyclones, and the inter-tropical convergence zone, they are presented as an extension of these data into the southern hemisphere. At present, satellite observations do not discriminate effectively between clouds and highly reflective ground surfaces such as ice, snow, and desert. The Miller data therefore contain systematic errors when interpreted in terms of cloud cover. Nevertheless, they probably represent the best cloud-cover data now available for the southern hemisphere.

Precipitation

The global distribution of the *annual* precipitation shown in Fig. 3.6A, which was included in R-915-ARPA (Schutz and Gates, 1971), was based on the work of Lvovitch and Ovtchinnikov (1964), and remains a valuable source of information. It may provide a direct comparison with the June-July-August distribution or prove useful in future research in conjunction with Jacobs' (1968) seasonal (quarterly) apportionment of precipitation (Table 2.1) over the oceans.

The June-July-August distribution of global precipitation shown in Fig. 3.6B was obtained from visual interpolation of Möller's (1951) seasonal analysis to a 5° latitude, 5° longitude grid, followed by linear interpolation to the points of the present grid. Although Möller performed some empirical partitioning of the observed annual precipitation similar to that done by Jacobs (1968), they are apparently the only global seasonal distributions available.

Evaporation

The July mean surface evaporation shown in Fig. 3.7 was drawn from data interpolated from those of Budyko (1963). There are very few isopleths over the land in the northern hemisphere, since there the evaporation is generally less than 1.0 mm per day. The rapid increase of evaporation over the oceans, however, produces a packing of the isopleths, especially along the eastern coasts of the continents. In mountainous areas in both hemispheres, the evaporation isopleths are interrupted by a lack of data.

Albedo

The values of mean *surface* albedo for July shown in Fig. 3.8A were transcribed directly onto the 4° latitude, 5° longitude grid from the data of Posey and Clapp (1964). These data show the measured July albedo for various types and amounts of ground cover, and include the latitudinal variations of solar angle over the oceans.

Radiation and Heat Balance

The July solar radiation received at the earth's surface, shown in Fig. 3.8B, was interpolated onto the 4° latitude, 5° longitude grid from the data of Budyko (1963). The breaks in the isopleths over land are caused by the mountainous areas, for which no radiation data were available.

The July surface radiation balance shown in Fig. 3.9 and the surface sensible heat flux shown in Fig. 3.10 are also based on interpolations from the data of Budyko (1963), and, like Fig. 3.8B, show a lack of data in mountainous and polar regions. The distribution of the July surface heat balance shown in Fig. 3.11 was constructed by subtracting the interpolated data for the surface sensible heat flux (Fig. 3.10); the distribution of the heat lost by surface evaporation (proportional to the data of Fig. 3.7) was derived from the data for the surface radiation balance (Fig. 3.9). This latter quantity is itself the excess of the solar radiation absorbed at the surface over the net long-wave radiation lost by the surface.

UPPER-AIR DATA

Temperature and Relative Humidity

The values for the free-air temperature and the dew point represent unsmoothed information drawn from data used in the two NAVAIR publications by Crutcher and Meserve (1970) and Taljaard et al. (1969) mentioned above. Specifically, the July mean temperature at 800 mb, as shown in Fig. 3.12, was computed by linear interpolation from the data for 850 mb and 700 mb. The 400-mb July temperature distribution shown in Fig. 3.13 was constructed by a similar interpolation between the data at 500 mb and 300 mb. The resulting 800-mb and 400-mb data were then interpolated horizontally to the 4° latitude, 5° longitude grid.

The relative humidity distribution for 800 mb shown in Fig. 3.14 was computed from the dew point and pressure according to Eqs. (1) through (3), where the 800-mb dew point was itself found from linear interpolation between the taped dew-point data for 850 mb and 700 mb.

Height

The heights for the 800-mb and 400-mb surfaces shown in Figs. 3.13 and 3.20 were found from the heights of the 850-mb and 500-mb surfaces, respectively, as well as from the values of the temperature at 850 mb, 700 mb, 500 mb, and 300 mb, as shown below. If $\bar{T}$ is an average temperature, the height of an isobaric surface z relative to that at a reference surface z_0 may be written from an integration of the hydrostatic equation as

$$z - z_0 = \frac{R\bar{T}}{g} \ln (p_0/p) \quad (5)$$

where R is the gas constant, g the acceleration of gravity, and p_0 the reference isobaric surface. Selecting 850 mb and 500 mb as reference surfaces, we then have for the 800-mb and 400-mb heights the relations

$$z_{800} = z_{850} + 1.480 \text{ m deg}^{-1} T_{850} + 0.296 \text{ m deg}^{-1} T_{700} + 484.9 \text{ m} \quad (6)$$

$$z_{400} = z_{500} + 4.843 \text{ m deg}^{-1} T_{500} + 1.695 \text{ m deg}^{-1} T_{300} + 1784.9 \text{ m} \quad (7)$$

Here the subscripts denote evaluation at pressure surfaces and the temperatures are in degrees Centigrade [with the last terms representing the conversion to degrees Kelvin as in Eq. (5)]. Specifically, the mean temperature between 850 mb and 800 mb has been written as

$$\left(\frac{5}{6} T_{850} + \frac{1}{6} T_{700} \right)$$

and the mean temperature between 500 mb and 400 mb as

$$\left(\frac{3}{4} T_{500} + \frac{1}{4} T_{300} \right)$$

corresponding to the assumption of a temperature distribution linear in pressure between 850 mb and 700 mb and between 500 mb and 300 mb, respectively.

Winds

The distribution of the observed winds at 800 mb and 400 mb shown in Figs. 3.15, 3.16, 3.21, and 3.22 were obtained by interpolation from the data published by Crutcher (1961) in the form of July mean cross sections at every 10° longitude, with subsequent linear interpolation to the present grid. These data are given for the northern hemisphere only, in view of the scarcity of even seasonally averaged wind data in the southern hemisphere. To alleviate this absence of data, the average July geostrophic winds at both 800 mb and 400 mb were computed for the globe from the data of Crutcher and Meserve (1970) and Taljaard et al. (1969), and are shown in Figs. 3.17, 3.18, 3.23, and 3.24. It may be noted that the observed and geostrophic winds agree well in the northern hemisphere at both the 800-mb and 400-mb levels.

The wind in the Mintz-Arakawa model is computed on a "u,v grid" whose points are centered within the primary or pressure grid used for the other calculations. Values at the u,v grid points were found through a bilinear interpolation of the source data, so that the first value falls at 88°N , 177.5°W , rather than at 90°N , 180°W . Because of this staggered wind grid, the maps of the zonal and meridional wind components should be offset 2 deg south and 2.5 deg east of the indicated grid. The latitude marked 90°N thus indicates 88°N in Figs. 3.15 through 3.18, 3.21 through 3.24, 4.15 through 4.18, and 4.21 through 4.24; there is no wind defined at the latitude marked 90°S .
