13. ABSTRACT

Data are presented that give the absorption and extinction efficiencies for both homogeneous spherical aerosol particles and inhomogeneous spherical shell aerosol particles as a function of the size parameter $x = 2\pi r/\lambda$. The data giving the scattering properties of aerosols were computed with machine procedures using Mie theory. Calculations were run to investigate the effect of the atmospheric humidity on the macroscopic scattering properties of aerosols for visible and near infrared light. Data are also presented that give scattering, absorption, and extinction coefficients and the phase matrix for visible and infrared light scattering with tropospheric, stratospheric, and fog particles.

PREFACE

This report is Supplement No. 1 to the Final Report (Part I) under Contract No. F19628-73-C-0130. This report presents the results of computations of cross sections and angular scattering data for homogeneous and inhomogeneous particles using Mie theory. This report gives the results of Mie calculations for single particles as well as macroscopic scattering data for different aerosol size distributions in the visible and near infrared.

Supplement No. 2 of the Final Report (Part I) tabulates scattering data for different types of aerosol particles in the infrared using a $r^{-4.5}$ size distribution.

I. INTRODUCTION

Light transport in the atmosphere is remarkably influenced by aerosol particles. The optical effects of aerosols depend upon their physical structure, their chemical composition (index of refraction), their size distribution and concentration. The dependence of the sky intensity and its degree of polarization on turbidity and the size distribution of aerosol particles has been shown by numerous authors, Refs. 1 and 2 are excellent examples.

The interaction of light with aerosols may be computed by Mie theory if one considers the aerosols as spherical particles. Although this may not be true for a single particle, it may be assumed that the aerosol particles are randomly distributed; the assumption of aerosol particles being spheres is generally accepted. Mie's theory (Ref. 3) originally assumed homogeneous particles and was extended later on to particles of concentric spheres (Refs. 4 and 5) and to particles with the index of refraction varying continuously with the radial distance from the particle center (Ref. 6). The scattering properties of homogeneous aerosols and of particulates consisting of two concentric spheres are of utmost importance for the atmosphere. Currently, there exist four RRA programs that compute scattering data for spherical particles. These programs, designated as MIE-2, MIE-3, MIE-4, and MIE-5, compute cross sections and angular scattering data for homogeneous particles and "two-layer particles" consisting of a spherical kernel and a spherical shell of different material. All four versions of the Mie programs allow for integrating microscopic data over a given size distribution. The programs are based on the fundamental theory outlined by MIE (Ref. 3), Deirmendjian (Ref. 7), Aden and Kerker (Ref. 4) and Penn and Oser (Ref. 8). A detailed description of the codes is given in Ref. 9. In addition to these four programs, a new program, designated as MIE-6, has been

written in order to compute scattering functions by combining the scattering functions for different size distributions and for different indices of refraction.

Sample calculations with these programs are given in this report for inhomogeneous particles (Sections II and III), aerosol size distribution in the troposphere (Section IV) and stratosphere (Section V), and fog particles (Section VI).

II. EFFICIENCY FACTORS FOR HOMOGENEOUS AND INHOMOGENEOUS PARTICLES

The MIE-5 program was used for calculations of the efficiency factors (see Ref. 9 for definition) for particles of different physical and chemical composition. The results are presented in Figs. 1 through 10 as function of the size parameter, $x = 2\pi r/\lambda$, where r is the particle radius and λ the wavelength of the radiation incident on the particle. In the graphs, the indices of refraction of the inner material (kernel) of the particles are designated by MI and the refractive indices of the shell material by MS.

Some of the indices of refraction chosen for the computations are based upon wavelength-dependent measurements of the real and imaginary part of the refractive index for aerosol particles taken by Hänel (Ref. 10) and Fischer (Ref. 11). The index of refraction for "average aerosol in summer 1966 of Mainz, Germany" is given in Ref. 12 as $1.68 - 0.040i$ for 0.3μ wavelength light and as $1.61 - 0.072i$ for $\lambda = 1.0\mu$. Figure 1 shows the well-known shape of the curves giving the efficiency factors of homogeneous particles as function of the size parameter (see Ref. 13, for example) with peak values of the efficiency factors for extinction occurring for size parameters between 1 and 10 and with a limiting value of 2 for large particles. In the example given, the efficiency factor for absorption peaks at $x \approx 20$ for $m = 1.68 - 0.04i$ and $\lambda = 0.3\mu$ and at $x \approx 7$ for $m = 1.61 - 0.072i$ and $\lambda = 1.0\mu$ where the peak values are slightly higher than 1. The refractive indices used for the computations given in Fig. 1 are for dry aerosol. In order to describe realistic conditions, the growth of the aerosol particles with the relative humidity and the related changes of the index of refraction are of special interest. The ratio of the particle radius at a given humidity f to that at $f = 0$ for "Mainz aerosol" is given by Hänel (Ref. 14) to be

Fig. 1. Efficiency Factors for Dry Aerosols ($MI = MS = 1.680 - 0.040I$ for $\lambda = 0.3\mu$ and $MI = MS = 1.610 - 0.072I$ for $\lambda = 1.0\mu$)

Fig. 2. Efficiency Factors for Inhomogeneous Aerosol Particles at a Relative Humidity of 75% ($MI = 1.680 - 0.040I$ and $MS = 1.358 - 0.000I$ for $\lambda = 0.3\mu$ and $MI = 1.610 - 0.072I$ and $MS = 1.324 - 0.000I$ for $\lambda = 1.0\mu$)

Fig. 9. Efficiency Factors for Hydrosol Particles

Fig. 10. Efficiency Factors for Water Bubbles

$r(f)/r_0 = 1.348, 2.0$ and ~ 8.0 for relative humidities of $f = 75\%$, 95% , and 99.9% , respectively (the ratio $r(f)/r_0$ is somewhat dependent upon the particle size for high humidities which will not be considered in this study). The average index of refraction at humidity f is then given by

$$m_f = m_w + (m_o - m_w) \left(\frac{r(f)}{r_0} \right)^{-3}, \quad (1)$$

where m_w and m_o denote the indices of refraction for water and dry aerosol. The efficiency factors for "Mainz aerosol" are given in Figs. 2, 3 and 4 for $f = 75\%$ and in Fig. 5 for relative humidities of 95% and 99.9% . For the data shown in Figs. 2, 3, 4 and 5 for inhomogeneous particles, the index of refraction of the kernel was taken as that of the dry aerosol; the shell material was assumed to be water with the ratio of the particle size to the size of the kernel chosen as $r(f)/r_0$. The data shown in Figs. 2, 3, 4 and 5 for homogeneous particles were computed using the average index of refraction given by Eq. (1). For $f = 75\%$, differences in the calculations are seen mainly for size parameters smaller than ~ 30 with the efficiency factors for the homogeneous particles being smaller for absorption and larger for extinction than those calculated for the spherical-shell particles. For $f = 95\%$ (Fig. 5), some differences in the dependency of the efficiency factor for extinction upon the size parameter are seen for all size parameters $x > 3$. Homogeneous particles are seen in Fig. 5 to be more absorbing than shell particles, especially for large particles with the absorption efficiency factors for $x = 125.66$ calculated to be 0.95436 and 0.43785 for homogeneous and inhomogeneous particles, respectively. For $f = 99.9\%$ (Fig. 5), no apparent differences were found between the efficiency factor calculations for both homogeneous and inhomogeneous particles in the entire range $2.5133 \leq x \leq 113.0973$.

The efficiency factors for homogeneous carbon particles and for carbon particles surrounded by water shells with the ratio of the maximum and minimum shell radii taken to 1.35 are shown in Fig. 6. The graph shows the well-known smooth curves without the oscillations for the pure carbon particles (see also Ref. 8). The curves shown in Fig. 6 for the shell particles make it apparent that the observed oscillations in the extinction efficiency factor are caused by scattering and not by absorption.

Figure 7 gives the efficiency factors for water particles coated with a material of higher refractive index, with the ratio of the particle to the kernel size taken to 1.348. These data were previously reported in Ref. 15, pp. 90/91, with the indices of refraction erroneously given in reversed order.

For particles suspended in media other than gases, the effective index of refraction is obtained as the ratio of the refractive indices of the particle, m_p , and of the surrounding medium, m_m :

$$m_e = m_p / m_m = (\alpha_p - ik_p) / (\alpha_m - ik_m) =$$

$$= \frac{\alpha_p \alpha_m + k_p k_m - i(\alpha_m k_p - \alpha_p k_m)}{\alpha_m^2 + k_m^2} \quad (2)$$

For the case of carbon particles in water and 0.3μ wavelength light, Eq. (2) leads to

$$m_e = \frac{1.95}{1.358} - \frac{0.66}{1.358} i = 1.436 - 0.486i$$

Examples of the scattering and extinction by such hydrosols are given in Figs. 8 and 9. Figure 8 refers to gas bubbles in water (the refractive index of 0.775 corresponds to a wavelength of approximately 2.25μ) and to carbon particles; Fig. 9 to "aerosol particles" in water. The indices of refraction shown in Figs. 8 and 9 are "effective" indices of refraction given by Eq. (2).

Figure 10 shows the application of the MIE-5 program to "water bubbles", i.e. water spheres having gaseous kernel. The ratio of the outer radius to the inner radius was taken to be 1.35 for $\lambda = 0.3\mu$ and 1.01 for $\lambda = 1.0\mu$.

III. SCATTERING PROPERTIES OF HUMID AEROSOL PARTICLES

The data in Section II revealed differences in the efficiency factors for homogeneous and inhomogeneous particles. In particular, it was found that there are differences in the efficiency factors for aerosol particles consisting of a spherical kernel of water-insoluble material and a spherical water shell and for homogeneous particles assuming an average index of refraction that is calculated by mixing rules. It is of special interest how macroscopic scattering data would compare when calculated with these two methods.

The data given in Figs. 2 and 3, corresponding to a relative humidity of 75%, were integrated over a power-law size distribution,

$$n(r) = 1.0638r^{-4},$$

with the limiting radii taken as $r_{\min} = 0.05392\mu$ and $r_{\max} = 13.48\mu$. For the spherical-shell model the ratio of the outer and inner radii was assumed to be 1.348. The ratio of the mass of the aerosol particle at $x\%$ relative humidity to the mass at 0.0% relative humidity is given by

$$\frac{m_x}{m_0} = 1 + \frac{\rho_w}{\rho_0} \left[\left(\frac{r}{r_0} \right)^3 - 1 \right]$$

where ρ_w and ρ_0 are the densities of water ($\rho_w \approx 1 \text{ g/cm}^3$) and the dry aerosol particles, respectively and r/r_0 is the ratio of the outer to the inner radii of the spherical shell particles. For $r/r_0 = 1.348$ and a relative humidity of 75%, the mass ratio is given by

$$\frac{m_{75\%}}{m_{0\%}} = 1 + \frac{1.449}{\rho_0}.$$

The density of dry aerosol particles, ρ_0 , is assumed to be 3.0 g/cm^3 in Ref. 12 (Model 1). For the homogeneous model, Eq. (1) was used to calculate the index of refraction. The computations were made for 5 wavelengths ranging from 0.3μ to 1.0μ , the indices of refraction for dry aerosols were taken from Ref. 12 (model 1).

The calculated optical parameters from these calculations are listed in Table I. The tables lists the indices of refraction, the attenuation coefficients (σ_{EXT} , σ_{SCAT} , and σ_{ABS} denote the extinction, scattering, and absorption coefficients, respectively), the single scattering albedo, the average cosine of the scattering angle, $\overline{\cos\theta}$, and the maximum value of the degree of polarization, P_{max} . As expected from the results presented in Figs. 2 and 3, the absorption coefficients are higher for the spherical-shell particles when compared with those for the homogeneous particles with an average index of refraction. The scattering coefficients are found to be smaller for the spherical-shell particles. This produced somewhat smaller extinction coefficients and smaller values of the single scattering albedo. With the exception of 0.3μ wavelength light, the maximum degree of polarization is smaller for the inhomogeneous particles for all wavelengths being considered.

The normalized phase matrices are given for all wavelengths in Tables A1 through A5 for spherical-shell particles and in Tables A6 through A10 for homogeneous particles. The scattering and polarization functions for 0.3μ and 1.0μ wavelength light are presented in graphical form in Ref. 15 for a similar problem. It was found in Ref. 15 that larger differences in both computations occur for both the scattering function and the degree of polarization, especially for scattering angles larger than 100 degrees. The effects of inhomogeneity of the shell particles do not appear to be important for scattering angles less than about 4° . The scattering function for the homogeneous particles exceeds those for the shell particles for scattering angles between 4° and 40° by up to 20%. At scattering angles greater than about 45° the scattering function for shell particles exceeds that computed for homogeneous particles.

* Shell particle with outer radius/inter radius = 1.348

** Homogeneous particle, index of refraction computed with Equation (1)

Figure 11 presents plots of the ellipticity, $\tan\beta$, as function of the scattering angle. For the data in Fig. 11 it was assumed that the radiation incident on the particles is linearly polarized with the plane of polarization inclined to the reference plane by 45° . The ellipticity, which is dependent on the four elements of the phase matrix, is given by the equation

$$\tan\beta = \frac{-i_4}{\sqrt{0.25(i_1-i_2)^2 + i_3^2 + i_4^2} + \sqrt{0.25(i_1-i_2)^2 + i_3^2}} \quad (3)$$

It was found that the ellipticity is more sensitive to the homogeneity of the particles than are the scattering function and the degree of polarization (Ref. 15). The data in Fig. 11 show a shift of the peak value of the ellipticity for 0.3μ wavelength light from 122° to 160° scattering angle when two-layer particles are assumed.

The data presented in Sections II and III show large differences in the scattering properties, especially in the polarization features, for "Mainz aerosol" at a relative humidity of 75% when homogeneous and inhomogeneous particles are assumed. The differences are expected to be even larger for a relative humidity of 95% (see Fig. 5). Since natural aerosols consist of roughly 50% water insoluble material (Refs. 16 and 17, the ratio of water-solubles to water insoluble materials shows large fluctuations and is highly dependent upon the origin of the particles), care has to be taken in interpreting data of the elliptical polarization (Ref. 18). Previous studies of the scattering properties of aerosol particles as function of the relative humidity, such as those reported in Ref. 12, should be extended to consider the scattering properties of water-insoluble materials as well as water solubles.

Fig. 11. Ellipticity for Aerosol Particles at 75% Relative Humidity

IV. SCATTERING PROPERTIES OF TROPOSPHERIC AEROSOL PARTICLES

The size distribution of continental aerosol particles in the troposphere may be classified into three different scattering types, designated in Ref. 19 as types A, B, and C. According to Ref. 19, different scattering types result mainly from different size distributions of the aerosol particles in the region $0.15\mu < r < 0.60\mu$, where r is the particle radius. Size distributions of scattering types A, B, and C are obtained through a concave, linear, and convex shape of the particle size distribution (on double logarithmic scale), resulting generally in a concave, linear and convex shape of the curve giving the relation between extinction coefficient and wavelength, and also resulting in increasing, constant, and decreasing values of the scattered intensity ratios, $I(\text{red})/I(\text{blue})$, for decreasing scattering angles in the range from 50° to 10° . Data are given in this section for the angular scattering of aerosol particles having different size distributions. Though listed under a specific scattering type, some of the size distributions used are transitions between different scattering types (type AB, etc.).

4.1 Scattering Functions for Type B Aerosols

Type B aerosols are described by power-law size distributions. Scattering functions for aerosols with power-law size distributions are published by numerous authors, see for example Ref. 20. Most of these data, however, are obtained assuming that the absorption of light by aerosol particles may be neglected, an assumption which, according to earlier mentioned measurements by Fischer (Ref. 11), is very doubtful. Some model calculations were therefore accomplished for type B aerosol and indices of refraction of $1.50 - 0.01i$ and $1.55 - 0.01i$ (similar refractive indices are obtained for models 5 and 6 in Ref. 12 for relative humidities of $f \approx 50\%$).

For the calculations, the parameter ν in the size distribution

$$\frac{dN}{dr} = c \cdot r^{-\nu} \quad (4)$$

was taken as 4.0, 4.5, and 5.0. The parameter c was taken such that the particle number was constant for each size distribution at a particle radius of 0.55 micron. The lower limit of the particle radii was varied between 0.01 μ and 0.12 μ , the upper limit was taken to 10 μ or 20 μ . The total number of particles per unit volume is given by

$$N = c \int_{r_{\min}}^{r_{\max}} r^{-\nu} dr = \frac{c}{\nu-1} \left[r_{\min}^{(-\nu+1)} - r_{\max}^{(-\nu+1)} \right] \quad (5)$$

A complete description of the models used is given in Table II. Values of the attenuation coefficients, as obtained from the MIE-2 program, are listed in Table III; the corresponding scattering functions are tabulated in Tables B1 through B28.

The scattering functions listed in Tables B1 through B28 were used to calculate the sky radiance in the solar almucantar for each of the models being considered; the computations were performed with the FLASH and BRITE Monte Carlo Programs (Ref. 15). The aerosol optical thickness was chosen such that the optical thickness would equal 0.23 for the size distribution with $\nu = 4.5$, $r_{\min} = 0.06\mu$ and for 0.55 μ wavelength light. The aerosol optical thickness for other models and wavelengths is then given by multiplying 0.23 with the ratio of the extinction coefficient for that model and the one for 0.55 μ , $\nu = 4.5$ and $r_{\min} = 0.06\mu$. The atmosphere was assumed to be homogeneous, the angle of incidence was taken to be 70°. The receiver azimuth angle, α , is then related to the scattering angle, ϕ , through

$$\cos\phi = 0.1170 + 0.8830 \cdot \cos\alpha \quad . \quad (6)$$

Some of the Monte Carlo calculated data have been reported in Ref. 15. Out of all of the models considered, it was found that the model with $v = 5.0$, $r_{\min} = 0.06\mu\text{m}$ and an index of refraction of $1.55 - 0.01i$ (model 504) gives the best approximation to observed scattering functions and color ratios for type B aerosol (Ref. 19). The sky scattering functions for this model are plotted in Figs. 12 and 13 for single scattering (SS) and for total scattering assuming ground albedo values of $A = 0.0$, 0.2 , and 1.0 ; the calculated aerosol scattering function (dotted line; normalized to give the same value as the sky scattering function for 0.1 degrees) is given for comparison. As one would expect, the sky scattering function is more affected by molecular and multiple scattering for 0.45μ wavelength light (Fig. 12) than it is for 1.60μ . The color ratios, $I(0.7\mu)/I(0.45\mu)$ and $I(1.6\mu)/I(0.7\mu)$, are given in Fig. 14.

Measurements in Europe under visual conditions usually produced by Type B aerosols (Ref. 21) gave results in the near IR that were not in agreement with the Mie calculations described in this report for aerosols with Type B size distributions. More recent measurements in Nova Scotia and Bedford, Massachusetts (Ref. 22) conform to the results presented here for $\lambda = 1.60\mu\text{m}$. A very low refractive index or a large influence of a possibly existing small deviation of the size distribution at $r \geq 1\mu\text{m}$ from the power law had to be assumed to explain the steep IR scattering functions in the European data. More model calculations are required to resolve the problem.

4.2 Scattering Functions for Type A Aerosols

Three models, denoted as models 200, 500, and 600, have been chosen as examples of the size distributions for aerosol particles of scattering type A. The size distributions used are tabulated in Table IV and plotted in Fig. 15. For the computations, a total of 600 radii was used for the integration over the particle size distribution. Two methods were used to interpolate the number density of a particle of radius r within the interval r_1 and r_2 (where r_1 and r_2 are the radii given in Table IV). For model 200, the interpolation was done using the formula

$$n(r) = n(r_1) + (n(r_1) - n(r_2)) \frac{\log(r/r_1)}{\log(r_2/r_1)} \quad (7)$$

The number densities for models 500 and 600 were interpolated through

$$n(r) = n(r_1) \cdot \left(\frac{r}{r_1} \right)^\alpha,$$

where

$$\alpha = \frac{\log(n(r_2)/n(r_1))}{\log(r_2/r_1)} \quad (8)$$

The index of refraction for type A aerosols was taken to be $1.55 - 0.01i$. Attenuation coefficients for type A aerosol particles as a function of wavelength are given in Table V, the scattering functions are listed in Tables C1 through C12. The scattering functions are plotted in Fig. 16 for all three models and for 0.7μ wavelength light, the color ratios $(I(0.7\mu)/I(0.45\mu))$ are given in Fig. 17 (the color ratios were obtained from the normalized phase-functions

TABLE IV. SIZE DISTRIBUTIONS FOR TYPE A AEROSOL MODELS

and not from the volume scattering functions). It is seen that the forward scattering is more pronounced for the models that have relatively more large particles. The scattering function is therefore highest for model 200 and lowest for model 600, an opposite effect is observed for the color ratio ($I(0.7\mu)/I(0.45\mu)$) at small scattering angles. The color ratios show peak values at scattering angles of $\sim 1^\circ$ and 180° ; the ratios are low for scattering angles of 0° and $\sim 40^\circ$ for all models being considered.

4.3 Scattering Functions for Type C Aerosols

The index of refraction for type C aerosols was taken to be $1.55 - 0.01i$. Size distributions for type C aerosol particles are given in Table VI and in Fig. 18 (Eq. 7 was used to interpolate the size distributions for models 100 and 300, resulting in curves that are not as smooth as those shown in Fig. 15). Attenuation data are listed in Table VII, the corresponding scattering functions in Tables D1 through D20.

The normalized scattering functions for 0.70μ wavelength light are plotted in Fig. 19, and the color ratios ($I(0.7\mu)/I(0.45\mu)$) are given in Fig. 20. Figure 19 shows the high dependency of the magnitude of the forward scattering upon the (relative) number of large particles. All size distributions show a relative maximum of the scattering function at about 20° scattering angle. The scattering functions are almost identical for larger scattering angles. Figure 20 shows that maxima of the color ratios ($I(0.7\mu)/I(0.45\mu)$) occur at scattering angles of $\sim 1^\circ$ and $\sim 50^\circ - 60^\circ$, the second maximum corresponding to the so-called Bishop-ring that is observed for type C aerosol size distributions (Ref. 19).

Model 100 was used for calculating the sky radiances in the solar alumcantar (see also Section 4.1 and Ref. 15). Plots of the sky scattering functions are given in Figs. 21, 22, and 23 for

Fig. 22. Sky Scattering Function for Model 100,
 $\lambda = 0.70\mu$

Fig. 23. Sky Scattering Function for Model 100, $\lambda = 1.60\mu$

$\lambda = 0.45\mu$, 0.70μ , and 1.60μ , respectively. The corresponding color ratios are given in Fig. 24. Data giving the scattering functions and color ratios as obtained from the MIE data for model 100 are shown in the graphs for comparison (broken lines, normalized to the corresponding single scattering values at 0.1° scattering angle). It is seen that the scattering functions are more affected by molecular and multiple scattering at shorter wavelengths for scattering angles larger than $\sim 10^\circ$ resulting in a noticeable decrease of the color ratio in the area of the Bishop-ring. The Bishop-ring almost disappears for albedo values $A \geq 0.2$. It is seen in Fig. 24 that the color ratios for Model 100 are not significantly dependent on the magnitude of the ground albedo.

A comparison with measured sky scattering functions and color ratios in Ref. 19 reveals that a good approximation of the size distribution for type C aerosols would be obtained by combining models 400 and 700, using model 700 for particle radii $r > 1\mu$ and increasing the number of particles for model 400 and $r < \sim 0.4\mu$.

Fig. 24. Color Ratios of Sky Radiances for Model 100.

V. SCATTERING FUNCTIONS FOR STRATOSPHERIC AEROSOLS

Little is known about aerosol in the stratosphere and there exist only a few direct measurements of aerosol size distributions in the stratosphere. A more recent paper by Friend (Ref. 24) shows that -- at least in the 20 km layer -- ~ 93% of the stratospheric aerosols are Aitken particles and ~ 6% are particles having radii in the region around $0.3\mu\text{m}$. Friend's size distribution for the dust particles can be approximated by the gamma distribution (Ref. 25) as

$$\frac{dN}{d\log r} = c \cdot r^{8.5} e^{-28.33r} \quad (9)$$

or

$$\frac{dN}{dr} = a \cdot r^{7.5} e^{-28.33r} \quad (9a)$$

with the peak of the distribution (9) obtained at $r_p = 8.5/28.33 = 0.3\mu\text{m}$ and of the distribution (9a) at $0.265\mu\text{m}$.

Mie calculations were performed for Aitken particles (model 30) and for the size distribution given by Eq. (9a) (model 20). For the Aitken particles, the size distribution was chosen to be constant (18.68) with limiting radii of $r_1 = 0.01\mu\text{m}$ and $0.06\mu\text{m}$. The total number of Aitken particles is therefore $18.68 \cdot 0.05 = 0.934\text{cm}^{-3}$. The value a in the distribution (9a) was taken to $1.0396 \cdot 10^7$, the lower and upper limit of the particle radii was chosen to $0.1\mu\text{m}$ and $10.0\mu\text{m}$. The total number of particles is then approximately (Ref. 22) $N = 1.0396 \cdot 10^7 \cdot 28.33^{-8.5} \cdot \Gamma(8.5) = 0.066\text{cm}^{-3}$. The index of refraction was taken to $1.50 - 0.01$ for both model 20 and model 30.

The computed scattering coefficients are listed in Table VIII, the normalized phase matrices are given for wavelengths of 0.41μ , 0.50μ , 0.55μ , 0.70μ , and 0.85μ in Tables E1 through E5 for model 20 and in Tables E6 through E10 for model 30.

TABLE VIII. SCATTERING COEFFICIENTS FOR STRATOSPHERIC AEROSOLS (cm^{-1})

$$m = 1.50 - 0.0i$$

Wavelengths	Model 20	Model 30
0.41μ	6.500-10	2.943-12
0.50μ	7.184-10	1.357-12
0.55μ	7.315-10	9.299-13
0.70μ	6.834-10	3.548-13
0.85μ	5.747-10	1.629-13

It can be seen from Table VIII that the scattering coefficients of particles in the $0.3\mu\text{m}$ region is almost independent of the wavelength, whereas the scattering coefficient for the Aitken particles varies proportionally to $\lambda^{-3.97}$ (the scattering coefficient for molecules varies by λ^{-4}). The scattering coefficients for particles having the size distribution (9a) are much larger than those for the Aitken particles even though the Aitken particles outnumber the larger particles by a factor of $.934/.066 = 14.15$. These high values can be verified by a simple hand calculation. The ratio of the scattering coefficients for models 20 and 30 can be approximated by

$$\frac{\sigma_{20}}{\sigma_{30}} \approx \frac{N_{20} \cdot 0.263^2 \cdot \pi \cdot Q(x_2)}{N_{30} \cdot 0.035^2 \cdot \pi \cdot Q(x_1)}$$

$$= 4.05 \cdot \frac{Q(x_2)}{Q(x_1)} \quad (10)$$

where $Q(x)$ is the efficiency factor for particles of size $x = 2\pi r/\lambda$ (r = radius, λ = wavelength). For $\lambda = 0.41\mu$ we obtain (MIE-3 program) $Q(2\pi \cdot 0.265/.41) = Q(4.06) \approx 4.05$ and $Q(2\pi \cdot 0.035/.41) = Q(.536) \approx .02$ and therefore $\sigma_{20}/\sigma_{30} \approx 820$; for $\lambda = 0.85\mu$ the ratio σ_{20}/σ_{30} is computed to $\sim 5.03 \cdot 10^3$. Both of these ratios are in the same order of magnitude as those obtained from Table VIII.

A combined phase function for models 20 and 30 may be calculated by

$$p(\phi) = (\sigma_{20} \cdot p_{20}(\phi) + \sigma_{30} \cdot p_{30}(\phi)) / (\sigma_{20} + \sigma_{30}), \quad (11)$$

where p_{20} and p_{30} denote the phase functions for models 20 and 30, respectively. Even though the phase functions for these two models are quite different (Fig. 25), it can be seen from Table VIII and Eq. (1) that the stratospheric aerosol scattering is dominated by the large particles and -- under the assumption of the particle concentrations for Aitken particles and large particles as reported in Ref. 24 -- that light scattering by Aitken particles may be neglected in the stratosphere.

Fig. 25. Normalized Phase Function for Stratospheric Aerosols, $\tau = 0.55$.

VI. FOG SCATTERING IN THE VISIBLE AND NEAR IR

The gamma distribution (Ref. 22)

$$\frac{dN}{dr} = D \cdot r^m \cdot e^{-br} \quad (9b)$$

was used for MIE calculations in fog. Four different types of fog particles were assumed. These size distributions are designated as models 1, 2, 3, and 4 (see Refs. 26 and 15 ; the constants needed in Eq. (9b) are listed in Table IX. Plots of the size distributions for fog models 1, 2, 3, and 4 are given in Fig. 24 of Ref. 15. Using Eq. (9b), the mean particle radius is given by

$$r_2 = \frac{(m+1)(m+2)}{b} \quad (12)$$

and the total number of particles by (Ref. 25)

$$N_0 = D \cdot \Gamma(m+1) \cdot b^{-(m+1)} \quad (13)$$

The extinction coefficient may then be approximated by

$$\sigma = 2\pi \cdot N_0 \cdot r_2^2 \cdot 10^{-3} (\text{km}^{-1}) \quad (14)$$

where N_0 and r_2 are expressed in cm^{-3} and μm , respectively.

The calculations were performed for wavelengths of 0.40μ , 0.6943μ (Ruby laser wavelength), and 0.80μ . The indices of refraction for these three wavelengths were taken to be $1.343 - 0.0i$, $1.330 - 0.24 \cdot 10^{-6}i$, and $1.328 - 0.0i$, respectively. The computed attenuation coefficients are compared in Table X with the extinction coefficient given by Eq. (14). The corresponding phase matrices for all models and wavelengths under consideration are given in Tables F1 through F12. Plots for $\lambda = 0.6943\mu$ and fog models 1, 2, 3, and 4 are given in Fig. 26.
