EUSTIS DIRECTORATE
U.S. ARMY AIR MOBILITY RESEARCH AND DEVELOPMENT LABORATORY
FORT EUSTIS, VIRGINIA 23604**

This report has been reviewed by the Eustis Directorate, U. S. Army Air Mobility Research and Development Laboratory and is considered to be technically sound.

The data presented were acquired from oscillograph recorders installed on U. S. Army CH-54A "Skycrane" helicopters conducting heavy-lift operations in Southeast Asia. These data indicate the missions flown and the accelerations associated with the combat deployment of this aircraft.

The report is published as an aid in establishing mission profiles and attendant design criteria for future aircraft.

ABSTRACT

During a structural flight loads program on six CH-54A helicopters operating in the Vietnam theater, 1048 hours of 11-channel flight data were recorded between August 1968 and February 1970. To study the adequacy of a 200-hour data sample, as well as to derive appropriate environmental loads spectra, two sets of valid data, one representing 204 hours and the second 207 hours, were processed and analyzed according to four distinct flight phases, termed mission segments: (1) takeoff and ascent; (2) maneuver; (3) descent, flare, and landing; and (4) steady state. Data are presented in the form of time and occurrence tables, histograms, and exceedance curves. These data indicate the time spent in the mission segments and parameter ranges; the number of peak parameter values occurring in the ranges of the given parameter, during each of the mission segments, and in the ranges of one or more related parameters; and the time to reach or exceed given maneuver and gust normal load factors. The analysis of the two sets of data presentations revealed that the two samples differed little and compared closely in their distribution of the flight data.

FOREWORD

Technology Incorporated, Dayton, Ohio, prepared this report to cover its efforts on a flight loads data program to collect, process, and analyze a 400-hour sample of valid flight data obtained from six CH-54A helicopters operating in Southeast Asia. This program was sponsored by the U.S. Army Aviation Materiel Laboratories, Fort Eustis, Virginia, under Contract DAAJ02-68-C-0075, Task 1F162204A14607. The project monitor for the Army was Mr. William T. Alexander.

The prime Technology Incorporated personnel engaged in this program were as follows: Mr. Henry C. Pender, project engineer, who supervised the installation and operation of the data recording system; Messrs. John F. Nash and Ronald I. Rockafellow, who directed the data processing; Mr. William E. Morrin, who prepared the computer programming for the data processing; and Mr. F. Joseph Giessler, who assisted in the data presentation and compilation.

INTRODUCTION

For the continued Army study of helicopter operations, a multichannel flight loads program was conducted on six CH-54A helicopters flying assault support missions in the Vietnam theater from August 1968 to February 1970. During this period, 1048 hours of in-flight data were recorded for each of 11 time-related parameters. The chosen parameters were selected to reflect the structural loads along the three major axes in the light of several helicopter variables. As reported in References 1 through 6, similar multichannel data were previously collected in six programs on Army helicopters, specifically the UH-1B, CH-54A, CH-47A, and AH-1G models. Of these programs, three—one each for the UH-1B, CH-54A, and CH-47A—were conducted under training conditions in the U.S., and three—one for the armed and armored CH-47A model, one for the cargo CH-47A model, and one for the AH-1G model—were conducted under combat conditions in Vietnam.

Figure 1 illustrates the CH-54A helicopter which is designed to carry heavy, outsized payloads or special-purpose vans or pods from either a single-point or a four-point suspension system. The single-point suspension system features a 100-foot cable with an hydraulically operated hoist and electrically actuated hook. Loads can be raised or lowered at a rate of 50 feet per minute. Twenty thousand pounds can be carried with the winch locked at a selected cable length. The four-point system uses four 6,000-pound capacity hoists mounted at hard points on the side of the fuselage. Each hoist has 50 feet of cable and a damping device to isolate aircraft or load vibration. The crew consists of a pilot, a copilot, and an aft-facing hoist operator.

The oscillograph type of recording system measured the following 11 in-flight variables: airspeed; altitude; normal, lateral, and longitudinal acceleration at the aircraft's center of gravity; outside air temperature; rotor rpm; collective pitch stick position; longitudinal cyclic pitch stick position; and each of two engine torques—all related in time. Additional information, called supplementary data, was extracted from "tally" sheets which the pilots filled in during flight. Supplementary data consisted of time, fuel, and cargo weight at takeoff and landing; base pressure and temperature at takeoff; mission type; and aircraft configuration. The data processing derived additional parameters: the instantaneous weight, the rotor tip speed ratio, and the ratio of the thrust coefficient to the rotor solidity. In addition, for the more meaningful interpretation of all parameters, the data for each flight were divided into four major phases, called mission segments: (1) takeoff and ascent; (2) maneuver; (3) descent, flare, and landing; and (4) steady state. Moreover, data

recorded during cargo pickups or drops while the aircraft were hovering were separated and grouped into "hoist," a subcategory of the steady-state mission segment.

Characteristics

Rotor diameter	72 ft
Rotor solidity	0.08649
Engines (two)	P&W JFTD-12A-4A
Des. max. gross weight	42,000 lb
Empty weight	19,234 lb

Limitations

Normal rated power	*4000 shp
Takeoff power	*4500 shp
Usable power (continuous)	*4000 shp
Usable power/des. max. gross weight	0.0953
Max. allowable airspeed	110 kn
	*each engine

Figure 1. Multiview Drawing of CH-54A Helicopter.

Whereas the five helicopter flight loads programs reported in References 1 through 5 were each designed to collect 200 hours of valid in-flight data, those for the AH-1G's, as reported in Reference 6, and the current CH-54A's were each intended to gather 400 hours of like data. Each of the 400-hour data samples was to be separated into two 200-hour data sets to make comparisons that would test the validity of 200 hours as an adequate data sample.

The objective of the CH-54A program, therefore, was twofold: (1) to present comprehensive flight loads data on the current operation of this helicopter model in the combat environment of Vietnam, and (2) to test again the validity of the 200 hours as an adequate data sample.

This report describes the installation and operation of the recording systems, details the data collection, defines the recorded and derived parameters, outlines the data processing and quality control, explains the data computations, and finally presents and analyzes the processed data. Both of the 200-hour sets of data were treated separately. The results for each set appear as histograms of the percentages of time within various parameter ranges; as "exceedance" curves, that is, curves of the number of flight hours required for a parameter to reach or exceed given levels; as tables of time distributed among the coincident ranges of two or more parameters; and as tables of peak frequencies in the coincident ranges of the peaking parameter and other variables.

DATA COLLECTION

AIRCRAFT INSTRUMENTATION

At the Southeast Asia facility of the Army's 273rd Assault Support Helicopter Company, an oscillographic system was initially installed in each of three CH-54A helicopters, identified by serial Nos. 68-18436, 66-18411, and 67-18421. Because of maintenance scheduling and combat loss, additional systems were installed in three more CH-54A's with serial Nos. 68-18437, 68-18443, and 67-18420. Except for serial No. 66-18411, whose operational problems prevented proper recorder functioning, valid data were acquired from each of these helicopters.

After each selected helicopter was equipped with the Class A provisions to accommodate its recording system, the components were installed as follows: a Century Model 409B oscillographic recorder to measure all 11 in-flight parameters and a Technology Incorporated Model 49776 bridge control unit to regulate the voltage signals from the various transducers were mounted on a shelf in the lower right equipment bay.

To derive airspeed, a Statham Model PM96TC $\pm$ 0.5-350 ($\pm$ 0.5 psid) pressure transducer was employed to measure the dynamic pressure. To derive pressure altitude, a Statham Model PA731TC-15-350 (0 to 15 psia) pressure transducer was employed to measure the absolute pressure. Both transducers were connected to the aircraft's pitot-static system.

For the three linear acceleration measurements, a B&F Model LF5-15-350 accelerometer was employed to sense the vertical acceleration; a B&F Model LF3-8-350 accelerometer to sense the longitudinal acceleration; and a Statham Model AJ17-3-350 accelerometer to sense the lateral acceleration. All accelerometers were mounted as close as possible to the helicopter's center of gravity.

A frequency-to-voltage converter and associated circuitry were incorporated in the recording system to measure the rotor rpm by sensing the frequency of the rotor tachometer generator.

A Minco Model S6B resistance thermal ribbon to measure the outside air temperature was installed on the outer skin under the cockpit area.

Two Lockheed Electronics Co. Model WR-8-15B position transducers were employed to sense the stick positions of the collective pitch and the longitudinal cyclic pitch controls. Both transducers were connected to each of the stick control tubes.

The engine torque was obtained from the output of the aircraft's torque generator. The torque from each engine was recorded separately.

The block diagram in Figure 2 illustrates the functional integration of the components making up the recording system.

OSCILLOGRAPHIC RECORDER

The Century Model 409B recorder with 14 data channels, each capable of recording a dynamic or a static parameter on a 3-5/8-inch-wide photosensitive paper, was employed in this program because of its inherent design to withstand severe shock and vibration and extreme environmental conditions. Eleven channels were used to record the in-flight variables. Of the remaining three channels, one was used to monitor the voltage supply, another was used to delineate a time pattern reflecting a 1-second cycling, and the last was used to trace a constant line for measurement reference.

The recording system operated from two types of power supplied by the helicopter: 110 v, 400 Hz ac, which after rectification was used in the special frequency-to-voltage circuit to measure the rotor rpm, and 28 vdc, which was used for all other operations. As manipulated by the pilot to record only in-flight data, a circuit breaker in the cockpit provided the means of controlling the recording system operation.

DATA RECORDING

During the period from August 1968 to February 1970, 1048.4 hours of in-flight data were recorded. For the desired two 200-hour data samples, 410.9 of these hours were processed and divided, for the most part chronologically, into 203.4 hours for Sample I and 207.5 hours for Sample II. Of the 410.9 hours, 351.2 were valid for all 11 parameters, and 59.7 were valid for all parameters except the 2 for engine torque. USAAVLABS had approved the use of the 59.7 hours. The distribution of the 351.2 hours is 182.6 in Sample I and 168.6 in Sample II, and that of the 59.7 hours is 20.8 in Sample I and 38.9 in Sample II.

Some of the discrepancies causing the invalidity of the recorded data were erratic trace deflection, no trace deflection, insufficient trace deflection, malfunction of the oscillogram drive motor, bad galvanometer, and no supplemental flight data. When developing the oscillogram and observing such discrepancies, the field technician was aware of the cause of most of the malfunctions and took remedial action as soon as possible. Occasionally, malfunctions in the helicopter system prevented the recording of the parameters intended to monitor the helicopter's operations, notably rotor rpm and engine torque.

Figure 2. Block Diagram of CH-54A Instrumentation System.

During each flight the pilot logged the following information on a "tally" sheet: date, aircraft serial number, sortie number, task number, takeoff and landing base pressure and temperature, takeoff and landing fuel, cargo weight, maximum indicated airspeed and rotor rpm, departure and arrival time, and total flight time and distance. Since the foregoing information provided the supplemental data needed to process the in-flight data, the tally sheets, hereafter referred to as supplemental data sheets, were attached to the corresponding oscillograms.

DATA DEFINITIONS

RECORDED PARAMETERS

The 11 in-flight parameters recorded on the oscillograms against a time base were (1) altitude, (2) airspeed, (3) outside air temperature, (4) vertical acceleration, (5) lateral acceleration, (6) longitudinal acceleration, (7) rotor rpm, (8) No. 1 engine torque, (9) No. 2 engine torque, (10) longitudinal cyclic pitch control stick position, and (11) collective pitch control stick position. For each of these parameters, Table I lists the ranges selected to study the parameter relationships most practically and significantly.

With the assumption of a standard atmosphere prevailing during the data recording, the altitude and airspeed trace measurements proportional to the static pressure and the pitot-static pressure differential, respectively, were converted from pressure units to the conventional pressure altitude and indicated airspeed units. The outside air temperature was then used to convert the pressure altitude to the density altitude, the derived form of the altitude expressed in the final data. Of the remaining parameters, acceleration is represented as a load factor, engine torque as a percentage, and the control stick positions as percentages of full deflection with both the full-forward position of the cyclic pitch stick and the full-down position of the collective pitch stick being zero percent.

COMPUTED PARAMETERS

From the fuel and cargo at takeoff and landing, as logged on the supplemental data sheets, the gross weight was computed for the start and end of each flight. A constant rate of fuel consumption was assumed to obtain an average weight-loss rate which was used to compute the instantaneous gross weight. Weight changes because of cargo drops or pickups were introduced at the times noted on the supplemental data sheets.

For each data reading point, two derived parameters were added to the data bank: (1) the rotor tip speed ratio, and (2) the ratio of the thrust coefficient to the rotor solidity.

The rotor tip speed ratio, u , was computed by

$$u = \frac{V}{\Omega R}$$

where

TABLE I. PARAMETER RANGES WITH CODE IDENTIFICATION

V = airspeed, ft/sec
 Ω = rotor angular velocity, rad/sec
 R = rotor radius, ft

And the ratio of thrust coefficient to the rotor solidity, C_T/σ , was computed by

$$C_T/\sigma = \frac{W}{\rho \pi R^2 (\Omega R)^2}$$

where

C_T = thrust coefficient
 W = gross weight, lb (instantaneous)
 ρ = air density at altitude, slugs/ft³
 σ = rotor solidity

MISSION SEGMENTS

For the more meaningful analysis of the helicopter performance and loads, the data for each flight were separated into four mission segments: (1) takeoff and ascent; (2) maneuver; (3) descent, flare, and landing; and (4) steady state. As the transient, or unsteady, regimes of flight, the first three segments were distinguished from the steady-state segment by the variation in the stick position, airspeed, and altitude traces. The segments were identified and defined as follows: Mission Segment 1 (takeoff and ascent) included both the takeoff and climb to the initial cruise altitude and all unsteady ascents to other altitudes. Mission Segment 2 (maneuver) included all those altitude changes not appearing in Segments 1 or 3. Mission Segment 3 (descent, flare, and landing) included the unsteady part of flare and landing and all other unsteady descents. Mission Segment 4 (steady state) included cruise, hover, steady ascent (after the initial climb), and steady descent. Flare and landing initiated from hover was included in Mission Segment 4. Steady-state flight regimes were evidenced by minimal fluctuations of the stick position traces about mean values and the constancy or smooth change of the airspeed and altitude traces. To study the accelerations encountered during either a cargo pickup or a cargo drop while the aircraft were hovering, the data covering these operations were separated and grouped into "hoist," a subcategory of the steady-state mission segment. The hoist data are reported separately in Tables VIII and XLIV, which give torque values, and in Tables XXVI, XXVII, LXII, and LXIII, which give maneuver n_z peak distributions. All other tables for steady-state documentation include the hoist data.

DATA PROCESSING

DATA EDITING

Each oscillogram is examined by the data processing editors for evidence of any instrumentation anomaly such as a missing trace or improper sensitivity. Any record discovered as faulty is classified as malfunction data and is not processed. The editors then time all acceptable records and identify the bounds for the mission segments in each flight.

After demarcating the flights into mission segments, the editors marked the traces to govern the data reading. The normal acceleration trace was marked wherever a peak met the following two conditions: (1) the peak fell outside prescribed threshold levels ($\pm 0.2g$ about the $1.0g$ mean), and (2) the peak had a rise and fall (or fall and rise) that were each 50 percent of the peak value or $0.2g$, whichever was greater. Although the prescribed thresholds were 0.8 and $1.2g$, the editors used levels of 0.84 and $1.16g$ to ensure the inclusion of all valid peaks. However, any of the peaks read within the fixed threshold levels of 0.8 and $1.2g$ were eliminated during the computer processing. In addition, the editors identified each selected peak as being maneuver- or gust-induced. To determine whether a peak was induced by a maneuver or a gust, the editors noted the behavior of the stick position traces. Whenever the peak was the result of maneuvering, one or both of the stick traces would always deflect just before and in the same sense as the peak. Ascertaining the gust-induced peaks required either that both stick position traces be steady or that any movement of these traces just before the peak be in the sense opposite that of the peak.

The editors marked primary peaks on the lateral and longitudinal acceleration traces wherever they deflected outside the prescribed threshold of $\pm 0.1g$. These peaks were not identified as being maneuver- or gust-induced. As before, to ensure inclusion of all valid peaks, the editors used levels of $\pm 0.097g$ instead of the $\pm 0.1g$. Again, however, any peaks read within the prescribed threshold of $\pm 0.1g$ were eliminated during the computer processing.

In treating the two stick position traces, the editors marked those peaks whose rise or fall was 10 percent of the full stick travel and at least 10 percent from the normal value. Each normal value depended on the mission segment. For the steady-state mission segment, the normal values were the steady values of the stick positions just before and after the peak. For the three transient mission segments (where no "steady" stick positions prevailed), an arbitrary set of normal values was chosen to approximate the stick positions during hover. The selected values are listed by aircraft serial number in Table II.

TABLE II. CONTROL STICK NORMAL VALUES USED DURING
TRANSIENT MISSION SEGMENTS

Aircraft Serial No.	Longitudinal Cyclic Normal %	Collective Normal %
68-18436	68.8	49.4
68-18437	71.8	47.5
67-18421	60.5	57.6
68-18443	65.9	43.3
67-18420	62.2	50.4

In each of the three transient mission segments, all traces except those for the stick positions were marked when the acceleration or stick position traces peaked. During all mission segments, however, all traces except that for acceleration were marked at critical points to permit an adequate representation of the parameters. At the peaks of normal acceleration, n_z , the corresponding values of longitudinal acceleration, n_x , and lateral acceleration, n_y , were read. At the peaks of n_x and n_y , the corresponding values of n_z and cyclic stick position were read.

The peak values of the three linear accelerations were measured from normal positions of the respective traces. For both the vertical acceleration, n_z , and the lateral acceleration, n_y , the normal position was defined when the helicopter was at rest. For the longitudinal acceleration, n_x , the normal position was defined when the helicopter cruised at a 90-knot airspeed. The positive sense of the longitudinal load factor, n_x , is acceleration forward, and the positive sense of the lateral load factor, n_y , is acceleration to the right.

DATA READING AND QUALITY CONTROL

All data points selected during the editing were measured on semiautomatic oscillogram readers which transcribed the measurements directly to punched cards. When all data were extracted from a flight, a printout of the cards was given to the Quality Control Section for preliminary data checking. Using standard quality control techniques, this section manually remeasured random points comprising an adequate sample and compared the measurements with those produced by the semiautomatic readers. The differences between the two sets of readings were used to establish the mean and standard deviations as a control of the desired reading accuracy. The flights whose measurements did not meet the established accuracy standard were reread by the semiautomatic readers.

In addition to obtaining accurate values, this procedure ensured a uniform interpretation and measurement of the traces.

When all data had been processed, the mean and standard deviations were calculated for the entire data sample. Assuming a normal distribution of reading errors, 99.7 percent of the readings should be within three standard deviations of the true values. Based on average calibration values, Table III shows the three standard deviations for each parameter.

TABLE III. DATA READING VARIATIONS BY PARAMETER

<u>Parameter</u>	<u>3σ Variation (99.7% confidence limit)</u>
Altitude	± 182 ft (at 1000 ft)
Airspeed	± 1.88 kt (at 120 kt)
n_x	$\pm 0.033g$
n_y	$\pm 0.035g$
n_z	$\pm 0.029g$
OAT	$\pm 1.38^\circ F$
Rotor rpm	± 7.3 rpm
Engine Torque 1	$\pm 9.7\%$
Engine Torque 2	$\pm 10.5\%$
Collective Pitch	$\pm 2.8\%$
Cyclic Pitch	$\pm 3.0\%$

Of the 410 hours of valid data processed for this program, 131 hours were edited and read by the U. S. Army Aviation Materiel Laboratories, Fort Eustis, Virginia, and the remainder were edited and read by Technology Incorporated. The procedures followed by both organizations were identical with the exception of the reading increment. The Fort Eustis data was read with an increment of 100 counts per inch and the Technology Incorporated data was read at 200 counts per inch.

DATA COMPUTATIONS

The load factor, n_z , for each normal acceleration peak was measured directly from the oscillogram trace. However, to present load factors for positive and negative peaks conveniently, an incremental normal load factor, Δn_z , was derived from each n_z value by using the relationship

$$\Delta n_z = n_z - 1.0$$

The following equation (see Reference 6) was used to compute density altitude, since this parameter is normally used in describing helicopter performance:

$$h_d = 145,300 \left[1 - \left(\frac{518.4 P_a}{29.92 (OAT + 460)} \right)^{0.235} \right]$$

Since the instrument installation correction to derive the calibrated airspeed was judged to be negligible, only indicated airspeeds were considered. Rotor rpm and outside air temperature were computed by applying linear calibrations to the trace measurements. With the displacements of the stick position traces representing the deflections of the longitudinal cyclic stick from the full-forward position and the deflections of the collective stick from the full-down position, the respective stick positions were computed from the trace measurements in units of percent of full deflection. By an approximate differentiation of the altitude trace, the rate of climb was computed continuously during each segment. At the same time that the rate of climb was computed, the "longitudinal acceleration," or rate of change of airspeed, was derived by an approximate differentiation of the airspeed trace.

DATA PRESENTATION

Some 400 hours of valid data were separated into two sets of about 200 hours each, identified as Sample I and Sample II, to test the adequacy of the 200-hour data sample. Sample I consists of 203 hours and Sample II of 207 hours. Most of the Sample I data was recorded before the Sample II data. Some of the data overlap chronologically because of the order of processing.

The data presented in this report consist of two types of figures and two types of tables. The figures are (1) histograms of the percentages of time within various parameter ranges and (2) plots of the time in hours to reach or exceed given levels of the incremental vertical load factor, Δn_z . For convenience, these plots have been called "exceedance curves." The two tabular types are (1) flight time distributed among the coincident ranges of two or more parameters and (2) the vertical acceleration peak frequencies distributed among the ranges of the vertical load factor, n_z , and the coincident ranges of other variables.

DISCUSSION OF FIGURES

The results from the two data samples are summarized in Figures 3 through 28. In each type of graphic representation, the graphs for Samples I and II are presented consecutively.

Figures 3 and 4 for Samples I and II, respectively, show the breakdown of flight time into the four mission segments. The similarity of the two samples is quite evident. The low percentage of maneuver time is due to the cargo operation of the CH-54A. The large amount of time spent in ascent and descent as compared with that in steady state is attributed to relatively short flights. In contrast, the data reported in Reference 2 for peacetime operation had 6.86% of flight time in ascent, 1.92% in maneuver, 12.6% in descent, and 78.62% in steady state.

Figures 5 and 6 present the time spent in each weight range broken down by mission segment. The distributions of the two samples are again quite similar. Whereas the lower weights have a larger percentage of time in descent, the higher weights show a larger percentage of time in ascent. With the time in each weight range broken down by mission segment, Figures 7 and 8 show a double-peaking distribution for gross weight: the lower peak is between 25,000 and 27,000 pounds and the higher peak is near 40,000 pounds. Thus the CH-54A in the reported program spent over 90% of the flight time either below 29,000 pounds or above 37,000 pounds. The maximum gross weight in Sample I was 44,009 pounds, and that in

Sample II was 42,963 pounds. Figures 9 and 10 present the rotor rpm distributions in each mission segment. In both samples more than 75% of the time was spent in the 185- to 195-rpm range. In Sample I, the maximum rpm of 198 occurred at 60 knots, 40,344 pounds, and 2486 feet; in Sample II, the maximum rpm of 203 occurred during a hover at 25,009 pounds and 2139 feet.

Figures 11 and 12 show the distribution of time in ranges of density altitude. Both samples show nearly the same distributions. Related to the altitude distribution is the distribution of outside air temperature shown in Figures 13 and 14. These again show similar distributions for each data sample. The rate-of-climb distributions shown in Figures 15 and 16 are again very similar for both data samples. The small increments of descent time in the ascent segment and the small increments of ascent time in the descent segment are due to short altitude corrections in either a generally ascending or descending part of a flight. These increments were not sufficiently long to warrant separate identification.

The torque range distributions in the mission segments are presented in Figures 17 and 18. Each engine torque is presented separately. Whereas the No. 1 torque distributions for both samples are generally uniform in the ranges, the No. 2 torque distribution for Sample II is slightly more concentrated in the mid-ranges.

Figures 19 and 20 distribute the flight time in airspeed ranges. The two samples are in good agreement. No airspeed over 120 knots was recorded.

Figures 21 through 24 represent the maneuver vertical acceleration peaks recorded during the program. The occurrence of these peaks is expressed as the hours to reach or exceed given values of the incremental value, Δn_z . Both positive and negative values are shown. In general, both samples indicate that all mission segments encountered similar peaks. As mentioned in the data processing section, the load peaks encountered during load pickups and drops were separated and grouped under hoist, a subcategory of the steady-state mission segment. Figures 21 and 22 show that all the load peaks above $\Delta n_z = 0.5$ were recorded during hoist which accounted for only 0.26 and 0.23 hours in Samples I and II, respectively. The highest n_z peak of 1.88g, which was recorded in the Sample I data, occurred during a hoist at a gross weight of 40,100 pounds and an altitude of 1641 feet. Figures 23 and 24, which present the same data broken down by gross weight, show that the high values of Δn_z generally occurred at low gross weights. Figures 25 and 26 show the relationship between the maneuver incremental load factor peaks, Δn_z , and the tip speed ratio, u . All these figures indicate that the results from the two data samples compare very closely.

The composite gust vertical acceleration peaks are summarized in Figures 27 and 28. The gust data in Sample I is slightly more severe than that in Sample II; however, the general trend is the same.

DISCUSSION OF TABLES

All final computer printouts resulting from the processing of the 410 hours of valid data are presented in Tables IV through XXXIX for the Sample I data and in Tables XL through LXXV for the Sample II data. All times in these tables were rounded off to the nearest tenth of a minute. Therefore, the "TOTAL" time and the individual times in each table are accurate to within 0.05 minute. However, since the individual times comprising the respective totals were summed before the totals were rounded off, the sum of individual times may differ from the corresponding printed total time by some tenths of a minute. Any time between 0 and up to but not including 0.05 minute was printed as "0.0", and no time measured was printed as "0.". Tables having neither points nor time were not printed.

Table headings are arranged so that the first-mentioned variable refers to the horizontal ranges at the top of the table and the second-mentioned variable refers to the vertical ranges at the left of the table. Where a third or a fourth variable is given, it is followed by its range in the heading. As an example, the heading "MINUTES FOR ALTITUDE VS AIR-SPEED BY WEIGHT 6000 BY MISSION SEG. ASCENT" indicates the time spent in coincident ranges of altitude and airspeed at a weight between 6000 and 7000 pounds during the ascent mission segment. Note that all printed range values are the lower limits.

Tables IV through IX for Sample I and Tables XL through XLV for Sample II give the flight time recorded in the coincident ranges of the various variables. In the tables containing engine torque data, the total time is less than that reported for the other parameters, as explained above under Data Recording.

To analyze the stick position variations, Tables X through XXIII for Sample I and Tables XLVI through LIX for Sample II present the frequencies of stick position peaks in the coincident ranges of each of the two stick positions and other variables.

For the review of the normal accelerations encountered, Tables XXIV through XXVII for Sample I and Tables LX through LXIII for Sample II present the frequencies of both the maneuver and the gust normal acceleration peaks in the coincident ranges of incremental normal load factor and other variables.

Tables XXVIII through XXXIII for Sample I and Tables LXIV through LXIX for Sample II present the frequencies of the longitudinal and lateral acceleration peaks in the coincident ranges of the corresponding load factor and other variables.

Finally, for the correlation of the accelerations along each of the three major axes, Tables XXXIV through XXXIX for the Sample I data and Tables LXX through LXXV for the Sample II data present the peak frequencies of each type of acceleration in the coincident ranges of the given type of acceleration and of each of the other two types.

SUMMARY AND CONCLUSIONS

The CH-54A program produced twofold results: (1) a set of comprehensive loads and operational data defining the CH-54A performance in the combat environment of Vietnam, and (2) evidence that 200 hours of recorded data serves as a valid data sample. The resultant data may be used to determine the loading spectrum for cyclic load tests on helicopter structures as well as to conduct a parametric fatigue analysis and, thereby, project the safe life of each helicopter. The comparison of the histograms and exceedance curves for the first 203 hours of data (Sample I) and the second 207 hours (Sample II) indicates that the two data samples closely agree.

13. ABSTRACT During a structural flight loads program on six CH-54A helicopters operating in the Vietnam theater, 1048 hours of 11-channel flight data were recorded between August 1968 and February 1970. To study the adequacy of a 200-hour data sample, as well as to derive appropriate environmental loads spectra, two sets of valid data, one representing 204 hours and the second 207 hours, were processed and analyzed according to four distinct flight phases, termed mission segments: (1) takeoff and ascent; (2) maneuver; (3) descent, flare, and landing; and (4) steady state. Data are presented in the form of time and occurrence tables, histograms, and exceedance curves. These data indicate the time spent in the mission segments and parameter ranges; the number of peak parameter values occurring in the ranges of the given parameter, during each of the mission segments, and in the ranges of one or more related parameters; and the time to reach or exceed given maneuver and gust normal load factors. The analysis of the two sets of data presentations revealed that the two samples differed little and compared closely in their distribution of the flight data.
