A COMPENDIUM OF BALLISTIC PROPERTIES OF PROJECTILES OF POSSIBLE INTEREST IN SMALL ARMS

ABSTRACT

The report is a compendium of the ballistic properties of projectile shapes of possible interest in small arms applications. The shapes cover a range of L/D ranging from conventional bullets (~3.5) to that of flechettes (~20) and include such shapes as cones, cone cylinders, and cone flares. The ballistic properties are mapped over a range of calibers and projectile densities. A drag-reducing tracer is included as one of the prime design considerations as a means of reducing base drag. Tabulations include velocity, energy, angle of fall, time of flight, and height as a function of range, with constraints on recoil momentum. Aerodynamic coefficients are also included.

I. INTRODUCTION

The Ballistic Research Laboratories have traditionally been a source of information on artillery projectiles and systems. As small arms systems began to undergo critical scrutiny, the Ballistic Research Laboratories were drawn into the studies and asked to furnish inputs to the Army Materiel Systems Analysis Agency and other agencies concerned. These exercises have usually involved evaluations of generally similar projectiles, from the same or similar weapons, or a few quite different candidate systems in a particular role. Thus the candidates and constraints were quite specific, and the scope of the BRL studies were correspondingly limited. In spite of the large number of highly constrained studies undertaken, no comprehensive small arms projectile study exists. In point of fact, each of these evaluations suggested that peripheral avenues should also have been investigated, at least by a limited paper study, but the necessary inputs, theoretical or experimental, did not exist or were not adequate. There have been a number of areas of concern, but two are oft repeated. These are:

(1) That currently available information on small calibers is limited to a relatively few, generally similar, conventional bullets and a few, generally similar, flechette shapes. This "spectrum" of small arms projectiles can be viewed as follows.

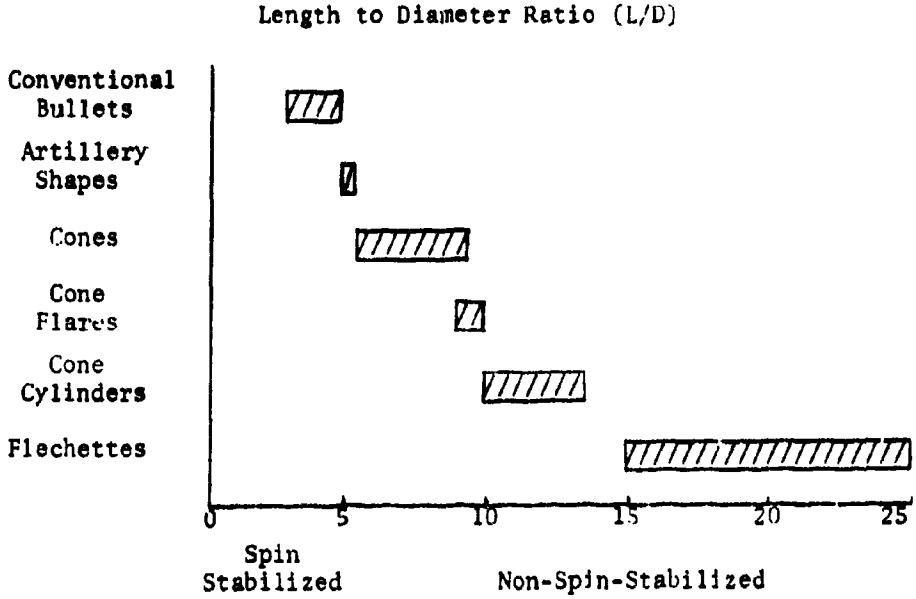

Thus there is information on low L/D full-bore projectiles and on the very high L/D, subcaliber, fin-stabilized, saboted projectiles--and nothing to permit considerations of the in-betweens or permutations of options available for conventional bullets and flechettes.

(2) The possible effect of the tracer on the flight characteristics was not a part of exterior considerations and/or was not available.

It is the intent of this report to present a more comprehensive treatment of small-caliber projectiles, filling in the aforementioned voids and some others. Obviously it is impossible to produce a "handbook of effectiveness" because such an effort would have to include such things as the various measures of effectiveness, considerations of particular targets, terminal ballistics, wound ballistics, interior and exterior ballistics, etc. The permutations would be far too large to handle in any manageable fashion. It did appear, however, that the interior and exterior ballistics aspects could be handled in a general fashion.

In a final evaluation of a given weapon system, in a given role and against a specified target, the hit probability P(H) and the probability of incapacitation given a hit P(I/H), all as a function of cost, weight, etc., are the final arbiters. To obtain P(H) and P(I/H), however, specific interior and exterior ballistics inputs are essential, and in general the initial input to terminal effectiveness is the remaining energy of the projectile. N.B. The terminal energy is only an input, not necessarily a direct measure of effectiveness.

The Ballistic Research Laboratories, as part of an in-house program on small arms, undertook a study in the areas of interior and exterior ballistics which could be done with relative generality and uniform accuracy and which would provide as outputs those characteristics most readily used as inputs in effectiveness studies. A major part of the interest was in possible designs "between" bullets and flechettes with permutations of options around each type of projectile considered. The spectrum of "possible" small arms projectiles was expanded as shown on the following page.

The shapes which were considered are illustrated in Figure 1 and described in Section II-A. The identification code shown on the shapes in Figure 1 is as follows:

CB = conventional bullet
AR = artillery shape
C = cone
CC = cone cylinder
CF = cone flare
FL = flechette
SC = subcaliber

The numbers following designate types within the class, identified by the letter prefixes.

Although there was available measured data on some bullets and some flechettes, for the sake of relative uniformity, interior and exterior ballistic computations were used rather than mixing computed and measured results within the same framework. The computations were done at the highest level of complexity possible considering the lack of definition in a general problem of this nature and the necessity to undertake the computation of almost one thousand cases.

The tracer question addressed in this report is not the classical one associated with ball and tracer ammunition, known frequently as tracer matching. This classical question arises from the following sorts of events. A ball round is selected for a weapon. A companion tracer round is designed and tested. It is observed that the tracer round, though with the same muzzle velocity as the ball round, travels faster and further than the ball. The tracer matching exercise then consists of degrading the performance of the tracer round until its trajectory "matches" that of the ball. The degradation process consists of increasing the drag of the tracer round. A drag increase is necessary because the tracer, by adding heat and/or mass at the base of the projectile, has reduced the base drag component. If a tracer, whose function is to produce light, is an effective way of reducing base drag, hence overall drag, should not drag-reducing tracers be considered? It is in this context that tracers are addressed in this study. Drag-reducing tracers are considered, as a component of projectile design, as means of reducing base drag in the same manner as is boat-tailing, for example. A drag-reducing tracer, as conceived for this study, in no way compromises the light-producing function of conventional tracers. Both functions, light production and drag reduction, could be performed by a tracer of appropriate design.

The work was performed by a team involving members from the Exterior Ballistics Laboratory and the Interior Ballistics Laboratory, with assistance from the office of the Technical Director, the Vulnerability Laboratory, the Army Materiel Systems Analysis Agency, and the U. S. Army Small Arms Systems Agency in setting up logical ground rules, limits, and outputs.

II. DISCUSSION OF VARIABLES, CONSTRAINTS, AND OUTPUTS

The exercise consisted of generating ballistic data on the shapes shown in Figure 1 as a function of those variables to which performance is most sensitive. The variables included, for example, initial velocity, density of projectile, methods of drag reduction, etc. These

variables and the constraints applied provided the bounds or limits for mapping. The choice of variables and the constraints are discussed in this section.

The overall consideration that the desired utility was primarily for the rifle and/or light machine gun roles placed natural constraints on most of the variables used in the mapping. Beyond this, it was necessary to space the variables so that various properties or conditions could be interpolated reasonably. In those instances where it did not interfere with logical spacing or limits, points were selected so that they could be identified, in part, with existing systems. Thus the caliber range included 5.56 mm and 7.62 mm, and the center of the weight spectrum for the full bore study was a homogeneous lead projectile. Thus the user of the results can identify with known data in some areas and make a judgment whether the computed results are pessimistic or optimistic for his purpose. With the definition of a caliber and weight spectrum and a span of initial impulses ranging from the level of SPIW to just below that of the M-14, it was possible to conduct the full-bore diameter projectile phase of the mapping. This was done for the inert projectile and for a projectile with a drag-reducing tracer. All projectiles, except the conventional flechette, were treated in this phase. This was done without excluding cases that seemed dubious for rifle or light machine gun application. Concession was made to reality, however, in that those projectiles that lacked reasonable bore riding surface were saboted to provide two calibers of cylindrical riding surface and tarage losses in muzzle energy subtracted. It is probably true that many of the interpolated designs are of interest only as subcaliber projectiles and a separate phase involving one specially designed projectile, in various sizes, was considered over the bore caliber spectrum, again with and without drag-reducing tracer.

A. The Shape Spectrum

All the shapes discussed in this section are shown in Figure 1.

The usual lead bullet is relatively short, $L/D \leq 4.5$, while the usual subcaliber fin-stabilized flechette is long, $L/D \sim 20$. In between

these two areas there are a variety of possibilities. To anchor the bullet end of the spectrum, three bullet shapes were chosen; nominally these can be identified with the 5.56-mm M-193, the 5.56-mm I.W.K., and the 7.62-mm M-118 match bullet. Two of these are boattailed, and one has a square base.

Because spin stabilization is possible with projectiles of L/D higher than that of conventional bullets (artillery projectiles have L/D's of up to 6), two so-called artillery types were introduced. These have an L/D of 5.5, one model is boattailed, and the other has a square base. These two are scaled down versions of the present and a proposed version of the long-range 175 mm-shell. These two complete the spin-stabilized portion of the spectrum of projectiles of more or less conventional shape.

The high L/D end of the shape spectrum was a clean version of the SPIW flechette. In between the artillery shapes (L/D = 5.5) and the flechette (L/D ~ 20), a number of geometrically simple shapes were introduced: cones with rather low volumes, cone cylinders with higher volumes, and cone flares with yet higher volumes. These selections were all biased toward the lower drag, high-head-length end of the choices of possibilities and have L/D's ranging from 5.7 to 13.5. In that there are a variety of drag levels, volumes, and lengths involved, the use of geometrically simple models does not appear to be a limitation--ogival-cylinder configurations, for example, should be readily interpolatable.

For the purpose of the computations, all projectiles were assumed smooth and to have cleanly cut pointed ogives, cylindrical sections, and boattails. Thus the rounding of junctions and the bulging of tapered areas, common to lead-core bullets, for example, were not reproduced.

B. The Size Spectrum

The size consideration has two facets. The bore size considerations were 5.56 mm, 6.5 mm, and 7.62 mm. In the full-bore projectile phase, these, of course, determined the size of the projectile. In the sub-caliber phase, the same bore size range was used, but the projectile

diameter was varied from 2.54 mm (about a 50 percent subcaliber in a 5.56 mm) in small increments up to 7.62 mm. The same size projectiles (not same relative size) were used in all boros as subcalibor projcctiles up to the point that they could be housed in the given caliber. Thus there are 13 cases for the 5.56 mm and 17 for the 7.62 mm. This mesh had much closer spacing than the full bore because it was felt that there was less known about the expected variations and it might consequently prove more difficult to interpolate logically.

C. The Weight Spectrum

The method of choosing the weight spectrum of the full-caliber phase was conveniently selected by specifying homogeneous shapes of materials with densities equal to that of steel, lead, and tungsten. This has the twofold advantage of identifying with conventially used or proposed materials as well as establishing a range of densities in which projectiles of composite materials will fall. For example, A.P. or A.P.-I-T will have average densities in between or involve small extrapolation.

The possible exception was considered to be the mass-stabilized subcaliber projectile which might be a "light-heavy" metal composite whose total weight would be limited by stability considerations. In this case a trial design was felt to be the only solution, and this was the approach taken. While the design used for the weight estimation was a practical projectile in the stability and structural sense, it represents a particular case and in some situations, if other considerations warranted it, higher weights might be achieved without undue stability penalties. The large number of possible parameters in a multi-metal design, however, would have pyramided the effort; consequently only one design was used in the study, and its equivalent density is about 4.08 gm/cc. All subcaliber projectiles required saboting, and a two bore caliber long plastic one was assumed.

D. Recoil Momenta Spectrum

For a given projectile (or projectiles) having specified shapes, weights, etc., a variety of initial conditions are available for

comparative performance, e.g., equal muzzle velocity, equal muzzle energy, equal recoil momentum, etc. Recall that the ultimate item of interest is effectiveness, i.e., P_I, the probability of incapacitation, as a function of weight, cost, etc.; and that P(I) = P(H) x P(I/H) where P(H) is the probability of a hit and P(I/H) is the probability of incapacitation given a hit. Recall further that the ballistic properties tabulated in this report bear more directly on the latter term P(I/H) and less directly on the former P(H). It is prudent then to select initial conditions that relate most directly and importantly to the hit probability term P(H). Recent work, BRL Report 1764, for example, points out that the aiming error, and hence hit probability, is a fairly strong function of the recoil momentum of the weapon. Hence recoil momenta, rather than initial energy or an arbitrary range of velocities, was selected as one of the constraints defining initial conditions. Discussions with systems analysis agencies and using agencies indicated that the recoil level of the M-14 was probably too high while that of some of the SPIW candidates represents a reasonable lower bound. The points finally selected, i.e., 0.8, 1.2, and 2.1 pound-seconds, can be roughly identified with the SPIW, the M-16, and something slightly less than the M-14 (actually about that of the AK 48). This choice results in slightly more emphasis on the lower end of the spectrum, but this is where the guidance led.

E. Tracer Effect

The inclusion of tracer effect in the scenario requires a different type of consideration from those previously discussed, in that a technical assumption is required because the behavior is not completely understood.[1,2,3,6,7,8,9,10*] It is known that live tracers usually produce drag changes and these changes are usually that of decreasing drag. Observed changes have been from approximately three percent of total drag for larger projectiles and up to 20 percent for some bullets. It can be shown that this cannot be a momentum thrust effect (as a rocket), and the limited available data suggest that it is more akin to a base pressure

**References are listed on page 626.*

change induced by mass and/or heat injection. If this is the mechanism, then it operates only on the base drag component of the total drag, and the reductions in total drag previously cited correspond to 50 to 75 percent decreases in the base drag coefficient. In that the observed effects were produced by devices never designed specifically to decrease drag, some further decreases should be possible if one set out with that as the prime design objective. Other evidence, however, suggests that changes of the base drag component by much more than 100 percent are improbable. With these evidences in mind, a value of 100 percent in base drag reduction was assumed for this study. This implies that the base pressure is raised to one atmosphere. This is, admittedly, a very convenient assumption in that the change to the drag-reducing tracer condition involves only omitting the computed base drag.

While mass and/or heat injection, with consequent base drag reduction, seems to be the most probable mechanism, and the level of reduction assumed does not seem too overly optimistic, the very nature of the assumption has the effect of favoring certain configurations. The maximum benefit will occur for those configurations and in the velocity ranges for which the base drag is highest. A momentum thrust model would have yielded results that were less configuration-sensitive. The nature of the assumption suggested inclusion of some shapes in the study, e.g., cone-flares, that otherwise would not have been considered because of their high base drag. If the assumption were to be substantially incorrect, then some of the configurations would be less attractive than they appear here.

Because the drag-reducing tracer was beneficial, it was assumed to last for essentially the duration of the flight, and enough combustible material was assumed present to last for the longest expected flight time (~3 secs). Even this amount did not perturb the weight or inertial properties of the full-bore projectiles very much, and the effect on launch weight was neglected. Thus the tracer and non-tracer round of the same size are assumed to have the same launch weight, but tracer mass was allowed to burn away during the flight. In the case of bi-metal

subcaliber projectiles the relative volume required by the tracer was higher and, because the projectiles were mass-ballasted, this influenced their stability. Under these conditions the tracer volume and mass were considered more completely in the design and in the computations.

F. Trajectory Constraints

The maximum range of interest, for computational purposes, was selected to be 1100 meters. This more than covers the range of interest for the rifle role and is more the range of interest for light machine guns. The trajectories were adjusted in elevation angle so as to cause projectile impact to occur at 1100 meters. A maximum elevation angle of 100 mils was applied and in those cases where an elevation of 100 mils would not yield 1100 meters, the computed trajectory was terminated at ground impact.

G. Computational Procedure

Within the framework of the preceding constraints and ground rules, the aerodynamic properties of the shapes were computed. The process and results are discussed in the appendix on Exterior Ballistics. The inertia properties for each case also had to be computed, and these are given on the facing page of each tabular section with a sketch of the projectile.

The projectile mass and any auxiliary launch mass were used with the momentum constraints and interior ballistic contribution to determine initial launch conditions. Point mass trajectories were then computed for all the cases. The point mass trajectory involves only drag and gravity, it being implicitly assumed that the projectile is stable and well behaved. The fact that a trajectory could be or was computed for a given case does not imply that the projectile involved is readily made stabilizable; indeed, the fact that a trajectory was computed does not imply that the projectile of a material of the given density could even be launched in one piece.

For those cases where spin stabilization is the probable mode, an ancillary computation was made to determine the twist necessary to yield

a gyroscopic stability factor of 1.4. The computed twist rate is for a homogeneous projectile of the given density. If the given density is achieved by bi-metal construction, or other forms of non-equal distribution of mass, then the tabulated twist rate does not apply.

Further discussion is given in the appendix on Exterior Ballistics.

H. Tabulated Outputs

The most immediately useful tabulated output is probably the remaining energy as a function of range. As previously noted, this is the starting point for most terminal effects computations, for both soft and many hard targets, and these are the penultimate steps in effectiveness or systems analysis. In some circumstances, the velocity is also important in determining terminal effects. The remainder of the trajectory information, height, angle, and time of flight, are involved more in estimating the hit probability against some types of targets.

Some factors of the "differential effects" type are also included, and the usefulness of these may not be so immediately obvious. They are of interest, of course, to the specialist, but in addition they do transmit general information as to the sensitivity of the particular design to change. The sensitivity factors include:

1. The increase in drag due to a unit change in level of yaw.

2. The change in velocity (at each point on the trajectory) due to a one percent increase in drag.

These factors are useful, for example, in the following considerations. The trajectories were run assuming a zero level of yaw, and the relative magnitude of the sensitivity factor between cases indicates the relative sensitivity of the compared cases to, for example, poor launching that induces large yaw. Again, where it is suspected that an average level of yaw may exist over most of the trajectory, the sensitivity factors can be used to determine velocity degradation. Though the sensitivity factors are expressed as drag change as a function of yaw, or velocity change as as function of drag change, they are more general-purpose factors than

the units would suggest. Actually the second factor means a change in retardation, or $\frac{\rho \pi d^2 C_D}{8m}$, where

ρ = air density
d = projectile diameter
C_D = drag coefficient
m = mass of projectile .

This second sensitivity factor serves to reflect a one percent change in air density, or a one percent change in cross sectional area, or, in the reciprocal sense, a one percent change in projectile mass, or any combination that alters the retardation by one percent. Hence departures from the ideal, which do occur in the real world, due to manufacture, launch, etc., may be assessed in a general way through the use of the sensitivity factors.

The corrective term given for velocity change per percentage of drag change permits construction of new cases where the drag change is as much as ±5 percent, retaining essentially the accuracy of the original table.

III. DISCUSSION OF OBSERVATIONS DERIVED FROM STUDY

A. Introduction

As previously noted, it was not the object of the study to produce an effectiveness study per se. Rather, the objective was to provide information essential to effectiveness studies by mapping projectiles, or classes of projectiles, which might be useful in small arms applications. To this end, the effort has been directed more to covering less conventional areas, although a few conventional bullets and a standard flechette are included as base lines.

In the discussions that follow, the remaining energy will be used as a criterion of "goodness" and, as a result, the discussion will have many of the features of an effectiveness presentation. It must not be so construed. At the expense of being overly cautious, let it be

recognized that, though some of the outputs (remaining energy primarily) appear similar to those presented in effectiveness studies, they are not that. Remaining energy, for example, is a measure of effectiveness if and only if all other related factors are assumed to be equal. The burden of making this assumption rests with the user of the information, and indeed for minor perturbations around a given design this assumption may be sufficiently valid for some purposes.

B. General Observations

In a general survey of the cases mapped, a few elements stand out. Some of these are inherent in the physics of the situation, some are influenced by the assumptions used, but some were, in degree at least, surprising enough to note.

1. The drag-reducing tracer yields significant decreases in drag and retardation in many cases and always yields some improvement. Figures 2 through 10 show the effect for full-bore projectiles at a range of 400 meters, and Figures 11 through 19 show the effect at 1100 meters. Figures 20 through 37 show the effect for the subcaliber projectiles at the same two ranges. Showing the effect at two selected ranges is not intended to tell the complete story--the tabulated data do that. A range of 400 meters was selected as an example because it is a reasonable range of interest for rifles. Indeed the QMA for the future rifles specifies an interest in engaging point personnel targets for a range of at least 400 meters.

The 1100-meter range was chosen because it is a range of interest for light machine guns and also to provide better insight to the 400-meter data. For example, many projectiles have quite similar performance (remaining energy) at 400 meters, but at 1100 meters a quite different picture emerges. These disparities in behavior should be an invitation to consult the tabulated data for the details between 400 and 1100 meters.

Our explanation of the effect of the drag-reducing tracer in decreasing drag, consequently increasing energy down-range, is based, we think, on realistic assumptions. In fact, drag reductions of this magnitude have

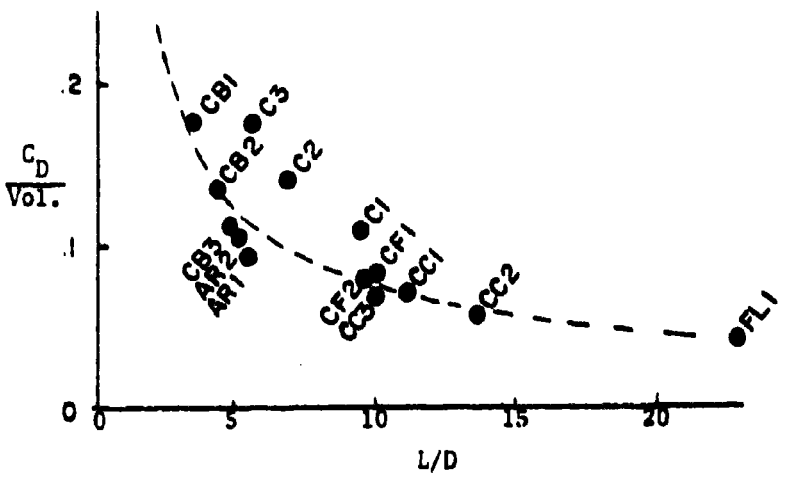

been observed, in limited testing, for some conventional tracers which were, of course, not designed as drag reducers. Some examples are:

a. The Hispano Suiza 20-mm round[5]

b. The M-246 tracer round for Vulcan

c. The NATO family of 7.62 mm, M-62[4]

2. Low-drag artillery shapes (AR-1, AR-2) and some intermediate shapes can have sufficiently lower drag than some conventional bullets to the degree that composite projectiles with the average density of steel (and, of course, a homogeneous steel projectile) can have less velocity fall off than some current lead projectiles. They are also often lighter in weight and hence can have greater initial velocity and energy, for a given level of impulse. A convenient way of viewing the shape spectrum and for getting a feel for how some of the shapes of intermediate L/D compare with flechettes and bullets is as follows:

Thus if one were working on the outer limits of L/D, flechettes for example, and if for some reason it was desirous to decrease L/D, then from exterior ballistic considerations there would be little penalty--over a fairly broad range of L/D.

3. Despite the fact that the general trend of an initial impulse limitation is to favor light, and hence lower density projectiles, there are cases where high-density projectiles appear quite favorably--particularly for small projectiles at longer ranges. In addition, it is apparent that average projectile densities between those of homogeneous steel, lead, or tungsten are optimum in some cases and composite metal projectiles are a way of achieving this optimum. In 7.62 mm and larger sizes, bullets involving three or more materials are not unusual. Where composite projectiles are indicated anyway, consideration should also be given to whether the amount and portioning of the materials can be managed so as to achieve a more optimum design as well as serving their original purpose.

C. Usefulness of the Tabulated Data

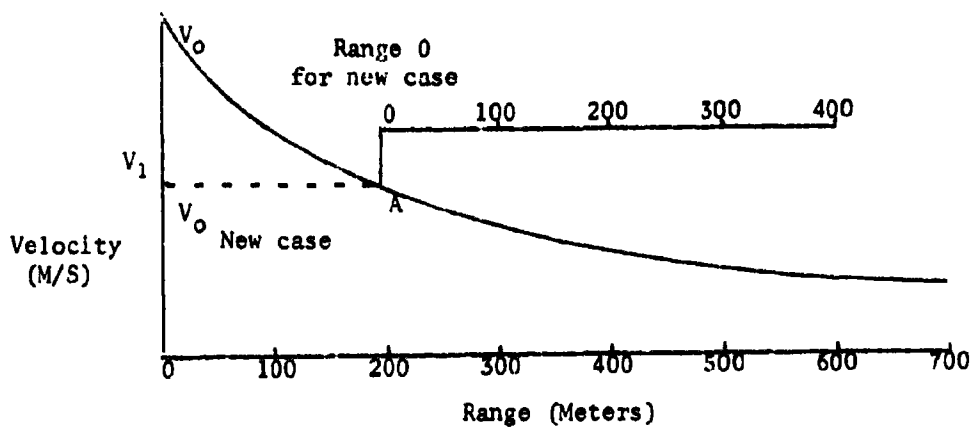

At first glance it might appear that the tabulated data are for very specific projectiles under specific constraints, i.e., specific and unique data points. In that the study was a mapping exercise, they should more correctly be viewed as coordinate points within the map. As such, the data provide a means of exploring more territory than that represented by the cases in the tables. No attempt will be made in this section to illustrate or even list the many and varied ways the data can be used. A few illustrations will be cited or illustrated hopefully to induce the reader to think of others. In addition to the simple and elementary examples used here, a separate appendix is devoted to the solution of sample problems utilizing the tabulated data.

The results tabulated are primarily the trajectories, the remaining velocity, and the remaining energy for the various particular cases. Secondarily, those results that were necessary to obtain the earlier ones, such as the computed aerodynamic data and the computed inertial properties, are also given. These results can be used in various wonderful ways. Among these are:

1. Subfamilies of the actual cases can be plotted to determine trends or sensitivities. For example, for a given caliber and shape, one can investigate the effect of a particular parameter, e.g., bullet weight (or density) on remaining velocity and energy.

2. New concepts or proposals arise, many of which may be near a given case or bounded between two cases. Hence the proposed performance can be often roughly checked or missing elements of performance generally determined rather quickly. Further, the proposed performance can be judged, in the comparative sense, within the context of the full spectrum of small arms projectiles.

3. Many new cases can be interpolated between those tabulated and are implicit in the cases given. For example, the high impulse case for a given projectile and caliber contains the velocity and energy history information for all lower impulse cases--although over a shorter range. The following illustrates this feature for velocity:

The curve is for a tabulated case where the muzzle velocity is V_o. If, for the same projectile, one is interested in a lower initial velocity, say V_1, one simply comes across to the intersection at A and constructs a new range table with origin at point A.

These three examples of how the tabulated data can be used are cited simply as representative of more that can be found in the appendix devoted to that purpose.

To the degree that we have chosen wisely our variables and their magnitudes, the report should present a very comprehensive coverage of the shapes of projectiles that might be of interest in small arms. At the very least, we have brought together under one cover a wealth of information, under comparable conditions, which either did not exist before or was scattered in hundreds of references.

IV. GUIDE TO SECTIONS AND PAGES

The tabulated data are presented in sections--each section devoted to one of the shapes of Figure 1 and containing all data relevant to that particular shape. The sections are ordered (roughly) in increasing L/D. The following is a listing of the order with a brief description of each shape:

Symbol	Description	L/D (Approx.)	Page
CB-1	M-193 type, blunt nose, ogive head, short boattail	3.6	71
CB-2	M-118 type, less blunt, ogive head, longer boattail	4.2	101
CB-3	IWK type, least blunt, ogive head, no boattail	5.0	131
AR-1	Long secant ogive, boattail	5.5	161
AR-2	Longer secant ogive, no boattail	5.5	191
C-1	6° total angle cone	9.5	221
C-2	8° total angle cone	7.2	251
C-3	10° total angle cone	5.7	281
CF-1	8° total angle cone, 4° total angle flare	8.4	311
CF-2	10° total angle cone, 4° total angle flare	7.6	341
CC-1	6° total angle cone, 2-caliber cylinder	11.5	371
CC-2	6° total angle cone, 4-caliber cylinder	13.9	401
CC-3	8° total angle cone, 3-caliber cylinder	10.2	431
FL-1	M-144 type	21.4	461
SC-1	Bimetal similar to CC-1	11.5	491

Each page within a section is numbered serially in the lower right-hand corner, e.g., CB-1-1, CB-2-2, AR-2-3, etc. The first three pages of each section contain details describing the particular shape treated in that section. Page No. 1 of each section contains a sketch with physical dimensions and aerodynamic data. Page No. 2 shows drag coefficient (C_{D_0}) vs. Mach number. On page 3 is normal force coefficient, center of pressure vs. Mach number and static moment coefficient vs. Mach number.

Each page of ballistic data, within a section, contains a heading describing the projectile pertinent to the data on that page and the constraints on the trajectory. The ballistic data in the top center of the page is the data for the projectile without a drag-reducing tracer. The tabulation in the lower portion is that for the projectile with a drag-reducing tracer.

The information in the heading is as follows:

Caliber:	Bore diameter of weapon
Impulse:	Recoil momentum of weapon due to projectile, sabot, and propellant gases with no compensating device at the muzzle
Projectile Weight:	Flight projectile weight as it leaves the muzzle
Projectile Diameter:	Diameter of the projectile (Diameter of a cone flare is the diameter at the juncture of the cone section and the flare.)
Average Density:	As represented, this is the density of a homogeneous body with the volume of this shape and size.
Drag Reducer Weight:	Weight of drag reducing tracer Zero for non-tracer trajectory
Charge Weight:	Weight of propellant charge necessary to attain tabulated muzzle velocity. (See appendix, Interior Ballistics, for assumptions.)
Sabot Weight:	Weight of 2-caliber nonmetallic sabot

Twist Rate:	Rifling necessary (in units of revolutions/ inch of travel) to stabilize the homogeneous body of the tabulated density. Nonhomogeneous projectiles, of the same average density, would require a different twist rate. N.A. appears if stabilization is by other than spin, or if the launch velocity is less than Mach 1.0. The latter convention was adopted on the assumption that velocities lower than this are of no interest in the rifle role.
Pct Drag Change/ (Deg Yaw)**2:	(Read percent drag change per degree yaw squared) A measure of the sensitivity of drag due to yaw. For example, if Pct. Drag Change/(Deg. Yaw)**2 is, say, 0.78, then a 2^{0} yaw will induce an effect of $(2)^{2} \times 0.78 = 3.12\%$ drag change.

The information in the tables is as follows:

The data in the tables represent a point mass trajectory for the projectile, under the conditions, described in the heading. The angle of fire is that required to reach 1100 meters with 100 mils as the maximum allowable angle of elevation.

Columnar data is: range, height, time of flight, angle of fall, velocity, energy, and change in velocity for a unit change (%) in drag. Note that there are two lines for zero range. They differ in that the energy in line one includes the sabot weight and line two only the projectile weight. The angle of fall is the angle of the velocity vector with respect to the horizontal. The D(V)/D (percent drag change) is the change in remaining velocity at the given range for an increase of one percent in drag.

The tabular values in the lower half are for the same round but with a drag-reducing tracer.

Each section is concerned with one shape and the parameters of caliber, impulse, and density were varied in the same sequence for each shape. As a consequence, comparable conditions are found on the same section page number within each section as follows for full-bore projectiles:

Section Page No.	Caliber (mm)	Impulse (lb. sec.)	Average Density gm/cc
4	5.56	.8	7.8 (steel)
5	5.56	1.2	7.8 "
6	5.56	2.1	7.8 "
7	5.56	.8	11.0 (lead)
8	5.56	1.2	11.0 "
9	5.56	2.1	11.0 "
10	5.56	.8	16.7 (tungsten)
11	5.56	1.2	16.7 "
12	5.56	2.1	16.7 "
13	6.50	.8	7.8
14	6.50	1.2	7.8
15	6.50	2.1	7.8
16	6.50	.8	11.0
17	6.50	1.2	11.0
18	6.50	2.1	11.0
19	6.50	.8	16.7
20	6.50	1.2	16.7
21	6.50	2.1	16.7
22	7.62	.8	7.8
23	7.62	1.2	7.8
24	7.62	2.1	7.8
25	7.62	.8	11.0
26	7.62	1.2	11.0
27	7.62	2.1	11.0
28	7.62	.8	16.7
29	7.62	1.2	16.7
30	7.62	2.1	16.7

For subcaliber projectiles there are small departures from the format just described. These are:

(1) The flechette does not have a trajectory associated with a drag-reducing tracer.

(2) The bi-metal subcaliber is concerned with one shape but with emphasis on diameter as a prime variant.

As a consequence, the tabulations are best viewed in this fashion:

Caliber (mm)	Projectile Weight (grams)	Projectile Diameter (mm)	Impulse 0.8 lb.sec. See page No.	Impulse 1.2 lb.sec. See page No.	Impulse 2.1 lb.sec. See page No.

APPENDIX A

INTERIOR BALLISTICS

I. INTRODUCTION

Interior ballistics generally is concerned with predicting the pressures in guns necessary to achieve particular velocities for desired weight projectiles. Many reports have been written describing techniques for these computations, and confidence has been obtained by experimental verification. For small arms systems this predictive capability is not so clear cut; uncertainties of initial burning surfaces, composition and burning rates allow limited predictions to be made. Many empirical relationships, however, are in use that allow interpolations between known results to be used. In this appendix some semi-empirical relationships will be described for finding the velocity and charge associated with a given impulse level for a particular projected weight.

It is to be noted that certain constraints normally considered in small arms have not as yet been mentioned. These include maximum pressures, muzzle blast, noise, erosion of the gun tube, and size and weight of the case.

If we consider a rifle as a weapon used for years, we find that compromises have been made. The pressures are low enough to have a man-portable barrel, muzzle blast and noise are not objectionable, and the useful life of the barrel is expected to decrease (because of rapid fire), hence, replaceable barrels. Size and weight of cartridge must also be compatible to the system. The pressure can be reduced by lengthening the gun (for a given velocity), or contained by a better steel, with a higher yield strength for the same weight gun. Muzzle blast and noise can be reduced by muzzle devices, and erosion of the gun tube can be controlled by lining the barrel, use of additives, or cooler propellants. The size of cartridge can be reduced by compacting or molding the charge (hence, lower charge volume), or the weight of the case reduced by going to a lighter metal or even utilizing the caseless concept. It is not intended to rationalize the implied interior ballistics, but to see what

is necessary for our main constraints, and maybe worry later if we are outside the normal rifle for certain situations.

With the above put on the shelf, but not forgotten, let us detail the procedures used in this study.

II. DETERMINATION OF VELOCITY AND CHARGE

The present study required the determination of velocities that a variety of projectiles would attain with certain assigned recoil momenta. In the past few years recoil momenta have been measured for many small arms projectiles, and the results were used to establish semi-empirical relationships. Since then the predictions of recoil momenta for several small arms system studies have been verified when actual firings were conducted.

The basic equations follow:

$$J = \frac{MV}{g(7000)} + 0.023\ (1 - \varepsilon)C \qquad \text{(A-1)}$$

where J = recoil momentum (pound-seconds)
M = weight of projectile (grains)
V = velocity (ft/sec)
g = gravity constant (ft/sec^2)
C = charged weight (grains)
ε = ballistic efficiency

$$\varepsilon = \frac{\frac{MV^2}{2g}}{\frac{FC}{\gamma - 1}} \qquad \text{(A-2)}$$

where F = specific force of propellant (ft-lbs/lb)
γ = ratio of specific heat of propellant gas

Equation (A-2) was simplified for the many situations by assuming a specific force of 360,000 ft-lbs/lb and a gamma of 1.25; hence

$$\varepsilon = \frac{2.48 \times 10^{-10}}{0.023} \frac{MV^2}{C} \qquad \text{(A-3)}$$

Furthermore, in BRL Technical Note No. 1557 by Carroll and Carn, a plot of velocity versus projectile weight to charge weight ratio is shown and was used by Carroll to determine (see Figure A-1):

$$\frac{M}{C} = \frac{11189 - 1.64V}{V - 758} \qquad \text{(A-4)}$$

Equation (A-1) was then simplified to

$$\frac{J}{M} = 2.48 \times 10^{-10} V^2 + 4.45 \times 10^{-6} V - 0.014 + \frac{85.4}{6823 - V} \qquad \text{(A-5)}$$

For the various recoil momentum and projected weights (weight of projectile and sabot), Equation (A-5) was solved to determine the velocity in this study. Note that the charge weight is not a required input to solve Equation (A-5).

The charge weight was determined from Equation (A-4), which is valid only between 1000 to 6000 ft/sec and, indeed, calculates negative charges below 758 ft/sec and above 6823 ft/sec. Few rounds in this study had velocities higher than 6000 ft/sec, and a linear relationship was used for determining the charge weight for low velocity rounds (i.e., the charge at V_1 equals charge weight at 1000 ft/sec × ratio $V_1/1000$). Usually at the low velocities additional propellant would be needed to ensure uniformity, and the amounts are small compared to the weight of the projectile.

The original plan for this study expected to limit the velocities to between 2000 and 5000 ft/sec. Within these limits the above techniques should be adequate to calculate recoil momenta. The implied error due to incorrect charge weight at low velocity is very small, since the recoil momentum is then almost equal to projectile momentum. At the high velocity limit we have no experimental data but believe the method to be sufficiently accurate to enable relative comparison of the few rounds to be made.

III. SABOT WEIGHT DETERMINATION

In order to determine the weight of the sabot required for the sub-caliber, coned, and coned flared projectiles, the following equation was used:

$$S = K\rho \frac{\pi}{4} (D^2 - d^2)D$$

where

S = sabot weight

K = constant

ρ = density of sabot material

D = diameter of bore

d = average diameter of projectile for the rear two caliber lengths

The value of K accounts for the weight of the pusher plate, and thus the density and length of the pusher plate are not required.

Using weights of existing sabots from several systems, K was assumed to be 4 and ρ 252 grains/inch^3 (~ 1 gm/cm^3).

Thus,

$S = 792(D^2 - d^2)D$ (Gives S in grains when D is in inches)

$S = 51.3(D^2 - d^2)D$ (Gives S in grams when D is in inches)

$S = 3.13 \times 10^{-3}(D^2 - d^2)D$ (Gives S in grams when D is in millimeters)

There are not many available rounds to compare calculated and actual sabot weights, but several examples follow:

AAI SPIW:

$S = 792\ (0.22^2 - 0.1^2)\ 0.22 = 6.7$ grains

Actual 5-6 grains

BRL 3 Flechette Pusher - Caliber 0.35:

$S = 792\ (0.35^2 - 3(0.1)^2)\ 0.35 = 25.6$ grains

Actual 25-30 grains

TRW 25mm Sabot Round

$S = 792\ (0.984^2 - 0.590^2)\ 0.984 = 485$ grains

Actual 610 grains

105mm APDS

$S = 792\ (4.13^2 - 2.5^2)\ 4.13 = 35{,}300$ grains

Actual 21,560 grains

IV. TRACER WEIGHT DETERMINATION

The weight assigned to the drag-reducing tracer material was based on the 7.62-caliber (M62), i.e., 0.39 grams, and for the other calibers the weight was scaled as the cube of the caliber.

	Tracer Weight
5.56 caliber	0.151 grams
6.50 caliber	0.241 grams
7.62 caliber	0.389 grams

For the subcaliber projectile (SC1) the assumed weight was 0.32 grams for the caliber 7.62 and again scaled as the cube of the caliber. The difference in weight, for the 7.62, was required by the design of the projectile where the tracer weight was included in the balance for stability.

All tracers were assumed to burn for three seconds, and weight was lost proportional to time.

V. DESK CALCULATION METHODS

For the convenience of the user, several graphs and nomographs are presented to enable rapid estimates to be made for systems which are not considered in the basic report. The reader is cautioned, however, in using this section, since the accurate results are found by using Equations (A-1) and (A-2) in this appendix. The nomographs are to be used only for their simplicity and when insufficient data are available. For rigorous solution there might be errors in values below 2000 ft/sec and above 5000 ft/sec.

Figure A-2 is a simple nomograph showing the relationship of impulse, muzzle velocity, and projected weight. By laying a straight edge on two known quantities, one can read the third (from Equation (A-5)).

Figure A-3, while similar to Figure A-2, is a somewhat more complicated nomograph. Dual values are shown--grams and grains, meters per second and feet per second, pound-seconds and newton-seconds--to aid in conversion from conventional to cgs units. Also, on the right side, an auxiliary nomograph allows computation of sabot weight for a given projectile weight.

Figure A-4 is a nomograph that relates the energy in joules, as a function of projectile weight and velocity. Note that this can be used anywhere in the trajectory (or range) where the velocity can be estimated. Again the key is simple. By laying a straight edge on two known values, one can read the third. This nomograph solves $E = \frac{1}{2}MV^2$.

Figure A-5 shows graphically how the impulse increases with projectile velocity, very much more so than projectile momentum alone, which is linear with velocity.

Figure A-6 is a graph which shows the relationship of velocity and projected weight for the three impulse levels in the basic study. It is useful for interpolation for special cases.

APPENDIX B

EXTERIOR BALLISTICS

I. INTRODUCTION

The application of exterior ballistics in design work is ideally to select an external configuration which will (1) have stable flight and (2) have a minimum (or acceptably low) retardation due to drag. These two criteria have to be attained within the framework of constraints dictated by the interior ballistics (the projecting of the shape) and the terminal ballistics (the production of the desired effect).

With the above in mind, the computations chronologically followed the scheme of first determining the aerodynamic coefficients for the presented shapes and then, with the given spectrum of mean densities, bore diameters and muzzle velocities corresponding to the impulse levels, trajectories were computed to determine the effect of drag on the projectile's flight.

II. BASIS OF COMPUTATIONS

A. Aerodynamic Coefficients

The aerodynamic computations were made using a model involving the Van Dyke hybrid method[1*] for the potential flow, the Van Driest method[2] for the compressible turbulent boundary layer, and the Chapman-Sternberg model[3,4] for the base pressure. The overall model, as used, is limited to pointed projectiles that have reasonably large L/D ratios and high enough velocities so that the flow is supersonic over all parts of the projectile, yet not so high that significant entropy losses occur in the shock wave system. The program yields the drag coefficient, C_D, the components of the drag--skin friction, base drag, and wave drag; the change in drag due to yaw; the normal force and center of pressure; and, given the center of mass position, the static moment. These are obtained under

*References are listed at the end of the Appendix (page 658).

the assumption that the yaw is small. The restriction to a relatively thin, pointed body in a purely supersonic flow is basic to the method. The assumption of a turbulent boundary layer is not; a laminar one could have been assumed with essentially equal ease. The turbulent one is obviously proper for shell and the larger bullets; the smaller bullets could, however, be expected to have laminar layers over about one third of the body, and some flechettes have had laminar flow over most of the body. Excepting the latter case, the turbulent boundary layer assumption seems to give the better result, even if a considerable portion of the flow is laminar. This can in part be ascribed to the following: (1) The relatively low frictional drag level of the laminar applied to the whole projectile leads to a more serious underestimate if part of the full diameter after section is turbulent than the overestimate made by assuming full turbulent flow if part of the nose is laminar. (2) The computation is basically for a smooth body; most real projectiles have rings, bumps, and engraving. The thicker turbulent layers partially immerse these and reduce the added increment of drag, the thin laminar layer does not, and there can be larger incremental drags. Admittedly, the latter effect is fortuitous in the sense that two slightly incorrect assumptions tend to cancel. The assumption that the bullet is pointed has appeared to produce little error for most cases of military bullets that have been studied.

In order to show the general level to which the program reproduces experimental results, and also to show the differences that can be expected to occur between idealized cases and actual bullet data, the computed drag and several experimental drag curves are given in Figure B-1. The computed curve is for an idealized version of the preproduction 5.56mm M193, the CB-1. The ogive has been pointed, the intersections of the ogive and the boattail with the body have been made clean, and no cannelure is used. The first measured case is for a bronze model of the idealized shape insofar as the outer contour was concerned, but it was engraved. Although the test model had a short section of laminar flow, the agreement is very good. The drag curve for a production M193

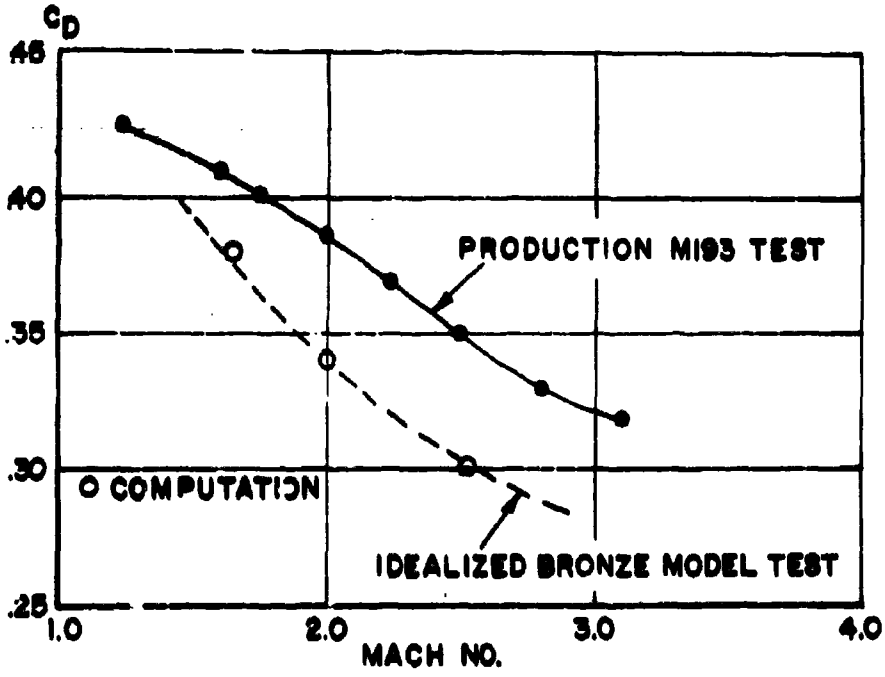

Figure B-1. Comparison of Computed and Measured Drag Coefficients for Undeformed Projectiles and Ball Projectiles

is also given and it is considerably higher. Most of this difference can be attributed to differences between the flight shape and the drawing shape for this relatively soft bullet. Larger, or harder, bullets have yielded differences that were only about five percent higher than that of the idealized shape. Thus it is apparent that a mixture of real and computed data in the study would have yielded biased shape comparisons.

To some degree the flow computation used recognizes violations of the assumptions during the computing process and is self limiting. For the blunter projectiles the valid region can be as small as from Mach 1.4 to slightly over Mach 2, while for the longer ones in the study it ran from just over Mach 1 to Mach 6 and covered the entire range of interest. In those cases where the computation did not cover the range of supersonic interest, the computed curve was continued using the trend of experimental data for similar projectiles. Although subsonic and transonic speeds were not considered as being very relevant to the basic

study, some computed cases used these regions and the same continuation procedure was used. The supersonic extension probably does not influence the realism of the results. Transonic flows are sensitive to the details of the projectile design, and the absolute drag levels are probably more poorly predicted.

B. Tracer Assumption

The assumption of the tracer effect was based on the suggestive behavior of some tests on 20mm, 7.62mm, and 5.56mm projectiles. Characteristically the total drag level of the projectiles fired with functioning tracer was from 20 to 30 percent lower than that for those fired without tracer. The effect varied with Mach number, yielding less difference at the higher speeds. This is also the trend of the drag due to base under-pressure, or base drag. This Mach number trend is shown in Figure B-2 for a 20mm shell with and without tracer operation. Comparing the computed base drag with the actual total drag results indicated that an effective base drag reduction of 50 to 70 percent fitted the results best.

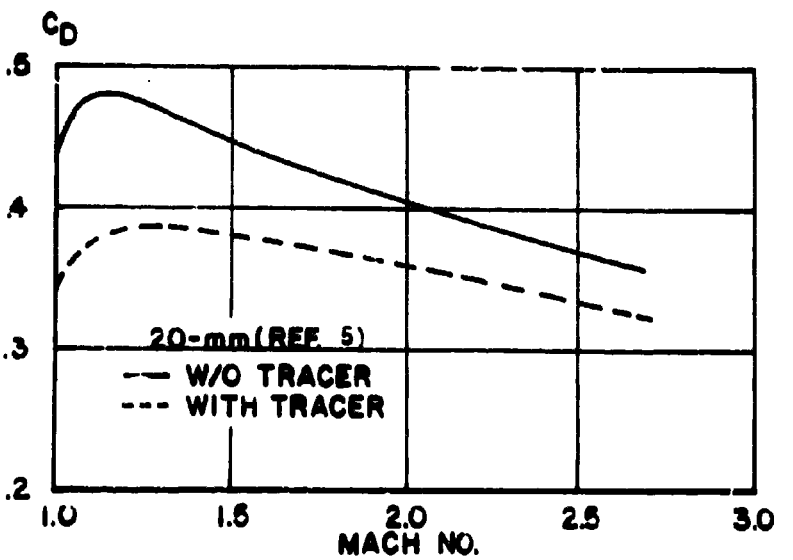

Figure B-2. Drag Coefficient of 20mm Shell With and Without Tracer as a Function of Mach Number

In the case of the 7.62mm tracer round, it was possible to measure the drag changes as a function of range as the tracer element came into operation. At least briefly the increment equaled 100 percent of the computed base drag for this bullet. The drag coefficient history is given in Figure B-3.

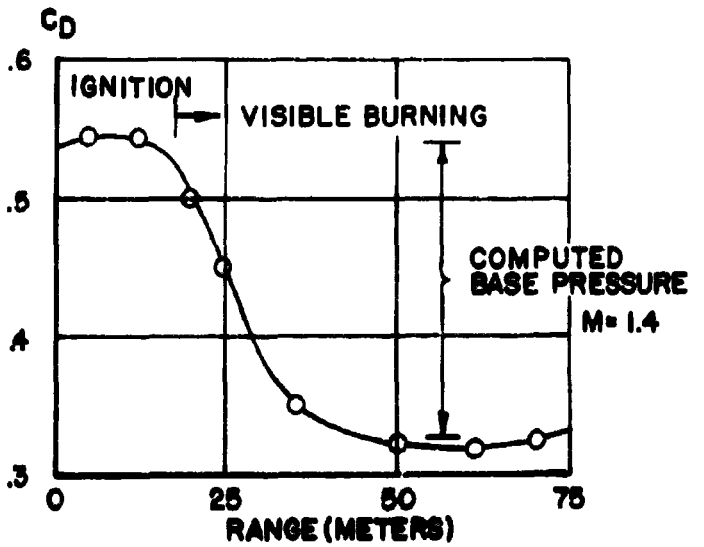

Figure B-3. Drag Coefficient Variation during Tracer Initiation

It has also been noted that the effect is less pronounced with boattailed projectiles, and this is consistent with the assumption that there is, primarily, a modification of the base drag. Testing of missile configurations has indicated that heat or mass addition to the base region can produce favorable base pressure changes, as can heat addition to the boundary layer; it should, however, be noted that the results are not always favorable. The tracer does add both heat and mass to the base region. Attempts have been made to measure the momentum thrust of the tracer, and the thrust levels have appeared too small to produce the observed effects.

The tracer effect, for the purpose of these computations, was assumed to be entirely a base pressure change. It was assumed that the base pressure was raised to one atmosphere, thus effectively canceling

the base drag. This is admittedly a very convenient assumption for the computation, but it is also only slightly more optimistic than the limited experimental results. Therefore, even if the mechanism is not precisely the assumed one, the results should not be too misleading. The nature of the assumption, that it is a base pressure effect, has a predictable result on the computations and this should be noted in case future evidence suggests a change in the assumption. The present assumption must favor those configurations with high base drag components over those with smaller ones. To the degree that the assumption is in error or incomplete the results would be biased similarly. For example, an alternate suggestion that the tracer acted as a pure rocket, essentially a momentum thrust, would yield the result that the tracer effect was primarily independent of configuration, a quite different result from the present one.

C. Stability Considerations

The stabilizability of the projectile, either gyroscopic or static, is not directly considered by the trajectory computation used; it assumes that the projectile flies at essentially zero yaw and, hence, that it is quite stable. The aerodynamics of the shape and the inertial properties of the projectile influence the stability considerations and hence it is impractical to consider the general stability problems for a given shape because of the large number of possible permutations. In some cases, such as the conventional bullet types (CB) and the artillery shapes (AR), it might be anticipated that gyroscopic stabilization of an essentially homogeneous projectile is a probable case and hence that the spin level necessary to yield a particular level of gyroscopic stability factor has directly useful meaning, and this value is provided. In other cases it appeared more probable that multimetal construction would probably be used either (1) to move the center of mass position and change the moments of inertia so that the projectile could be stabilized with a reasonable amount of spin, or (2) to move the center of mass position far enough forward so that the projectile would be statically stable, or stable without spin. Thus, in the cases of the cones, the cone-cylinders, and the cone-flares, with homogeneous center of mass positions,

the spin needed to obtain gyroscopic stability would be impractical in the rifle role and hence is not printed out. If a given shape requires a spin level of one turn in four calibers of travel for stabilization, then it is obviously a greater problem than one that needs only a twist of one turn in six calibers of travel. In those cases where prediction of the spin level to give gyroscopic stability would involve the extrapolated or estimated static moment data in the subsonic and transonic region, no value was given. First, this is beyond the rifle role contemplated. Second, the results could hinge on the cruder results of the assumptions used in these cases.

The projectile is considered to be statically stable if the center of pressure of the normal force is behind the center of mass. If the center of mass position is ahead of the center of pressure position, as is the case of most conventional bullets, the projectile must be spun to provide stability. For the CB and the AR types, the spin level to yield a gyroscopic stability factor of 1.4 is printed out for those cases with Mach numbers above Mach one. For the finned flechette (FL), the fins move the center of pressure behind the center of mass, and the projectile is known to be statically stable. For the remaining cases, C, CC, and CF, the center of pressure is ahead of the homogeneous center of mass point. The aerodynamic data indicate the center of pressure point and hence the degree to which the mass center must be moved to stabilize the projectile statically. Although the possibilities are too numerous to consider, the possibility of shifting the c.m. part way and changing the moments of inertia so that the projectile can be spin-stabilized should not be ignored. The reference level of 1.4 for the stability factor is probably adequate for most ground-to-ground roles but is not necessarily sufficient for air-to-ground roles. Comparison of the indicated twist level required with the range in current use, from as low as one turn in 60 calibers for some rifles to one turn in 18 calibers for tank cannon, assists in placing the computed cases in perspective. The tables, it should be noted, give the twist values per inch, however, as is usual for small arms.

D. Trajectory Model

The trajectory computations were based on a point-mass model; only projectile mass, drag, gravity, the angle of launch, and the muzzle velocity are inputs. The projectile is implicitly assumed to be flying in a stable fashion at small yaw. The equations used in generating the data are given below:

$$\dot{\underset{\rightarrow}{V}} = \frac{1}{2}\frac{\rho S}{m} C_D V \underset{\rightarrow}{V} - \underset{\rightarrow}{g},$$

where

$\underset{\rightarrow}{V}$ = velocity vector of the projectile

$V = |\underset{\rightarrow}{V}|$

$\dot{\underset{\rightarrow}{V}} = d(\underset{\rightarrow}{V})/dt$

ρ = atmospheric density (ICAO Standard - 1962).

The base level for the computations was essentially sea level at 45° North Latitude. For the tracer trajectories, the assumption was made that

$$m = m_o - \frac{m_{tracer}}{3} t \qquad \text{for } t \leq 3 \text{ seconds}$$

$$m = m_o - m_{tracer} \qquad \text{for } t > 3 \text{ seconds}.$$

III. AERODYNAMIC PROPERTIES AND SOME BALLISTIC IMPLICATIONS

The aerodynamic information computed for the program, and estimates for those regions where it could not be computed, are given for each type on the beginning pages of the trajectory results. The nondimensional physical data that were computed, center of mass, volume, wetted area, and radii of gyration, are also given. These have a utility in their own right and can be used to determine the retardations and stability properties of other projectiles that have the same shape but not the same size or the same homogeneous inertial properties as those computed in the program. In the following, some relations will be given

for these computations. Within a reasonable range of sizes, the aerodynamic coefficients tabled are only slightly influenced by size, and these could be used up to 15mm caliber at least.

A. Stability Level

The tables also indicate the twist level necessary to give a stability factor of 1.4 for the various types and sizes in the computed net. This may be too low for some purposes, and possibly higher than desired in a few special cases. The stability factor, s_g, is given by

$$s_g = \frac{2I_x^2 \left(\frac{pd}{V}\right)^2}{\pi I_y \rho\, d^5 C_{M\alpha}} \qquad \text{(B-1)}$$

where (pd/V) is the spin in radians per caliber of travel or $(2\pi/n)$ where n is the twist in calibers per turn. For homogeneous projectiles of different sizes and inertial properties, only new values of the I_x, I_y, and d need be introduced in order to establish new stability factors or the required new spin levels to yield the original stability level. In the case of bimetallic projectiles the center of mass position can also change and the $C_{M\alpha}$ is a function of (c.m. - C_{PN}), where C_{PN} is the center of pressure of the normal force,

$$C_{M\alpha} = (\text{c.m.} - C_{PN})C_{N\alpha}, \qquad (2)$$

where c.m. and C_{PN} are measured from the nose of the projectile. This can also be used to treat the aerodynamically stable cases (those stable without spin) where the center of pressure must lie aft of the center of mass for stability, and $C_{M\alpha}$ is negative. The criterion in this case requires only the relative center of mass to center of pressure position and not the other inertial properties, as does the gyroscopic stability factor. The necessary margin cannot be specified simply for a range of conditions, but it is often considered that design margins less than about ten percent of length are a risk for computed cases.

B. Drag

The present program was concerned with supersonic projectiles, in the sense that they have the shape characteristics of usual supersonic designs. In the next several figures the C_D values for some of the projectiles are plotted against several variables to afford some insight into some of the trends that can be observed in the figures and tables of the main report. Supersonically, pointedness and length of head are important. In Figure B-4 the drag coefficients of some of the computed

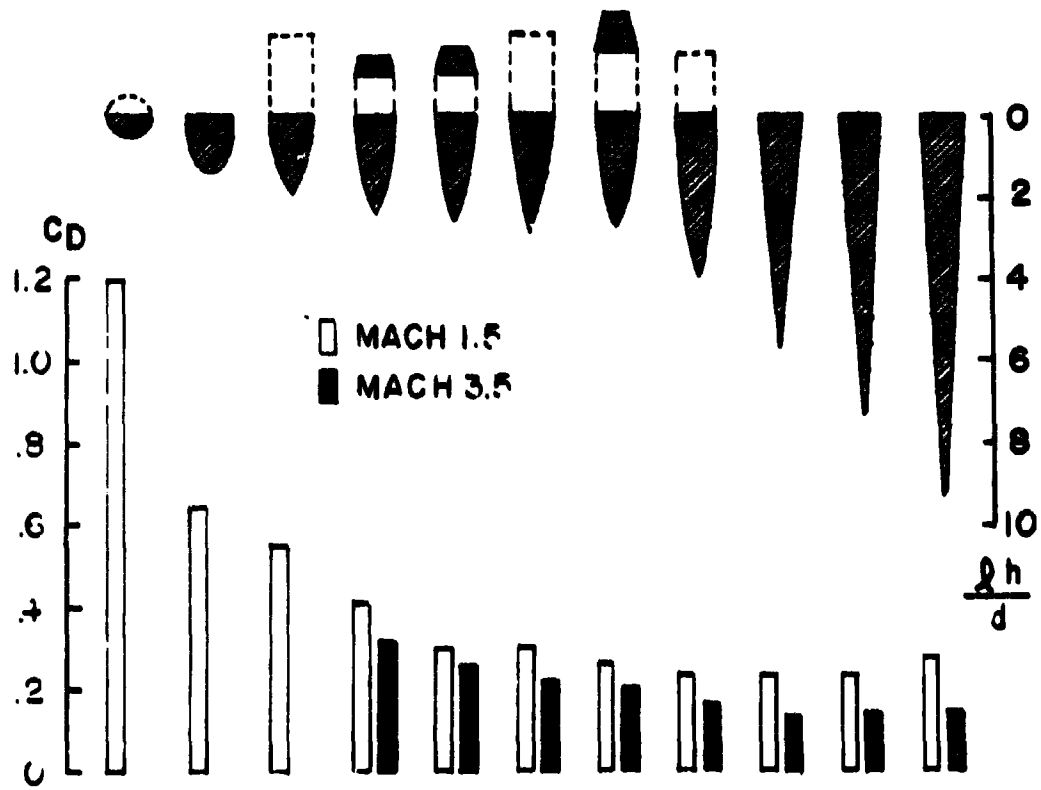

Figure B-4. General Trend of Drag as a Function of Head Length

configurations and of some bluntor shapes are plotted versus head length. The general trend is apparent in spite of the heterogeneous selection of

projectiles. There are large decreases in C_D with increased head length at the blunt end of the scale, but the variation is much weaker for head lengths greater than about three calibers. The trend is more distinct at the higher Mach numbers. Since the computed configurations are all in the middle to high L_h/D range, they are mostly in the relatively flat region of the curve. To show some other variations, the computed configuration data are presented at an enlarged scale in Figure B-5. The

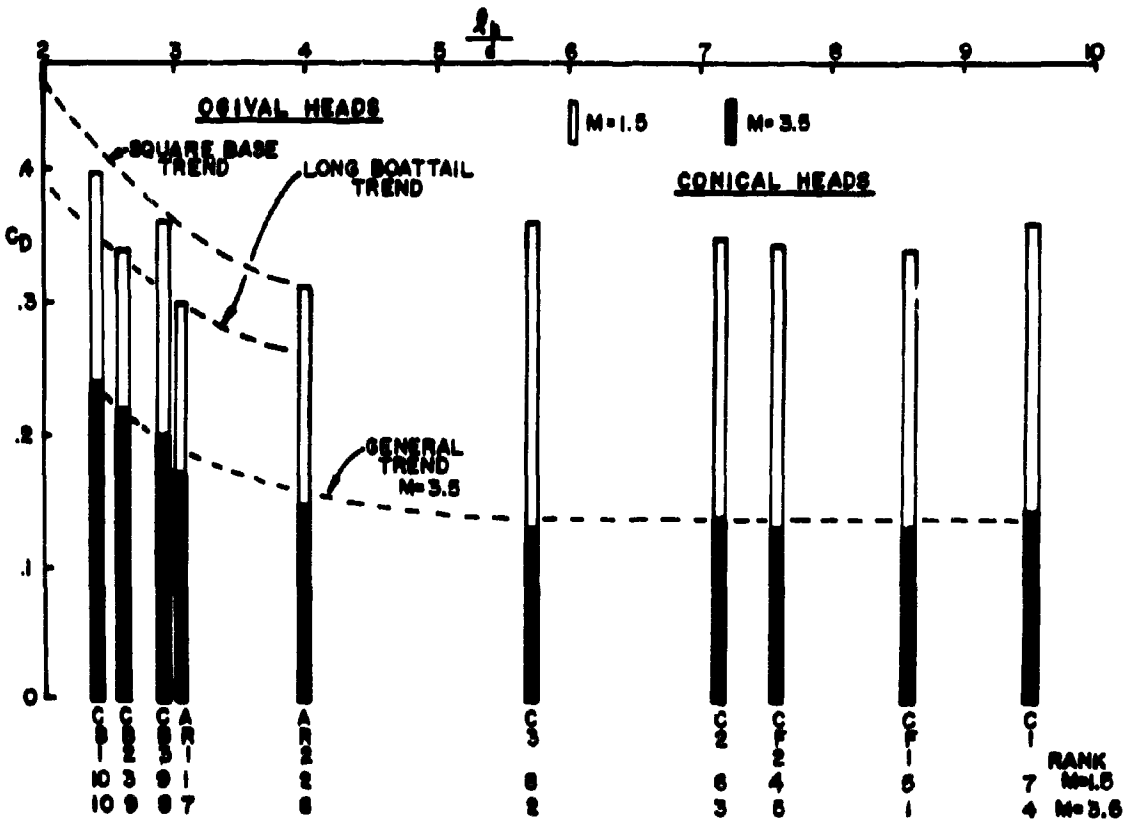

Figure B-5. Trend of Drag Coefficient as a Function of Head Length for the Computed Configurations

results are again plotted against head length and for Mach numbers of 1.5 and 3.5 and are also ranked from the lowest to the highest in drag level. At the lower Mach number the previous trend is recognizable only

at the lower L_h/D values, and other influences are more apparent. The boattailed projectiles are at a lower level and rank well even with shorter ogives, and the shape advantage of the ogive head over the cone is also visible. At the higher Mach numbers, however, the head-length trend reestablishes its dominance.

The general conclusions are: (1) For projectiles with flight Mach numbers of about two or less over most of the trajectory, and which have adequate head length, significant drag gains can be made by the use of optimum head shapes and boattails. (2) For projectiles that have considerably higher average Mach numbers, the head fineness ratio becomes the dominant factor.

The trade-off of boattailing for two cases, the AR-1 and AR-2, is shown in a different form in Figure B-6, and the effect of the assumed

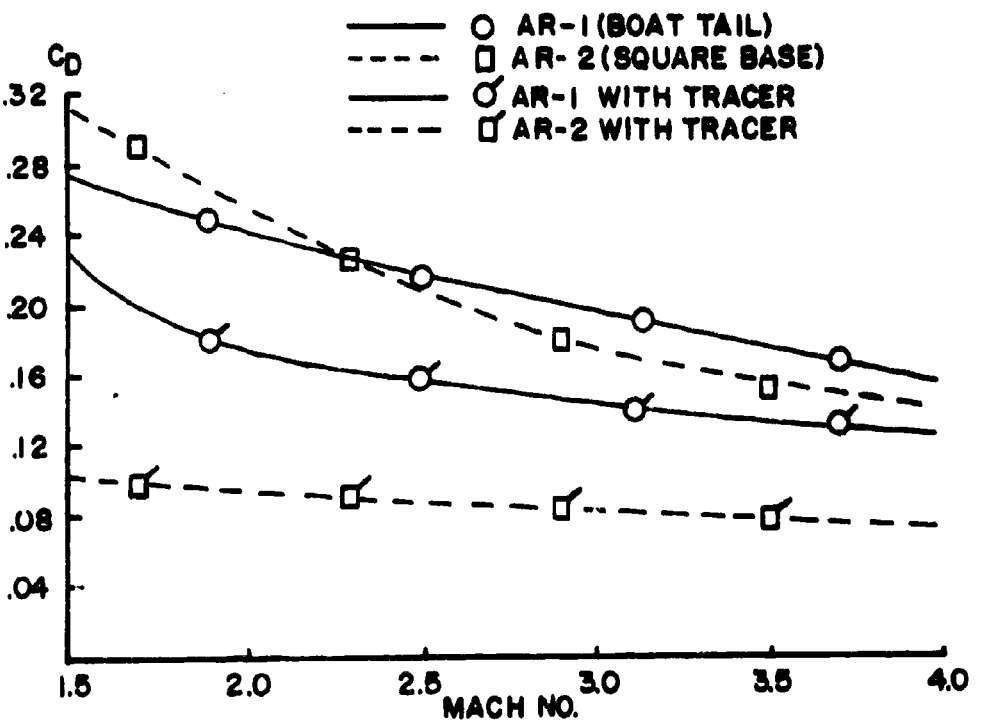

Figure B-6. Drag Coefficients of the Two AR Shapes With and Without Tracer

tracer-drag reducer is also included. In this example the drag coefficient is plotted as a function of Mach number. These two shapes were designed to have the same maximum range when fired from a cannon at a launch Mach number of three. The drag coefficient of the boattailed shape, AR-1, is the lower below about Mach 2.3, and would remain so for subsonic speeds also. Above this Mach number the square-based version with a longer ogive has the lower drag. Obviously an increase in the launch velocity requirement would lead to the square base being the better projectile, and a decrease would favor the boattail. The effect of the tracer assumption, since it reduces the base drag, lowers the drag of the square-base version dramatically, the boattailed version less so. At Mach 2 the AR-2 shows a decrease of 60 percent in the drag coefficient between the ball and tracer version, while the AR-1 shows a decrease of only 25 percent. The effect decreases absolutely as the Mach number increases, as it must from the assumption made, but the percentage improvements remain about the same.

The total drag has three components: the wave, or form drag, the skin friction drag, and the base drag. The variation of these components and their relative size for various types of projectiles explain most of the previous trends. The drag coefficient components for the various types are shown in Figure B-7 as a function of total length-to-diameter ratio for several Mach numbers. It can be seen that the frictional drag component is relatively small; it decreases with increasing Mach number and increases with length because it is related to wetted and not cross sectional area. Over the usual length range of bullets the variations in the frictional drag are not important, but it can become a major component for very long projectiles, such as flechettes. The square-based projectile's largest component is the base drag, more distinctly at Mach 1.5 than at 3.5. The form drag is considerably lower for the higher L_h/D designs. The picture reverses for the boattailed projectile. The direct pressures on the boattail add to the form drag, but the shape has a smaller base area and the base drag is less. This trade-off is Mach number sensitive.

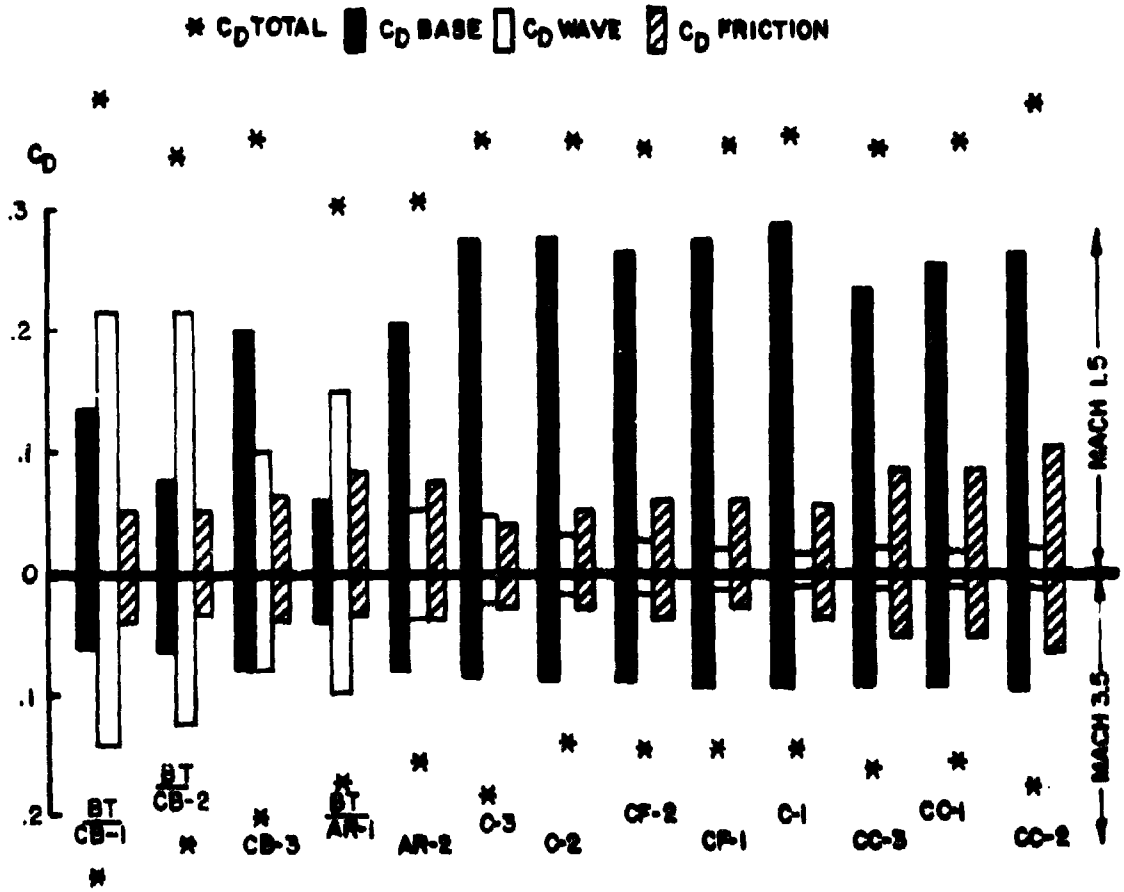

Figure B-7. Variation of the Drag Components as a Function of Length

C. Drag-to-Volume Ratio Considerations

The use of small projectiles, particularly if subcalibered, makes the concentration of more mass behind the smaller area desirable. Consider the previously given retardation factor in the dimensional form

$$\alpha = \frac{\rho \frac{\pi d^2}{4} C_D}{2\rho_p v d^3}, \qquad (3)$$

where ρ = air density, ρ_p = projectile density, d = diameter, and v = volume in cubic calibers.

It is apparent that if one just uses smaller and smaller projectiles of the same form and density the retardation in absolute units will vary as $(\frac{1}{d})$ and increase as the projectile becomes smaller; thus the ability to retain velocity becomes less. The above formula points at some possible ways around the problem; longer, cleaner projectiles improve the C_D/v ratio and higher density projectiles also can mitigate the trend. Some values of C_D/v were given in the main text, page 24, and an expanded version is given in Figure B-8. It is seen that for the shorter projectiles with relatively high C_D values impressive gains are possible by

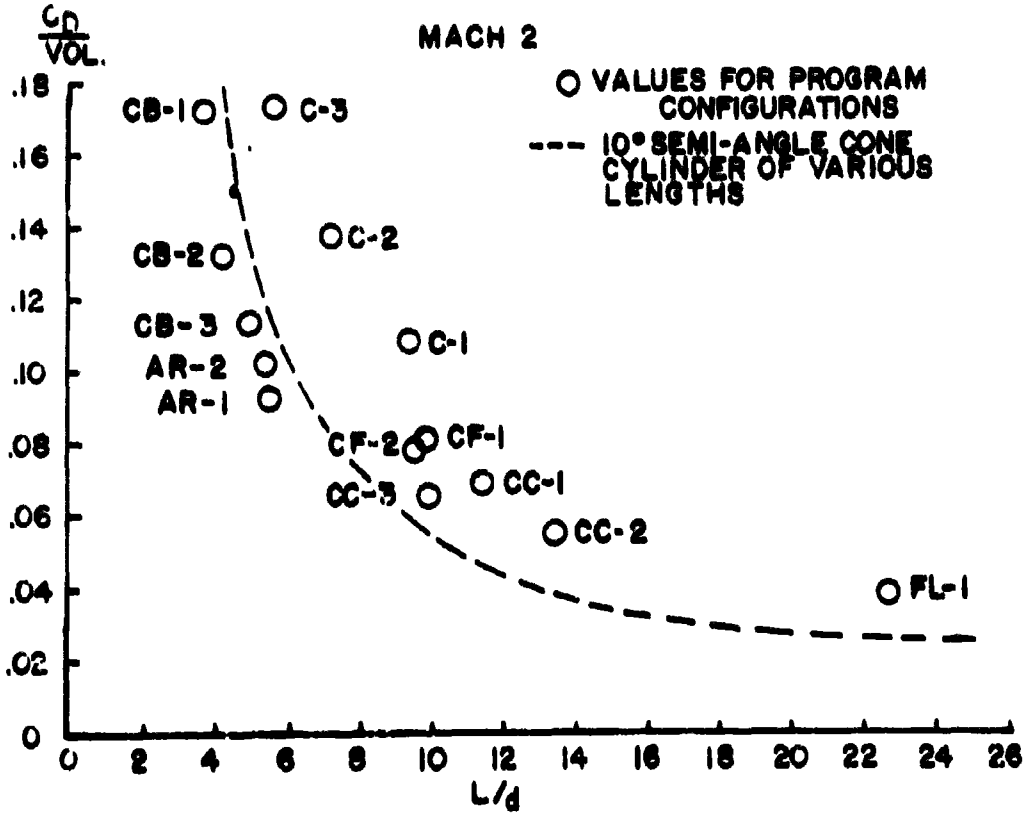

Figure B-8. Typical Variation of the Drag-to-Volume Ratio with Shape

cleaning up and small lengthening. However, once we have a relatively clean projectile on the order of five calibers long, the gains come more slowly. At first C_D/v drops almost linearly as L/D increases, since C_D varies little and the volume is increasing. Beyond the present scale, say for very long flechettes, the skin friction becomes more prominent, and this increases with length so that the drag-to-volume ratio tends to become more constant in this regime.

One can also visualize the curve as multiplied by a ratio of the proposed projectile density to that of lead, and it is apparent that the better 5 to 6 caliber long projectiles have enough C_D/v margin so that as a steel projectile they could have the same retardation as a lead CB-1, or could be about 30 percent smaller if of the same material. This indicates the rationale of the attractiveness of dense, low C_D/v projectiles for the smaller calibers. Since the tracer effect decreases C_D directly, it tends to give lower L/D projectiles with tracer the same performance level as higher L/D ballistic projectiles.

D. Deceleration Factor

The factor $\frac{\rho S C_D}{2m}$ has a particular significance and is often denoted by α and termed the deceleration factor. The previously given differential equation is then:

$$\dot{\underset{\rightarrow}{V}} = -\frac{\rho S C_D}{2m} V \underset{\rightarrow}{V} - \underset{\rightarrow}{g} = -\alpha V \underset{\rightarrow}{V} - \underset{\rightarrow}{g}. \qquad (4)$$

The α is a function of Mach number through the variation of the drag coefficient. If two types of projectiles have the same α function and the same initial conditions, then the integrated velocity histories must be the same. There are several useful rearrangements of the equation:

$$\alpha = \frac{\rho_{air} \pi d^2 C_D}{8 \rho_{proj} v d^3} = \frac{\pi}{8} \rho_{air} \frac{C_D}{v} \frac{1}{\rho_{proj} d} \cdot \quad (1/\text{meter}) \quad (5)$$

These are useful for a homogeneous projectile and v is the volume in

cubic calibers. The drag coefficient and the volume term are a function of the shape alone, while the factor $\rho_{proj}d$ reflects the size and material of the projectile. For a given projectile shape, the α will be the same for all projectiles for which $(\rho_{proj}d)$ is a constant. Thus a given computed case, the 7.62mm, 7.8 gm/cc, AR-2 case for example, also represents a 5.4mm, 11 gm/cc, AR-2 projectile and a 3.56mm, 16.7 gm/cc, AR-2 projectile. The various equivalent cases are tabled below.

Computed Cases		Diameter for Equivalent Cases		
Diameter mm	Density gm/cc	7.80	11.0	16.7
	7.80	-	3.89	2.61
5.56	11.0	7.94	-	3.71
	16.7	11.9	8.44	-
	7.80	-	4.55	3.06
6.50	11.0	9.29	-	4.33
	16.7	13.83	9.88	-
	7.80	-	5.40	3.56
7.62	11.0	10.46	-	5.08
	16.7	16.20	11.58	-

If C_D/v is considered part of the factor that is being held constant, e.g., $\left[\frac{C_D}{v}\frac{1}{\rho_{proj}d}\right]$ = Constant, other possibilities for a constant α factor occur. However, two different projectile shapes are not apt to have drag coefficients that are in constant proportion over an extended range of Mach number. Over a limited range of Mach number the condition can hold well enough to permit the concept to be useful.

Most rifle trajectories have little curvature and are classed as flat fire trajectories. The effect of the gravity component along the

trajectory can be neglected to a first approximation, and this permits a simplified velocity equation:

$$\dot{V} = -\alpha V^2, \text{ and with } \frac{dV}{dz} = V', \frac{V'}{V} = -\alpha. \tag{6}$$

This equation has the solution $V = V_o \text{Exp}(-\alpha z)$. The relation can be used as an interpolation or extrapolation mechanism for the existing computations. Given a plot of a computed case, subscript 1, and a neighboring case of interest, subscript 2, for which $V_{o1} = V_{o2}$ and the ratio α_1/α_2 is nearly constant over the region of interest, then:

$$V_1 = V_{o1}\text{Exp}(-\alpha_1 z) \quad \text{and} \quad V_2 = V_{o2}\text{Exp}(-\alpha_2 z).$$

Considering the condition for which $V_1 = V_2$ yields:

$$\text{Exp}(-\alpha_1 z_1) = \text{Exp}(-\alpha_2 z_2)$$

or
$$\alpha_1 z_1 = \alpha_2 z_2,$$

and
$$z_2 = \frac{\alpha_1}{\alpha_2} z_1. \tag{7}$$

Therefore, the velocity history of 2 is that of projectile 1 replotted on a scaled distance basis. Similarly it is clear that if two of the computed velocity histories are plotted as a function of range on a semilog scale then a third case with a value of α intermediate to the values for the first two can be interpolated, since:

$$\frac{\ln V_1 - \ln V_x}{\ln V_1 - \ln V_2} = \frac{-\alpha_1 + \alpha_x}{-\alpha_1 + \alpha_2}. \tag{8}$$

The concept of scaled distance and a nondimensional α has even further utility. The previous values of α have had the units of 1/range in the physical units used in the integration. However, the equation

$$V = V_o \text{Exp}(-\alpha z)$$

can also be written in terms of the calibers of travel of the projectile, or z/d, to define a nondimensional α:

$$\bar{\alpha}\,(z/d) = \alpha z$$

or
$$\bar{\alpha} = \alpha d = \frac{\pi}{8}\,\rho_{air}\,\frac{C_D}{v}\,\frac{1}{\rho_{proj}}\,. \qquad (9)$$

Thus $V = V_o\,\mathrm{Exp}(-\bar{\alpha}\,z/d)$ represents all projectiles of the same shape and a given material irrespective of caliber size, to within the assumptions used, if the distance scale is in calibers of travel. Examples showing the use and the range of validity of these methods are given in Appendix C.

APPENDIX C

EXAMPLES AND INTERPOLATION METHODS

The data produced in the report:

(1) Have a direct utility in that they can be examined for trends due to variation of projectile weight, initial impulse, and other parameters, and also provide a network that permits some quick comparisons of proposed cases by gross interpolation.

(2) Provide a basis, through the corrective terms supplied, for creating data for new cases neighboring those computed with essentially the same accuracy as the computed ones.

(3) Provide the basis for considering many apparently quite different cases than those tabulated by the use of various scaling rules.

In this appendix examples illustrating these facets will be given. Those examples chosen for the first purpose are presented as plausible real problems in order to permit some identification and to stimulate thinking up others more germane to the reader's interest. They will also be used to explain in detail some of the trends noted in Section III of the main text. The other examples are chosen primarily as mechanisms to explain clearly particular scaling methods. The first three examples use the tabulated results directly and are based on three hypothetical questions based on the situation stated below.

An existing 6.5mm rifle system is scheduled to be upgraded by product improvement. It currently uses the CB-1 lead projectile, has a dissimilar tracer round, and has an impulse level of 2.1 lb-sec (see CB-1-18). It is considered to have adequate remaining energy (defined as 500 joules for this example) at 750 meters. Possible ammunition and minor rifle changes are to be considered to "improve" the effective range to 1000 meters (in the remaining energy sense alone). Specifically it is asked:

(1) What bullet replacements for CB-1 are available and will any meet the "requirement" at the original impulse level?

(2) What are the problems of obtaining a matching tracer round?

(3) What is the implication of using only a tracer round?

A. Example 1. Investigation of a New Ball Projectile

Since only relatively conventional bullets are postulated, only a review of the tabulated results for the CB-1, CB-2, CB-3, AR-1, and AR-2 6.5mm cases is needed. The results for selected ranges are given in Table C-I and are summarized below:

(1) All of the high-density (16.7 gm/cc) projectiles, except CB-1, which is close, meet the longer range energy requirement; however, the initial energy and velocity levels are lower.

(2) Of the projectiles with the middle density, lead (11.0 gm/cc), only the AR-1 and AR-2 types strictly meet the condition of 500 joules at 1000 meters, but both the CB-2 and CB-3 cases are close. All cases have lower initial energy than the original projectile, although the CB-2 case is nearly equivalent.

(3) Of the projectiles with the lower density, steel (7.8 gm/cc), only the AR-1 and AR-2 shapes meet the condition of 500 joules at 1000 meters range. These cases also have higher energy and velocity than the base case at all points, an obviously attractive condition.

Comments on Example 1: The reasons for the previous rankings are simply explained. Figure B-8 shows that the CB-1 shape has a higher drag-to-volume ratio than the others and that the AR shapes are nearly on the low plateau of the high L/D shapes. Thus, for a given density, the CB-1 has the highest drag-to-weight ratio and loses velocity and energy in flight at a higher rate than the other cases. The CB-1 does have a low volume and hence weight, and under the impulse constraint can have higher initial energy. Assuming that only the projectile momentum and energy are significant (propellant gas energy losses negligible) and using the simplified velocity equation from Appendix B for a constant C_D yields:

$$V = V_o \, \mathrm{Exp}\left(-\frac{\rho_{air} \, S \, C_D}{2\rho_p v d^3} Z\right)$$

$$I_o = m_p V_o = \rho_p v d^3 V_o$$

Table C-1

Remaining Energy for 6.50mm Caliber, 2.1 lb-sec Impulse Cases

AR-1	11.0	7.77	846	2779	612	1454	507	998	412	659
AR-2	11.0	7.58	861	2809	624	1475	513	996	410	636
AR-1	7.8	5.51	1081	3218	730	1468	572	900	432	513
AR-2	7.8	5.37	1098	3239	754	1530	590	936	439	518

$$E_o = \frac{m_p V_o^2}{2} = \frac{I_o^2}{2m_p} = \frac{I_o^2}{2\rho_p v d^3}$$

and the remaining energy becomes:

$$E_R = \frac{\rho_p v d^3}{2} V_o^2 \, \mathrm{Exp}\left\{\left[- \frac{\rho_{air} S C_D}{\rho_p v d^3} \right] Z\right\}$$

The lighter projectiles will have the higher initial energies; however, if their C_D/m_p is larger than competitive projectiles, they will lose velocity more rapidly--this is the case for the CB-1 versus the others at the same density. In general, it loses its advantage within a few hundred meters. Two projectiles can be compared by the ratio of their remaining energies:

$$\frac{E_{R_1}}{E_{R_2}} = \frac{\rho_{p_2} v_2}{\rho_{p_1} v_1} \, \mathrm{Exp} \left\{ - \frac{\rho_{air} S}{d^3} \left[\frac{C_{D_1}}{\rho_{p_1} v_1} - \frac{C_{D_2}}{\rho_{p_2} v_2} \right] Z \right\}$$

For projectiles of the same density, if $\frac{C_{D_1}}{v_1} > \frac{C_{D_2}}{v_2}$ for $V_{o_1} = V_{o_2}$, the exponent is negative and the energy ratio decreases with range and will become less than 1 at some range even if the initial energy ratio was greater than 1. The interesting case occurs when $\frac{C_{D_2}}{v_2}$ is so much smaller than $\frac{C_{D_1}}{v_1}$ that a change to a lighter material is possible and will still leave,

$$\frac{C_{D_1}}{\rho_{p_1} v_1} \geq \frac{C_{D_2}}{\rho_{p_2} v_2} .$$

Now the initial energy ratio will be less unfavorable to projectile 2. If the change can be made and projectile 2 becomes lighter, then it will have the higher initial energy, hence a higher energy at all points. This is the case of the steel AR's versus the lead CB-1. The steel AR's

have an initial energy advantage over the lead CB-3 and CB-2, but their drag-to-volume ratio is not enough to make up the density change and their advantage decreases with range. Since the advantage extends beyond 1000 meters, the practical result, for the postulated problem, is a superiority.

B. Example 2. Matching Tracer Rounds for Example 1

Extending the previous case, consider the possible problems if a matching tracer round is also desired. While it is not essential, it would seem desirable that the tracer projectile be quite similar to the ball projectile. In the comparison of matching trajectories the velocity history of the base case, CB-1, and competitive cases are given for no tracer and for tracer conditions in Figure C-1. This figure shows that all tracer rounds have increased velocity* relative to the nontracer counterparts. The degree of the improvement is most for the square-based CB-3 shape and least for the highly boattailed AR-1 shape. Under the assumptions, the only option is to modify the head shape of the tracer projectile to increase the drag so that it is equivalent to that of the ball projectile. For the AR-1 an 18 percent increase would be required; for the CB-2, 20 percent; and for the CB-1, 35 percent. The square-based CB-3 would need a 65 percent increase. It is apparent that the more boattailed shapes require less drag increase to match. The potential candidates, such as the AR-1, then will be easier to match than was the CB-1.

It should be noted that the simplifying and general assumptions made have an effect. (1) The tracer projectile was assumed to have the same weight and shape as the ball projectile--actually one would expect it to be a little lighter and hence have a higher initial velocity and a higher rate of falloff. (2) The tracer was assumed to operate through the base pressure only, thus differentially influencing square-based and boattailed projectiles. (3) The tracer was assumed not to influence the flow forward of the base--this is the logical first approximation for supersonic flow conditions. However, rocket motors and tracer elements have been observed to produce plumes and induce flow separation forward of the base for steep boattails--this would change the drag level.

In addition to the above, two other occurrences are notable; the first was expected, the second accidental. (1) The remaining energy of the lead CB-1 with tracer is now 655 Joules, well above the "requirement," and hence commitment to only a tracer round would be a technically valid solution. (2) The lead CB-1 tracer has slightly lower initial velocity and a slightly lower rate of falloff than the steel ball AR-1. Decreasing the weight of the CB-1 will increase initial velocity and increase velocity falloff. It would appear that decreasing the weight of the lead CB-1 tracer by about 6 percent would yield a near match--assuming that the quite dissimilar projectile family was acceptable.

C. Example 3. Consideration of a Tracer Projectile as the Prime Round in Example 1

The shape favoritism shown in Example 2 warns that the spectrum of consideration should be reopened. The five shapes given in Table C-I for the ball projectile are given for the tracer condition in Table C-II. The tracer introduction has markedly changed the selections; the square-based projectiles now dominate almost completely. The table shows that all projectile types improve in remaining velocity but that the low-drag square-based models show by far the most dramatic effect. The preferred projectiles are now clearly the AR-2 and, other factors considered, the CB-3. The remaining energy of these projectiles exceeds the hypothetical 1000-meter requirement by so much that if this were the only requirement (an unlikely situation) the initial impulse level of the weapon could be considerably reduced. Again we note that the tracer assumption used has a distinct impact on the magnitude of the effects quoted; however, the differences between the ball and tracer rounds are so large that it is doubtful that modifying the assumptions would change the qualitative picture presented.

The table also shows another significant trend. In this caliber, increases in density of the projectile always yielded improved remaining energy beyond about 500 meters for the ball projectile. For the square-based tracer cases and even the boattailed AR-1, the optimum density at 1000 meters is clearly less than that of tungsten and perhaps lower than

Table C-II

Remaining Energy for 6.5mm Caliber, 2.1 lb-sec Impulse-Tracer Cases

	Range →	0	250 meters	500 meters	750 meters	1000 meters
Case	Density gms/cc	Remaining Energy - Joules				
CB-1	7.8	3391	2173	1318	758	402
CB-1	11.0	3133	2217	1528	1022	655
CB-1	16.7	2557	1985	1516	1135	840
CB-2	7.8	3317	2218	1418	862	490
CB-2	11.0	2943	2146	1527	1055	704
CB-2	16.7	2335	1840	1430	1095	822
CB-3	7.8	3187	2539	2003	1563	1204
CB-3	11.0	2738	2298	1918	1591	1310
CB-3	16.7	2132	1873	1642	1434	1244
AR-1	7.8	3218	2440	1795	1265	846
AR-1	11.0	2779	2202	1705	1284	939
AR-1	16.7	2172	1787	1453	1171	938
AR-2	7.8	3239	2771	2355	1990	1670
AR-2	11.0	2809	2485	2192	1926	1687
AR-2	16.7	2204	2013	1836	1673	1522

that of lead in some cases. Thus, when two methods that optimize remaining kinetic energy are used together, the resultant trend is less obvious.

The concepts that appear in the first three examples are summarized below to reinforce the previous comments of the main text and to enlarge on them. On the sole basis of remaining energy at longer ranges:

(1) Low values of C_D/v are needed.

(2) Relatively long, highly boattailed shapes are the most attractive for ball projectiles with an average Mach number less than about 2.0--stability considerations apart.

(3) The use of the more highly boattailed configurations makes ball and tracer matching with nearly similar configurations easier.

(4) Low-drag, square-based projectiles are favored quite markedly if a tracer projectile is considered either as the prime or as the only round.

(5) Some shell shapes have a sufficient margin of C_D/v over standard bullets that they can afford to have densities equivalent to steel. This results in higher energies over the whole trajectory for a fixed initial impulse. This would be at the expense of higher stabilization twist requirements and, probably, longer rounds.

(6) The tracer-on effects are so large on the low-drag, square-based projectiles that reliability of tracer operation could become a serious factor in accuracy of fire at longer ranges.

In the first three examples there were evidences that various parameters systematically affected the remaining energy as a function of range. The next example will be an explanation of these trends; it will also show the difficulties of focusing too closely on a single variable, or on the use of too simple a model, for the purpose of extrapolating trends.

The next series of examples are devoted to treating cases which are variants of the computed cases. The background for the methods are explained in Appendices A and B.

D. Example 4. Examination of the Drag-to-Weight Ratio on Remaining Energy as a Function of Range for Various Impulse Levels

This problem will be approached by examining a single shape, CB-1, in a single caliber, 5.56mm. This means that the drag-to-weight ratio varies only with the density of the projectile. The remaining energy level as a function of range for the three tabled impulse levels and densities is plotted in Figure C-2. At the lowest impulse level, 0.8 lb-sec, the lightest projectile has the highest energy level until about 275 meters; the heaviest one has the highest energy level beyond about 310 meters. The 1.2 lb-sec impulse level is more distinct; the lightest is "best" until 210 meters, and the heaviest beyond about 400 meters. It would appear, from these cases, that there is an optimum density which will yield maximum remaining energy at a given range. The highest impulse level plot breaks the pattern; the lightweight steel projectile is never in contention, and the lead projectile is superior to the tungsten projectile only to about 100 meters.

Comments on Example 4: Under the simplified assumptions used earlier, constant drag coefficient and no propellant gas energy losses, the initial energy is:

$$E_o = \frac{I_o^2}{2m_p}$$

and the remaining energy is:

$$E_R = \frac{I_o^2}{2m_p} \text{Exp}(-\rho_{air} S\, C_D/m_p)z.$$

As the projectile mass decreases, the momentum level constraint permits the initial energy level to increase. The velocity decay exponent also contains m_p in the denominator, however, and energy is dissipated more rapidly. At short ranges the increased initial energy is more relevant, but as the range increases the dissipation rate will become more important. The equation for E_R can be differentiated with respect to m_p and set equal to zero to yield an optimal condition for a given range of

$z = R$. This yields the simple relation

$$\frac{\rho_{air} S C_D}{m_p} = \frac{1}{R} .$$

Since, for this case, ρ_{air}, S, C_D, and volume are constant, the projectile density factor controls the equation. The longer the range of primary interest, the more dense the projectile should be. This simplified expression predicts about 200 meters as the optimum range of a steel CB-1 and about 350 meters for the lead 5.56mm case. This is in general agreement with the actual results for the two lower impulse computations. The simplified equation is not a function of impulse level so that it is apparent that something has gone wrong with the assumptions for the higher impulse case. The steel and lead CB-1 cases for this impulse level are also very high initial energy and velocity cases, and the gas momentum energy losses are becoming dominant. (See Figure A-5.) The printed cases reveal this fact only indirectly, through the velocity and propellant charge terms, since neither initial energy nor peak pressure was a variable in the net.

The low-impulse, heavy projectile case also furnishes an instance where a strange solution appears; that is, the velocity levels of the optimum case are clearly not in the rifle category. It should be clear that in using the results one should keep in mind the physical system that is being implied--or strange "solutions" can appear. The high-velocity cases were retained because flatness of fire and energy density can also be important in selecting a system, and this suggested that the computations should not be truncated arbitrarily as long as the computational process was still valid. It was recognized that the low-velocity, heavy-bullet case was not strictly in the rifle picture; however, they added little to the total effort, and they do furnish a limited basis for considering carbine and submachine gun cases.

E. Example 5. Comments on the Use of the Same Flechettes in Various Caliber Weapons

The subcaliber flechette with its high velocity, and hence significant gas energy and momentum losses, and the tare of the sabot shows a more complicated behavior than the lower velocity full-bore projectile samples. In Figure C-3 the total projected energy of the flechette and its sabot, as a function of the total projected mass, is given for the three calibers and the three impulse levels. The high impulse level shows the trend most strikingly; initially the energy of the projected parts increases very strongly as the projected mass increases. This is in contrast to what would be expected if the momentum of the projected parts was the dominant factor in the process; then the energy for the projected parts would be:

$$E_{o_{m_p}} \approx \frac{I_o^2}{2(m_p + m_s)} .$$

This would yield a decrease in initial energy for any increase in total mass projected. Instead, the energy increases and peaks in the vicinity of 4 grams and then the curve turns downward as the mass of the projected parts becomes dominant. In Figure C-3, representing the steel, lead, and tungsten, 1.78mm flechette cases are shown on the curves. For the 2.1 lb-sec impulse case, they are all on the rising part of the curve. Obviously the heaviest projectile is best, and it is not heavy enough to yield maximum interior ballistic efficiency. Since the heaviest projectile of the same size will also have the least retardation, the case will also be the best at all ranges.

The shape of the total projected energy curve is dependent on the interior ballistic assumptions made. In the case of the lower impulse constraints, the velocity levels are lower and the curve peaks earlier; in fact, the lowest impulse level of 0.8 lb-sec indicates that the tungsten projectile has a lower total projected energy level than the lead one for the 5.56mm caliber. The steel flechette yields the highest projected total energy in the larger calibers. Because the energy

distribution between the sabot and projectile depends on their relative weights, the maximum flechette initial energy maximizes at a different point than does the projected metal parts energy.

The energy of the flechette is also plotted in Figure C-4. For the 5.56mm, 2.1 lb-sec impulse case the curve has been computed beyond the three different flechette points, and it is seen that the peak is at higher total projected weights than that of the total projected energy because of sabot tare. Excepting possibly the 0.8 lb-sec, 5.56mm case, the tungsten flechette is still too light to develop maximum initial energy. Since this is about the largest flechette of this design, FL-1, that can be housed in the 5.56mm and a density much above that of tungsten is improbable, the tungsten 1.78mm flechette is about the best that can be done even if it is really too light for the higher impulse cases. For the larger calibers, larger size projectiles could be housed, and the results of the fixed size program of FL-1 are not conclusive because the larger size possibilities were not considered. Restricting ourselves to the same size flechette with various densities, the net results are:

(1) The densest 1.78mm flechette of the FL-1 design is always best with initial energy as criteria; however, only in the case of the 5.56mm, 0.8 lb-sec impulse case is it probably near optimum.

(2) For the 1.78mm flechette the densest projectile will also have the highest energy retention, and hence it is also the best at longer ranges--in the remaining energy sense, of course.

(3) The 1.78mm tungsten flechette is nearly optimum only for the 5.56mm case at 0.8 lb-sec impulse; all other cases optimize at heavier weights of projectiles. The larger caliber guns could achieve more optimum performance if larger flechettes, which they could house, were used.

These conclusions would appear to be based on a peculiarity of the high-velocity region; however, the same general trends appear if the momentum of the projected parts dominates and the simplified momentum equation is a good approximation;

$$I_o = (m_s + m_p)V_o$$

and

$$E_o = \frac{I_o^2}{2(m_s + m_p)} .$$

Since we are dealing with a fixed flechette size, the sabot weight, $2\,\rho_s \frac{\pi}{4}(D^2 - d^2)D$, increases with the gun caliber and the sabot losses cut into the energy. Conversely, the increase of projectile weight via the density increase decreases the sabot tare ratio. This is large for the 3-diameter fin span flechette, and hence the net result is a gain.

While this would appear to have disposed of the problem of shooting the same flechette in various guns as being non-optimum; in fact, creating a multitude of flechettes is expensive and the question of what a given flechette would do in a different caliber is valid. For the particular flechette design, in this case the FL-1, the velocity and energy curves are unique for each projectile density. The energy curves are plotted in Figure C-4. One can enter these curves at any point, as will be shown for the velocity curves in Example 7. If the present assumption on total parts projected energy is accepted, then we can investigate the effect of being able to reduce the sabot weight to half of the present assumption. The 5.56mm tungsten case is assumed. If the sabot weight of 0.49 grams is halved, the total projected energy of the sabot and flechette would decrease from 1920 to 1880 Joules due to poorer interior ballistic efficiency, but the better ratio of projectile to sabot mass weight would yield an increase of projectile launch energy from 1430 to 1600 Joules. Entering the tungsten curve in Figure C-4 at this latter point and reading 1100 meters further on yields 750 Joules. This is 25 percent higher than the base case at 1100 meters, and hence the gain by improved saboting is important.

Table C-III

Kinetic Energy (Joules) and Velocity (mps) at the Muzzle for FL-1

		0.8 lb-sec Impulse			1.2 lb-sec Impulse			2.1 lb-sec Impulse		
		Steel	Lead	Tungsten	Steel	Lead	Tungsten	Steel	Lead	Tungsten

F. Example 6. Discussion of the Effect of Varying the Diameter of a Subcaliber Projectile

In the design of a subcaliber projectile for a given weapon system, one optimization parameter is subcaliber diameter. The subcaliber case SC-1 for 6.5mm bore diameter will be used for this discussion. This projectile has the exterior profile of CC-1, but has been constructed as a bimetallic projectile--tungsten, aluminum, and tracer material being the materials used. Mass distribution has been chosen to insure static stability; i.e., spin is not necessary. As a result of the choice of distribution, the projectile has an average density of 4.08 gm/cc and is relatively light. With remaining kinetic energy as the criteria, the energy level variation will be discussed at fixed ranges of 0 meters, 400 meters, and 1100 meters (Figure C-5 (a), (b), (c), with and without tracer).

1. Kinetic Energy of Projected Metallic Mass as a Function of Diameter of Projectile.

The plots (a), (b), and (c), Figure C-5, demonstrate kinetic energy as a function of projectile diameter at impulses of 0.8, 1.2, and 2.1 lb-sec, respectively. For projected mass, the combined mass of projectile and sabot, the data for (a) and (b) depicts maxima at 4mm and 5mm, respectively, with (c) not attaining a maximum by full caliber. The initial positive slope of kinetic energy with increasing diameter (which implies increasing projected mass) seems strange, using the simplified argument presented in a previous example. With the constraint of constant impulse,

$$(m_p + m_s)V_o = I_o,$$

then the initial kinetic energy is

$$E_o = \frac{I_o^2}{2(m_s + m_p)} .$$

This implies that increasing projected mass should decrease initial

kinetic energy. However, as in all simple ("crude") arguments, often a term becomes significant and an effect is unexplainable.

Looking back to Figure A-5, one observes that the momentum of the projected mass at high speeds becomes a smaller percentage of total momentum of projected weights and gas combined. This indicates, as A-5 shows, that

$$I_o = (m_p + m_s)V_o + f$$

where f represents a gas tarage and is increasing with velocity increase.

Returning to the plots of kinetic energy, Figure C-4, the shape of the curves state:

(1) For (a) and (b), at the smaller diameters, which is in the higher velocity regime, f is high. The effect of increasing diameter decreases velocity, increasing markedly the interior ballistic efficiency. Thus, initially the total energy increases with increasing diameter. Then, as the velocity decreases further (diameter increases), the gain in efficiency is less and the total energy curve peaks, after which the curve begins to behave qualitatively as the simplified argument implies.

(2) For (c), the increase in ballistic efficiency dominates throughout, and no maximum is attained.

2. Kinetic Energy of Projectile at Muzzle as a Function of Diameter of Projectile.

[Brief Aside: Given a positive function g(x) with a maximum at x_o, if h(x) is a monotonically increasing positive function, then the maximum of G = gh is shifted in the direction of increasing x, i.e.,

$$G'(x_o) = g'(x_o)h(x_o) + g(x_o)h'(x_o) > 0.]$$

The kinetic energy of the projectile is

$$E_{o_p} = \left(\frac{m_p}{m_p + m_s}\right) E_{o_{\text{projected mass}}}$$

By the property in the brief aside, the maxima of (a) and (b) will be shifted toward the larger diameter. For case (c) where h' is always positive, an expansion of the brief aside shows the slope remains positive; i.e., a maximum will not be attained. This indeed is the effect observed.

3. Kinetic Energy of Projectile at a Fixed Range as a Function of Diameter of Projectile.

By equations previously demonstrated (Example 1),

$$E_{R_p} = \frac{m_p V_o^2}{2} \text{ Exp } \left[\frac{-\rho_{air} S C_D^2}{\rho_p v d^3} \right]$$

$$= E_{o_p} \text{ Exp } \left[\frac{-\rho_{air} S C_D^2}{\rho_p v d^3} \right]$$

The exponential is a monotonic increasing function of d, for constant C_D and range. The effect of this function, all other things constant, is again to move the maxima to the right. Observe (a) and (b) at 400 meters and 1100 meters, with tracer. It also keeps the slope of (c) always positive. In summary, if kinetic energy is the criteria for "goodness," then for this example:

(1) The better interior ballistic efficiency indicates larger diameters (decrease gas tarage).

(2) The amount of sabot tarage indicates still larger diameters (decrease sabot tarage).

(3) Retardation favors the larger projectiles and again indicates still larger diameters (decrease retardation).

G. Example 7. Use of the Plotted Velocity, or Energy, Curves of a Computed Case to Obtain the History of a Lower Velocity Case

The flat fire assumption permits the use of the given velocity, or energy, curves over a wider spectrum. Under these conditions, the highest velocity case for a given size, weight, and shape of projectile

contains the histories of all lower velocity cases within its span of velocity. The range coverage will be less than the 1100-meter span of the original case, however. This was noted in the main text because of its utility and is shown in more detail below.

The 5.56mm lead CB-3 case (page CB-3-8) at 1.2 lb-sec impulse is plotted in Figure C-6. This case has a muzzle velocity of 772 mps, while the same bullet at an impulse of 0.8 lb-sec has an initial velocity of 557 mps. If we interpolate the first curve (Figure C-6) for the 557 mps point, it occurs at a range of 359 meters. By picking this as the origin of a new range scale, the second computed case (page CB-3-7) plots on the original curve as is shown. Since $E = mV^2/2$, the remaining energies could be plotted in the same way and new cases similarly investigated.

In order to deal with an unknown case as an example, suppose that it is desired to fire the previous projectile at an impulse level of 1.0 lb-sec. To start the procedure the corresponding muzzle velocity must be determined; this can be done using either the equations or the nomograph (A-3) in Appendix A. The latter indicates that a muzzle velocity of 670 mps corresponds to the 1.0 lb-sec impulse for this bullet. This velocity occurs at 169 meters for the original curve in Figure C-6; the range scale for this new case is set up at the bottom of the figure. If the full range of the original case, 1100 meters, had been plotted, information on this new case would be available for 931 meters without extrapolation. It is, of course, not essential to construct the new scale physically nor to even plot the original, since the tabulated data can be interpolated for the new range zero and each tabulated range point, z_{tab}, taken to correspond to $(z_{tab} - z_o)$ for the new case.

H. Example 8. Construction of the Velocity History for a Neighboring Case Using the Differential Velocity Correction

Assume that there is a companion projectile to the 5.56mm lead CB-3 projectile; it is a jacketed steel and carbide AP projectile weighing 10 percent less than the ball projectile but fired at the same velocity, 773 mps. Having the velocity history of the basic CB-3 case, what is

the velocity history of the companion projectile? Since the projectile weight is in the denominator of the retardation expression, the 10 percent weight change yields an effect equivalent to about an 11 percent drag coefficient change; thus eleven times the listed unit effect, change in velocity for 1 percent change in drag, must be applied. The base case and the postulated AP projectile case derived from it are partially tabled below.

Table C-IV

Base Case			Derived Case	
5.56mm Lead CB-3 (Page CB-3-8)			5.56mm AP Projectile, 10% Lighter	
Range meters	Velocity mps	$\Delta V/\%C_D$ mps	Correction mps	Velocity mps
0	773	0	0	773
200	650	-1.2	11.3	639
400	534	-2.2	24.2	510
600	429	-3.0	33.0	396
800	341	-3.1	34.1	307
1000	295	-2.0	22.0	273

At the correction level of about 10 percent, errors are due primarily to the rounding off of the unit effect, change in velocity for 1 percent change in drag, at 0.1 mps and the velocity at 1 mps, and hence the created case is essentially as accurate as the basic tabulated case. While the correction term can often give adequate results for considerably larger percentage changes, the resultant accuracy level is not readily predictable and hence the use of corrections involving much more than ten times the correction term is not recommended.

The same table would also serve, as noted earlier, if the difference had involved a 10 percent increase of air density, or if it involved another projectile which had a 10 percent higher drag coefficient over the region of interest. Dissimilar projectile shapes are not apt to have similar drag coefficient curves over the entire range of subsonic,

transonic and supersonic speeds. However, for utility purposes when the region of interest is only subsonic or supersonic speeds, it can be assumed dissimilar projectiles have nearly equal or nearly proportional drag curves for a considerable range.

I. Example 9. Effect of Crosswind on the Trajectory

The printed tables also contain the time of flight to each range point. For flat fire conditions this permits a good determination of the crosswind effect on the path of the projectile by multiplying the lag time (time of flight minus vacuum time of flight) by the magnitude of the crosswind velocity. The vacuum time of flight is simply the range divided by the muzzle velocity. The direction of the drift is downwind. Some sample results are given below.

Table C-V

Downwind Deflection for a Crosswind of One Meter per Second
6.5mm Projectiles, 2.1 lb-sec Impulse Cases

	CB-1 (11.0 gm/cc)	AR-1 (11.0 gm/cc)	CB-3 (6.8 gm/cc)	CB-3 (6.8 gm/cc) with Tracer
Range (meters)	Inflection (meters)	Deflection (meters)	Deflection (meters)	Deflection (meters)
0	0	0	0	0
200	0.042	0.030	0.034	0.014
400	0.185	0.139	0.157	0.067
600	0.467	0.329	0.410	0.150
800	0.850	0.609	0.784	0.284
1000	1.312	0.948	1.277	0.467

J. Example 10. Mapping the Velocity History of a Family of Flechettes

The relatively high velocity flechettes furnish a good condition for using the caliber scaling rules for extending the computed cases, since they do fit the flat fire assumption over a wide range. When the

velocity history can be represented by

$$V = V_o \, Exp(-\alpha z)$$

adequately, the equation can also be transformed to a calibers of travel basis (z/d) from the real distance variable z. Thus, as noted in Appendix B, Z = z/d, or

$$\frac{\rho \frac{\pi d^2}{4} C_D z}{2\rho_p v d^3} = \bar{\alpha} (z/d)$$

and

$$\bar{\alpha} = \frac{\rho \frac{\pi}{4} C_D}{2\rho_p v} .$$

The latter is independent of everything but the shape of the projectile and its density. It follows that all projectiles of the same shape and density, if fired at the same velocity, have the same velocity history curves if they are plotted in terms of calibers of travel. Thus the velocity of a 3.56mm flechette at 200 meters will be the same as that of a 1.78mm flechette of similar shape and material at 100 meters, if the launch velocities are the same. A construction on this basis for a range of flechette sizes is given in Figure C-7. On a given material basis, this represents steel flechettes of various sizes. However, we note that the real distance equation for α is invariant whenever the product $(\rho_p d)$ in the denominator is invariant. The steel (7.8 gm/cc) projectile of 1.78mm diameter is also then equivalent to a 3.9 gm/cc model of 3.56mm diameter, or any combination that is equivalent. This has been used to double-code the curves for various size and weight combinations to extend their utility. The procedure can be used to identify the tungsten 1.78mm flechette curve, and this has been done as an extrapolated exceptional case labeled as such in Figure C-7; the actual case, on page FL-1-10, is plotted also. At the plotting scale the difference is not noticeable, although an extrapolation from the 7.8 gm/cc 1.78mm flechette case by over a factor of 2 has been made. It was noted, however, that the flechette case is quite favorable for extrapolation.

Figure C-7 has been constructed so that it can be used to estimate the velocity falloff of various sizes of steel flechettes directly, assuming the muzzle velocity is known. This is done by applying the method of Example 7. In a more indirect manner, the chart may also be used to compare flechettes of the FL-1 type in various sizes and densities. The curves in Figure C-7 also represent constant values of $(\rho_p d)$. For example, an aluminum flechette (2.7 gm/cc) 5.8 millimeters in diameter would have a $(\rho_p d)$ product of 15.7 and hence would have a velocity history curve that would lie midway between curve (b) (13.9 gm mm/cc) and curve (c) (17.4 gm mm/cc) on Figure C-7.

K. Example 11. Computation of Twist Required to Stabilize a Bimetallic Cone Cylinder

Assume that there is a proposed 6.5mm, CC-3 shape projectile whose construction is tungsten (16.7 gm/cc) nose, to the juncture of cone and cylinder, and the cylinder section is aluminum (2.7 gm/cc). What twist is required for a gyroscopic stability factor (s_g) of 1.4, if launched at a velocity corresponding to a Mach number of 1.5?

Physicals		Aerodynamics	
m	= 10.409 gm	C_{N_α}	= 2.59
I_x	= 0.3694 gm cm^2	C_{P_N}	= 5.47 cal
I_y	= 14.6177 gm cm^2	C_{M_α}	= (c.m. - C_{P_N})C_{N_α}
c.m.	= 5.94 cal		= (0.47)2.59 = 1.22

From the equation for s_g on page 647, nondimensional spin (twist) is

$$\frac{pd}{V} = \left[\frac{1.4\,\pi\, I_y \rho d^5 C_{M_\alpha}}{2I_x^2}\right]^{\frac{1}{4}} = 0.0322 \text{ rad/cal.}$$

This is equivalent to 1.0 rev/7.96 in.

13. ABSTRACT

The report is a compendium of the ballistic properties of projectile shapes of possible interest in small arms applications. The shapes cover a range of L/D ranging from conventional bullets (~3.5) to that of flechettes (~20) and include such shapes as cones, cone cylinders, and cone flares. The ballistic properties are mapped over a range of calibers and projectile densities. A drag-reducing tracer is included as one of the prime design considerations as a means of reducing base drag. Tabulations include velocity, energy, angle of fall, time of flight, and height as a function of range, with constraints on recoil momentum. Aerodynamic coefficients are also included.
