FOREWORD

This report documents test activities performed under the auspices of the Degradation Effects Program (DEP) between June 1968 and May 1969. DEP consists of three working groups: Test and Data Acquisition (TDAWG), Methodology and Evaluation (MEWG), and Environmental Characterization (ECWG). Fuze function data obtained by TDAWG may be found in ADTC-TP-70-198 and PGOWQ-3 data to be published. Acknowledgement is extended to Mr J. Brown of the U. S. Army Engineers Waterways Experiment Station (WES) for his training and data gathering techniques and equipment usage, and to Mr R. F. Brandt and personnel of Range 22, all of DLRD, Eglin Air Force Base, Florida.

This technical report has been reviewed and is approved.

CHARLES K. ARPKE, Lt Colonel, USAF
Chief, Technology Division

ABSTRACT

Test data was obtained by Environmental Characterization Working Group from two sand test sites to determine how selected environmental factors affect fuze functioning. The sand is described in terms of density, percentage moisture, and penetrometer readings, and each of these was evaluated to determine its variability. Regression analysis tests were performed to determine if a relationship existed between the variables. The variables were first paired by test site and were then combined to learn if one of the variables could be predicted by knowing another. Linear correlation of the variables was also evaluated. The data is based on a controlled environment and the results should not be applied to other environments.

Distribution limited to U. S. Government agencies only; this report documents environmental conditions under which experimental and/or conventional munitions were tested; distribution limitation applied April 1971. Other requests for this document must be referred to Air Force Armament Laboratory (DLRD), Eglin Air Force Base, Florida 32542.

SECTION I

DESCRIPTION OF TEST RANGES

Investigations into the effects of a sand environment on munitions were conducted on Test Area (TA) B-76 and TA C-72 on the Eglin Air Force Base Reservation. TA B-76 was the site for static arena tests and for testing small conventional and/or developmental, munition items that were delivered by a pneumatic air gun (avalauncher). TA C-72 was the locale for testing munition items used in dynamic, or air-delivered, tests.

TA B-76 is in the northwest section of the Eglin Reservation at latitude 30°35' north and longitude 86°52' west, lying in the Yellow River basin and bounded by Bear Creek and Boiling Creek. The test site elevation is 20.2 feet (Figures 1 and 2). The soil was brought in from a nearby sand pit, and the results of the soil analysis are found in Figures 3, 4, and 5.

TA C-72 is located in the northeast portion of the Eglin Reservation at latitude 30°38' north and longitude 86°19' west, and at a recorded elevation of 199 feet. The test site is located on the top of a hill and has a gentle downward slope to the northeast (Figures 6 and 7). Soil for these tests was insitu (its natural and original position). Analyses of these samples and their findings are presented in Table I and Figure 8.

SECTION II

SOIL PREPARATION

Prior to testing, Sand I was described as loosely packed and having a low moisture content. Upon test implementation, Sand I characteristics data were modified to reflect a low moisture content and constant density. Penetrometer readings were taken as follows: surface, less than four; at a depth of 7.5 cm (3 inches), about 15; and at 30 cm (12 inches), not greater than 100 on the cone index gauge. To achieve these conditions, a soil stabilizer churned the sand to a depth of 30 cm. This process fluffed the soil for the penetrometer readings and aided in drying. Figures 9 and 10 show a field that has been prepared for testing.

Two observations were noted after the field had undergone preparation. The soil would crust rapidly to a depth in excess of one inch when high winds followed a rain. The top layers of soil would also crust when exposed to the sun for long periods of time. High penetrometer readings at surface reflect the degree of this crusting action. Figure 11 depicts crusting action as noted by the different shades of the soil. The top layer, which has dried and crusted, appears light in color, whereas the lower layers are quite moist and appear darker.

If a munition item landed in the tracks of the soil stabilizer, fuze function was not accepted as a valid data point.

Figure 11. Procedure for Taking Soil Samples

SECTION III

EQUIPMENT AND METHOD

The cone penetrometer consists of a pressure ring; a gauge, which measured the cone index reading from zero to 100; two 50.5 cm metal rods that are notched at increments from 2.5 to 15 cm (1 to 6 inches), at 22.5 cm (9 inches), and at 30 cm (12 inches); and a cone, which has a 3.22 sq cm (0.5 square inch) surface. With the 3.22 sq cm cone, index readings may be read directly into pounds per square inch, on a one-to-one correlation.

As the penetrometer was pushed into the ground with constant pressure, cone index readings were recorded as shown in Figure 12. Care was taken to set the scale at zero before each probe. Penetrometer data may be found in the Appendix.

Adjacent to where the penetrometer readings were taken, a soil sample was then extracted by means of a volume cylinder to determine the moisture content and density. The soil sample came from the 5.0 to 10.0 cm depth band as shown in Figure 11. It was then put into a can, sealed, and later weighed. After drying for 24 hours under controlled conditions, its dry weight was recorded. Moisture content and wet and dry densities were then calculated and are presented in Table II.

Wet Density = 0.24 (Wet soil weight in grams)

Dry Density = 0.24 (Dry soil weight in grams)

Moisture Content = $\frac{\text{Water weight in grams}}{\text{Dry soil weight in grams}}$

Where 0.24 is a constant for the volume cylinder.

SECTION IV

ANALYSIS

1. MEASUREMENTS OF VARIABLES

An examination of the measurements of the variables indicates how homogenous the test media was prepared. Since the soil sample came from the 5.0 cm (2 inch) to 10.1 cm (4 inch) depth band, the penetrometer, P, reading at a depth of 7.5 cm (3 inches) was chosen to correspond with the dry density, D, and percentage moisture, M. Data obtained from station numbers 694, 699, 700, 701, and 702 were not included in the analysis as they represented static tests conducted where the soil was not tilled. A frequency plot of each variable by range is found on Figures 13, 14, and 15. Additional properties of the variables may be found in Table III.

The coefficient of variation describes the amount of variation of each variable and is defined:

$$C = \frac{s}{\bar{x}} \times 100$$

where C is the coefficient of variation
s is the standard deviation of the variable and
 $\bar{x}$ is the mean deviation of the variable, expressed in percent.

C is relative to the magnitude of the mean.

The standard error is defined as follows:

$$\frac{s}{\bar{x}} = \frac{s}{n}$$

where: s is the standard deviation of the mean and
 $\bar{x}$
n is the number of samples.

The standard error from combining both ranges indicates a good estimate was obtained for the variable means. Plots of confidence levels on variable means, with the standard errors noted, are found on Figures 16, 17, and 18.

Table IV contains the average cone index values for all penetrometer readings taken on TA's B-76 and C-72, and the combined ranges. Figures 16, 17, and 18 show the confidence band width at any desired confidence levels from 50 to 99.9 percent.

2. RELATIONSHIP OF VARIABLES

A plot of the raw data, using paired variables, failed to show much of a relation (Figures 19, 20, and 21). Calculation of their correlation coefficient, r , is another method of measuring the relationship of the paired variables:

$$r = \frac{\sum (x_i - \bar{x}) (y_i - \bar{y})}{\sqrt{[\sum (x_i - \bar{x})^2] [\sum (y_i - \bar{y})^2]}}$$

The correlation coefficient measures the degree of closeness of the linear relationship between paired variables. The correlation coefficient is dimensionless and lies between $+1$. When the variables tend to increase together, r will be positive; when one tends to increase and the other decrease, r will be negative. Values of ± 1 denote perfect correlation between the paired variables, while $r = 0$ denotes no correlation. See Table V.

An analysis of variance table was calculated to see if a statistical relation existed. It was found that the sum of squares due to fitting the slope was so small that it had no effect upon predicting a dependent variable. The residual mean squares are given in Table V. The same residual mean square value was obtained for the dependent variable regardless of the independent variable.

C-72	-0.1780	0.4124	0.6476	18.53	19.46	1.65
COMBINED	-0.3093	0.5454	0.0433	38.46	21.53	2.57

SECTION V

CONCLUSION

It should be emphasized that the data are based on a unique environment and the results should not be applied to other environments. Variation in the individual variables from range-to-range can be seen in the frequency plots (Figures 13 through 15) and in the means (Table II). The coefficient of variation indicated a large spread of each variable except density, but the standard error indicates that a good estimate of the means was obtained.

Only density had a small variation. Moisture may have been affected by range location or weather conditions while human error or ability to till properly may have affected the penetrometer readings.

When the data from both ranges are combined, the resultant outcomes are biased toward TA C-72 because of the number of data points. The variations between ranges indicate the difficulty in attempting to predict outcomes in other locations, assuming similar conditions.

The analysis of variance table showed that the variables are independent of each other. Predicting a variable by guessing its mean is as accurate as calculating it from a regression equation.

10. DISTRIBUTION STATEMENT Distribution limited to U. S. Government agencies only; this report documents environmental conditions under which experimental and/or conventional munitions were tested; distribution limitation applied April 1971. Other requests for this document must be referred to Air Force Armament Laboratory (DLRD), Eglin Air Force Base, Florida 32542.		
11. SUPPLEMENTARY NOTES Available in DDC	12. SPONSORING MILITARY ACTIVITY Air Force Armament Laboratory Air Force Systems Command Eglin Air Force Base, Florida 32542	
13. ABSTRACT Test data was obtained by Environmental Characterization Working Group from two sand test sites to determine how selected environmental factors affect fuze functioning. The sand is described in terms of density, percentage moisture, and penetrometer readings, and each of these was evaluated to determine its variability. Regression analysis tests were performed to determine if a relationship existed between the variables. The variables were first paired by test site and were then combined to learn if one of the variables could be predicted by knowing another. Linear correlation of the variables was also evaluated. The data is based on a controlled environment and the results should not be applied to other environments.
