FOREWORD

This report was prepared by the Research and Engineering
Division, Aerospace Group, of The Boeing Company under
Air Force Contract F33615-72-C-1580, "Propulsion System
Installation Corrections", Project 1366. The program was
conducted under the direction of the Prototype Division,
Air Force Flight Dynamics Laboratory, Air Force Systems
Command. Mr. Gordon Tamplin was the Air Force Program
Monitor.

The program was initiated on 31 December 1971 and draft
copies of the final reports were submitted for approval
on 31 October 1972.

Dr. P. A. Ross was Program Manager and Mr. W. H. Ball
was principal investigator during the program. Significant
contributions to the program were made by the following
individuals: Mr. Joe Zeeben, engine performance; Dr. Franklin
Marshall, inlet and exhaust system technology; Mr. John Petit,
nozzle internal performance and nozzle/afterbody drag; and
Mr. Gary Shurtleff, programming.

This report contains no classified information extracted
from other classified reports.

Publication of this report does not constitute Air Force
approval of the report's findings or conclusions. It is
published only for the exchange and stimulation of ideas.

Lt. Col. Ernest J. Cross, Jr.
Chief, Prototype Division
Air Force Flight Dynamics Laboratory

ABSTRACT

This report presents the results of a research program to
develop a procedure for calculating propulsion system in-
stallation losses. These losses include inlet and nozzle
internal losses and external drag losses for a wide variety
of subsonic and supersonic aircraft configurations up to
Mach 4.5. The calculation procedure, which was largely
developed from existing engineering procedures and experi-
mental data, is suitable for preliminary studies of
advanced aircraft configurations. Engineering descriptions,
equations, and flow charts are provided to help in adapting
the calculation procedures to digital computer routines.
Many of the calculation procedures have already been programmed
on the CDC 6600 computer. Program listings and flow charts
are provided for the calculation procedures that have been
programmed. The work accomplished during the program is con-
tained in four separate volumes. Volume I contains an
engineering description of the calculation procedures.
Volume II is a programmer's manual containing flow charts,
listings, and subroutine descriptions. Volume III contains
sample calculations and sample input data. Volume IV con-
tains bookkeeping definitions and data correlations.

SECTION I

INTRODUCTION

This document presents the results from the application of
PITAP procedure to two typical aircraft configurations. The
two configurations used are the Lightweight Fighter (Figure 1)
and the F-4J (Figure 2). The Lightweight Fighter (LWF) in
the example is a study configuration used by the Boeing Company
during proposal competition, for which extensive analysis and
wind tunnel test data are available for comparison with pre-
dicted results. The F-4J is also a configuration that has
been extensively tested during the Exhaust System Interaction
Program (Contract F33615-70-C-1449). Data from these tests
are used to compare with PITAP predicted results.

The main part of the PITAP calculation procedure, which is
designated as Program TEM 333, has already been programmed
and is operational on the Air Force computer. This program
requires as input data:

1)   the engine performance characteristics in the form of
      tabulated data,

2)   flight conditions in the form of altitude, Mach number,
      and power setting,

3)   geometric constants describing the inlet and nozzle/after-
      body,

4)   tabulated data representing the performance characteristics
      of the inlet and the nozzle/afterbody reference drag

The first three of the above inputs are readily available for
most cases. The fourth input, the inlet performance
characteristics, must be generated using calculation procedures
described in Volume I: Engineers Manual, use of test data
or other analysis methods. The calculation procedures have
not yet been programmed for automatic computation, so the
discussion in this document is concerned primarily with the
procedures used to predict the inlet performance characteristics
used as input for the TEM 333 program. From this point on,
all that remains to be done is prepare the input data, submit
the program, and plot up the output results.
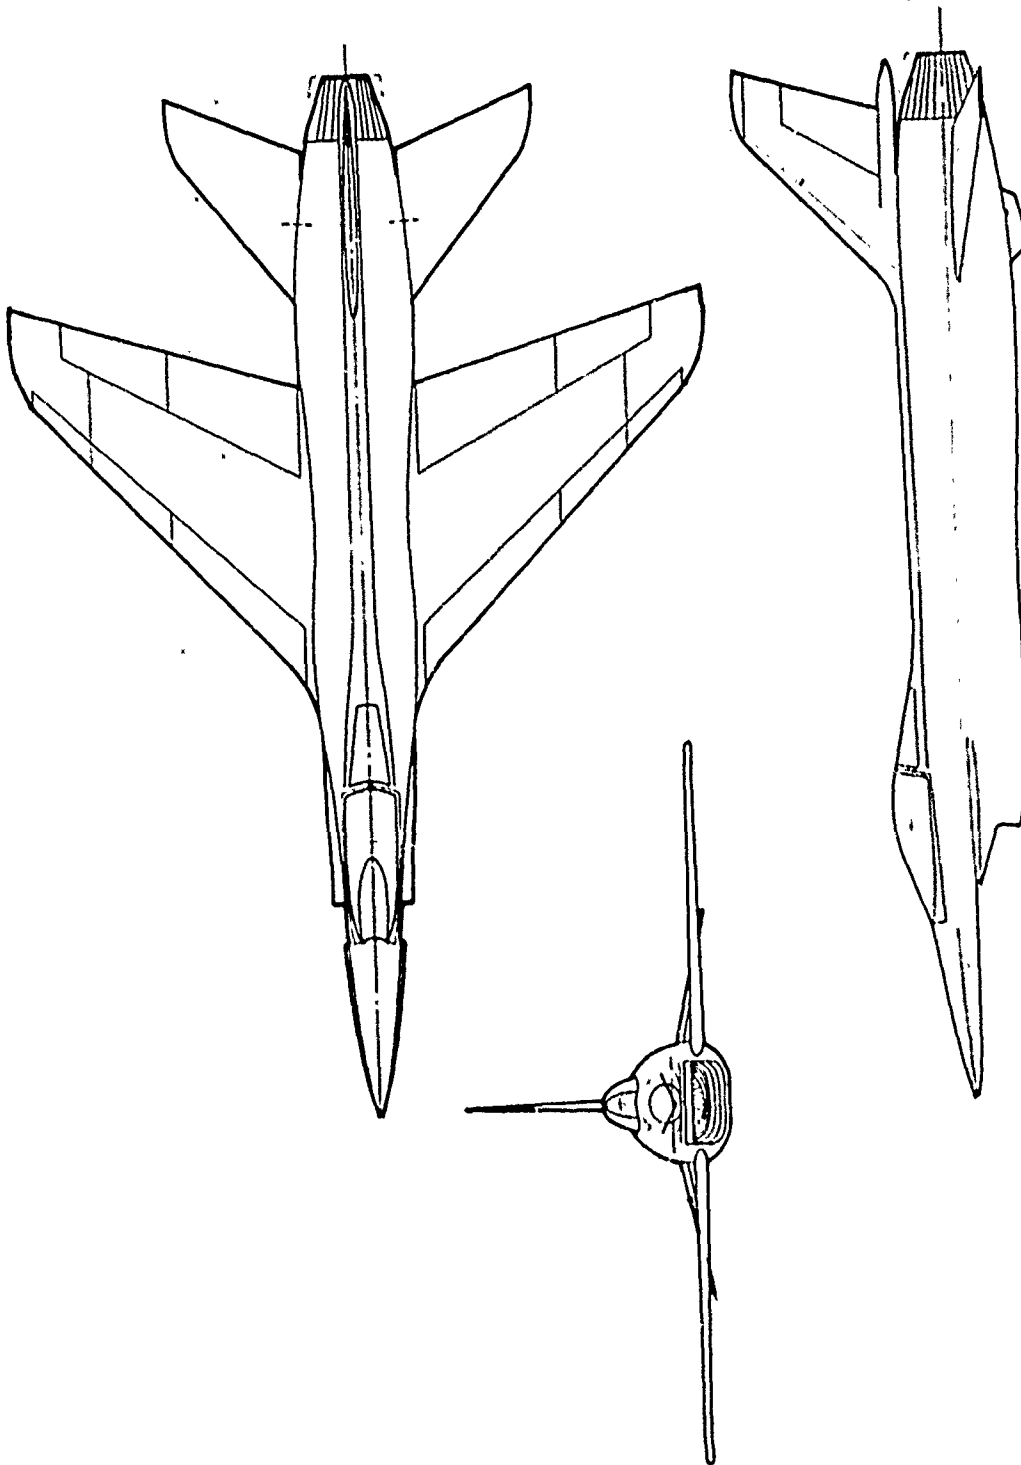

Figure 1: GENERAL ARRANGEMENT DRAWING OF
LIGHTWEIGHT FIGHTER STUDY CONFIGURATION
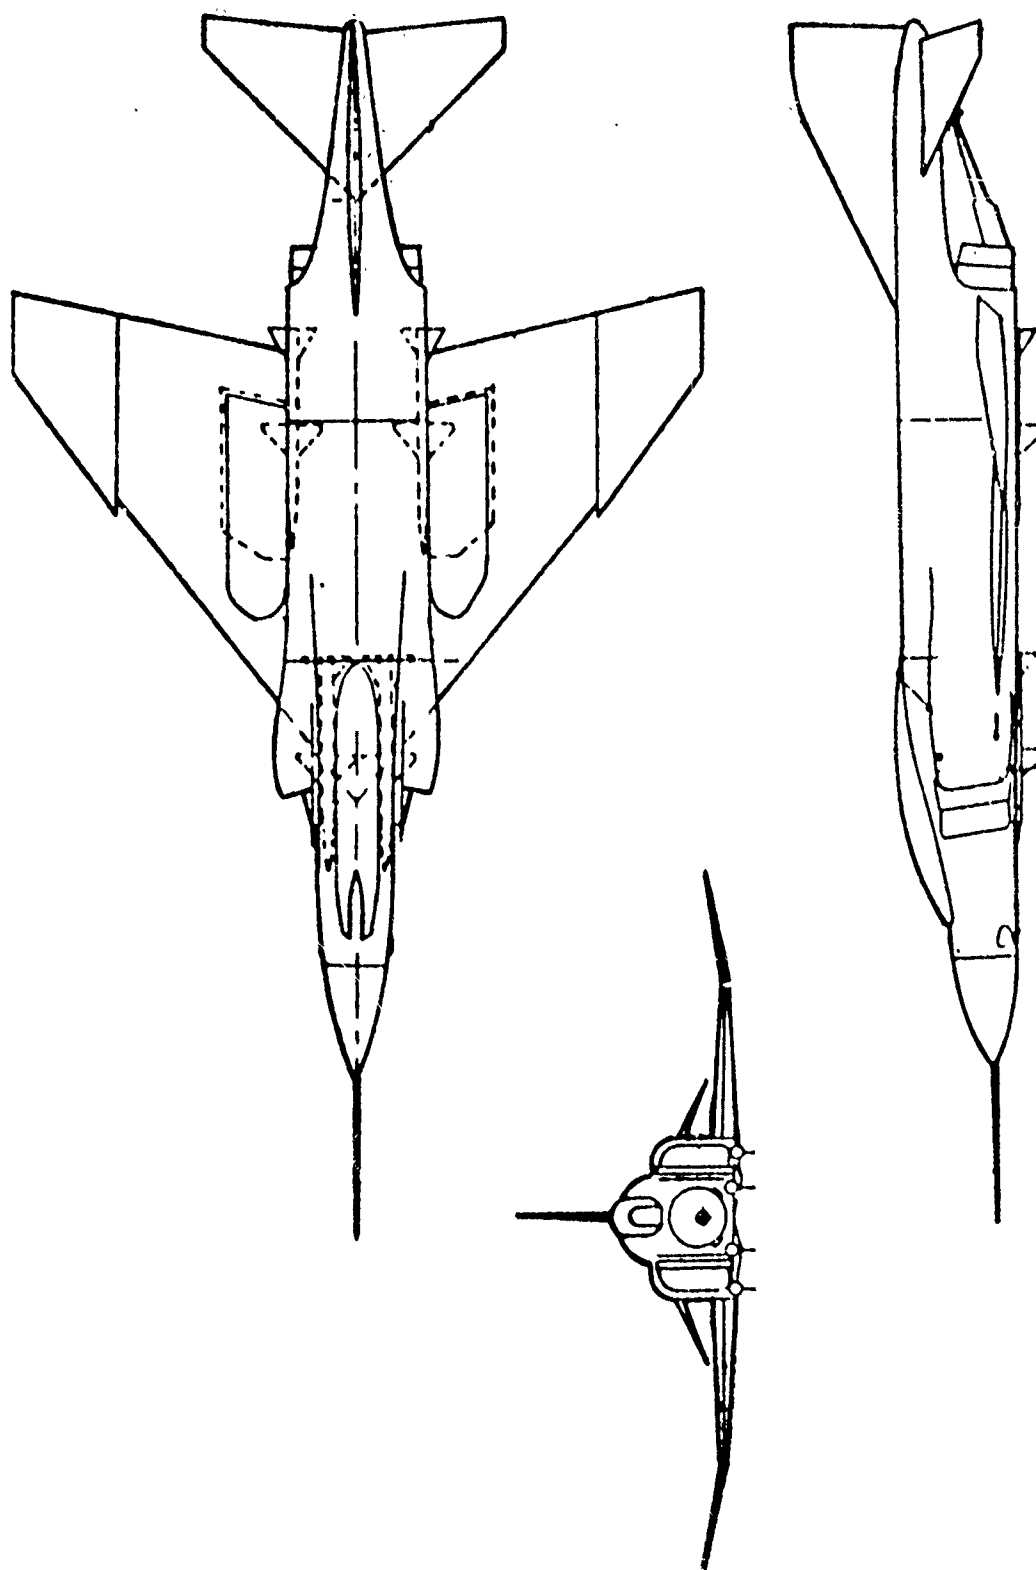

Figure 2: GENERAL ARRANGEMENT, F-4J

3

Installed propulsion system performance data have been
calculated for both the LWF and the F-4J sample cases.
Only the input and output data from the computer run for
the F-4J is presented in this document however, to avoid
making the document classified.

LIGHTWEIGHT FIGHTER SAMPLE CASE

2.1 CONFIGURATION

The general arranement of the LWF configuration is shown in
Figure 1. It is a single-engine aircraft with an under-
fuselage mounted inlet. The inlet is a two-dimensional, fixed
geometry design with throat slot bleed. No bypass system is
used. An advanced turbofan engine is used which has a
variable geometry convergent-divergent exhaust nozzle.

2.1.1 Inlet

The geometric details of the inlet are shown in Figure 3. The
critical areas required for analysis of the inlet performance
characteristics are shown in Figure 3. These areas would
normally be obtained from preliminary design drawings of the
configuration or, if not available, reasonable engineering
assumptions can be made.

The internal lines of the subsonic diffuser are shown in
Figure 4, and the diffuser area variation is shown in Figure 5.

2.1.2 Nozzle/Afterbody

The nozzle/afterbody external geometry is shown in Figure 6.
This drawing provides the dimensional data required to predict
nozzle/afterbody drag. The full open nozzle position is
used in calculating nozzle/afterbody reference drag.

2.2 PREDICTED PERFORMANCE CHARACTERISTICS

2.2.1 Inlet

The inlet performance characteristics which must be predicted
to use as input to TEM 333 (existing program) include total
pressure recovery, boundary layer bleed air drag, and spillage
drag. No bypass system is used, therefore bypass drag is not
predicted.

The LWF is designed to fly at speeds up to Mach 1.60, but the
leading edge of the fixed 7 degree ramp has been positioned
to keep oblique shocks out of the inlet up to Mach 2.0. The

following flight conditions were selected for use in the analysis procedure:

$M_\infty = 0$, 0.2, 0.6, 0.8, 1.2, and 1.60.

The low-speed pressure recovery for the $M_O = 0$ and 0.20 points is estimated using the procedure in Section IV, Vol. I, beginning on page 25. The calculation proceeds as follows:

The following input quantities are obtained from known geometric data, engine data, and data correlations (Vol. IV),

$$\frac{r}{D} = \frac{.23}{\left[\frac{(4)\ (700)}{(36)+(84)}\right]} = .01$$

$\varepsilon = 0.12$
Subsonic diffuser loss coefficient for subsonic flow. Average value from Figures 24 & 25, Vol. IV.

$\dfrac{W_2 \sqrt{\theta}_2}{\delta_2} =$ Engine Airflow for $M_O = 0$, 0.20

The above geometric and aerodynamic quantities are used as input to the low-speed calculation procedure documented in Vol. I, pages 33-41. This procedure has now been programmed as a separate subroutine, which is contained in Volume II, Programmers Manual. The results of the machine calculation are as follows:

M_O	$\dfrac{P_{T_2}}{P_{T_O}}$	$\dfrac{W\sqrt{\theta}}{\delta}$
0	0.8137	MAX
0.20	0.8937	MAX

Low-speed total pressure recovery can also be estimated from the correlation curve of Figure 20, page 33, Volume IV. The recovery values obtained using this correlation are nearly identical to the above values.

The transonic pressure recovery (M_∞= 0.6, 0.8, 1.2) is calculated from the subsonic diffuser loss coefficient and calculated throat entrance Mach number as a function of inlet airflow. Since throat Mach number is a function of engine airflow and engine airflow is a function of diffuser recovery, which depends on determine the transonic pressure recovery. This procedure is illustrated in the flow chart of Figure 16, of Volume I. Using this procedure, the following total pressure recoveries were calculated for the transonic cases:

M_∞	$\dfrac{P_{T_2}}{P_{T_\infty}}$
0.6	0.965
0.8	0.965
1.20	0.962

The supersonic inlet total pressure recovery through the shock system at the engine-matched condition is normally obtained from the charts of Figure 17, Volume I. To these shock losses are added the total pressure recovery losses due to the subsonic diffuser. The resulting total pressure is the normal recovery at the match point as a function of free-stream Mach number. For the LWF inlet, a two-shock supersonic diffuser design, the match point shock recoveries are obtained from Figure 17, Volume I for N=2. Next, the subsonic diffuser total pressure losses, calculated using a duct loss coefficient, ε = .12 (from Figure 24 of Volume IV) and an assumed throat Mach number of .75, are added to the shock losses to obtain the design point total pressure recovery as a function of Mach number. The calculated

quantities are summarized in the following table:

M_∞	(Fig. 17, Vol. I) $\dfrac{P_{T_{NS}}}{P_{T_0}}$	(Fig 7) $\dfrac{P_{T_0}}{P_{T_\infty}}$	(Fig. 15, Vol. I) $\dfrac{P_{T_2}}{P_{T_1}}$	$\dfrac{P_{T_2}}{P_{T_\infty}}$
1.0	1.0	1.0	0.9625	0.9625
1.2	0.99	1.0	0.9625	0.952
1.4	0.982	1.0	0.9625	0.945
1.6	0.968	1.0	0.9625	0.93

The above recovery values can be used for most preliminary
design studies where performance is required at design point
conditions over a range of flight Mach numbers. To fit
the format of the TEM 333 program however, it is necessary
to specify recovery as a function of engine-plus-bypass
mass flow ratio, A_0/A_c. This can be accomplished by using
the design point recovery values calculated above as constants
which do not change with mass-flow ratio below the design
point and which drop straight down form the design match
point. This results in a series of recovery vs. mass flow
ratio plots which are different from the actual variations
as shown by the following sketch:
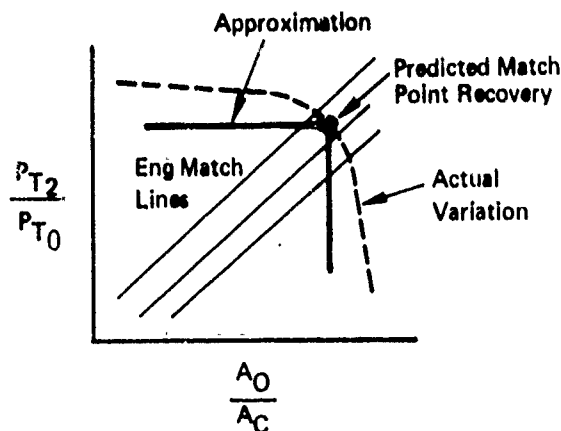

The above method does not result in large errors for engine
match lines are near the match point. However, it can result
in predictions of recovery that are slightly low for off-design

airflow demands. To demonstrate the use of an alternate recovery predicting method that can be used to improve on the recovery variations at off-design mass flow ratios, an existing computer program (Reference 1), available to industry, was used for the LWF sample case, as an aid in calculating off-design recoveries. This computer program, which was originally designed to calculate theoretical additive drag, also calculates the inviscid total pressure recovery through two-shock inlet systems. The program also calculates the mass flow spilled over sideplates of various amounts of cutback. The existing version of the program, however, does not take into account the effect of the spilled mass flow on the strength of the normal shock. It is necessary, therefore, to make an adjustment to the machine computed values of inlet lip total pressure recovery to account for this effect. This approach was used for the LWF sample case. It was assumed that the airflow spilled over the sideplates resulted in a directly proportional increase in A/A^* of the supersonic flow ahead of the normal shock. The new Mach number corresponding to this A/A^* was used to obtain the normal shock total pressure recovery. The inlet lip Mach numbers from the program (as a function of mass flow ratio, A_{O_I}/A_C) were then used with a subsonic diffuser loss coefficient of 0.12 to obtain overall total pressure recovery, P_{T_2}/P_{T_O}, as a function of inlet mass flow ratio. Using the above described methods the plotted data shown in Figure 8 were obtained for Mach numbers 1.20 and 1.60. The subsonic values for $M_O = 0.60$ and 0.80 obtained from the previously described calculation program are also shown in the same plot for the sake of completeness. Various engine airflow demand match lines are also shown in Figure 8 to indicate where the inlet/engine combination will actually operate. The matched recovery and mass flow as a function of local inlet Mach number are shown in Figures 9 and 10 respectively. Approximate inlet buzz and stall limits are input into the TEM 333 program to give indications of those operating points where inlet/engine compatibility problems may be likely to occur. These are not required to obtain performance data, and the calculations will not be stopped if one of the limits is exceeded, however, they do serve to point out possible problem areas. The buzz and stall limits shown in Figures 11 and 12 respectively, were obtained from trends in experimental data. If reliable buzz and stall limits cannot be obtained, the best available estimate should be made, by selecting appropriate points from the recovery vs. mass flow ratio plots of Figure 8.

14
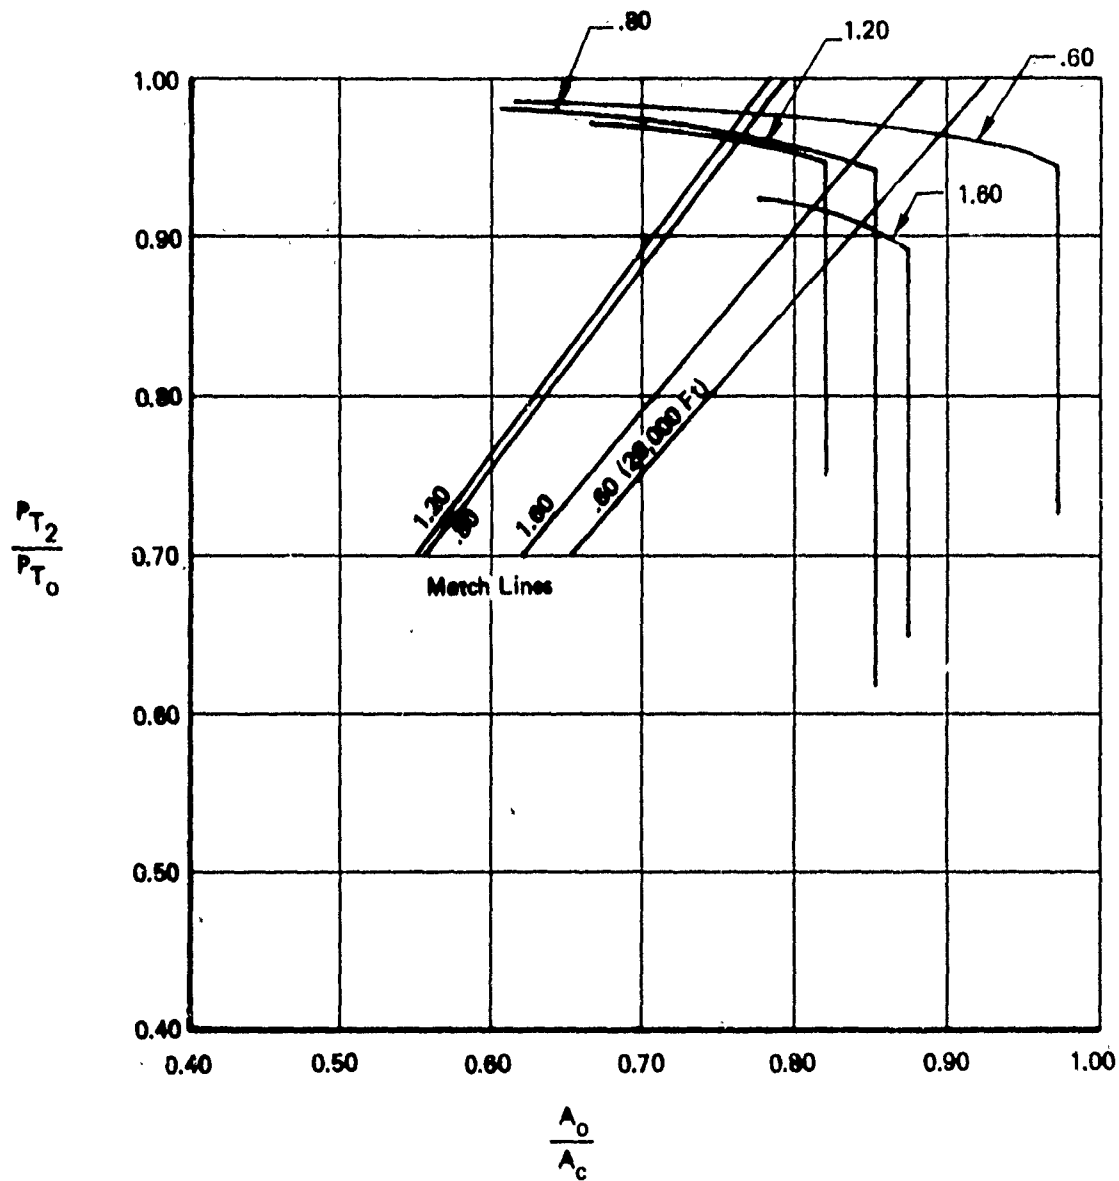

Figure 8: LWF RECOVERY VS MASS FLOW

15
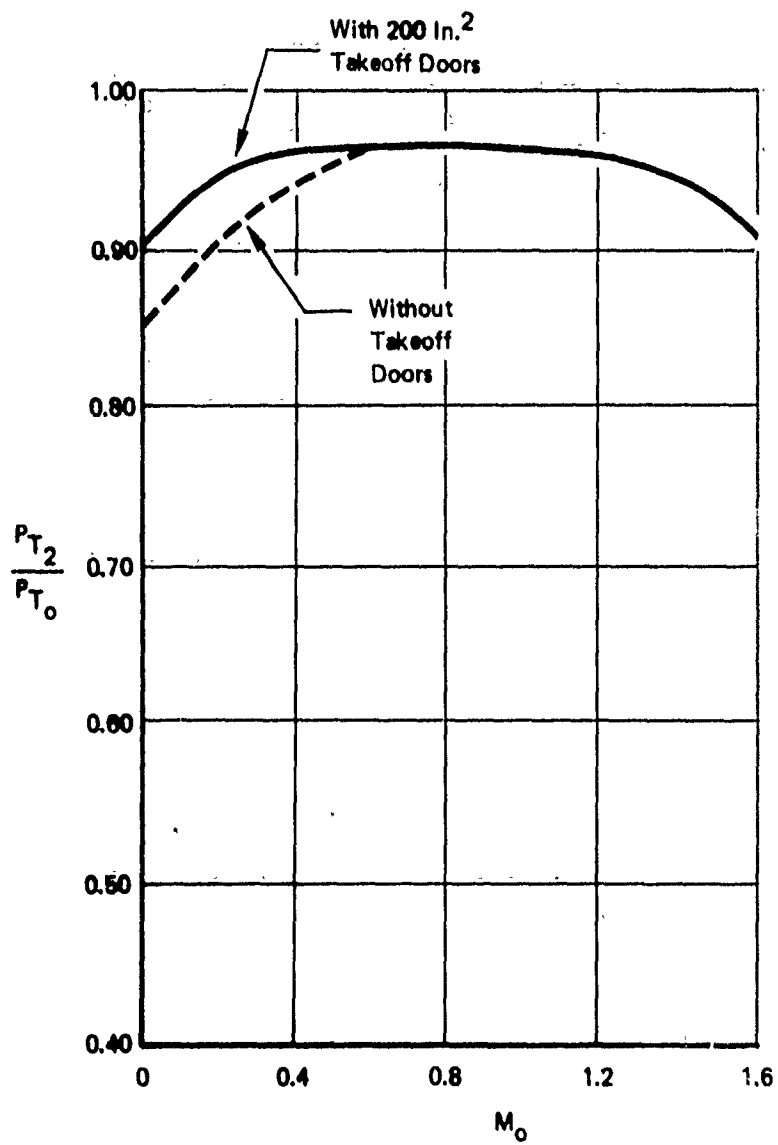

Figure 9: MATCHED INLET RECOVERY
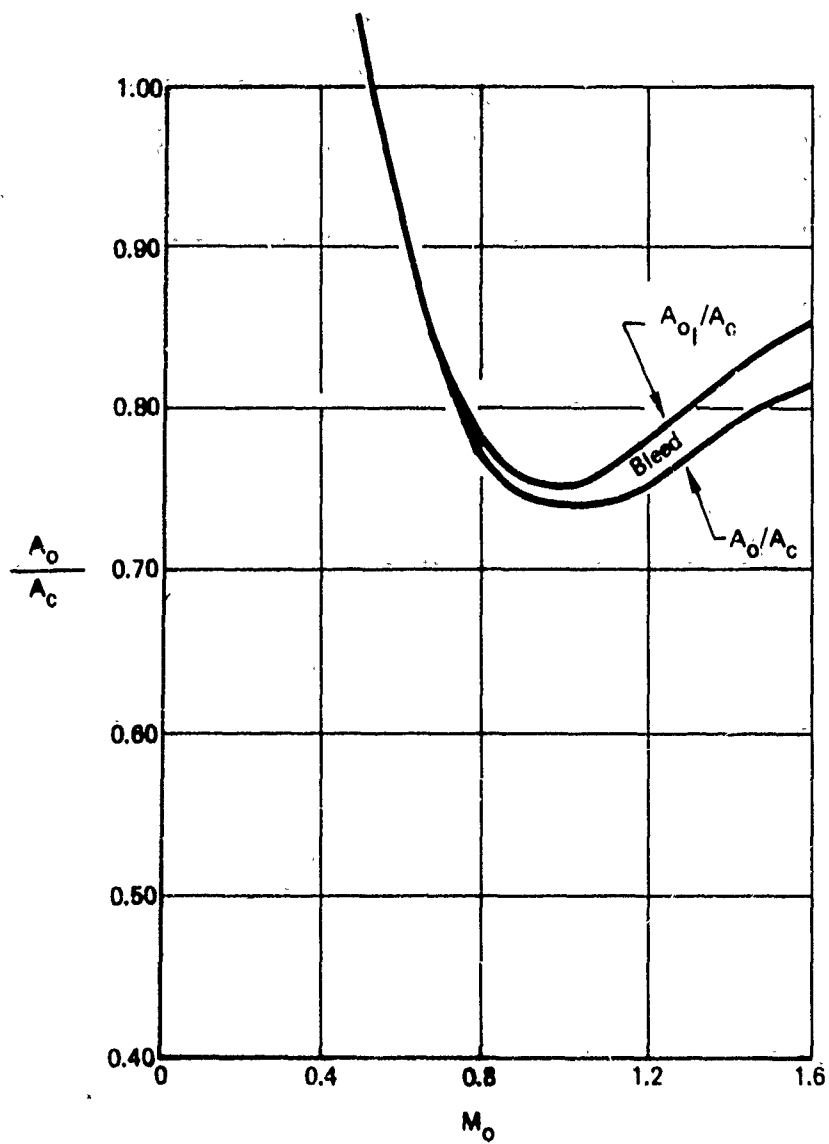

Figure 10: MATCHED MASS FLOW
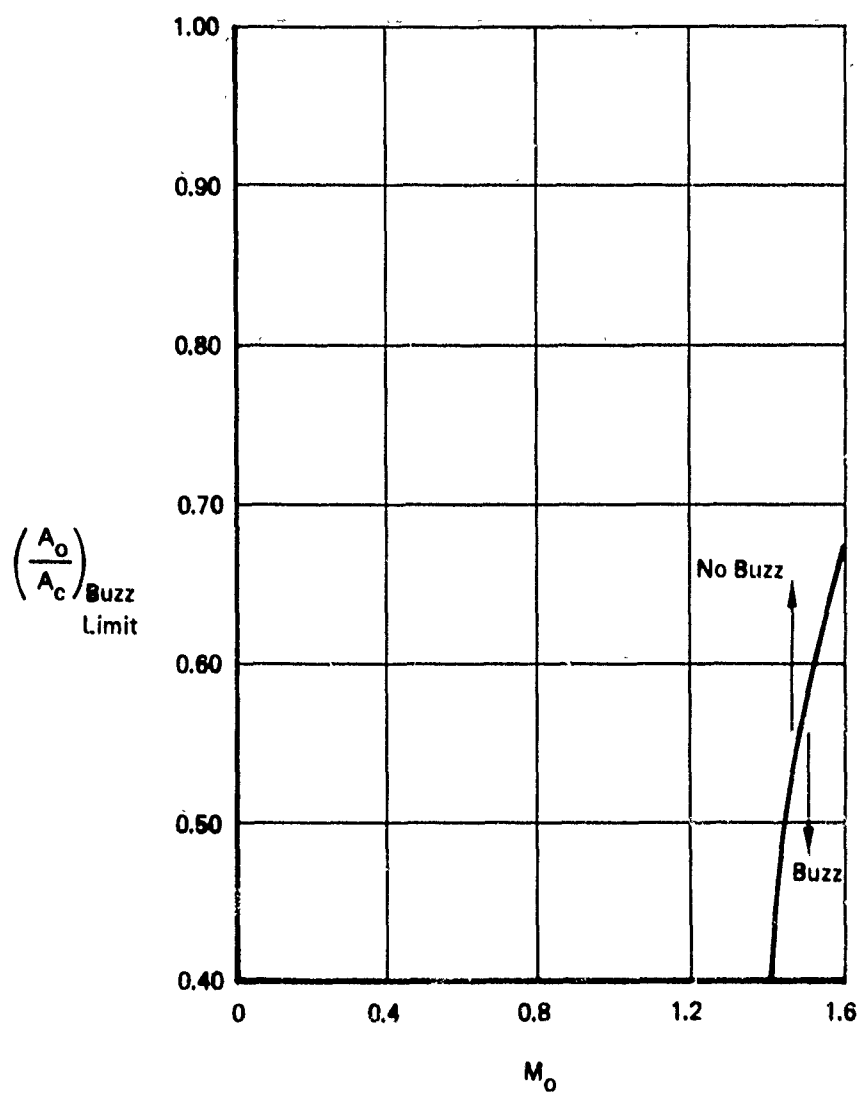

Figure 11: BUZZ LIMIT
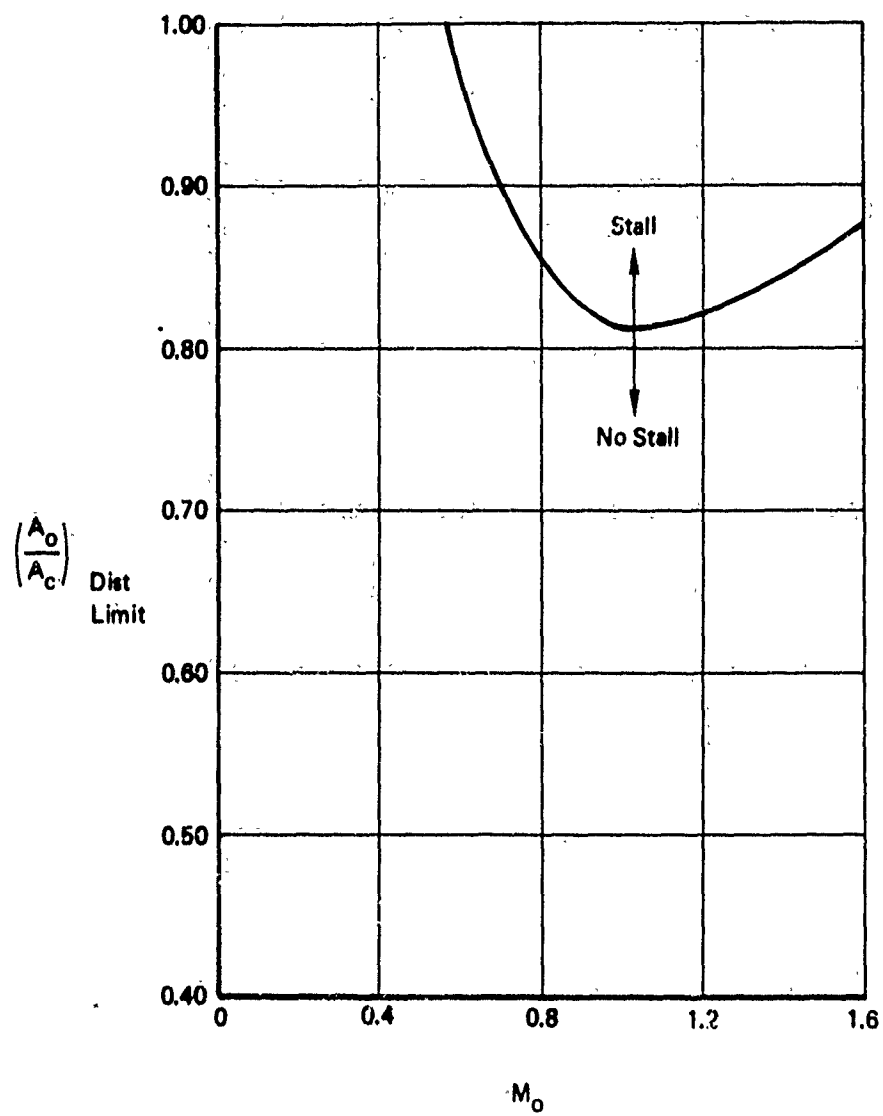

Figure 12: DISTORTION LIMIT

The first step in calculating the inlet drag is to establish an appropriate baseline mass flow ratio for use in bookkeeping aero and propulsion forces on the airplane. For subsonic Mach numbers, the baseline mass flow ratio is chosen as

$(\frac{A_{O_I}}{A_C})_{Ref} = \frac{A_T}{A_C}$. For supersonic Mach numbers, the baseline mass flow ratio is chosen as $(\frac{A_{O_I}}{A_C})_{Ref} = (\frac{A_O}{A_C})_{MAX}$ for each Mach number.

The maximum supersonic operating mass flow ratios for the LWF were obtained by use of the previously described computer program of Reference 1. The resulting baseline mass flow as a function of free-stream Mach number is shown in Figure 13.

The spillage drag calculation for the LWF was initiated by using the additive drag program of Reference 1 to calculate theoretical additive drag as a function of free-stream Mach number and inlet mass flow ratio. After the calculated additive drag was obtained, two adjustments were made:

1) The additive drags were adjusted so that the additive drag was zero at the baseline mass flow ratio condition. This resulted in plots of $\Delta C_{D_{ADD}}$ vs. A_{O_I}/A_C.

2) Next, the $\Delta C_{D_{ADD}}$ values were multiplied by K_{ADD} factors to correct the theoretical additive drags for configuration effects. These K_{ADD} factors (Figure 14) were obtained from the data of Volume IV. Due to the limited amount of data on K_{ADD} factors it was necessary to do a considerable amount of interpolation, extrapolation, and smoothing to obtain the K_{ADD} factors shown in Figure 14.

The final spillage drag data are presented in Figure 15.

The boundary layer bleed drag was calculated using the bleed airflow shown in Figure 16 and the bleed airflow total pressure recovery shown in Figure 17. These data were obtained from Volume IV, Section IV, "Data for Specific Configurations."

The final calculated boundary layer bleed drag is presented in Figure 18. The final bleed drag is presented as a single curve of $C_{D_{BLC}}$ vs. $\frac{A_{O_{BLC}}}{A_C}$ because there was little variation

$\left(\dfrac{A_{o_1}}{A_c}\right)_{Ref}$

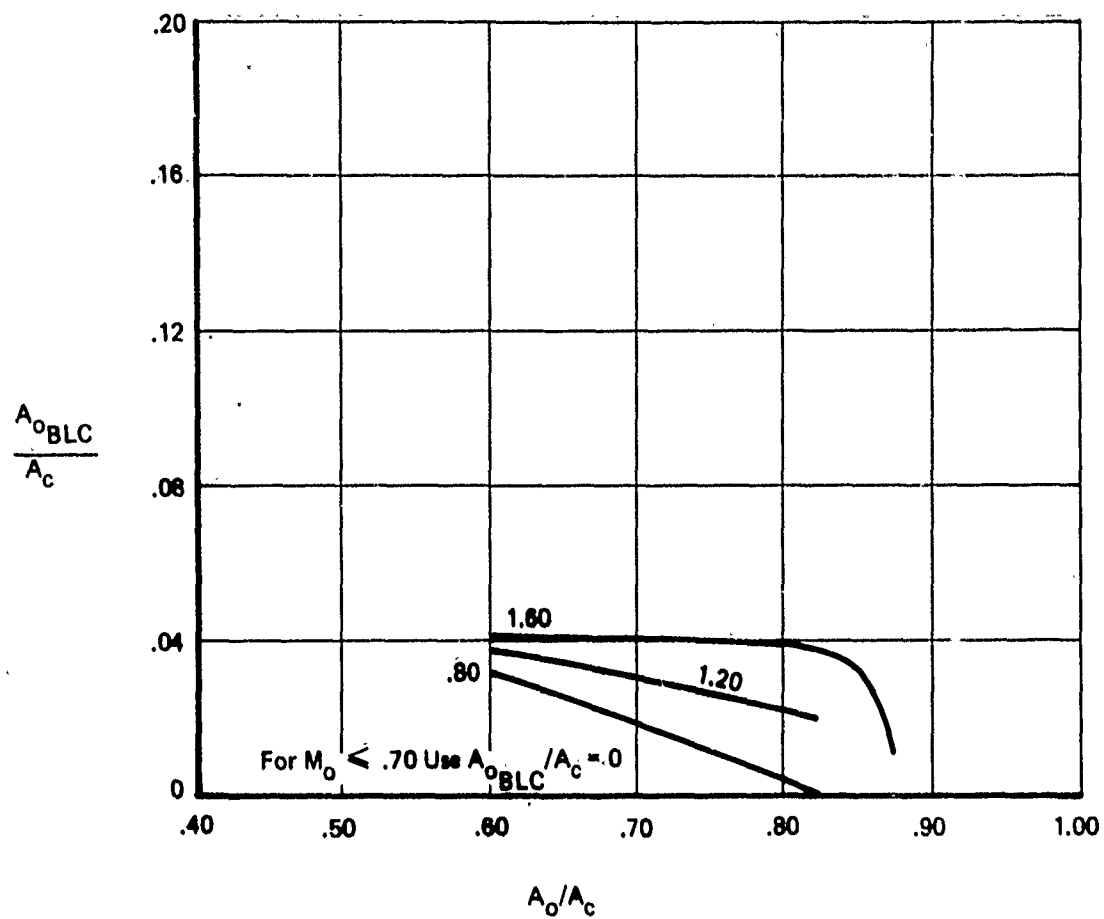

Figure 16: BOUNDARY LAYER BLEED AIRFLOW
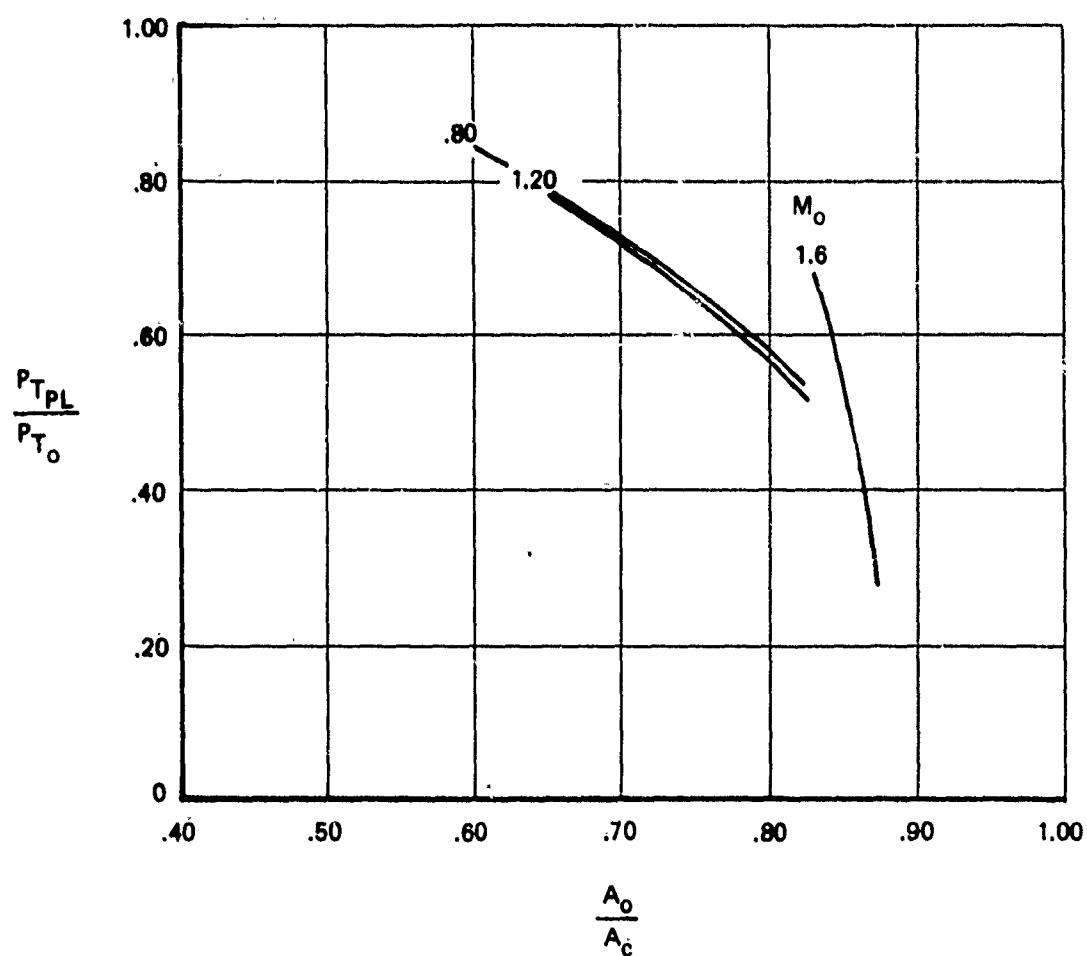

Figure 17: **BOUNDARY LAYER BLEED AIRFLOW**
TOTAL PRESSURE RECOVERY

25
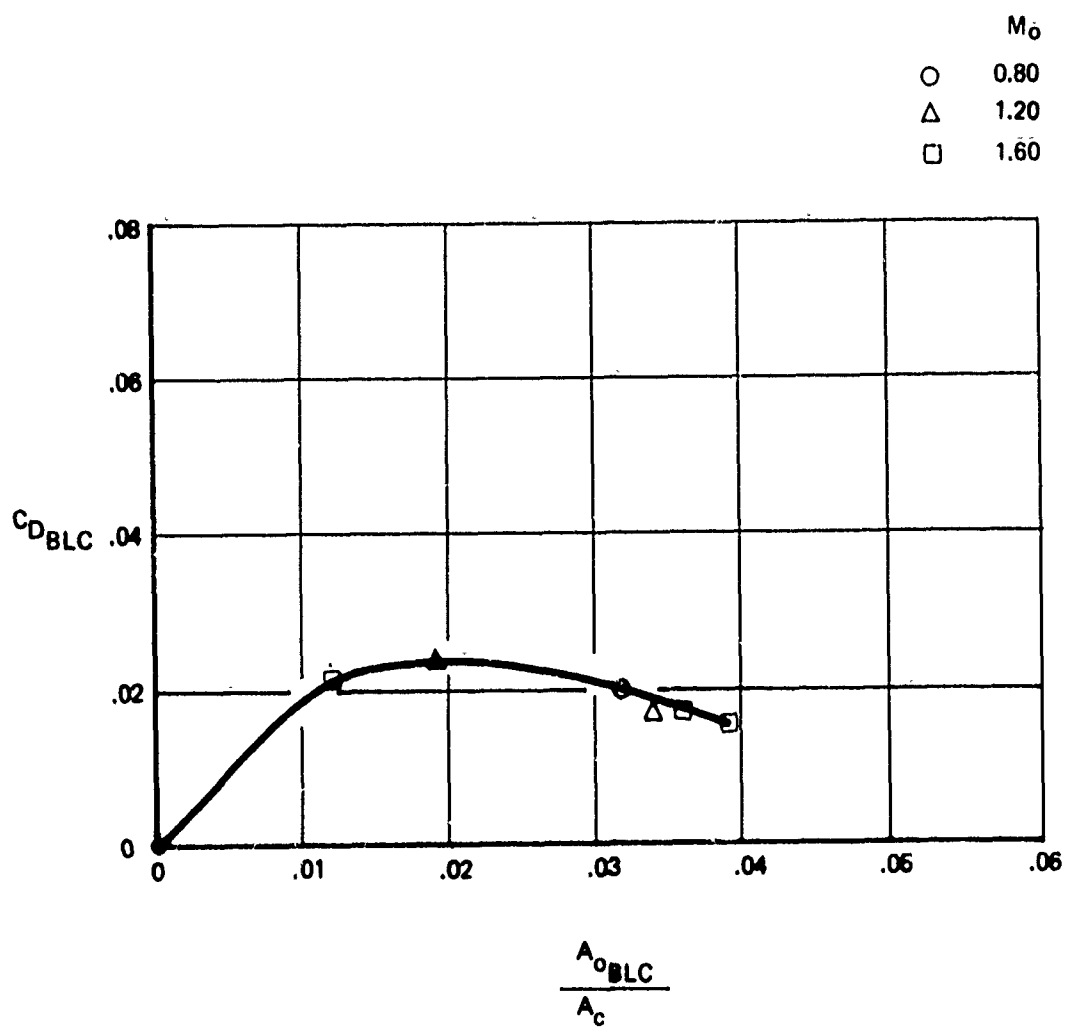

Figure 18: BOUNDARY LAYER BLEED DRAG

in the drag as a function of Mach number. Also, since the exact geometry and location of the boundary layer bleed exit was not know, the momentum drag of the boundary layer bleed air was increased by a factor of 1.25 to account for flap drag of the exit doors. This drag would normally be computed by the procedure detailed in Section IV of Volume I, if exit geometry were specified.

The drag increases to a maximum as bleed airflow is increased, then starts to decrease again. This is due to the fact that variations in bleed airflow are produced by variations in shock position. As shock position goes more supercritical, plenum pressure drops along with airflow. Conversely, as the shock goes more subcritical, the airflow goes up and so does the pressure recovery of the bleed air. These effects tend to flatten out the $C_{D_{BLC}}$ vs. $\dfrac{A_{O_{BLC}}}{A_C}$ curves, as shown in Figure 18.

2.2.2 Nozzle/Afterbody

The calculation procedures for computing nozzle/afterbody drag are computerized in the TEM 333 program; therefore, the sample calculations consisted of preparing the input data for the nozzle/afterbody portion of the calculation procedure and submitting the job to the computer. These input data consist of geometric constants specifying nozzle maximum diameter, D_{MAX}, nozzle boattail length, L, nozzle-to-nozzle spacing, S, and nozzle/afterbody reference drag as a function of Mach number for the reference geometry and the reference nozzle pressure ratio. The following table summarizes the LWF geometrical constants used by the nozzle/afterbody calculation procedure in the program:

GEOMETRICAL CONSTANT	VALUE
Nozzle Spacing, S	O (Single Engine)
Nozzle Maximum Diameter, D_{MAX}	51 in.
Boattail Length, L	50 in.

The above constants are used, together with the nozzle pressure ratio (obtained internally by the computer program from the tabulated engine performance input data), to obtain

27

boattail drag from the curves of Figures 19 and 20.

It is also necessary to specify as part of the input data for
nozzle/afterbody drag calculation, the variation of nozzle/
afterbody reference drag as a function of free-stream Mach
number. This reference drag is obtained from Figures 19
and 20 using the reference nozzle/afterbody geometry shown
in Figure 6. The reference nozzle/afterbody boattail angle
is 4 degrees (full open nozzle position). For this boattail
angle, the subsonic reference drag is obtained from Figure 19
as a function of free-stream Mach number. The supersonic
boattail reference drag is calculated from the equation
shown in Figure 19. Since the reference boattail angle is
only 4 degrees, no pressure ratio correction form Figure 20
is required. The final predicted reference drag for the
nozzle/afterbody is shown in Figure 21.

2.3 COMPARISON OF PREDICTED AND TEST DATA

The calculated data have been compared with test results
obtained from a series of aero and propulsion tests to
determine their accuracy in predicting the actual inlet
recovery and spillage drag and nozzle/afterbody drag.

The results of the inlet total pressure recovery comparison
are shown in Figure 22. Good agreement is obtained between
predicted recovery and measured recovery throughout the
flight Mach number range.

A comparison of predicted and measured inlet spillage
dracs is presented in Figure 23. Agreement between predicted
and measured drag is generally fair for most Mach numbers,
and is probably adequate for preliminary studies, however,
the limited amount of data available, and the scatter in
the data, from which to select the K_{ADD} factor, made it
necessary to spend considerable time in arriving at a
suitable set of K_{ADD} factors to use. This situation could
be considerably improved by the systematic gathering and
analyzing of an extensive body of drag data over a wide range
of configurations.

The results of nozzle/afterbody drag predictions for a
20 degree boattail angle nozzle are compared with measured
data over a Mach number range from 0.40 to 1.60 in Figure
24. The predicted drags are somewhat low subsonically and
slightly high supersonically. Figure 25 presents results
comparing measured and predicted subsonic nozzle drags as
a function of nozzle pressure ratio for a 20 degree boattail
angle nozzle.

SECTION III

F-4J SAMPLE CASE

3.1 CONFIGURATION

3.1.1 Inlet

The general configuration of the F-4J is shown in Figure 2.
The inlets are side-mounted, variable geometry, vertical
ramp, two-dimensional, with boundary layer bleed through a
porous second ramp and a small throat slot. Figure 26
shows the available details of the inlet and subsonic
diffuser. These lines were taken from a drawing of a
wind tunnel model used during tests reported in Reference 2.
The sideplates are cut back completely ahead of the cowl
lip. The initial ramp angle is fixed at 10 degrees and the
second ramp angle varies from 0 degree relative to the first
ramp angle relationships are shown in Figure 27.

The inlet geometry used for the analysis of the F-4J inlet
performance characteristics is shown in Figures 28 and 29.

3.1.2 Nozzle/Afterbody

The nomenclature used for the nozzle afterbody drag prediction
is shown in Figure 30. Typical nozzle geometries and operating
pressure ratios are shown in Figure 31.

The nozzle/afterbody geometric parameters (full scale) used
in the prediction method are summarized in the following
table:

PARAMETER		VALUE
Max Nozzle Diameter,	D_{MAX}	38.6 in.
Boattail Length,	L	23.4 in.
Nozzle Spacing,	S	53.8 in.

43
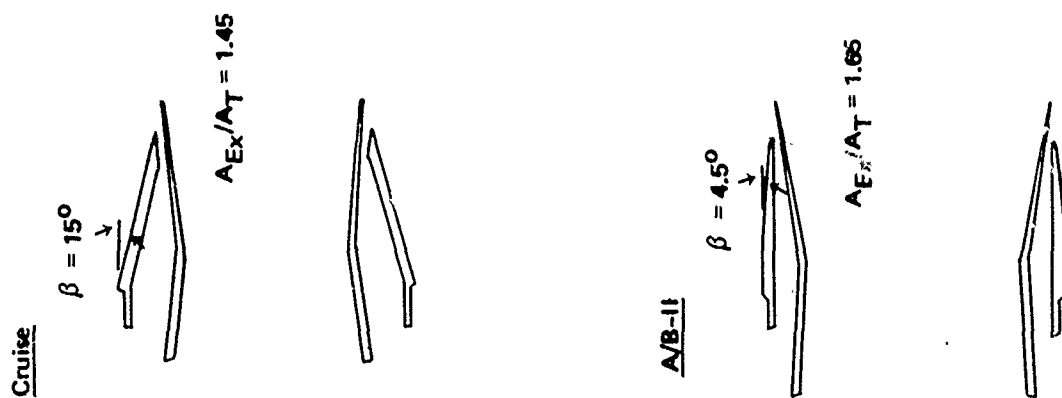

3.2 PREDICTED PERFORMANCE CHARACTERISTICS

3.2.1 Inlet

The same procedure was used to calculate the F-4J inlet performance that was used to calculate the inlet performance of the LWF previously discussed. The basic geometries of the two configurations are quite similar, except for the fact that the F-4J inlet is oriented with the ramp vertical instead of horizontal.

The same K_{ADD} factors were used for both the F-4J and the LWF. These factors are shown in Figure 14. The F-4J inlet geometry was used in the additive drag program (Reference 1) to obtain additive drags. These were then adjusted to the correct baseline mass flow ratio, and multiplied by the K_{ADD} factors to obtain the final spillage drags shown in Figure 39.

The predicted inlet performance characteristics for the F-4J are presented in Figures 32 through 41, in a format that is compatible with the TEM 333 program input.

3.2.2 Nozzle/Afterbody

Just as in the case of the LWF nozzle/afterbody drag calculation, the only input data required (in addition to geometric constants and engine performance tabulated data) is the nozzle/afterbody reference drag. This was determined from the data in Figure 40, 41 and 45, Volume I. The resulting reference drag is presented in Figure 42.

3.3 COMPARISON OF PREDICTED AND TEST DATA

Most of the F-4 experimental data which are available for comparing with predicted data are classified. To include these data in this report, it would be necessary to classify the report, which would limit its distribution.

Since the primary purpose of this report is to provide guidance in the use of the calculation procedure, it was decided not to include classified data, so the report could have the widest possible distribution.

3.5 SAMPLE INPUT AND OUTPUT DATA FOR F-4J

This section contains sample input and output data taken directly from the computer program printout for the F-4J installed performance calculation. It is included to illustrate the format of the input and output data and to present typical results of a calculation.

OUTPUT

Standard printed output includes:

1. A "card image" listing of all input cards.

2. Labeled listing of all input fields as stored in the computer. The expanded table 2A is output as is the internally generated table of Mach_9 as a function of A_8/A_9 for γ_1.

3. Output matrices including the input and output data for each of one to ten cases. A new matrix is printed whenever Mach number changes, altitude changes, or ten points have been computed at the current Mach and altitude. For each case the following are printed.

CASE	Sequential case number	
ALT	Pressure altitude - input	ft.
PS	Power setting - input	
FNA	Installed net thrust	lb.
WFT RF	Installed fuel flow corrected for recovery	
SFCA	(WFT RF)/(FNA)	
FNRF	Input thrust corrected for recovery	lb.
FRAM	Ram drag	lb.
RF	Recovery factor	
MILRF	Mil-Spec recovery factor	
DINLET	Inlet drag	lb.
CDSPL	Coefficient of spillage drag	

CDBLD	Coefficient of bleed drag	
CDBYP	Coefficient of bypass drag	
CDINL	Coefficient of inlet drag	
DNOZ	Afterbody drag	lb.
CDBT	Coefficient of boattail drag	
CDBASE	Coefficient of base drag	
DCINT	Coefficient of nozzle interference drag	
DNOZ REF	Reference afterbody drag	lb.
P8/PO	Nozzle pressure ratio - input	
A9	Nozzle exit area - input	sq. in.
A8	Nozzle throat area - input	sq. in.
CFG	Nozzle gross thrust coefficient	
BETA	Boattail angle	degrees
FN INPUT	Net thrust - input	lb.
WF INPUT	Fuel flow - input	lb/hr.
SFC INPUT	(WF INPUT)/(FN INPUT)	
W INPUT	Corrected airflow - input	lb/sec.
W ABS	Absolute airflow	lb/sec.
FN/DELTA	$FNA/\delta amb$	lb.
WF COR	$WFT\ RF/(\ \theta amb\ \delta amb)$	lb/hr.
SFC COR	(WF COR)/(FN/DELTA	
TAMB	Ambient temperature	^{o}R
PAMB	Ambient pressure	
TTO	Total temperature of free-stream	^{o}R
Q	Dynamic pressure	lb/sq. ft.

AOE/AC   Engine mass flow ratio

AOI/AC   Inlet capture mass flow ratio

AO/AC   Inlet mass flow ratio

STATUS   If equal to -99.999 a diagnostic message
              was written for this point.

4. Diagnostic messages. The diagnostic messages are all
   self-explanatory.

5. MARK II Output.

   If the code on card 5.1, field 1, is 1.0 or 2.0 a MARK II
   engine performance deck is written on TAPE 7. The format
   is 80 character BCD, "card image." The MARK II deck
   can then be copied to PUNCH or linked to a following
   program.

   The MARK II format is as follows:

   1. Title (card image of input card 1.0)

   2. Mach-alt (card image of input card 5.2)

13. ABSTRACT

This report presents the results of a research program to develop a procedure for use in calculating propulsion system installation losses. These losses include inlet and nozzle internal losses and external drag losses for a wide variety of subsonic and supersonic aircraft configurations up to Mach 4.5. The calculation procedure, which was largely developed from existing engineering procedures and experimental data, is suitable for preliminary studies of advanced aircraft configurations. Engineering descriptions, equations, and flow charts are provided to help in adapting the calculation procedures to digital computer routines. Many of the calculation procedures have already been programmed on the CDC 6600 computer. Program listings and flow charts are provided for the calculation procedures that have been programmed. The work accomplished during the program is contained in four separate volumes. Volume I contains an engineering description of the calculation procedures. Volume II is a programmers manual containing flow charts, listings, and subroutine descriptions. Volume III contains sample calculations and sample input data. Volume IV contains bookkeeping definitions and data correlations.
