## **ACKNOWLEDGMENTS**

The authors wish to give a special thanks to our statistician, Ms. Robyn Lee. She provided expert guidance in selecting appropriate challenge doses and determining the required number of animals to establish rigorous dose-response curves. She also trained the authors to perform a probit analysis of the data using the SAS program and provided a critical review of the draft manuscript. Her dedication and assistance are greatly appreciated.

## EXECUTIVE SUMMARY

An important objective of the Project Solicitation for Agent Therapeutics (Task Area 2.H) was to determine the effectiveness of current medical countermeasures against the acute toxicity of nerve agents. This project evaluated the efficacy of skin decontamination products and barrier skin creams. Doctrine described the use of Skin Exposure Reduction Paste Against Chemical Warfare Agents (SERPACWA) as a barrier skin cream and the M291 Skin Decontamination Kit (SDK), 0.5% hypochlorite solution (household bleach diluted 1 to 10) and 1% soapy water solution (liquid dish detergent) to decontaminate intact skin exposed to chemical warfare agents. Reactive Skin Decontamination Lotion (RSDL) was approved by the FDA in 2003 and subsequently selected as the Joint Services Personnel Skin Decontamination System (JSPDS) to replace the M291 SDK. This report, the twelfth in a series, directly compares the efficacy of the barrier skin cream SERPACWA and the four listed decontamination products in the haired guinea pig model following exposure to GF (EA1212).

In all experiments, guinea pigs were close-clipped and given anesthesia (ketamine and xylazine). SERPACWA was applied as a thin coating (0.1 mm thick), allowed to dry for 15 minutes and challenged with neat GF. After a 2-hour challenge any remaining GF was blotted off the animal, but no additional decontamination was done. In decontamination experiments, the animals were challenged with neat GF and decontaminated after a 2-minute delay for the standard procedure or at longer times for the delayed-decontamination experiments. Positive control animals were challenged with GF in the same way as the treated animals except that they received no treatment. A few of the positive control animals were challenged with 5% GF in isopropyl alcohol solution, but data from these experiments were not included in the data analysis. All animals were observed during the first 4 hours and again at 24 hours postexposure for signs of toxicity and death. The protective ratio (PR, defined as  $LD_{50}$  of the treatment group divided by the  $LD_{50}$  of the untreated positive control animals) was calculated from the derived median lethal dose-response curve parameters established for each treatment group and non-treated control animals. Significance in this report was defined as  $p < 0.05$  unless otherwise stated.

The results showed that SERPACWA provided superior protection against GF. The PR was estimated to be greater than 250. In the standard 2-minute decontamination experiments the calculated PR values (95% CI) for 0.5% bleach, M291 SDK, RSDL, and 1% soapy water were **6.82** (5.13, 9.09), **3.77** (2.64, 5.40), **25.9** (19.9, 33.6), and **6.04** (4.90, 7.44), respectively. All of the tested decontamination products provided significant protection against a GF challenge compared to untreated positive control animals. RSDL was the most effective decontamination product tested and significantly better than any of the other products. Bleach (0.5%) and soapy water (1%) provided equivalent protection and were significantly better than the M291 SDK.

In the neat GF delayed-decontamination experiments, the estimated  $LT_{50}$  (95% CI) values (the delayed-decontamination time where 50% of the animals died in the test

population following a 5 LD<sub>50</sub> challenge dose of 38.8 mg/kg) for 0.5% bleach, RSDL, and 1% soapy water were **0.234** (0.065, 0.845), **34.6** (28.3, 41.7), and less than **0.5** minutes, respectively. For GF, the window for effective decontamination for 0.5% bleach and 1% soapy water was extremely short, less than 0.5 minutes; however, the window for effective decontamination using RSDL was around 35 minutes for 50% survival. A more preferable time, however, is the time in which few deaths are expected. The 10% lethality delay time (95% CI) for RSDL was **24.2** (13.9, 29.3) minutes.

## INTRODUCTION

This report, the twelfth in a series, directly compares the efficacy of the four listed decontamination products and SERPACWA in the haired guinea pig model following exposure to GF [cyclosarin, EA1212, Cyclohexyl methylphosphonofluoridate, (Fluoromethyl-phosphoryl)oxycyclohexane]. Part 1 of the series (Braue et al., 2009) provided a detailed introduction to the decontamination products, Skin Exposure Reduction Paste Against Chemical Warfare Agents (SERPACWA), and the nerve agents, as well as to the threat nerve agents represent for warfighters and the civilian population. The first documented use of nerve agents in armed combat was during the Iran-Iraq War of 1980-1988 (Newmark, 2004). More than 100,000 US military individuals were potentially exposed to low levels of cyclosarin and sarin following the destruction of munitions at the storage facility at Khamisiyah, Iraq, in March 1991 (Smith et al., 2003).

GF (EA1212, cyclosarin)

## OBJECTIVE

The first objective of this study was to determine the efficacy of four decontamination products in guinea pigs challenged with GF: 0.5% bleach, the M291 SDK, Reactive Skin Decontamination Lotion (RSDL), and 1% soapy water. The second objective was to determine how the efficacy was affected by delaying application of these decontamination products following challenge with GF. The third objective was to

determine the efficacy of the pretreatment barrier skin cream SERPACWA challenged with GF.

## MATERIALS AND METHODS

A detailed description of the experimental methods used for this project may be found in the first published manuscript in the series (Braue et al., 2009). In all experiments, guinea pigs were close-clipped and given anesthesia (ketamine and xylazine). SERPACWA was applied as a thin coating (0.1 mm thick, over 7.1 cm<sup>2</sup>), allowed to dry for 15 minutes and challenged with neat GF. After a 2-hour challenge any remaining GF was blotted off the animal, but no additional decontamination was done. In decontamination experiments, the animals were challenged with neat GF and decontaminated after a 2-minute delay for the standard procedure or at longer times for the delayed-decontamination experiments. Positive control animals were handled in the same manner as the treated animals except that they received no treatment. Four positive control animals were challenged with 5% GF in isopropyl alcohol (IPA) solution, but these animals were not included in the SAS data analysis (see discussion). All animals were observed during the first 4 hours and again at 24 hours postexposure for signs of toxicity and death. The protective ratio (PR, defined as LD<sub>50</sub> of the treatment group divided by the LD<sub>50</sub> of the untreated positive control animals) was calculated from the derived median lethal dose-response curve parameters established for each treatment group and non-treated control animals. Significance in this report was defined as  $p < 0.05$  unless otherwise stated.

These experiments were conducted between 18 July 2006 and 14 September 2010. A 100% quality control audit was conducted by team members to verify that all data were correctly transcribed from the laboratory notebook to the Excel data base.

### Agent Application

GF [cyclosarin, EA1212, Cyclohexyl methylphosphonofluoridate, (Fluoro-methyl-phosphoryl)oxycyclohexane] was obtained from the U.S. Army Edgewood Chemical Biological Center (ECBC), Aberdeen Proving Ground, MD. The experiments used lot number GF-S-6092-CTF-2 with a purity of 95.5% as determined by NMR spectroscopy.

GF was applied to the marked area on the animal (side for decontamination and back for SERPACWA) using one of various pipetting devices, depending on the volume needed. Volumes smaller than 2.0 microliters ( $\mu\text{l}$ ) used either a Rainin micropipette (P-2, Rainin Instrument, LLC, Oakland, CA 94621) or a Hamilton microsyringe (0.5, 1, 5  $\mu\text{l}$ , The Hamilton Co., Reno, NV 89502). Experiments that required volumes greater than 2.0  $\mu\text{l}$  used a Rainin micropipette (P-10, P-20, P-100, P-200, P-1000) or a Drummond positive displacement microdispenser (10, 25, 50, 100, 1000  $\mu\text{l}$ , The Drummond Scientific Co., Broomall, PA 19008). Either neat GF or a 5% GF IPA solution was applied, but only a total of four positive control animals received 5% GF IPA solution, and these animals were not included in the SAS data analysis.

At least once per week quality control (QC) samples of GF were prepared by pipetting 9.5 µl of neat GF into a 10 ml volumetric flask and adding chloroform to the fill line. The diluted sample of GF was analyzed by a gas chromatography (GC) system (HP model 6890) using a flame ionization detector (FID). If any sample concentration was outside three standard deviation units from the study mean the data for that day were omitted.

## **Data Analysis**

Statistical analysis of the data from these experiments was performed using SAS software, version 6.12 (SAS Institute, Inc., Cary, NC 27513). Data sets were analyzed using specialized probit analysis programs for a stage-wise adaptive dose design (Feder, 1991) written using SAS NLIN to estimate the LD<sub>50</sub> and 95% confidence interval (CI). The PROBSEP program (Braue et al., 2009, Appendix B) produced a great deal of statistical information (see APPENDIX B: SAS ANALYSIS OUTPUT FILES for complete listing), but only a small portion will be given in the tables, including LD<sub>10</sub>, LD<sub>50</sub>, and LD<sub>90</sub> values with lower and upper 95% CIs based on Fieller's method (Finney, 1971), and the probit slope. An additional specialized program using SAS, called PRORATIO (Braue et al., 2009, Appendix C), used the output from the SAS PROBSEP program to calculate the PR of each of the treatments compared to the positive controls and to each of the other treatment groups. The PRORATIO program also estimated a confidence interval for the PR (using the delta method, Nelson, 1982), which was used to determine whether the PR was significant and therefore whether the LD<sub>50</sub> values of the groups were significantly different. Statistical significance was defined as  $p < 0.05$  unless otherwise stated.

The reported SAS analysis output for each treatment group used animals challenged with neat GF. The raw data tables for positive control animals included four animals challenged with 5% IPA solution of GF, but these animals were not included in the SAS analysis (see discussion).

SERPACWA data analysis presented a challenge. Twenty-two animals were initially administered doses ranging from 0.5 mg/kg to 250 mg/kg. Only one death occurred at the 25 mg/kg dose, and there were no deaths for the five animals given the 250 mg/kg dose. The death at 25 mg/kg was most likely an outlier. Doses over 250 mg/kg were difficult to apply because the volume of applied liquid was so large that some of it was likely to run off the skin site protected with SERPACWA. If GF was observed to run off the SERPACWA-protected skin, the animal was excluded from the data analysis. A combination of the EPA/OECD Acute Oral Toxicity Guideline (AOT) 425 (EPA, 2001) and a binomial probability distribution (R. Lee 2006) was used to estimate the LD<sub>50</sub> for GF using the results from the 10 animals dosed at the 250 mg/kg dose (see discussion).

## **RESULTS**

In Appendix A, Tables A1-A5 provide the raw data for the standard decontamination experiments (decontamination 2 minutes postexposure). These tables provide the 24-

hour survival data for positive control animals and animals decontaminated with 0.5% bleach, M291 SDK, RSDL, and 1% soapy water. Five percent GF IPA solution was used for only the first four positive control animals in stage 1 of dosing. All the other animals were challenged with neat GF.

In Appendix A, Table A7 provides the raw data for the SERPACWA experiments. This table provides the 24-hour survival data for animals pretreated with SERPACWA. Neat GF was used for all SERPACWA animals.

In Appendix A, Tables A7-A9 provide the survival raw data for the delayed-decontamination experiments. In delayed-decontamination experiments, the decontamination process was delayed from 0.5 to 90 minutes postexposure. All these animals were challenged with 38.8 mg/kg BW (body weight), representing a 5 LD<sub>50</sub> dosage.

Appendix B provides the SAS output files giving complete details of the data analysis. A fixed limit statistical test was used for the SERPACWA animals so there was no SAS output.

Figure 1 is a graph of the LD<sub>50</sub> values for the four decontamination products and positive control animals in the guinea pig model. The error bars represent the 95% CI. The number of animals used per treatment group was between 21 and 35. All animals were challenged with neat GF. The LD<sub>50</sub> values (95% CI) for positive control, 0.5% bleach, M291 SDK, RSDL, and 1% soapy water were **7.71** (2.51, 10.7), **52.6** (43.4, 9.26), **29.1** (20.1, 42.3), **200** (153, 252), and **46.6** (23.0, 52.0) mg/kg BW, respectively.

Figure 2 contains dose-response curves for decontamination products in the guinea pig model. The LD<sub>50</sub> values (mg/kg BW) are given in the text blocks. The dose-response curve slopes (95% CI) for positive control, 0.5% bleach, M291 SDK, RSDL, and 1% soapy water were **6.94** (-0.224, 14.1), **7.45** (1.88, 13.0), **4.43** (1.84, 7.02), **6.96** (2.10, 11.8), and **17.6** (-0.004, 35.2), respectively.

Figure 3 is a graph of the PR values with respect to the positive controls. The PR values (95% CI) for 0.5% bleach, M291 SDK, RSDL, and 1% soapy water were **6.82** (5.13, 9.09), **3.77** (2.64, 5.40), **25.9** (19.9, 33.6), and **6.04** (4.90, 7.44), respectively. PR values with the same letter were not significantly different.

In the SERPACWA efficacy experiments all animals were challenged with neat GF. The LD<sub>50</sub> value (95% CI) for control animals (same animals as the standard 2-minute decontamination experiments) was **0.771** (2.51, 10.7). The LD<sub>50</sub> value for SERPACWA animals was estimated to be > 250 mg/kg BW by using a combination of a fixed and sequential limit test and observing 1 death in 10 animals all challenged at 250 mg/kg BW. SERPACWA provided excellent protection.

Figure 4 is a graph of percent lethality when 0.5% bleach, RSDL, and 1% soapy water decontamination was delayed following challenge by 38.8 mg/kg (5 LD<sub>50</sub>s) of neat

GF.  $LT_{50}$  (50% lethality time with 95% CI) values for bleach and RSDL were **0.234\*** (0.065, 0.845) and **34.6** (28.3, 41.7) minutes, respectively. \*The  $LT_{50}$  for bleach was estimated using the less conservative delta method instead of the standard, very conservative Fieller's method. The  $LT_{50}$  value for 1% soapy water was estimated to be < 0.5 minutes by using a sequential limit test and observing 9 out of 10 deaths at a delay time of 0.5 minutes. The dose-response curve slopes (95% CI) for 0.5% bleach and RSDL were **2.04** (-0.270, 4.34) and **8.28** (3.07, 13.5), respectively.

Tables 1-3 provide a summary of the SAS probit analysis for all of the experiments. It consists of, for each treatment, the number of animals, the  $LD_{10}$ ,  $LD_{50}$  and  $LD_{90}$  ( $LT_{10}$ ,  $LT_{50}$  and  $LT_{90}$  for delayed-decontamination experiments), the lower and upper 95% CI, the dose-response curve slope, and the PR. The delta method was used to calculate confidence intervals for PRs and to determine which were significantly different.

Data includes SERPACWA experiments from 18 July 2006 to 23 August 2006 (Tables A1 and A6).

Notes for Tables 1-3:

- LD<sub>10</sub>, LD<sub>50</sub>, and LD<sub>90</sub> = the dosage (mg/kg BW) required to kill 10, 50, and 90%, respectively, of the test population by 24 hours postexposure (95% CI using Fieller's method).
- LT<sub>10</sub>, LT<sub>50</sub>, and LT<sub>90</sub> = the delayed-decontamination time at which 10, 50, and 90% of the animals in the test population die by 24 hours postexposure (95% CI using Fieller's method).
- PR = Protective ratio (LD<sub>50</sub> of treatment/LD<sub>50</sub> of control) with 95% CI using the delta method.
- Sig = Protective ratios with same letter were not significantly different (p < 0.05; using the delta method).
- Slope = The slope of the dose-response curve with 95% CI using Fieller's method.
- NA = Not available

## DISCUSSION

### Decontamination Efficacy Experiments

The four decontamination products evaluated can be divided into two categories based on cost and use. The M291 SDK and RSDL are relatively expensive (the RSDL packet costs about \$20 and the M291 SDK cost about \$3.35) and designed to be carried by individuals for immediate lifesaving spot decontamination on small intact skin areas following exposure. The U.S. military began to phase out the use of the M291 SDK in 2008, and it is no longer commercially available. On the other hand, 0.5% bleach and 1% soapy water are relatively inexpensive and generally used for whole body decontamination of an exposed person prior to moving the individual from a dirty zone into a clean zone. All four of these products were described in U.S. doctrine for CWA decontamination of intact skin; however, a comprehensive evaluation comparing the efficacy of these products was never accomplished prior to this study. This technical report is the twelfth in a series to provide a comprehensive comparison of the efficacy of these decontamination products and SERPACWA against many of the traditional agents and other toxic compounds.

The real world threat scenario is for exposure to neat agent not agent in solution. The toxicity of many nerve agents was so great, however, that the dosage volumes required to cover the full range of the dose-response curve for untreated animals were too small to be pipetted reliably. Initially, the decision was made to minimize the pipetting uncertainties in precision and accuracy by using neat agent only whenever the challenge dose required a volume greater than or equal to 0.5  $\mu\text{l}$ .

During the evaluation of toxic compounds, we discovered that the efficacy of a decontamination product can be greatly affected by whether the agent is neat or in solution. We observed that the decontamination products were significantly less effective for animals challenged with agent in solution than when the agent was neat. We theorized that this observation resulted from the solvent increasing the systemic uptake of agent by changing the barrier function of the skin and by spreading the agent over a larger skin area, thus making the decontamination process less effective. These observations caused us to re-think our decision to use agent in solution when evaluating cutaneous treatments. Following this analysis, the decision was made in November 2005 to use only a neat agent challenge for evaluating skin treatments in all future experiments. We recognized that trying to pipette very small volumes (0.05 to 0.5  $\mu\text{l}$ ) could not be accomplished with a high degree of accuracy or precision. We decided it was better to use neat agent and accept this uncertainty than to generate unreliable data from using agent in solution. The uncertainty in delivering these very small volumes was mitigated to some degree by using more animals for each experiment. For positive control animals, which received no treatments, agent in solution was still used if the required volume was  $< 0.5 \mu\text{l}$ . The rationale for this decision was that the agent had 24 hours to reach the systemic circulation; thus a modified penetration rate should not significantly affect the observed 24-hour lethality.

The first day of the GF study was a dose-ranging experiment that used a 5% solution of GF in isopropyl alcohol (IPA) for positive control animals and neat GF for all treatment animals. We observed that GF in untreated animals was much less toxic than many of the other nerve agents, so for the remainder of the study all animals, positive controls and treatment groups, were challenged with neat GF. For consistency, the four initial animals that were challenged with a 5% solution of GF in IPA were omitted from the SAS statistical analysis.

In the standard 2-minute decontamination experiments the calculated PR values (95% CI) for 0.5% bleach, M291 SDK, RSDL, and 1% soapy water were **6.82** (5.13, 9.09), **3.77** (2.64, 5.40), **25.9** (19.9, 33.6), and **6.04** (4.90, 7.44), respectively. All of the tested decontamination products provided significant protection against a GF challenge compared to untreated positive control animals. RSDL was the most effective decontamination product tested and significantly better than any of the other products. Bleach (0.5%) and soapy water (5%) provided equivalent protection and were significantly better than the M291 SDK.

The LD<sub>50</sub> value is traditionally used to compare the toxicity of chemicals; however, the dose-response curve slope is also an important parameter to indicate how quickly the percent lethality changes with applied dose. If the dose-response curve slope is flat, the percent of lethality changes very slowly with changes in dose, and a significant percentage of deaths is observed at doses far removed from the LD<sub>50</sub> dose. The PROBSEP program run in SAS to analyze this data set not only provided the LD<sub>50</sub> values but also gave doses for the complete range of lethality percentiles including 1, 10, 16, 30, 50, 70, 84, 90, and 99. The doses for this entire range are listed in the SAS output files recorded in Appendix B. Table 1 provides the slope, LD<sub>10</sub>, LD<sub>50</sub>, and LD<sub>90</sub> values along with the 95% CI values so that the reader can fully understand the toxicity of GF and the effectiveness of the products tested.

In a real-life scenario, warfighters or civilians may not realize that they have been contaminated with a toxic agent. Thus, they may not start the decontamination process until well after the recommended time of 1 or 2 minutes postexposure. The conventional wisdom for many years was that decontamination would only be effective if performed in the first few minutes after exposure. When this study started in 2005, no comprehensive evaluations were available on the effectiveness of decontamination products beyond the standard 2-minute delay time. A limited study (Hamilton et al., 2004) using only 3 animals per treatment group evaluated VX decontamination with RSDL in swine (Yorkshire-Landrace cross, 20 kg). In the Hamilton et al. study, RSDL was found to be significantly effective 15 minutes postexposure for neat VX challenge to the ear but not significantly effective 30 or 60 minutes postexposure for neat VX challenge to the epigastrium (belly). Recognizing the need for a comprehensive study, the scope our current study was expanded to include delayed-decontamination studies.

A fixed neat GF challenge dose of 38.8 mg/kg BW (5 LD<sub>50</sub>) was used for all GF delayed-decontamination studies. This value was based on the results for the positive control animals. We used a 5 LD<sub>50</sub> challenge because historically a 5 LD<sub>50</sub> dose was the

suggested minimum target for medical countermeasure therapeutics selected for fielding. The lethality delay time-response curves were generated using the stage-wise adaptive dose design similar to the LD<sub>50</sub> dose-response studies using the delay time in place of the mg/kg dose. The standard SAS probit analysis program was used to find the lethality percentiles associated with a given decontamination delay time. The LT<sub>10</sub>, LT<sub>50</sub>, and LT<sub>90</sub> values were defined as the delayed-decontamination times at which 10, 50, and 90% of the animals in the test population died following a 38.8 mg/kg (5 LD<sub>50</sub>) neat GF challenge. A PR of 5, which is directly related to protection from a 5 LD<sub>50</sub> challenge, was the decision criteria for choosing the decontamination products for the delayed-decontamination experiments. Any decontamination products with a PR > 5 would be evaluated for delayed decontamination. For the GF experiments RSDL, 0.5% bleach, and 1% soapy water met this requirement. The M291 SDK with a PR of only 3.77 was omitted from the delayed-decontamination experiments.

In the neat GF delayed-decontamination experiments, the estimated LT<sub>50</sub> (50% lethality time with 95% CI) values for bleach and RSDL were **0.234** (0.065, 0.845) and **34.6** (28.3, 41.7) minutes, respectively. The LT<sub>50</sub> for bleach was estimated using the less conservative delta method instead of the standard, very conservative Fieller's method. There were insufficient data for the Fieller's method to produce meaningful output. The less rigorous delta method was able to use the experimental results to estimate the dose-response curve with 95% CI values. Additional animals were not used because it was unlikely that useful data would be generated. This series of experiments suggests that the window (less than 30 seconds) for effective decontamination using 0.5% bleach is very short. It should be noted that the very short window for effective decontamination using bleach was not consistent with the data generated four years earlier in the standard 2-minute decontamination experiments. The PR (95% CI) for 0.5% bleach in the standard 2-minute delay experiments was 6.82 (5.13, 9.09), suggesting that decontamination at 2-minutes postexposure would protect at least 50% of the animals following a 5 LD<sub>50</sub> challenge. A possible explanation is the 4-year time difference and large variation in the observed data for the delayed-decontamination experiments.

The LT<sub>50</sub> value for 1% soapy water was estimated to be < 0.5 minutes by using a sequential limit test and the Binomial Exact Probability Table and observing 9 out of 10 deaths at a delay time of 0.5 minutes. For more details about the sequential limit test and the Binomial Exact Probability Table see the discussion about SERPACWA.

For GF, the window for effective decontamination for 0.5% bleach and 1% soapy water was less than 0.5 minutes; however, the window for effective decontamination using RSDL was around 35 minutes for 50% survival. A more preferable time, however, is the time in which few deaths are expected. The 10% lethality delay time (95% CI) for RSDL was **24.2** (13.9, 29.3) minutes.

Recent studies using Raman confocal microspectroscopy (Braue et al., 2015) demonstrated that RSDL has the ability to remove VX from a VX depot in the top layers of the stratum corneum. It is likely that GF also forms a GF depot in the stratum

corneum following percutaneous exposure. The effectiveness of RSDL against GF may partially be explained by the ability of RSDL to remove the GF depot. This speculation could be confirmed by experiments if funding were available.

## **SERPACWA Efficacy Experiments**

SERPACWA provided good protection against GF. The LD<sub>50</sub> was estimated to be at least 250 with a PR estimated to be greater than 32. SERPACWA data analysis, however, presented a challenge. Twenty-two animals were initially dosed with challenges ranging from 0.5 mg/kg to 250 mg/kg. Only one death occurred at the 25 mg/kg dose, and there were no deaths for the five animals given the 250 mg/kg dose. The death at 25 mg/kg was most likely an outlier. Dosing volumes higher than 250mg/kg were likely to likely to run off the skin site protected with SERPACWA. Therefore, the AOT 425 procedures were used to estimate the LD<sub>50</sub> for GF using the results from the 10 animals dosed with the 250 mg/kg dose.

The AOT 425 is used by the EPA to provide a gross classification of a chemical's toxicity. It consists of two tests, a limit test and a main test, which are sequential tests, i.e., dosing one animal at a time. The EPA uses these tests with maximum limit doses of either 2000 or 5000 mg/kg and a maximum of five animals. Based on the number of deaths among the five animals, the test determines if the LD<sub>50</sub> is above or below the limit dose.

The procedures for the limit test are as follows: dose one animal at the limit dose. If the animal dies, then switch to the main test. If the animal lives, dose four additional animals sequentially at the same dose for a total of five animals at the same dose. If during the sequential dosing, three animals have died, then switch to the main test. If three or more of the five animals dosed survive, then the LD<sub>50</sub> is greater than the limit dose used. If three or more animals die, then the LD<sub>50</sub> is less than the limit dose used, and an estimate of the LD<sub>50</sub> is made using the main test.

In this study, the first five animals that received the 250 mg/kg dose were dosed in a sequential manner along with the other animals that were dosed at lower doses. The last five animals dosed at 250 mg/kg were all dosed at once. Of those last five animals, only one died. By using the limit test approach from the AOT 425 with 250 mg/kg as the limit dose for each set of five animals, we can conclude that the LD<sub>50</sub> is greater than 250 mg/kg.

Another approach is to use a binomial probability distribution (R. Lee, 2006) on both groups of animals combined, n=10. If the LD<sub>50</sub> is 250 mg/kg then the death/survival rate would be 50%. We can determine the cumulative probability of observing one or fewer deaths out of ten animals using Table 4 below. We observe that the exact probabilities for 0 deaths out of ten animals is 0.1% and for 1 death out of ten animals is 0.98%. To obtain the cumulative probability, we add these two percentages together. Therefore, the cumulative probability of the 250 mg/kg dose being the LD<sub>50</sub> (i.e. having a 50% death/survival rate) is 1.08%. Since this is less than a 5% error rate, we reject the assumption that 250 mg/kg is the dose at which we would see 50% of the animals die (LD<sub>50</sub>) and conclude that the LD<sub>50</sub> is greater than 250 mg/kg.

Total Exposed	Deaths	Probability (%)	Deaths	Probability (%)
5	0	3.13	1	15.6
6	0	1.56	1	9.4
7	0	0.78	1	5.4
8	0	0.39	1	3.1
9	0	0.20	1	1.76
10	0	0.10	1	0.98

Table 4. Binomial Probability Distribution of Observed Death

In 2009, the Department of the Army decided that there was no longer a requirement for SERPACWA, since the new JSLIST protective suit was reported to solve the problem of leaking at the junction points (neck, wrist, waist, and ankle). Thus, SERPACWA was removed from the Army's stockpile and destroyed. Since that time, new evidence has suggested that a barrier cream like SERPACWA may still be needed.

## CONCLUSIONS

- RSDL provided good protection against GF with a protective ratio of **25.9** and was significantly better than the other products tested.
- The relative order of decontamination efficacy against GF was RSDL > 0.5% bleach and 1% soapy water > M291 SDK.
- The window for effective decontamination following percutaneous exposure from GF was about 35 minutes for RSDL but less than 30 seconds for 0.5% bleach and 1% soapy water.
- Skin Exposure Reduction Paste Against Chemical Warfare Agents (SERPACWA) provides superior protection against GF with a protective ratio of greater than 250.

## FIGURES

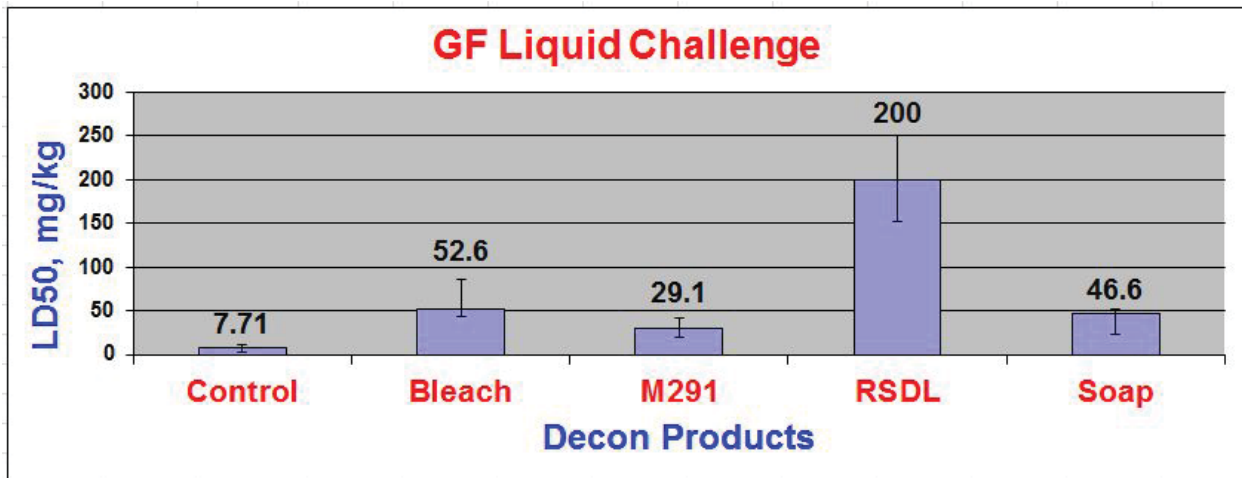

Figure 1. Graph of LD<sub>50</sub> values for decontamination products in guinea pig model. Error bars = 95% CI. The numbers of animals used per treatment group were 21 - 35. Animals were challenged with neat GF. The LD<sub>50</sub> values (95% CI) for positive control, 0.5% bleach, M291 SDK, RSDL, and 1% soapy water were **7.71** (2.51, 10.7), **52.6** (43.4, 9.26), **29.1** (20.1, 42.3), **200** (153, 252), and **46.6** (23.0, 52.0) mg/kg BW, respectively.

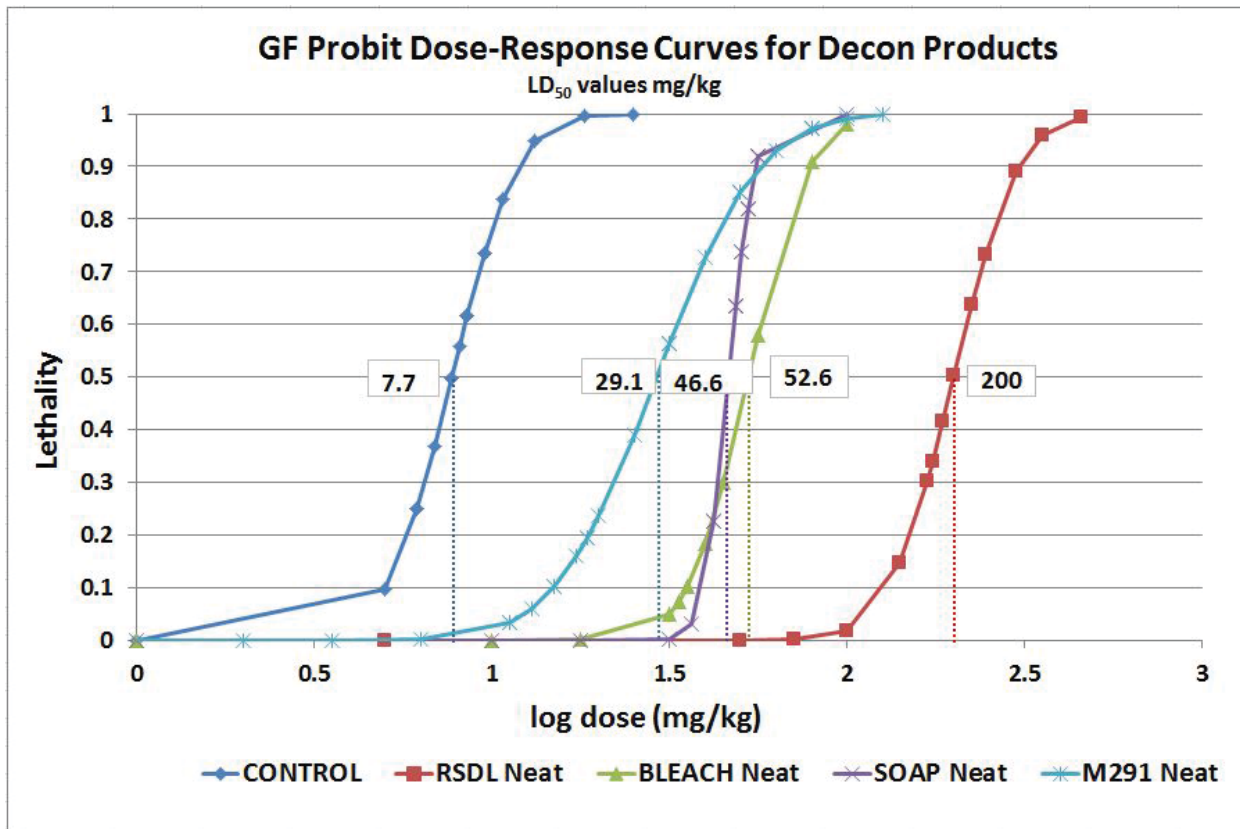

Figure 2. Dose-response curves for decontamination products in guinea pig model. Neat GF was used for all animals. LD<sub>50</sub> values (mg/kg BW) are given in text blocks. Dose-response curve slopes (95% CI) for positive controls, 0.5% bleach, M291 SDK, RSDL, and 1% soapy water were **6.94** (-0.224, 14.1), **7.45** (1.88, 13.0), **4.43** (1.84, 7.02), **6.96** (2.10, 11.8), and **17.6** (-0.0037, 35.2), respectively.

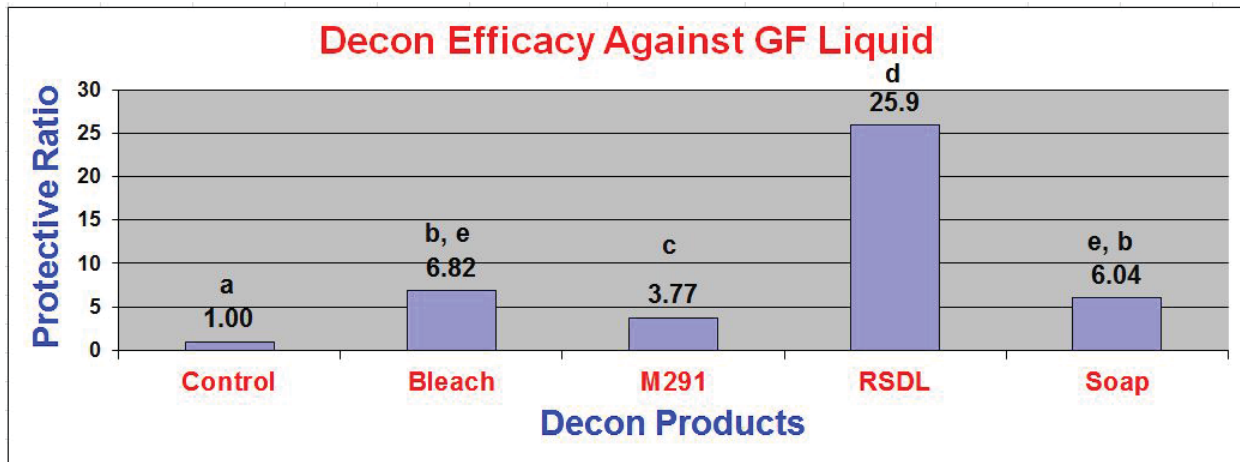

Figure 3. Graph of protective ratio (PR) values for decontamination products in guinea pig model. Animals were challenged with neat GF. The PR values (95% CI) for positive control, 0.5% bleach, M291 SDK, RSDL, and 1% soapy water were **1.00**, **6.82** (5.13, 9.09), **3.77** (2.64, 5.40), **25.9** (19.9, 33.6), and **6.04** (4.90, 7.44), respectively. PRs with same letter were not significantly different.

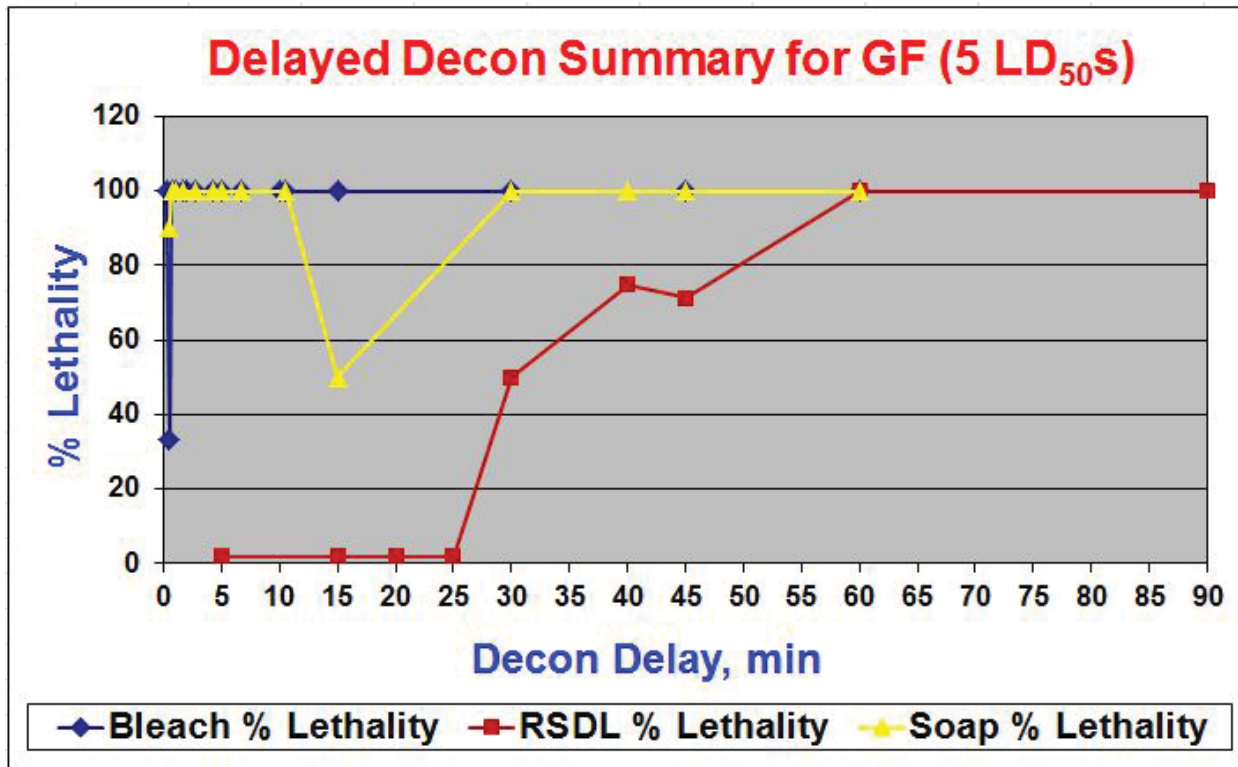

Figure 4. Graph of percent lethality when 0.5% bleach, RSDL, and 1% soapy water decontamination was delayed following challenge by 38.8 mg/kg (5 LD<sub>50</sub>s) of neat GF. LT<sub>50</sub> (50% lethality time with 95% CI) values for bleach and RSDL were **0.234\*** (0.065, 0.845) and **34.6** (28.3, 41.7) minutes, respectively. \*The LT<sub>50</sub> for bleach was estimated using the less conservative delta method instead of the standard, very conservative Fieller's method. The LT<sub>50</sub> value for 1% soapy water was estimated to be < 0.5 minutes by using a sequential limit test and observing 9 out of 10 deaths at a delay time of 0.5 minutes. The dose-response curve slopes (95% CI) for 0.5% bleach and RSDL were **2.04** (-0.270, 4.34) and **8.28** (3.07, 13.5), respectively.

## APENDIX C: EPA LIMIT TEST OUTPUT FILES

### EPA LIMIT TEST USING AOT425 STATPGM (version: 1.0) ANALYSIS FOR SERPACWA GF LD<sub>50</sub> Final Report After complete QC Audit of Data

File: GF SERPACWA Statistical Analysis Output 061018 Final.doc

AOT425statpgm (Version: 1.0) Test Results and Recommendations  
Acute Oral Toxicity (OECD Test Guideline 425) Statistical Program

Date/Time: Tuesday, August 29, 2006, 10:43:35 AM  
Data file name: braue2.dat  
Last modified: 8/29/2006 10:43:32 AM

Test/Substance: Enter test description.  
Test type: Limit Test  
Limit dose (mg/kg): 2000  
Assumed LD50 (mg/kg): Default  
Assumed sigma (mg/kg): 0.5

DATA:

Test Seq.	Animal ID	Dose (mg/kg)	Short-term Result	Long-term Result
1	1	250	O	O
2	2	250	O	O
3	3	250	X	X
4	4	250	O	O
5	5	250	O	O

(X = Died, O = Survived)

Dose Recommendation: The limit test is complete.

WARNING:

Please review the data for accuracy.  
The limit test data includes doses well below the limit dose.

SUMMARY OF LONG-TERM RESULTS:

Dose	O	X	Total
250	4	1	5
All Doses	4	1	5

Statistical Estimates:

The LD50 is greater than 250 mg/kg.

AOT425statpgm (Version: 1.0) Test Results and Recommendations
