Report Title

Final Report: Noble Gas Plasmas with Metallic Conductivity: A New Light Source from a New State of Matter

ABSTRACT

Dense plasmas form a non-ideal, correlated state. We have recreated the plasma inside sono-luminescing bubbles with sparks and laser breakdown, which has dramatically simplified their study. These plasmas can be used for rapid, broadband optical switching and high-harmonic generation.

Dense microplasma condensate
formed by laser breakdown

MicroPlasmas are Exotic Plasmas

Tachibana

40.kHz ; flash width ~35.ps
Plasma density ~ $10^{22}/\text{cc}$
Radius ~ $1.\mu\text{m}$

fs laser breakdown
In a dense gas

Spark discharge
Electrode spacing= $100\mu\text{m}$

Demonstration of Opaque Plasma Discharge Blocking Intense Laser Pulse-due to formation of dense plasma condensate

b) Intense laser pulse arrested at plasma surface

Practically limitless power handling capability. The switch cannot be broken as it is already the broken state of matter!

Blocking light over six orders of magnitude of intensity; rise time not resolved-here

Normalized laser transmission of spark discharges formed in 10 bar xenon gas as a function of time and spanning 6 orders of magnitude in laser intensity. Laser transmission was recorded for 532 nm laser pulses focused through the center of the spark plasma. Intensities below the laser breakdown threshold (solid curves) produced nearly identical transmission curves indicating a linear laser-plasma response. Intensities above the laser breakdown threshold (dashed curves) deviated from the former curves with an increasingly nonlinear laser-plasma response, resulting in greater opacity for a longer period of time.

Switch Turns on Sub-ns

Blackbody is Established Within a Few Microns

Sun is evenly bright and that is typical of a BB— contrast to a projection lamp

- Plasma is opaque within 500 ps making for an easier switch!
- Plasma opaque within 4 μm
- Plasma surface temperature (24,000K) is uniform in both time and space. The reason for this is unknown and points toward fundamental plasma processes.
- Plasma expansion is 2 km/s and points towards a hydrodynamic expansion...or perhaps an ionization wave?

Temporal and Spatial Line-Outs

Temporal line-out: Intensity flattop in time shows a uniform temperature in time and a blackbody which blocks incident light for over 20 ns.

Spatial line-out: Intensity flattop in space infers a blackbody. Furthermore, the plasma has a uniform temperature across the plasma surface. This feature is robust and not fully understood.

Sub-Nanosecond Opacity Switch

Opacity Rise Time is as fast as spark rise time and
3x faster than simple mobility model

Randomly triggered by uv lamp
Spark transit time estimate:
based on electron mobility in xenon gas

$t = L^2 / \mu V = 1.9$ ns, roughly consistent with
observations – MPD is about 3 times
FASTER than simple mobility model.

for $L = 170$ μm , $V = 5000$ kV, $\mu = 30$ cm^2/Vs
 μ from Huang and Freeman 1977

Temporal line-out

**Discharge reaches opacity in
~0.1% the speed of light!
Can block leading edge**

High-Power Dense Microplasma Optical Switch:

Dense Plasmas are Ideal for High Power Switching Because A Plasma is the Broken State of Matter

Spark Blocking Laser Pulse that is Incident from the Right

Spark Discharge

Laser Pulse

Spark is capable of blocking high-power laser pulse, with nearly infinite power-handling capability. Protect sensitive equipment or select individual laser pulses.

Plasma Shield

“Leading Edge” can be blocked
(with adapted device – not pictured)

Dense Microplasma Intensity Saturation

- Universal energy-density-limiting phenomenon seen in sonoluminescence, sparks, laser breakdown, and nuclear explosions.
- Review 1958 Vanyukov and Mak: *"High-Intensity Pulsed Light Sources."*
- Explanation has been debated for >50 years.
- Yusupaliev: energy out increases too rapidly to be overcome with any system → determines limiting temperature.
- T_{lim} is only gas dependent, system irrelevant.
- Uniform in space, time, voltage, pressure, gap distance
- Could make excellent calibration source.

Gas	T_{LIM}, K	Ξ_{LIM}	$I_f(I_{eff}), eV$	I_2, eV	$\frac{kT_{LIM}}{I_1 + I_2}$	
Xe	27000–29000 (2.33–2.5)	2.0	12.13	21.20	0.072	0.074
	30000				0.076	
Kr	32000 (2.76)	2.6	13.90	24.60	0.071	0.073
	34000 (2.93)				0.076

	37000 (3.187)				0.074	
Air	43000 (3.7)	5.6	16.0	32.36 oxygen atom		0.076
N_2	41000 (3.53)		16.5	29.60		0.077
Ne	52000 (4.48)	6.5	21.56	40.96		0.072
He	67000–71000 (5.77–6.12)	8.0	24.59	54.42	0.073	0.075
					0.077	

U. Yusupaliev 2010, also see 2012

Xenon 10 bar - 5 kV Discharge

Fs laser-breakdown seed

Luminosity Saturation in other systems: Sonoluminescence

- For a well-controlled system of water Sonoluminescence, where system parameters are kept fixed and gases are varied, $\chi / k_B T = \text{constant}$
- Almost all Sonoluminescence (1 MHz is the only exception) indicates a maximum achievable temperature of $\sim 20,000$ K, no matter how hard it is driven. Energy appears to be converted to a larger size (Ramsey, Cone Bubble, Shake Tube, Drop Tower).

Shock Wave Emission from a Dense MP

- Shock waves tell us hydrodynamic motion and that the plasma is expanding. This guides our efforts in both studying the dense plasma and designing an optimum switch.
- Shock waves also tell us the initial plasma energy and gives information towards an equation of state.

Although the field is as old as electricity, many spark discharge features remain unknown:

"We have pointed out that the problem of streamer head radius still remains to be solved. Today, there is no adequate theory, nor is there convincing experimental evidence to determine the head size reliably."

Dwell Time of Plasma Condensate

Ambient pressure before breakdown = 10.atm

Electron temperature after breakdown = 25,000K

Pressure. 3,000.atm

Plasma charge density $\sim 10^{21}/\text{cc}$

Yet H plasma dwells for 200ps; D plasma for 400.ps

Plasma Parameter = Γ ; $a \sim 8\text{\AA}$

$$\Gamma = e^2 / akT ; a = (3 / 4\pi n_e)^{1/3}$$

If the ions are at ambient Temperature
then $\Gamma(\text{ions}) = 70$

Which is very strong coupling

Electron- IonAcoustic phonon Interaction Dominates Thermalization

Ions and electrons should equilibrate in 10ps, but interaction is much slower, because energy transport in a plasma condensate is not due to binary collisions but is more like much weaker electron- phonon interactions.

Blackbody temperature vs. time

Is reduced scattering during dwell the key to achieving energy densities beyond the Yusupaliev limit?

Transmission measurements also match emission waist dwell times

Resonant Ion Acoustic Waves in Plasma Bulb

- We can excite **resonant** acoustic modes in plasma bulb.
- Can they be used to: 1) gain insight into ion behavior.
2) confine/stabilize dense plasma.

Beating between ~ 10 kHz drive frequency and nearby natural mode.

Can one achieve a confined steady state dense plasma

Plasma Harmonic Generation

Plasmas are intrinsically nonlinear especially at boundaries—where a sheath forms

Characteristic length for plasma sheath is:

$$\delta = \sqrt{\varepsilon_0 k T_e / e^2 n_0}$$

Dielectric boundary becomes charged so:

$$e\phi / kT_e \sim 5$$

Electron fluid oscillates in the static potential field of the ions

If amplitude of oscillation $\sim \delta$
we can expect non-linear
behavior in the sheath region

Non-linear Sheath Interaction

- Use external field to drive plasma to slosh between dielectric plates, forming dipoles with non-linear response.

$$\delta = \sqrt{\epsilon_0 k T_e / e^2 n_0} = 700 \text{ nm} \quad \text{for } T=10,000 \text{ K} \\ n_e = 10^{14} / \text{cm}^3$$

$$x_0 = \frac{q E_0}{m \omega^2} = 3 \text{ um} \quad \text{for } E_0 = 100 \text{ kV/m at } 2.5 \text{ GHz}$$

- Dipoles can be arranged for optimal harmonic radiation

Non-linear Sheath Interaction - Practice

Glass Capillary Array

- Plasma is generated inside the low pressure cell, and diffuses into the capillary array.
- The field forces the plasma to slosh back and forth non-linearly.
- Each capillary can be viewed as one element of an antenna array radiating into the cavity

and into microwave cavity

Inserted into low pressure cell

Recent Accomplishments under MPD Program at UCLA- Submitted by Seth Putterman ; Aug 7, 2015

- **Evidence that a metallic proton fluid microplasma forms under rapid ionization of hydrogen gas**
Based upon our plasma dwell time measurements 2015
- **Hydrogen microplasma has a long lived hot electron gas**
Based upon spectral measurements and explained by reduced scattering cross section with protons due to their liquid properties. 2015
- **Isotope effect observed in rapidly ionized microplasma 2015**
- **Nanosecond switch with infinite power handling capabilities from UV to IR-2014**
APPLIED PHYSICS LETTERS 105, 223501
- **Screening increases the time between collisions in a dense plasma- 2014**
Phys. Rev. Lett. 113, 024301
<http://physics.aps.org/articles/v7/72> News Story Physics Focus- "Plasma Extremes"

Nature likes to form dense microplasmas when gases are energized. We have seen that this can be achieved with Acoustics = sonoluminescence, Electrically = sparks; and Optically = laser breakdown

Condensate , opacity , dwell, resonant plasma acoustics.

These plasmas offer new equations of state; opportunities for new devices, including hhg

Laser Breakdown Lowering

- Liquids categorically have a breakdown threshold $\sim 10\times$ lower than gases.
- Adding impurities to liquid can lower threshold another 3-10x.

Circuit boards made as a simple fast method of measuring Optical prop and resistivity.

Potential active-medium: Silicon oil with or without additives

- Benefits:
- Transparent
 - Heals after breakdown
 - Stable. Can withstand high, used in HV caps
 - High resistivity
 - Added impurity: dispersed TiO_2 nanoparticles

Optical Arrangement for quickly testing optical breakdown of liquid mixtures:

Silicon Oil
with 0.2% TiO_2

Thickness fiberglass board 2mm
conductivity and optical accessibility--

Incoming Laser

Substance	Intensity for breakdown, W/cm ² 2.1 ns 532 nm pulse.
Air	$5 * 10^{11}$
10 Bar Xe	$2 * 10^{11}$
Water	$1.3 * 10^{11} +-. .4 * 10^{11}$
Si Oil	$5 * 10^{10} +-. 1 * 10^{10}$
Si Oil with .001% TiO ₂	$3 * 10^{10} +-. 1 * 10^{10}$

The observed reduction in the laser breakdown threshold of silicone oil as compared to high pressure xenon demonstrates that the dense plasmas studied throughout this program may be achievable with less energy when seeded in a denser precursor. This discovery widens our present ability to study how such plasmas handle excess energy beyond what is necessary for plasma formation. Knowing whether the excess is consumed for further local ionization, deposited into a larger profile, dissipated as heat, or radiated acoustically would inform on the limits of creating this state of matter. Additionally, these results indicate a need to examine the time scales over which plasma formation occurs in a more highly correlated starting medium. Such research may give insight into the sub-nanosecond turn-on times observed following the femtosecond laser-seeded high voltage breakdown.
