Security in an Agile World

Achieving Ongoing Authorization Decisions

DevOps Strategies

What are the core strategies of the DevOps paradigm?

Design flexible software architecture encompassing simple, independent components

Implement frequent, incremental changes

Integrate innovative, customizable tools that can automate maintenance processes to include communications, testing, deployment, cyber security . . .

DevOps is an Extension of Agile Thinking

Agile

Embrace Constant Change

Embed Customer in team to internalize expertise on domain and requirements

DevOps

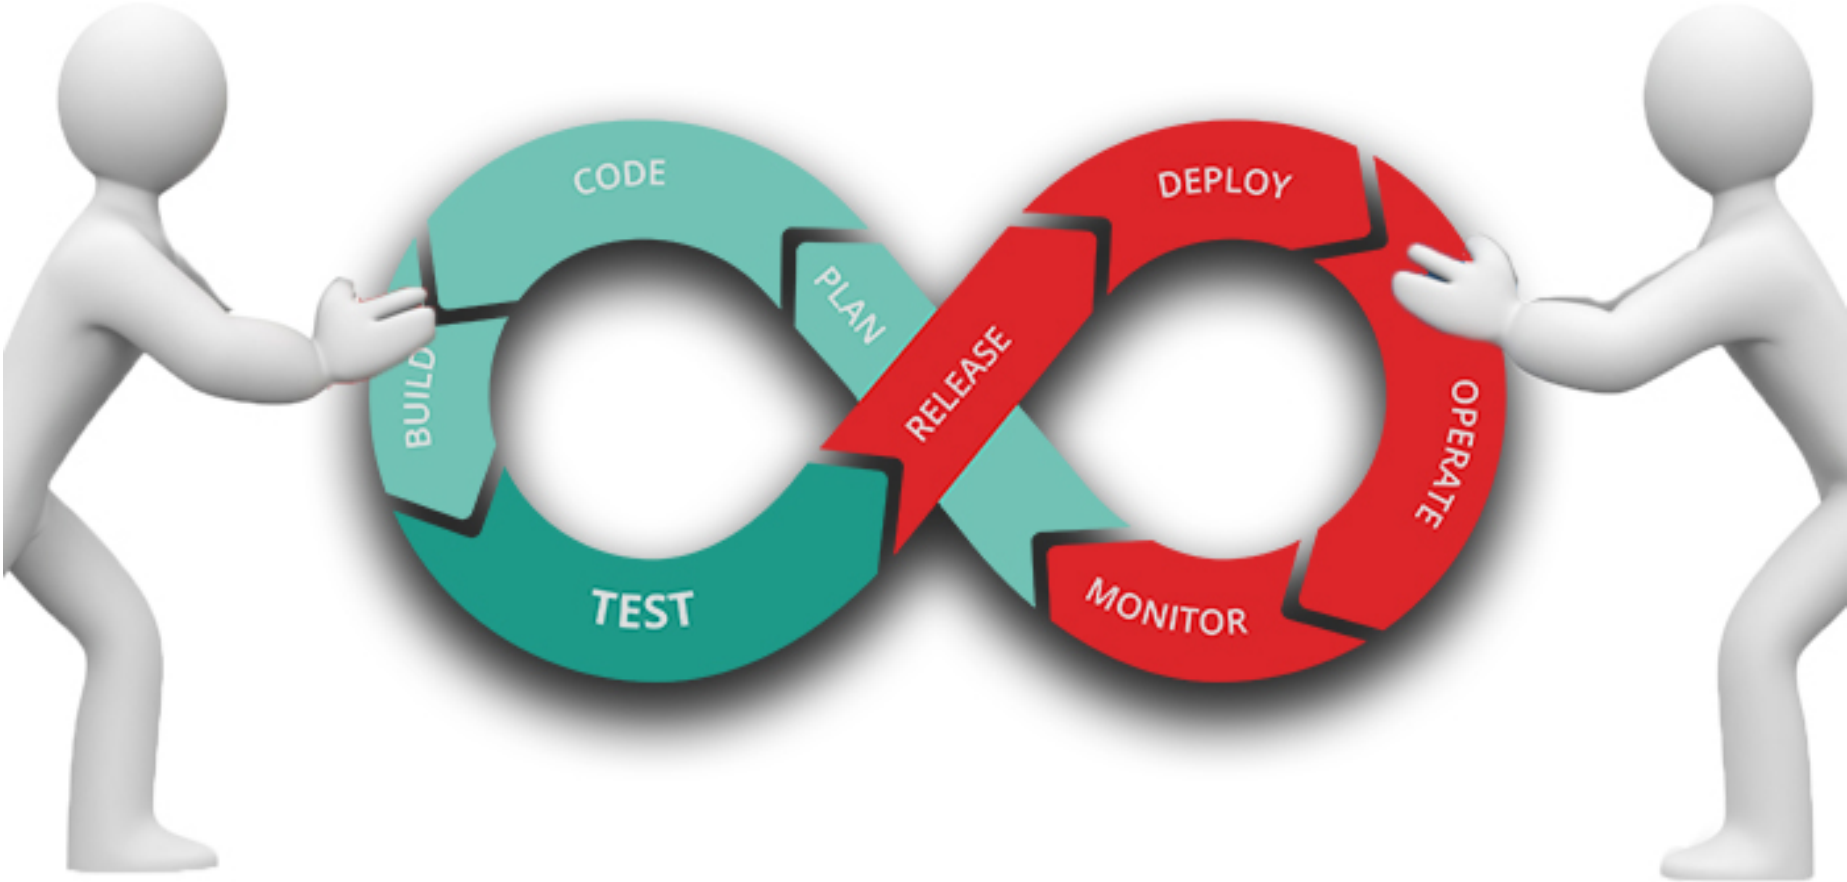

Embrace Continuous Integration, Testing, Delivery

Embed Operations in team to internalize expertise on delivery and maintenance

DevOps Phases

DEVELOPMENT

OPERATIONS

Security in an Agile World

Achieving Ongoing Authorization Decisions

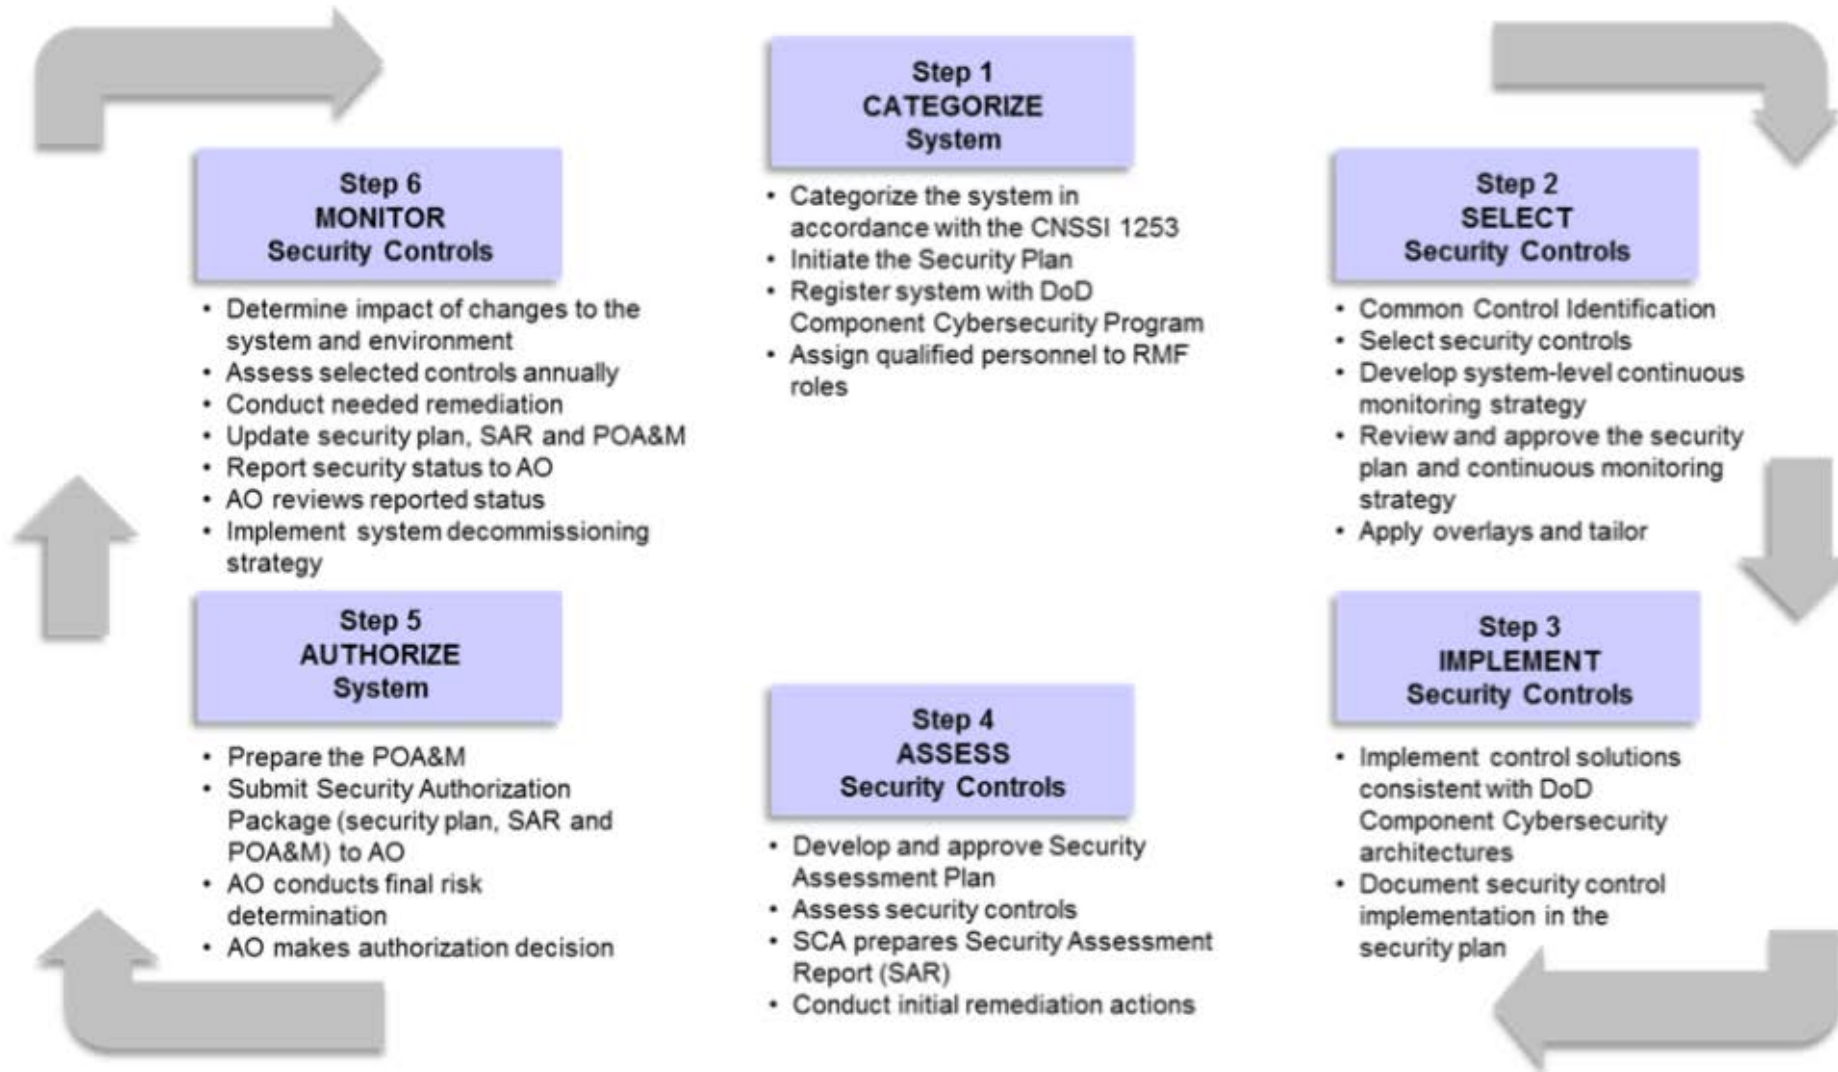

What is the Risk Management Framework (RMF)?

In 2014, the DoD started transitioning from the DoD Information Assurance Certification and Accreditation Process (DIACAP) to the Risk Management Framework for the DoD IT (RMF).

NIST Special Publication 800-37, "Guide for Applying the Risk Management Framework to Federal Information Systems", transforms the traditional Certification and Accreditation (C&A) process into the six-step Risk Management Framework (RMF).

The Risk Management Framework (RMF) provides a disciplined and structured process that integrates information security and risk management activities into the system development lifecycle.

What is the RMF?

The RMF/ATO Problem

Every system has **inherent risks** associated with it.

Program Manger (PM) is **graded** against the system's **KPP** and their compliance with all **regulations**, along with **cost** and **schedule** parameters.

PM makes **trades** between cost, schedule, quality, and functionality. With each trade **residual risks** occur.

Someone must **accept ALL residual risk** associated with the system before placing it into operations.

The Authorizing Official (AO) is responsible to **accepting information security risks**, which is done through the RMF process.

An ATO is usually good for 3 years, but **assumes no major changes** to the system's cybersecurity posture will be made during that time.

When **changes** do occur the AO may require a **reassessment** and **reauthorization**, which impacts the PM's cost and schedule and is **contrary to being Agile**.

RMF's Solution to Problem

RMF encourages an alternative approach to the traditional 3 year ATO process through ongoing authorization decisions or continuous reauthorization.

RMF assumes these systems have “been evaluated as having sufficiently robust system-level continuous monitoring programs”

Security in an Agile World

Achieving Ongoing Authorization Decisions

Security in an Agile World - 1

Security is often focused on testing, and security activities are often conducted outside and apart from the software development process.

As a result, the outcomes of security activities are presented in documents and outputs that do not naturally fit any of the software development activities.

Water - Scrum - Fall

Business

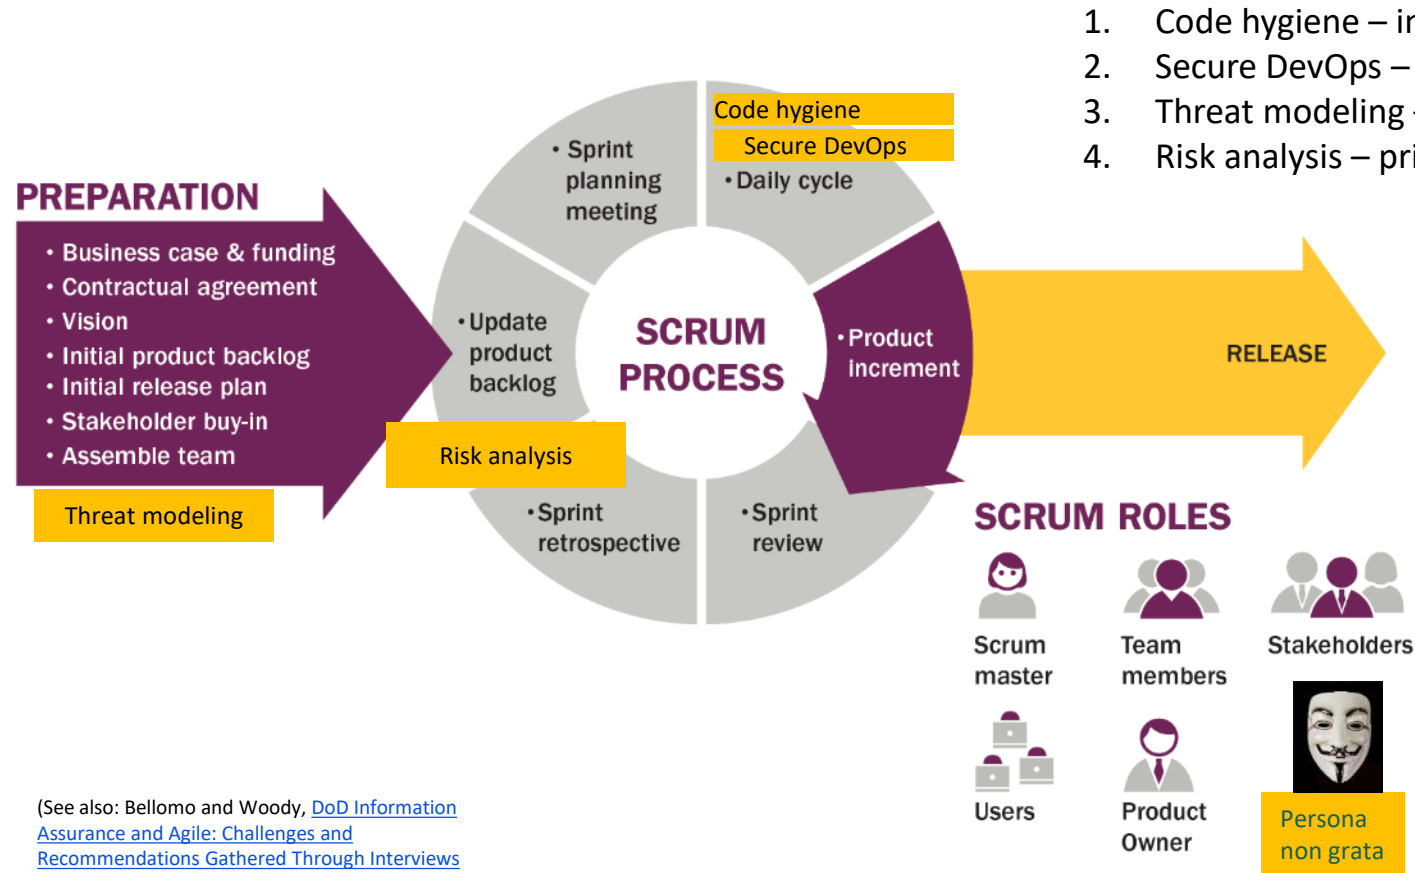

Development

QA
Operations

Integrating security into Agile (Scrum) development

1. Code hygiene – introduce secure coding
2. Secure DevOps – include security tools
3. Threat modeling – represent a new role
4. Risk analysis – prioritize in backlog

(See also: Bellomo and Woody, [DoD Information Assurance and Agile: Challenges and Recommendations Gathered Through Interviews with Agile Program Managers and DoD Accreditation Reviewers](http://repository.cmu.edu/cgi/viewcontent.cgi?article=1674&context=sei) (<http://repository.cmu.edu/cgi/viewcontent.cgi?article=1674&context=sei>))

Security in an Agile World - 2

The goal is to guide the development of new activities and make adjustments to existing activities to make it natural and efficient to build security into an agile process.

DevSecOps Manifesto (<http://www.devsecops.org>)

Leaning in over Always Saying “No”
Data & Security Science over Fear, Uncertainty and Doubt
Open Contribution & Collaboration over Security-Only Requirements
Consumable Security Services with APIs over Mandated Security Controls & Paperwork
Business Driven Security Scores over Rubber Stamp Security
Red & Blue Team Exploit Testing over Relying on Scans & Theoretical Vulnerabilities
24x7 Proactive Security Monitoring over Reacting after being Informed of an Incident
Shared Threat Intelligence over Keeping Info to Ourselves
Compliance Operations over Clipboards & Checklists

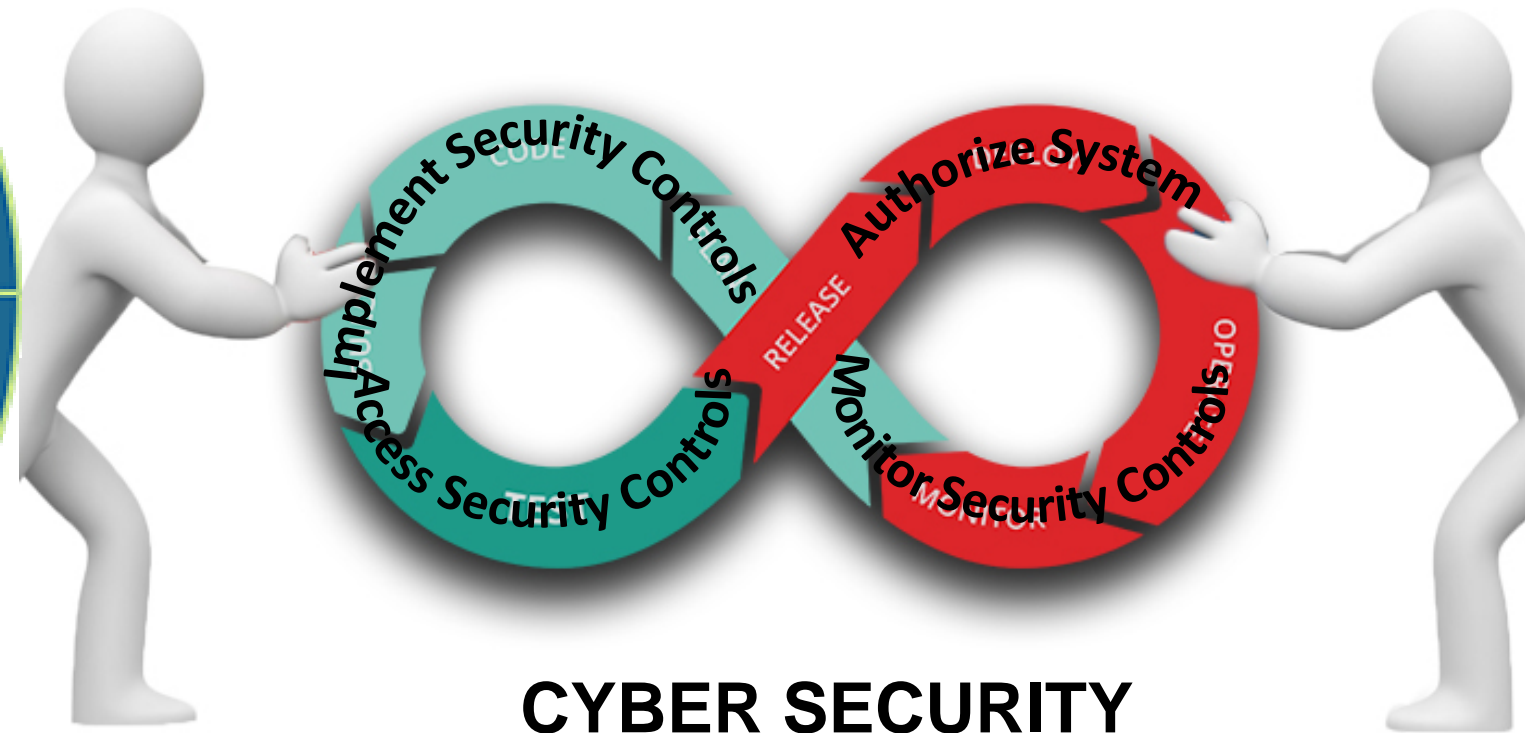

“By developing security as code, we will strive to create awesome products and services, provide insights directly to developers, and generally favor iteration over trying to always come up with the best answer before a deployment.”

DoD SDLC, RMF, and DevOps

RMF's Continuous Reauthorization concept directly aligns with DevOps

CYBER SECURITY

<http://www.truestonefed.com/wp-content/uploads/2016/09/risk-management-wheel.gif>

Effective Security Must be Integrated

The Application Layer is the new perimeter exploited by 84% of breaches

Security must be Engineered into the Lifecycle of Applications changing the way we build and buy technology

- “76 percent of U.S. developers use no secure application program process”⁴
- “More than 40 percent of software developers globally say that security isn't a top priority for them”⁴
- 2017 less than 5% of DevOps initiatives have achieved the level of security automation required to be considered fully DevSecOps.³

What is DevOps

What is RMF

Security in an Agile World

Achieving Ongoing Authorization Decisions

DevOps Has Four Primary Focus Areas

Collaboration between project team roles

Infrastructure as Code: Scripted Infrastructure Configuration

Automation of Tasks / Processes / Workflows

Monitoring Applications and Infrastructure

DevOps Uses Automation to facilitate Communication

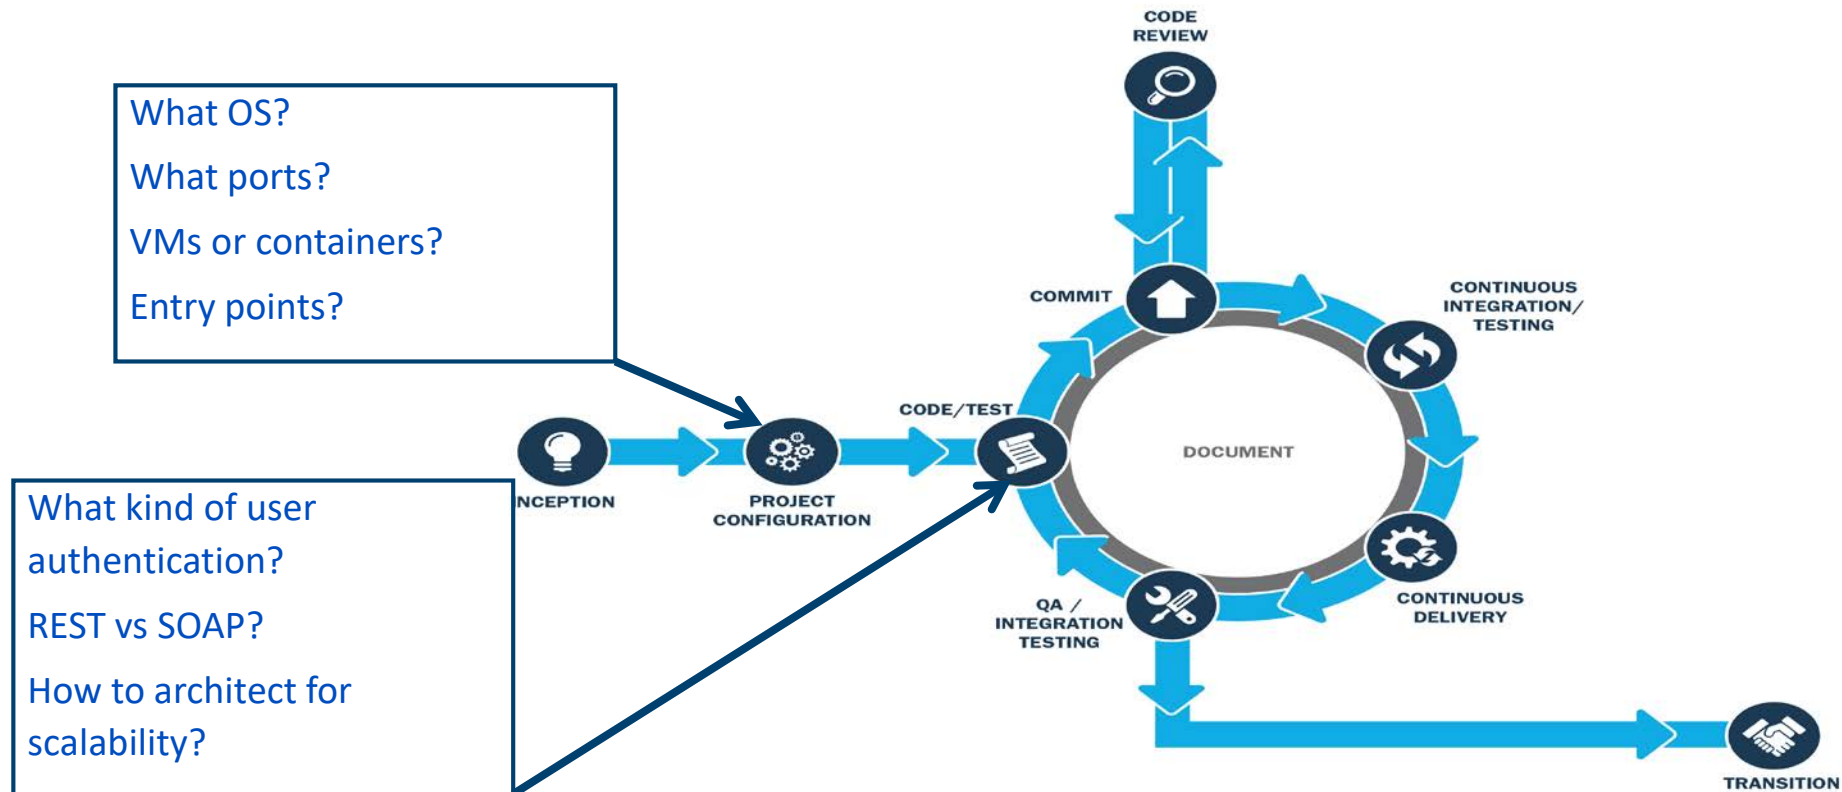

- Define Problem Domain
- Capture, Analyze, Track, and Communicate changes
- Collaborate Across Cross-Functional Team
- Used in support controls such as:
 - CA-7(1) Continuous Monitoring
 - CM-2 Baseline Configuration
 - CM-3 Configuration Change Control
 - CM-4 Security Impact Analysis
 - IR-4 Incident Handling
 - MA-6 Timely Maintenance

The SDLC is Full of Decision Points

Without Ops knowledge, developers continually make uninformed decisions, causing eventual *risk* or *inefficiency*

The SDLC contains many Decision Points with Security Implications

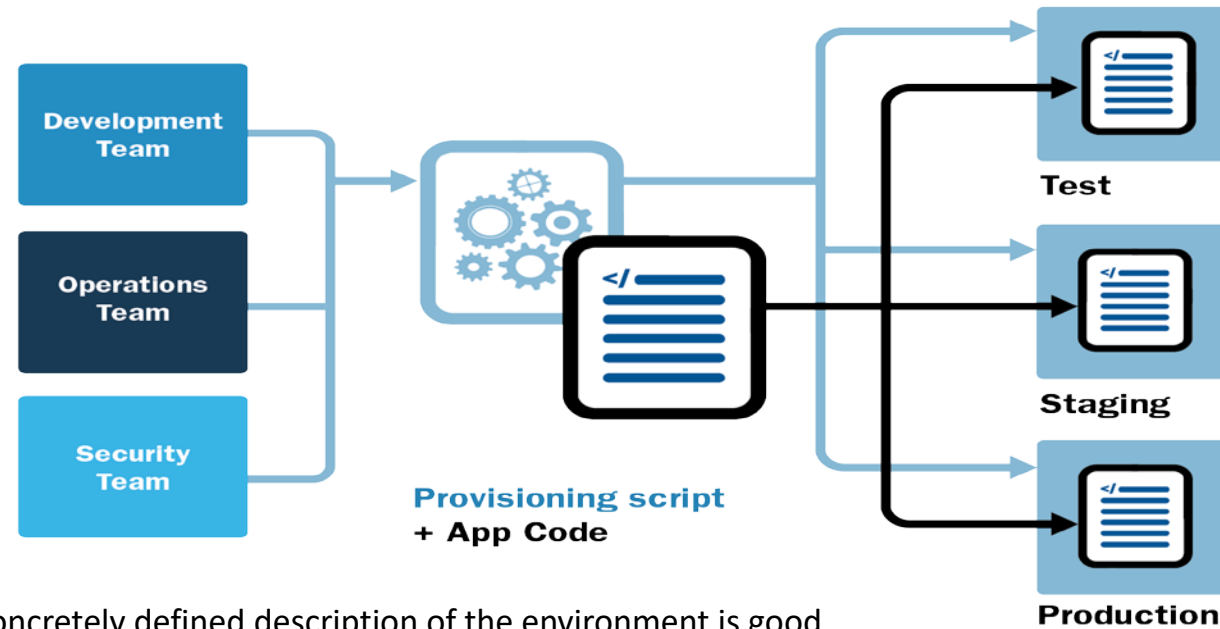

Infrastructure as Code

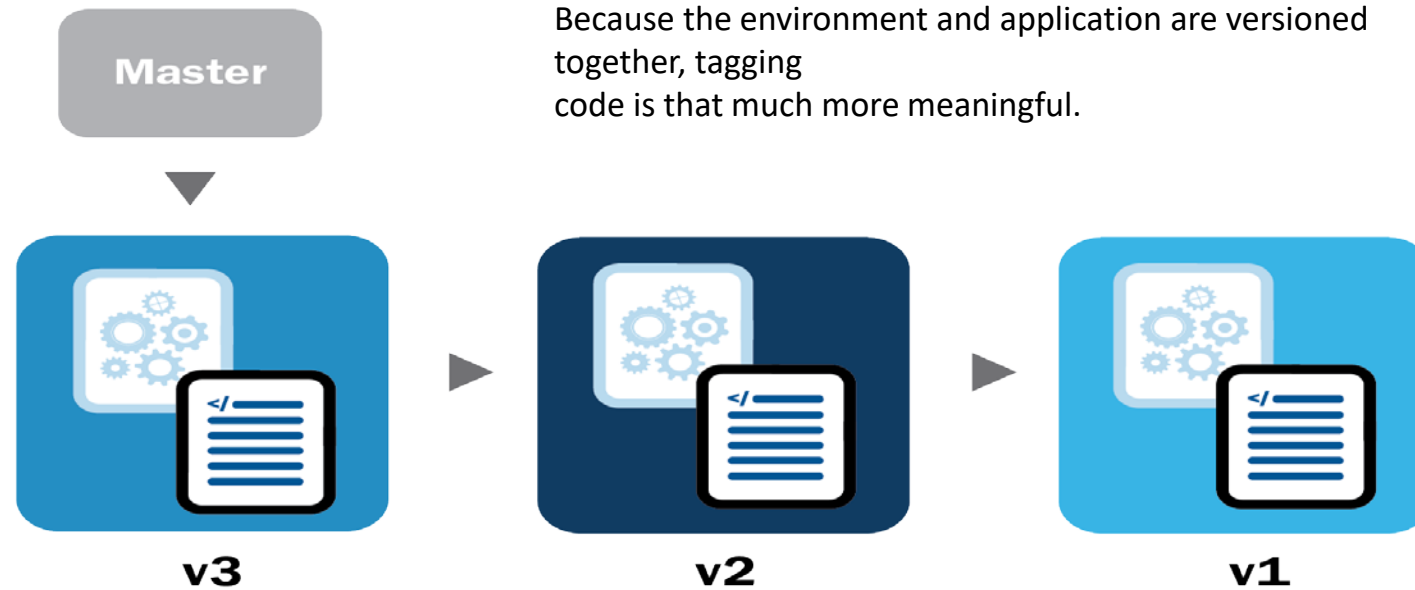

What is IaC?

A program that creates infrastructure

* A concretely defined description of the environment is good material for conversation between team members.

laC Apparent Benefits

IaC Provides a Solution – Scenario #1

Scenario #1

A vulnerability is being exploited in production that cannot be reproduced in development. Even rolling back development code to the production version doesn't allow it to manifest. It may be an issue with updated packages or OS in development.

Examples of related RMF Controls:

- IR-3 Incident Response Testing
- IR-10 Integrated Information Security Analysis Team
- SA-10 Developer Configuration Management

Versioned Environment

IaC Provides a Solution – Scenario #2

Scenario #2

The operations team is following recovery instructions for the production environment based on documentation. It turns out there is a dependency problem because an incorrect version of a package was cited.

Examples of related RMF Controls:

- CP-2 Contingency Plan
- CP-6 Alternative Storage Site
- CP-7 Alternative Processing Site
- CP-10 Information System Recovery and Reconstitution

Scripted Environment

IaC Provides a Solution – Scenario #3

Scenario #3

Security features that worked perfectly during testing fails when deployed to the production infrastructure.

Examples of related RMF Controls:

- CA-8 Penetration Testing
- CM-2 Baseline Configuration
- CM-3 Configuration Change Control
- CM-4(2) Security Impact Analysis | Verification of Security Functionality
- CM-6 Configuration Settings

Environment Parity

Common Tools

Shell scripts – scripting platform-specific commands

Vagrant - assists in managing virtual machines and provisioning

Chef or **Puppet** - wrappers around your shell

- provide hooks and convenience methods

- layer of indirection between script and OS-specifics

- provides portability

Docker – deployable Linux containers

- runs on Linux only (for now)

- whole environments can be easily shared

Automation of Tasks, Processes, and Workflows

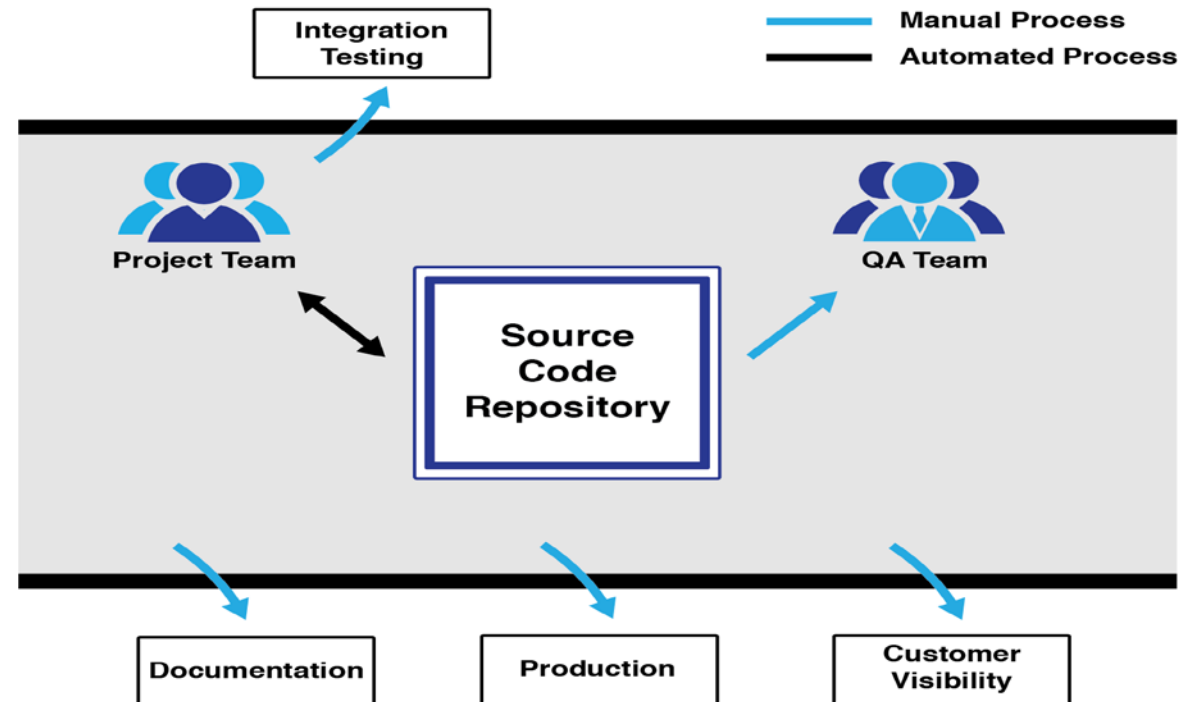

(SA-15 Development Process, Standards, and Tools)

Software projects consist of many artifacts

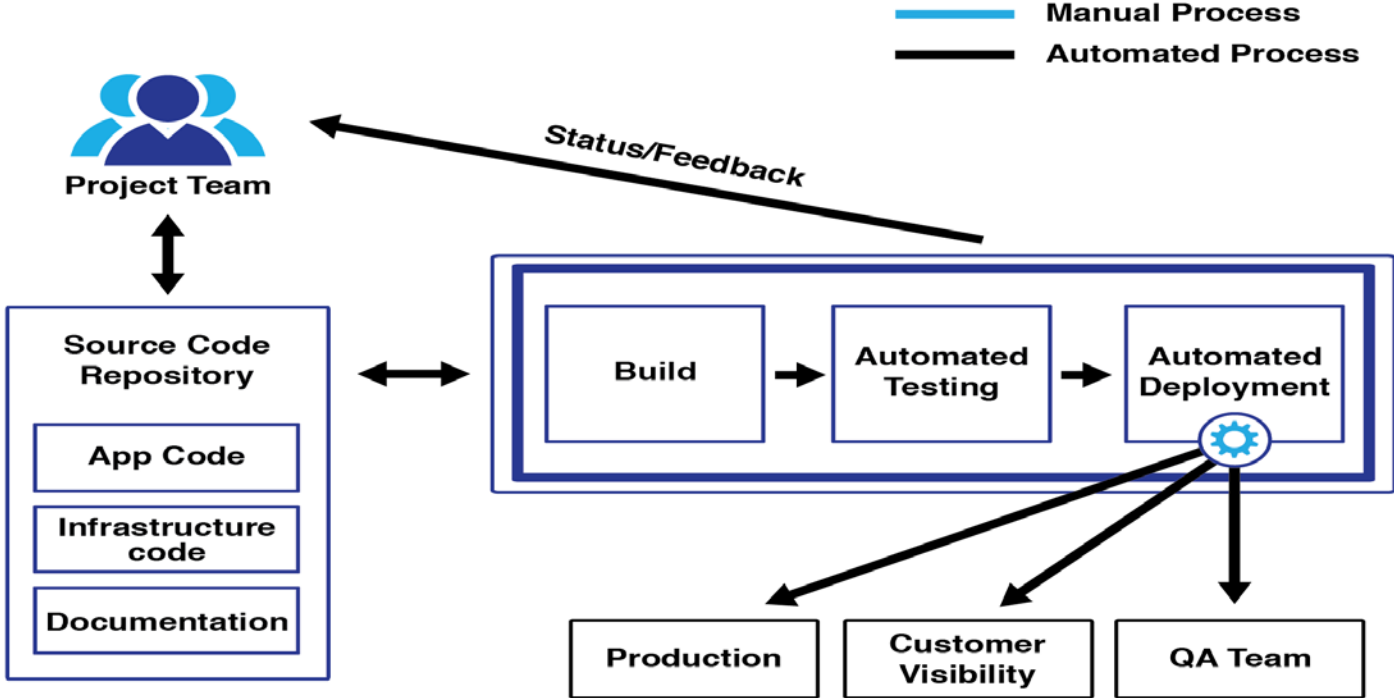

Integration can be challenging

This is often a manual process

Continuous Integration (CI) Model

Fail the Build When Software isn't Good Enough

Don't just configure failure for compile/build errors!

- Does the changes include a know weak coding practices (CWE)?
 - Automatically run changes against a static code analysis tool and fail the build if a new CWE is found
- Do any of the current or new libraries have known vulnerabilities (CVE)?
- Did any Functional Security Tests Fail?
- Example Security Controls:
 - SA-11 Developer Security Testing and Evaluation
 - SA-12 Supply Chain Protection
 - CM-4 Security Impact Analysis
 - RA-3 Risk Assessment

CI is your best tool to enforce security standards

Functional Security Tests

Automated unit, integration and acceptance testing tools can be used to verify security controls.

A large proportion of security tests are essentially checks that known weaknesses have not been introduced.

The following security controls are examples of controls that can be monitored/tested using existing acceptance testing browser automation tools like Selenium:

- AC-2(4) Account Management | Automated Audit Actions
- AC-2(5) Account Management | Inactivity Logout
- AC-2(11) Account Management | Usage Conditions
- AC-6 Least Privilege
- AC-12(1) Session Termination | User-Initiated Logouts/Message Displays
- AC-7 Unsuccessful Login Attempts
- CM-2 Least Functionality
- IA-2 Identification and Authentication (multi-factor)

Continuous Integration Systems

Jenkins

Monitoring Applications and Infrastructure

Clarifying Terms

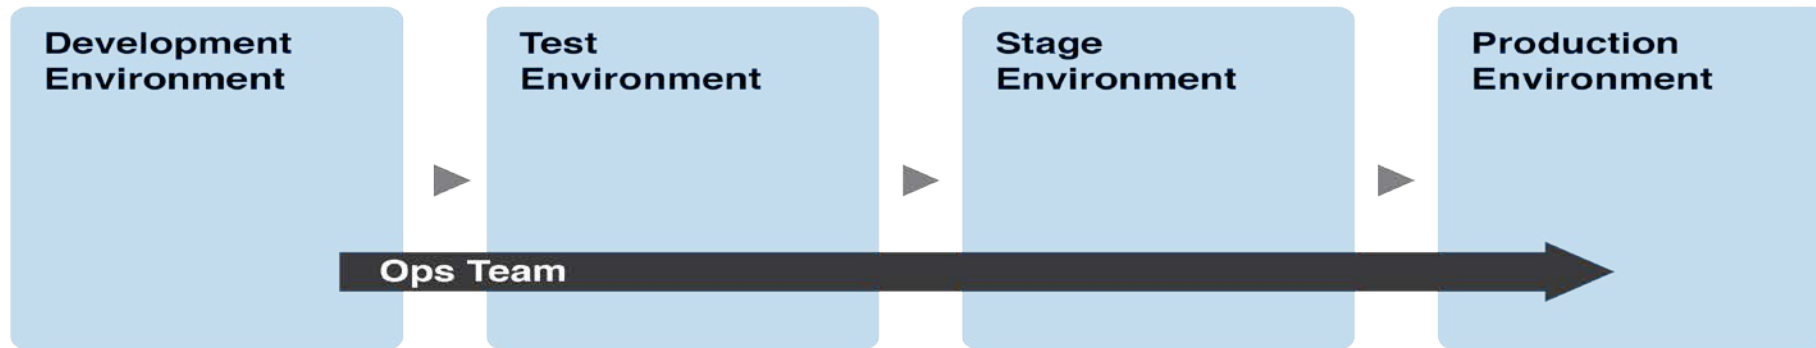

Continuous Deployment

Changes are deployed ASAP into production

Continuous Delivery

Changes are deployed immediately into a *production-like environment*, to ensure that they *could* be deployed into production

Shift Left Operational Concerns

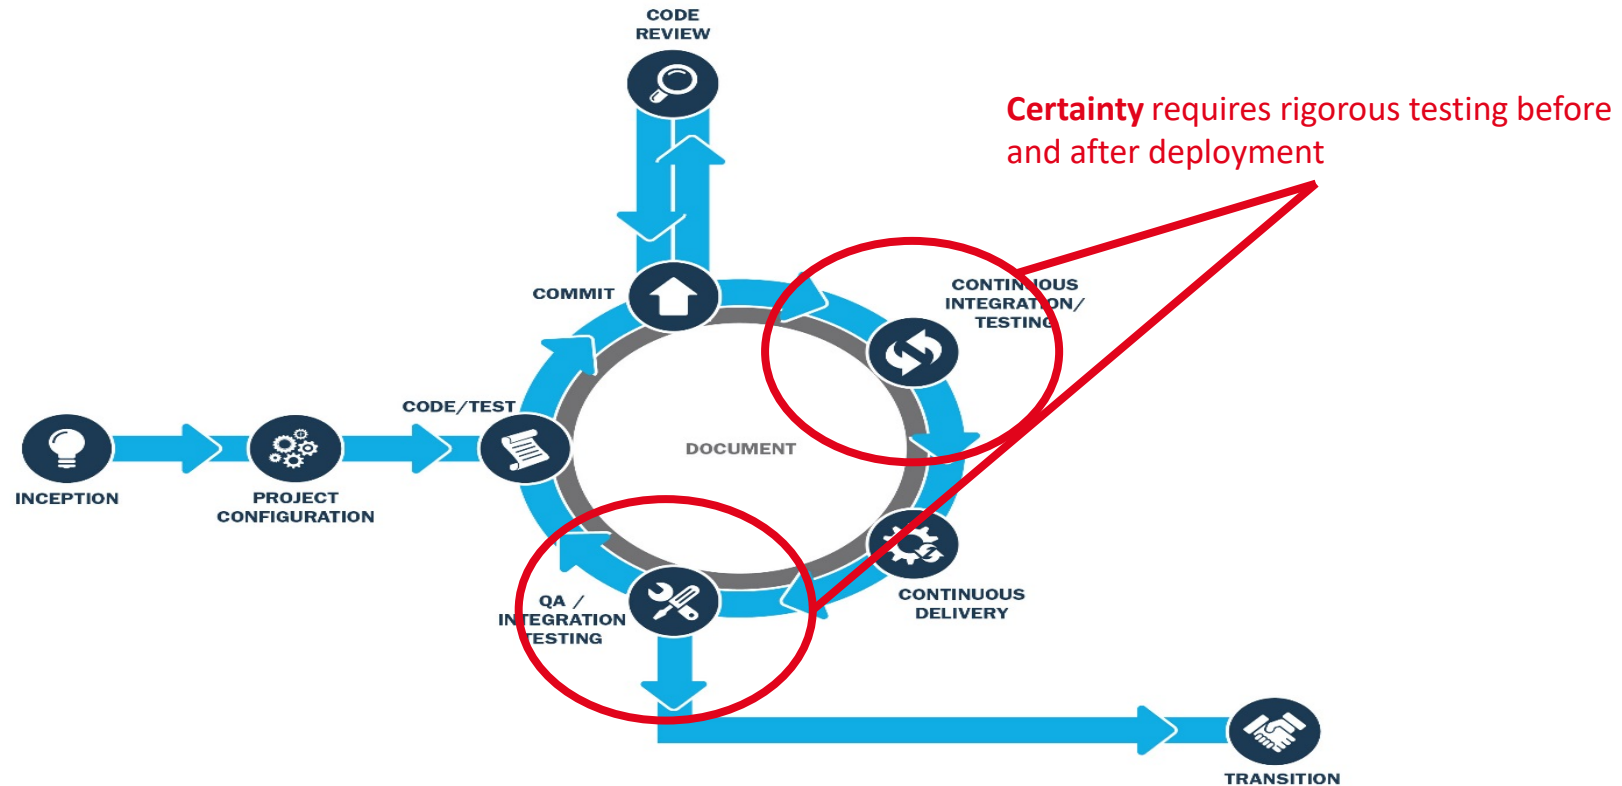

Benefits of Continuous Delivery

- Speed time to market
- Reduce cost
- Reduce risk
- Scale

Gold-standard deployment

- Environment Parity
- Process Parity
- Automate
- Perform incremental changes
- Appropriate Testing

Continuous Delivery Is REALLY About Rigorous Testing

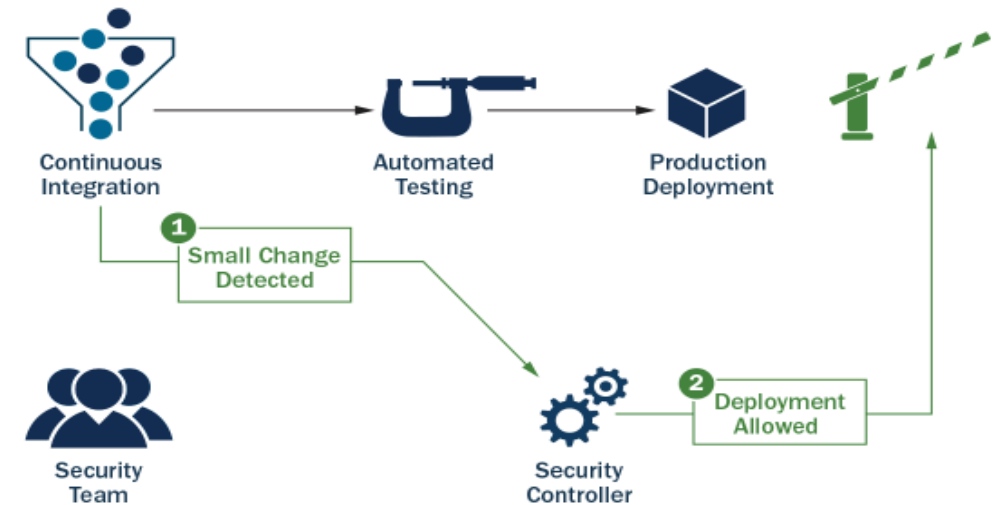

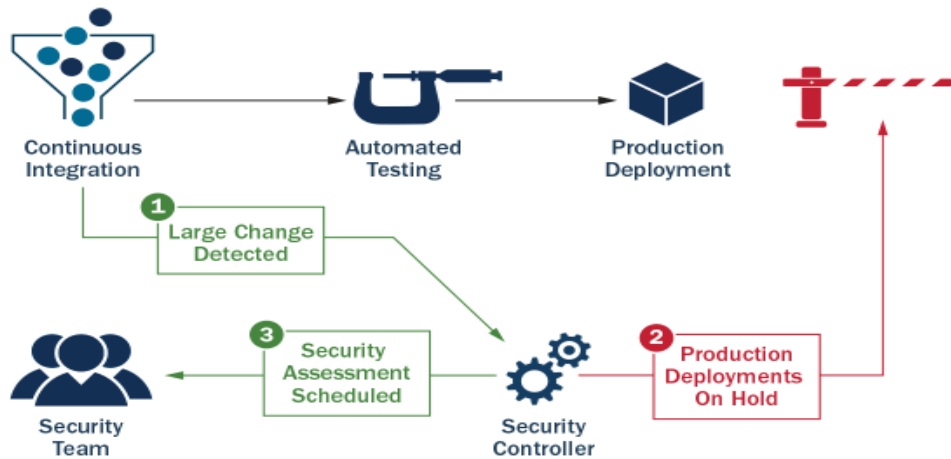

Test Enough That You Are Sure You Could Deploy Successfully

How much is enough?

What factors are important to you and your organization?

Security? Automate a large number of security-focused unit/integration tests

Design your CI/CD success criteria to enforce your goals

DevOps Operate Phase

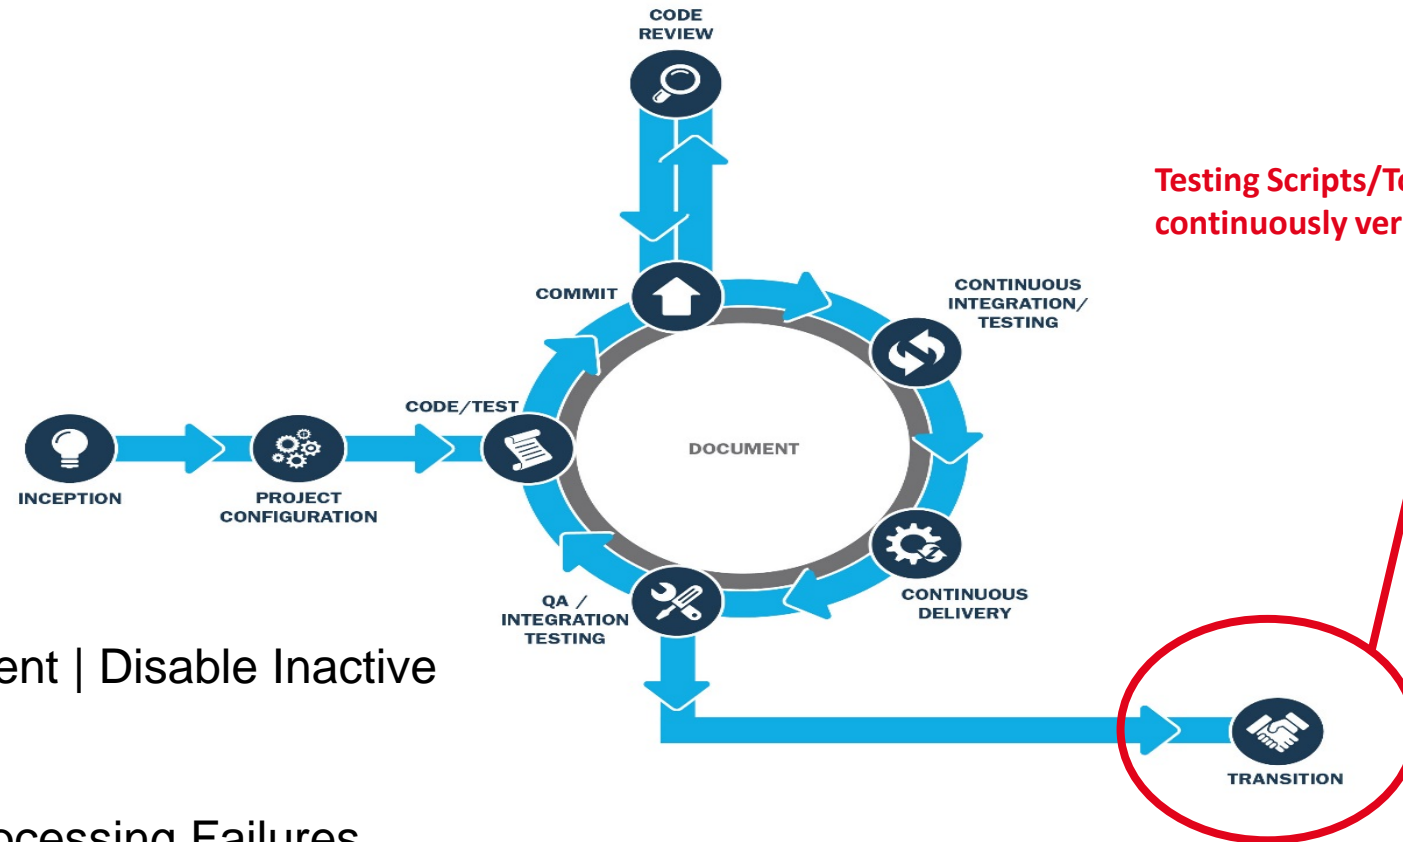

- Continuous Monitoring
- Performance Measurement
- Incident Management
- System Security
- Auditing

DevOps and RMF Integration

There are several RMF process steps that can be executed throughout the DevOps deployment pipeline including:

- **Develop Security Assessment Plan**
 - DevOps team provides details/scripts regarding the implementation and configuration of automated testing tools
- **Assess security controls**
 - DevOps practices improve this process by automatically providing outputs from team code reviews, application scanning and regression tests
- **Prepare Security Assessment Report**
 - Automated test tool output can be generated into a suitable format for inclusion as input
 - These reports are generated as part of the Continuous Testing cycle (not just annually), so assessment data is fresh and reports can be compared for differences
- **Conduct initial remediation actions**

Continue Automated Testing in Production

Example Security Controls:

- AC-2(3) Account Management | Disable Inactive Accounts
- AU-2 Audit Events
- AU-5 Response to Audit Processing Failures
- AU-9 Protection of Audit Information
- AU-11 Audit Record Retention
- SI-7 Software Firmware, and Information Integrity
- SI-11 Error Handling

DevOps Operate Phase: Integrate the Necessary Tools

docker

Nagios[®]

elasticsearch.

logstash

pagerduty

Prometheus

An open-source service monitoring system and time series database.

ANSIBLE

Kibana

Nessus 

MONIT

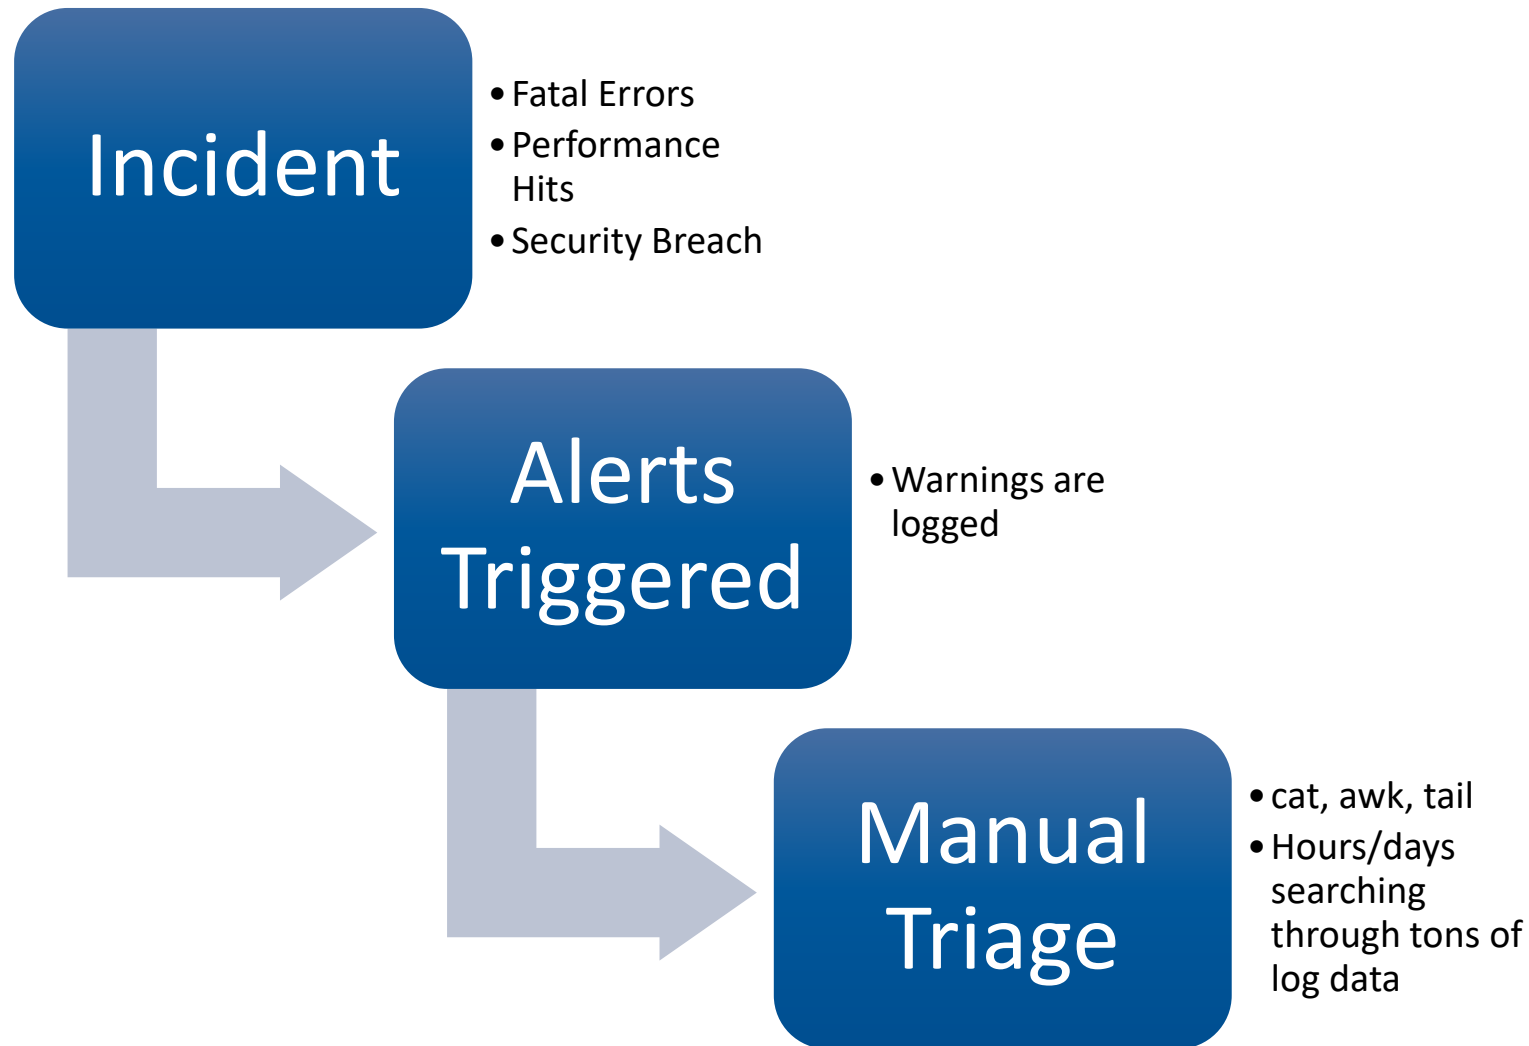

splunk >

DevOps Operate Phase: Performance Measurement

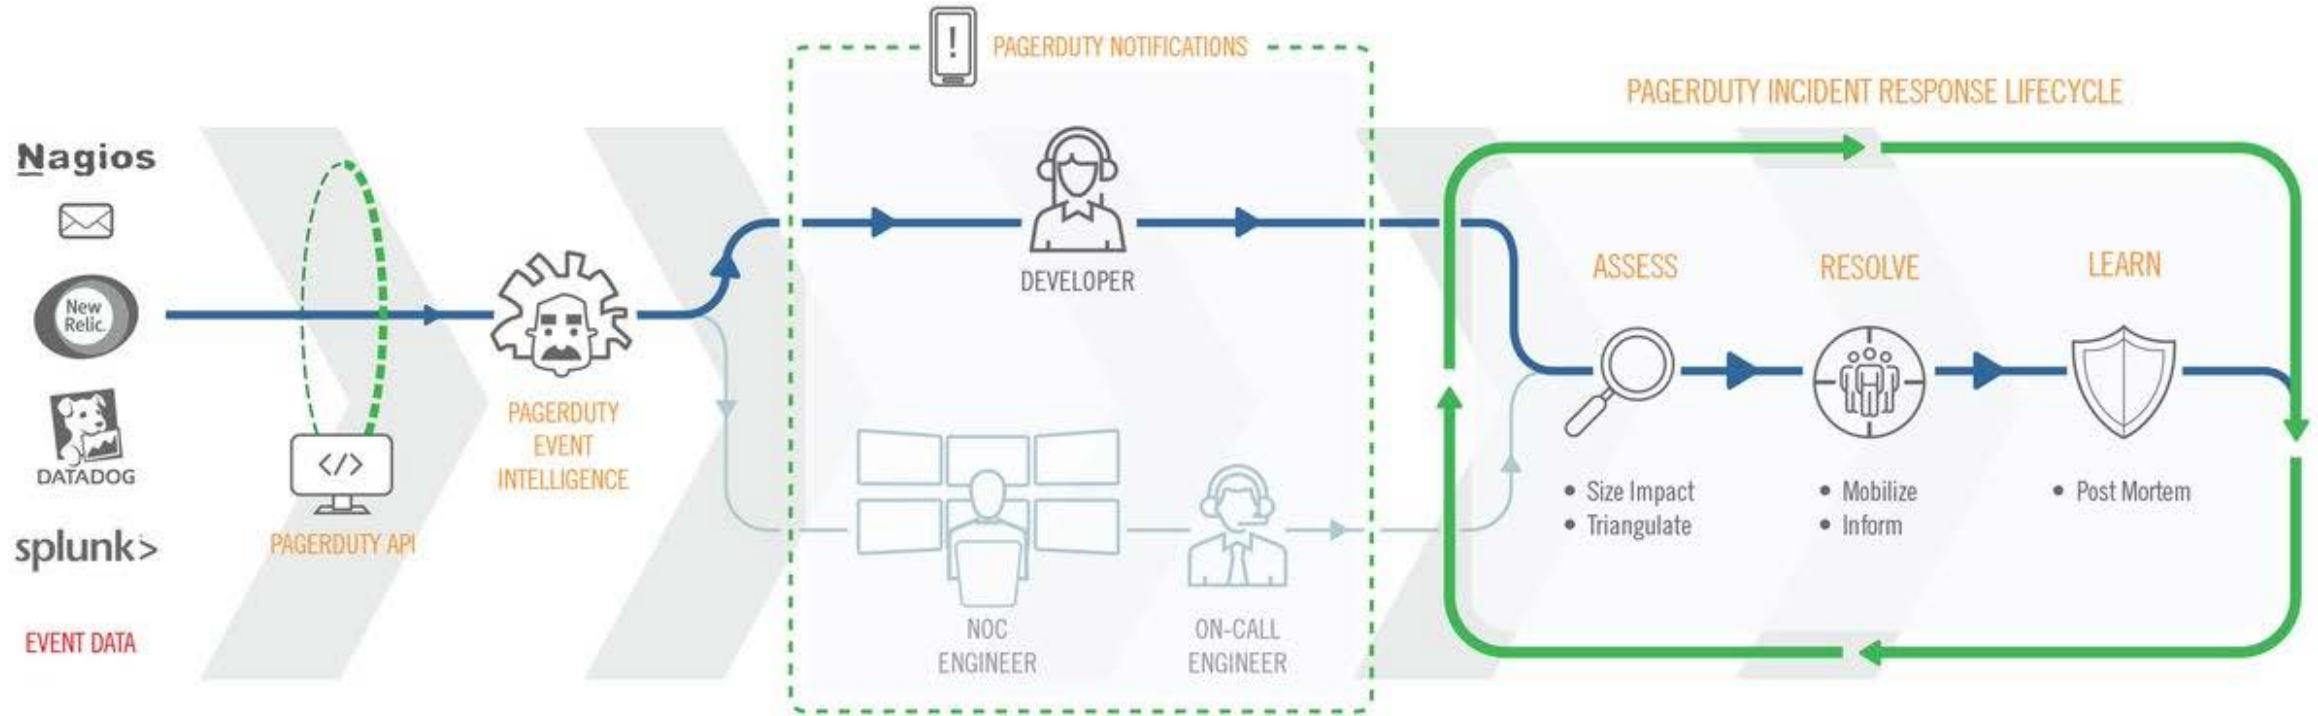

DevOps Operate Phase: Incident Management

Before the advent of DevOps strategies and associated tools, handling production incidents (application errors, performance hiccups, security breaches) was a tedious and time-consuming process.

Integrating DevOps tools (e.g. PagerDuty) can automate the process of incident monitoring, handling and reporting (IR-4, IR-5, IR-6, SI-4 Security Controls)

DevOps Operate Phase: Incident Management

DevOps Operate Phase: System Security

DevOps strategies and tools greatly enhance the tedium of implementing and managing application security (SI-4, SI-5, SI-6 Security Controls).

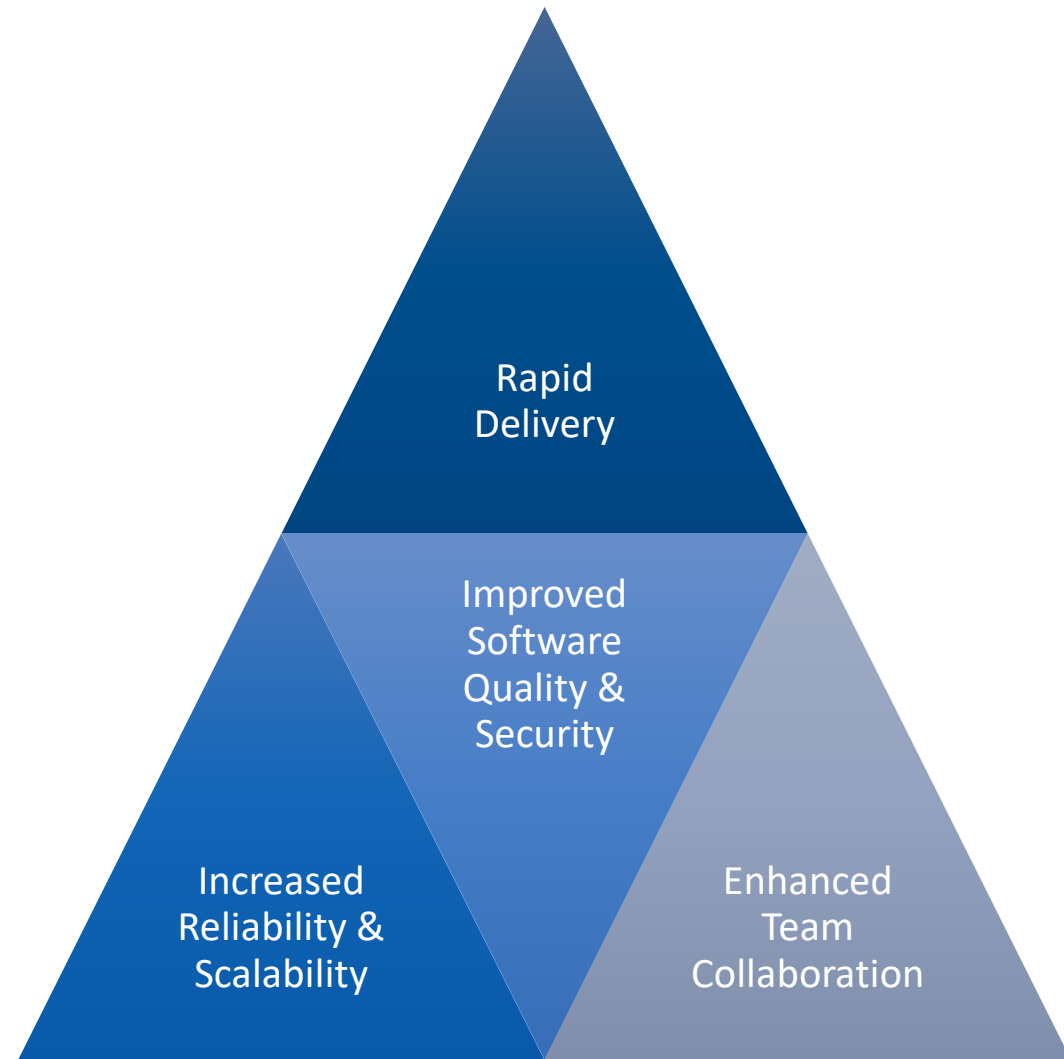

IaC tools such as Puppet can be used to configure, deploy and manage tools like Nessus and Snort.

Nessus scans systems and applications for weaknesses and vulnerabilities (RA-5). Reports are automatically generated and sent to necessary members of cross-functional team.

Snort can be deployed to automate intrusion detection (SC-38).

Benefits of DevOps

When security is fully integrated into the full Software Development, Maintenance, and Operational lifecycle a sufficiently robust system-level continuous monitoring program can be demonstrated in order to achieve a continuous reauthorization (ATO)
