Engineering and Development

Most Vulnerabilities Are Caused by Programming Errors

64% of the vulnerabilities in the NIST National Vulnerability Database due to programming errors

- 51% of those were due to classic errors like buffer overflows, cross-site scripting, injection flaws

Top vulnerabilities include

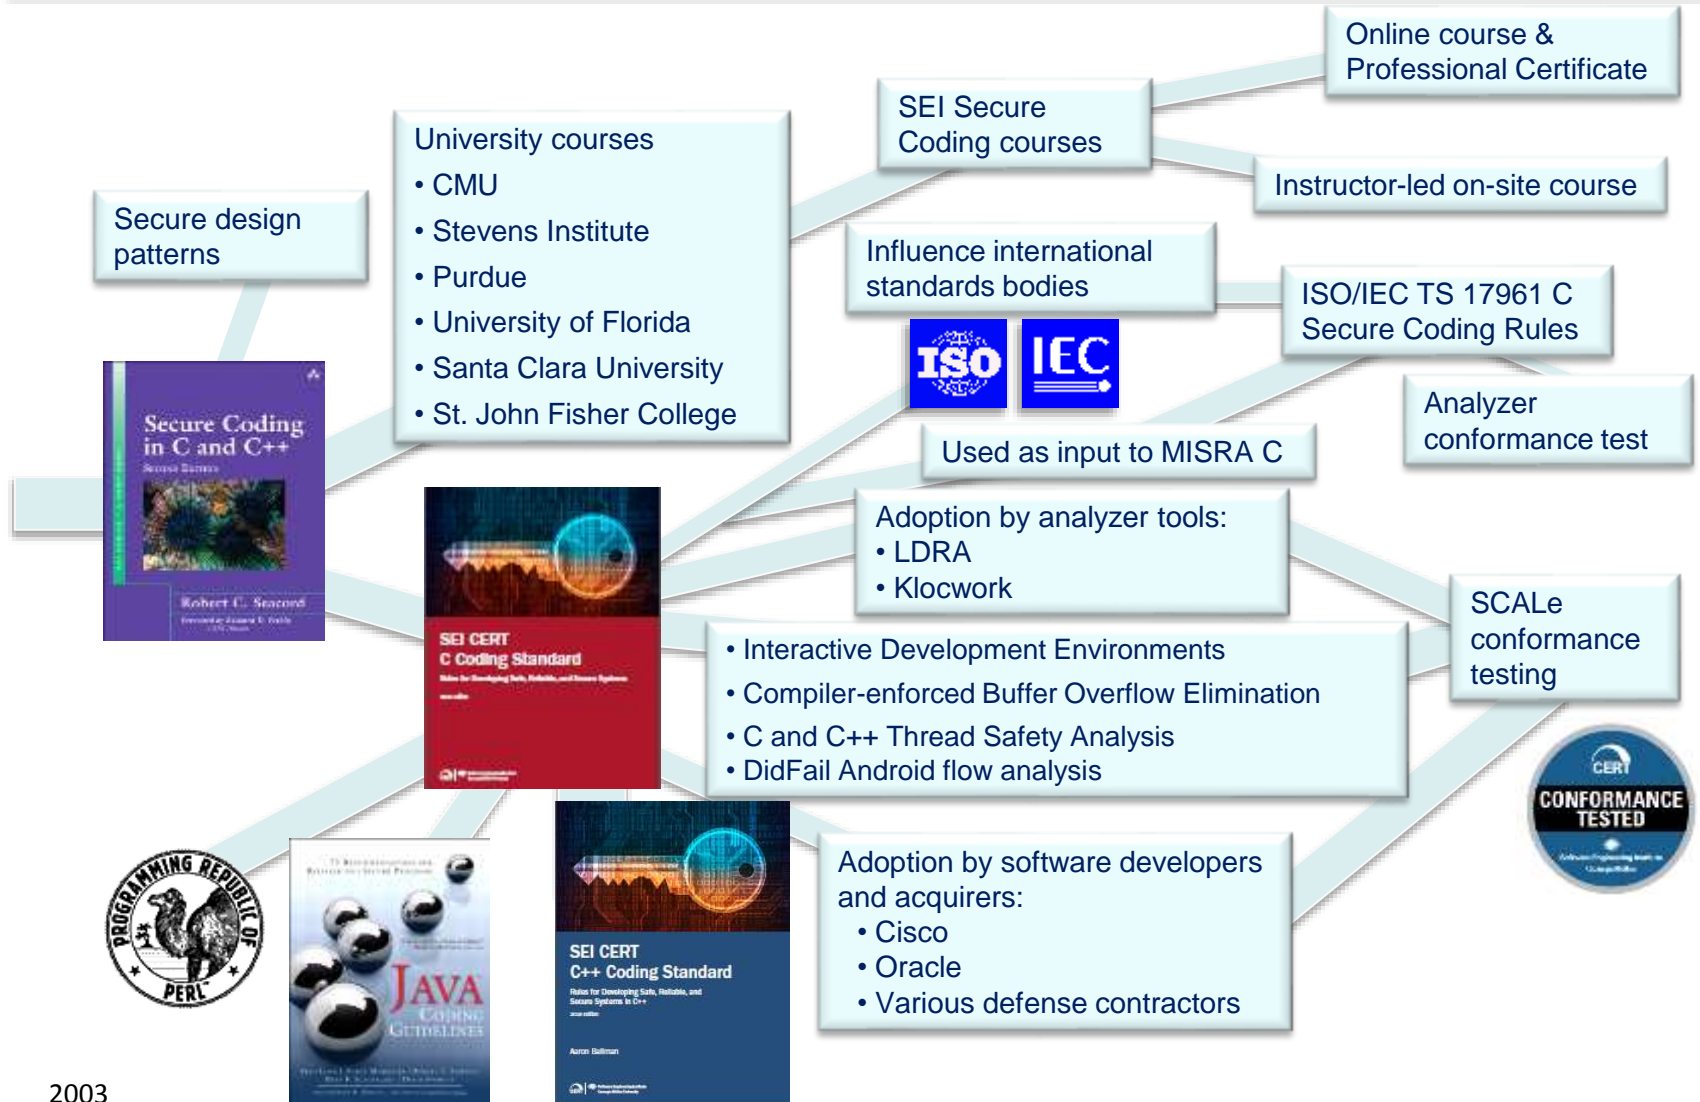

- Integer overflow
- Buffer overflow
- Missing authentication
- Missing or incorrect authorization
- Reliance on untrusted inputs (aka tainted inputs)

Sources: Heffley/Meunier: Can Source Code Auditing Software Identify Common Vulnerabilities and Be Used to Evaluate Software Security?

Buffer overflow has many causes

Buffer Overflow (BOF): The software can access through an array a memory location that is outside the array boundaries.

DCL22-CPP. Functions declared with `[[noreturn]]` must return void

Created by Aaron Ballman, last modified on Aug 24, 2016

Title

As described in [MSC55-CPP](#). Do not return from a function declared `[[noreturn]]`, functions declared with the `[[noreturn]]` attribute must not return on any code path. If a function declared with the `[[noreturn]]` attribute has a non-void return value, it implies that the function returns a value to the caller even though it would result in [undefined behavior](#). Therefore, functions declared with `[[noreturn]]` must also be declared as returning void.

Introduction &
Normative Text

Concise but not necessarily precise title

Precise definition of the rule

Rule Organization – NCCE & CS

Noncompliant Code Example

In this noncompliant code example, the function declared with `[[noreturn]]` claims to return an `int`:

```
#include <cstdlib>

[[noreturn]] int f() {
    std::exit(0);
    return 0;
}
```

This example does not violate [MSC55-CPP](#). Do not return from a function declared `[[noreturn]]` because `std::exit()` is declared `[[noreturn]]`, so the `return 0;` statement can never be executed.

Compliant Solution

Because the function is declared `[[noreturn]]`, and no code paths in the function allow for a return in order to comply with [MSC55-CPP](#). Do not return from a function declared `[[noreturn]]`, the compliant solution declares the function as returning `void` and elides the explicit return statement:

```
#include <cstdlib>

[[noreturn]] void f() {
    std::exit(0);
}
```

Noncompliant Code

Don't try this at home!

Noncompliant code examples or antipatterns in a pink frame—do not copy and paste into your code

Compliant Code

Fixes noncompliant code.

Compliant solutions in a blue frame that conform with all rules and can be reused in your code

Rule Organization – Risk Assessment & Detection

Risk Assessment

A function declared with a non-void return type and declared with the `[[noreturn]]` attribute is confusing to consumers of the function because the two declarations are conflicting. In turn, it can result in misuse of the API by the consumer or can indicate an implementation bug by the producer.

Rule	Severity	Likelihood	Remediation Cost	Priority	Level
DCL22-CPP	Low	Unlikely	Low	P3	L3

Automated Detection

Tool	Version	Checker	Description
Clang	3.9	-Winvalid-noreturn	

Risk Assessment

Risk assessment is performed using failure mode, effects, and criticality analysis.

<p>Severity—How serious are the consequences of the rule being ignored?</p> <p>Likelihood—How likely is it that a flaw introduced by ignoring the rule can lead to an exploitable vulnerability?</p> <p>Cost—The cost of mitigating the vulnerability.</p>	Value	Meaning	Examples of Vulnerability	
	1	low	denial-of-service attack, abnormal termination	
	2	medium	data integrity violation, unintentional information disclosure	
	3	high	run arbitrary code	
	Value	Meaning		
	1	unlikely		
	2	probable		
	3	likely		
	Value	Meaning	Detection	Correction
	1	high	manual	manual
2	medium	automatic	manual	
3	low	automatic	automatic

SCALe Secure Coding Conformance Process

Source Code Analysis Laboratory

Source Code Analysis Laboratory (SCALe)

- Consists of commercial, open source, and experimental analysis
- Is used to analyze various code bases including those from the DoD, energy delivery systems, medical devices, and more
- Provides value to the customer but is also being instrumented to research the effectiveness of coding rules and analysis

SCALe customer-focused process:

1. Customer submits source code to CERT for analysis.
2. Source is analyzed in SCALe using various analyzers.
3. Results are analyzed, validated, and summarized.
4. Detailed report of findings is provided to guide repairs.
5. The developer addresses violations and resubmits repaired code.
6. The code is reassessed to ensure all violations have been properly mitigated.

CERT Secure Coding Overview

- Secure Coding Guidelines
- SCALe Audits and Software
- **Training**
- International Standards
- Current Research

Secure Coding Professional Certificates

Course, Exam, and Certificates for “C and C++” and “Java”

Online and Onsite course options available

Includes Secure Software Concepts and Secure Coding in specified languages

SEI Secure Coding in C and C++ Training 1

The Secure Coding course is designed for C and C++ developers. It encourages programmers to adopt security best practices and develop a security mindset that can help protect software from tomorrow's attacks, not just today's.

Objectives

- Improve the overall security of any C or C++ application.
- Thwart buffer overflows and stack-smashing attacks that exploit insecure string manipulation logic.
- Avoid vulnerabilities and security flaws resulting from incorrect use of dynamic memory management functions.
- Eliminate integer-related problems: integer overflows, sign errors, and truncation errors.
- Correctly use formatted output functions without introducing format-string vulnerabilities.
- Avoid I/O vulnerabilities, including race conditions.

<http://www.sei.cmu.edu/training/p63.cfm>

SEI Secure Coding in C and C++ Training 2

Participants gain a working knowledge of common programming errors that lead to software vulnerabilities, how these errors can be exploited, and mitigation strategies to prevent their introduction.

Topics

- Integer security
- String management
- Dynamic memory management
- Formatted output
- File I/O

SEI Secure Coding in Java Training

The Secure Coding in Java course is designed to improve the secure use of Java. The course is useful to developers of Java SE, EE, and ME versions of the platform. Tailored to meet the needs of a development team, the course covers security aspects of

Trust and Security Policies

Validation and Sanitization

The Java Security Model

Expressions

Object Orientation

Methods

Vulnerability Analysis Exercise

Numerical Types in Java

Exceptional Behavior

Input/Output

Serialization

The Runtime Environment

Introduction to Concurrency in Java

Advanced Concurrency Issues

Secure Coding Course: Objectives 1

Strings

- Recognize the different string types in C and C++ language programs.
- Select the appropriate byte character types for a given purpose.
- Identify common string manipulation errors.
- Explain how vulnerabilities from common string manipulation errors can be exploited.
- Identify applicable mitigation strategies, evaluate candidate mitigation strategies, and select the most appropriate mitigation strategy (or strategies) for a given context.
- Apply mitigation strategies to reduce the introduction of errors into new code or repair security flaws in existing code.

Integer Security

- Explain and predict how integer values are represented for a given implementation.
- Predict how and when conversions are performed and describe their pitfalls.
- Select appropriate type for a given situation.
- Programmatically detect erroneous conditions for assignment, addition, subtraction, multiplication, division, and left and right shift.
- Recognize when implicit conversions and truncation occur as a result of assignment.
- Apply mitigation strategies to reduce introduction of errors into new code or repair security flaws in existing code.

Secure Coding Course: Objectives 2

Dynamic Memory

- Use standard C memory management functions securely.
- Align memory suitably.
- Explain how vulnerabilities from common dynamic memory management errors can be exploited.
- Identify common dynamic memory management errors.
- Perform C++ memory management securely.
- Identify common C++ programming errors when performing dynamic memory allocation and deallocation.
- Identify common dynamic memory management errors.

Concurrency

- Define concurrency and it's relationship with multithreading and parallelism.
- Calculate the potential performance benefits of parallelism in specific instances.
- Identify common errors in concurrency implementations.
- Identify common errors and attack vectors C++ concurrency programming.
- Apply common approaches for mitigating risks in C++ concurrency programming.
- Describe common vulnerabilities that occur from the incorrect use of concurrency.

ISO/IEC TS 17961

The screenshot shows the ISO Store website interface. At the top, there is a navigation bar with links for Standards, About us, Standards Development, News, and Store. Below this is a secondary navigation bar with links for Standards catalogue, Online collections, and Graphical symbols. The main content area displays the product title "ISO/IEC TS 17961:2013" and its description: "Information technology -- Programming languages, their environments and system software interfaces -- C secure coding rules". A "Subscribe to updates" button is visible on the right side of the product description.

Applies to **analyzers**, including **static analysis tools** and C language **compilers** that wish to diagnose insecure code beyond the requirements of the language standard.

Enumerates **secure coding rules** and requires **analysis engines** to **diagnose violations** of these rules as a matter of conformance to this specification.

These rules may be extended in an implementation-dependent manner, which provides a **minimum coverage guarantee** to customers of any and all conforming static analysis implementations.

Secure Coding Validation Suite

A set of tests to validate the rules defined in TS 17961, these tests are based on the examples in this technical specification.

Agenda

CERT Secure Coding Overview

- Secure Coding Guidelines
- SCALe Audits and Software
- Training
- International Standards
- **Current Research**

Secure Coding Research

Prioritizing Static Analysis Alerts using Classification Models

- Aggregating information from multiple analysis tools to make better predictions about whether a potential defect is true or not.

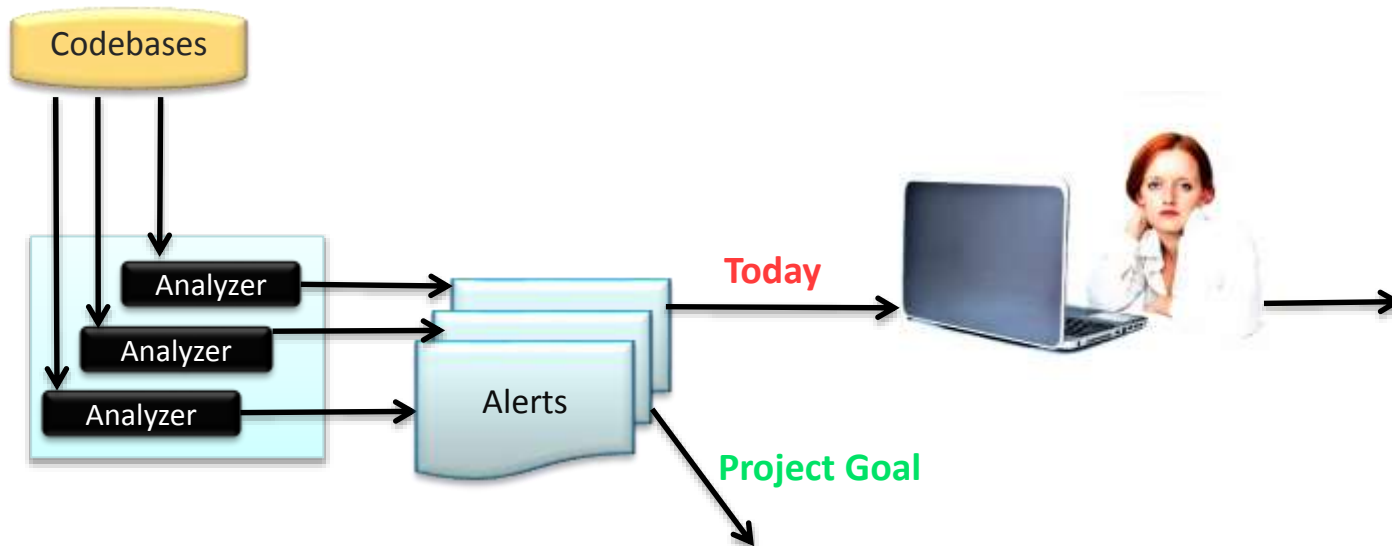

Automated Code Repair

- Fixing code based on anti-patterns and patterns for repair, rather than just alerting developers and testers to a potential defect.

Predicting Security Flaws through Architectural Flaws

- Using tools that identify architectural flaws in source code to predict and find latent security flaws

Prioritizing Vulnerabilities

Many alerts left un-audited!

Classification algorithm development using CERT- and collaborator-audited data, that **accurately classifies most of the diagnostics as:**

Expected True Positive (e-TP) or Expected False Positive (e-FP),
and
the rest as Indeterminate (I)

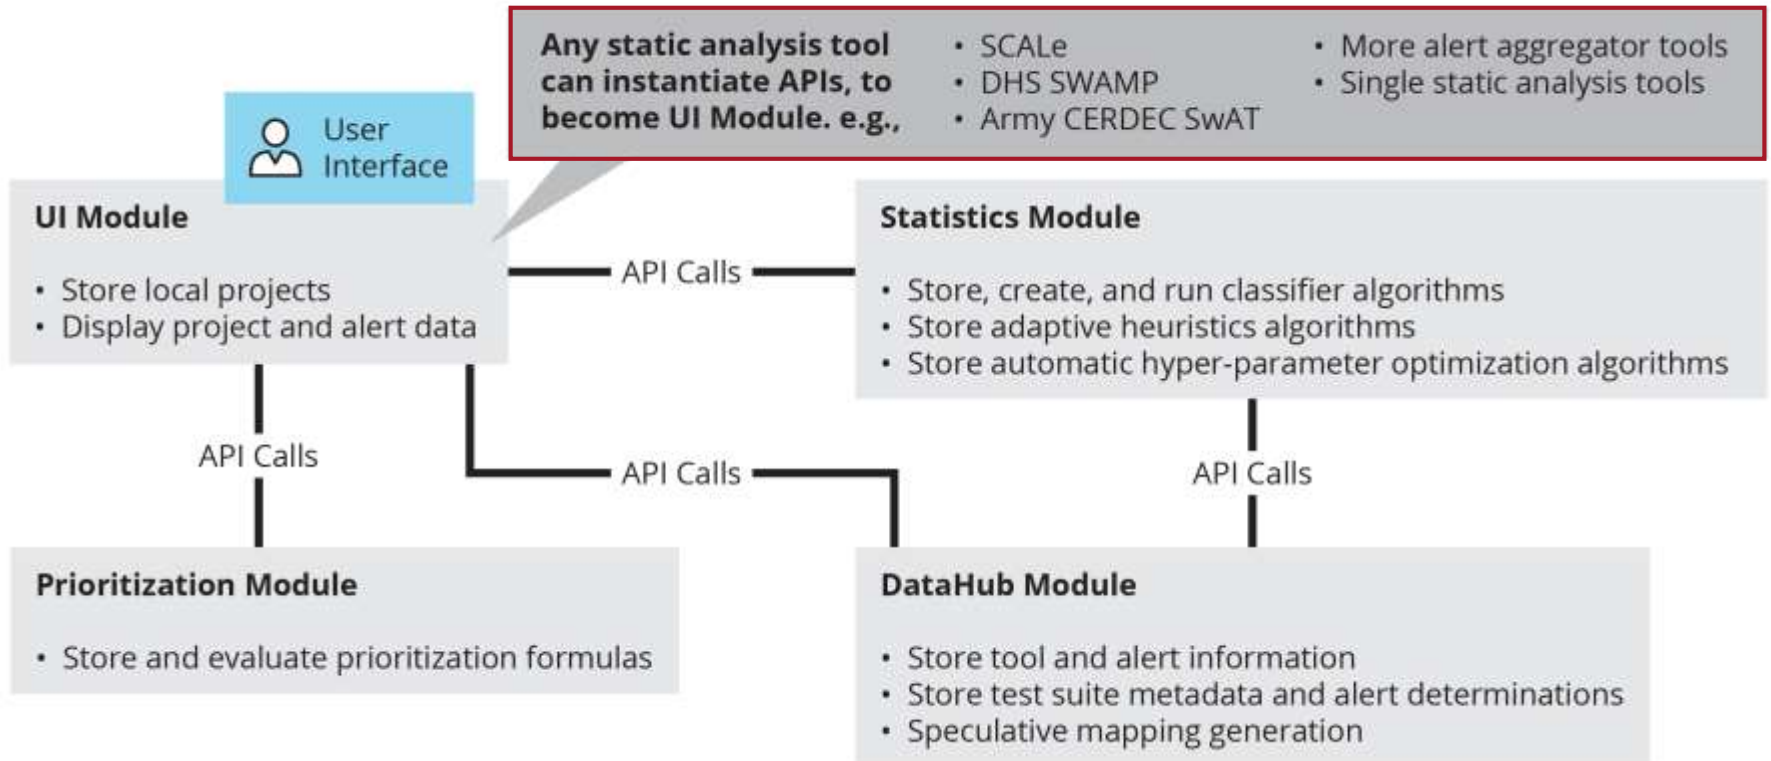

Prioritized, small number of alerts for manual audit

Long-term goal: Automated and accurate statistical classifier, intended to efficiently use analyst effort and to remove code flaws

Svoboda, Flynn, and Snavelly. “Static Analysis Alert Audits: Lexicon & Rules”, IEEE Cybersecurity Development (SecDev), November 2016.

Automated Code Repair

Hypothesis: Many violations of rules follow a small number of anti-patterns with corresponding patterns for repair, and these can be feasibly recognized by static analysis.

- `printf(attacker_string) → printf("%s", attacker_string)`

We propose to create a tool to automatically repair defects in source code resulting from violations of the CERT Coding Standards.

Formalizable Constraints (to be formally verified):

- The patched and unpatched program behave identically over the set of all traces that conform to the rules.
- No trace violates the rules.

Non-Formalizable Constraint:

- Repair in way that is plausibly acceptable to the developer.

Integer Overflow

This past year (FY16), we developed techniques for automated repair of **integer overflows** that lead to **memory corruption**

Integers in C are represented by a fixed number of bits N (e.g., 32 or 64).

- Overflow occurs when the result cannot fit in N bits
- Modular arithmetic: Only the least significant N bits are kept

How does integer overflow lead to memory corruption?

1. Memory allocation: `malloc(·)`.
2. Bounds checks for an array

Example: Android Stagefright bugs (July 2015)

Benefits

Eliminate security vulnerabilities at a **much lower cost** than manual repair

Integer overflows are a **very common** type of bug

- In CERT SCALe audits, about 80% of findings were related to fixed-width integers

Our technique:

- **Will not break working code**, provided *inferred specification* is correct (Next slide)
- Typically total slowdown < 5% (Based on theoretical model)
- False positives: Flagged operations that cannot actually overflow
 - Then our 'repair' just adds a little unnecessary overhead

wrappers.h

```
1. inline static size_t UADD(size_t lop, size_t rop) {
2.     size_t result;
3.     bool flag = __builtin_add_overflow(lop, rop, &result);
4.     if (flag) {result = SIZE_MAX;}
5.     return result;
6. }
```

Repair: **UADD(start, n)**

```
if (start + n <= dest_size) {
    memcpy(&dest[start], src, n);
} else {
    return -EINVAL;
}
```

- What if dest_size is SIZE_MAX?
- What if both sides of inequality overflow?
- What if overflow reaches a non-comparison sink?

Inference of Memory Bounds

Problem 1: Security vuls. Not just traditional buffer overflows.

Leakage of sensitive info (out-of-bounds reads):

- HeartBleed vulnerability, **BenignCertain** attack on Cisco PIX.
- Unaffected by mitigations such as ASLR and DEP.
- Re-usable buffer with stale data: bounded to valid portion of buffer.
- Affects even Java: e.g., Jetty leaked passwords (CVE-2015-2080).

Problem 2: Decompilation of binaries. We will reconstruct information of the form “bounds of pointer p is the interval $[n, m]$ ”.

Solution & Approach: Static analysis to find & evaluate likely bounds. (E.g., re-usable buffer: guess that upper bound for reading is the last position written.)

For decompilation: Report these bounds, use when naming variables.

For repair: Test with dynamic analysis – tentatively implement all bounds checks (even those subsumed by stricter bounds checks) as ‘soft-fail’ (just log a warning, don’t abort). Can also repair to *Checked C* (David Tarditi).

Predicting Security Flaws through Architectural Flaws

Problem Purpose: Use Architectural Analysis to predict and identify security flaws and estimate potential refactoring ROI

Approach: Retrospective analysis on open source projects that have issue data related to security flaws. Qualitative understanding of architectural and security flaw relationships, and quantitative analysis of correlations.

Results:

- Our analysis found weak correlation between architectural flaws and security defects at the distinct file level.
- Qualitative analysis and reproduction of previous study continues to suggest a relationship trend between architectural flaws and security defects.
- Collected lots of project data and developed tools for analysis

Problem

Software security defects  risk exposure and \$\$\$.

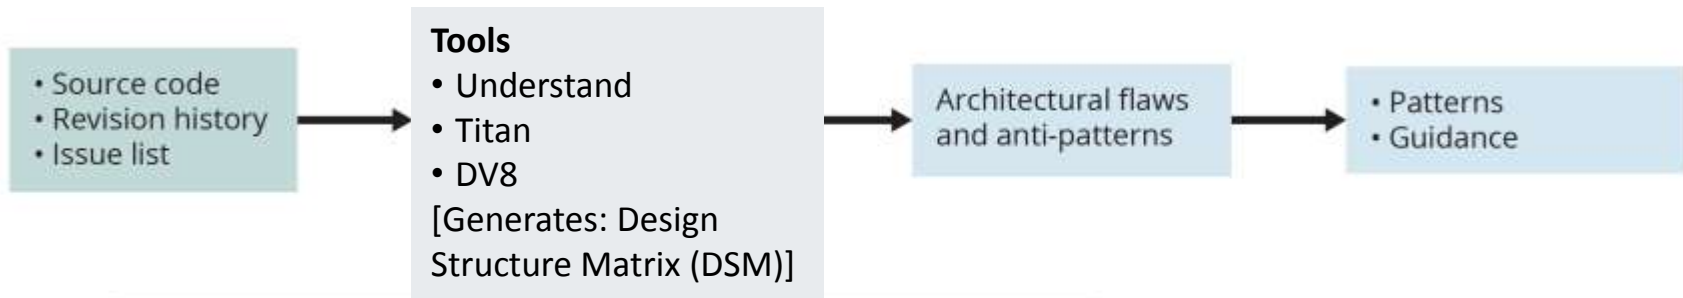

Existing analysis methods have limitations:

- Some security flaws influenced by code structure and module relationships.
- Not easily found or fixed locally.*

*"Analyzing Security Bugs from an Architectural Perspective," Kazman et al., 2017.

Approach – Today

Approach – Research and Vision

Data Collected and Analyzed

Chromium Browser

- ArchFlaw data
- Historical Issue type data (analyzed for “security” and “non-security” issues)
- Historical Commit data for all issues that were analyzed

Chromium Browser Issues x ArchFlaws	Has ArchFlaws	No ArchFlaws	Total
Files in Security Issues only	21	9	30
Files in Non-Security Issues only	14521	5038	19559
Files in Security & Non-Security Issues	798	41	839
Files in Neither Security nor Non-Security Issues	4591	3197	7788
Total	19931	8285	28216

Quantitative Analysis

Chromium Browser
LightGBM

R-squared (all_features): 0.12

Top features:

- fixed_nonsec_issue_ct
- cochange
- pathdepth
- neighbor_mean_tot_fixed_sec_issue_ct
- weighted_cochange
- age
- latest_loc
- tot_archflaws

Future Recommendations

Analyze for additional features

- Per-file churn
- Time-split analysis of past security bug data
- Historical Structural Architectural Flaws
- Deep learning of source code (multiple Line-funded efforts)

Causal Analysis

- Can we identify strong correlations, and can we statistically show that features that are controllable can affect bugs and security bugs.

Architecture and Code Defect Relationship Dynamics

- Better modeling or measuring the dynamics of architecture and architectural flaws as it changes intentionally or incidentally with code changes, along with the introduction and removal of code defects.
- Control for distribution of number of commits and total churn
