| <b>14. ABSTRACT</b><br><br>Distributed ledger technology such as blockchain could ideally be used to solve challenges in global supply chain assurance. In blockchain, consensus is achieved among active concurrent participants. The chain is, by design, required to be a single forward-building path of events; if branches appear, the chain consensus ensures that all but one branch is discarded. A supply chain in comparison, particularly on the production side, is a reversed architecture. In this case, small parts are used to build larger parts, hence requiring blockchain mergence (e.g., a final ready-for-use vehicle is comprised of multiple smaller parts sourced from various vendors, manufacturers, and even countries). Thus, the current capabilities of blockchain do not meet the fundamental demands of supply chains. Assuring supply chain integrity and visibility requires an adaptation of the technology to allow a form of blockchain mergence that the original concept was not designed to handle. This research looks at a possible solution among hash chains, blockchain, and ledger options for supply chain strategy. |                                    |                                           |                                         |                                                                  |                                                                             |

## **ABSTRACT**

Distributed ledger technology such as blockchain could ideally be used to solve challenges in global supply chain assurance. In blockchain, consensus is achieved among active concurrent participants. The chain is, by design, required to be a single forward-building path of events; if branches appear, the chain consensus ensures that all but one branch is discarded. A supply chain in comparison, particularly on the production side, is a reversed architecture. In this case, small parts are used to build larger parts, hence requiring blockchain mergence (e.g., a final ready-for-use vehicle is comprised of multiple smaller parts sourced from various vendors, manufacturers, and even countries). Thus, the current capabilities of blockchain do not meet the fundamental demands of supply chains. Assuring supply chain integrity and visibility requires an adaptation of the technology to allow a form of blockchain mergence that the original concept was not designed to handle. This research looks at a possible solution among hash chains, blockchain, and ledger options for supply chain strategy.

## I. BACKGROUND

Blockchain has been widely researched for applications due to the technology's ability to support consensus among distributed participants. The chain is, by design, required to be a single, forward path of events; if branches appear, the chain consensus ensures that all but one branch is discarded (Zheng et al., 2017). A supply chain, in comparison, particularly on the production side, is a reversed architecture. In this case, small parts are used to build larger parts, hence requiring a form of *mergence* (e.g., a final ready-for-use vehicle is comprised of multiple smaller parts sourced from various vendors, manufacturers, and even countries). Blockchain, according to its current design, fundamentally disallows this. Assuring supply chain integrity and visibility requires an adaptation of the technology to allow a form of blockchain mergence that the original concept was not designed to handle.

### A. APPROACH

To survey existing blockchain solutions for forms of mergence, i.e., solutions for merging chains into a single blockchain, such as would be necessary for supply chain assurance.

To analyze potential solutions using partner signatures (where supply chain partners commit to chain addenda by digitally signing new blocks while also committing to the entire previous chain). This requires analysis of security considerations based on different commitment variants. Furthermore, it requires consideration of potential timelines and timeline collisions of block production.

The above solutions are evaluated with respect to formal blockchain integration. In particular, the research investigates whether or not mergence of distributed ledgers is possible within exiting blockchain architectures, or if it is feasible as a parallel assurance mechanism, such that commitments are uploaded to an existing blockchain. This evaluation will be made on mathematical feasibility as well as use case comparison.

## **II. CURRENT RESEARCH ON LEDGER MERGENCE**

Blockchain technology has been often touted as solution to various challenges since its inception under Bitcoin and cybocurrency. However, blockchain technology may benefit Navy logistics. In essence, blockchains are a list of records, or blocks, cryptographically linked as a distributed ledger for recording transactions among parties in a permanent and verifiable way (Zheng et al., 2017). Blockchain could also support “smart contracts” which may be away to reduce administrative friction.

The hallmarks of a robust Distributed Ledger Technology (DLT) are decentralization between blockchain networks and the individual nodes in those networks, as well as the consensus reached when validating individual blocks when added to a network’s blockchain ledger (Khan, 2019). Khan (2019) also notes that characteristics such as the number of transactions per second (TPS) that a network can process, the network’s scalability, and how a particular network guards against malicious attempts to add false information, are also key to a good system.

This work focuses on authentication of changes at the micro-level, with transparency in a ledger for support of supply chain assurance. Industry is working on a number of efforts involving supply chain logistics and supply chain management such as Hyperledger (2020), Everledger (2020), and Ethereum (2020) that may have an application to the Navy’s logistical systems and perhaps could contribute to an agile logistical system. The central challenge is applying such efforts beyond acquisitions to the whole lifecycle of the supply chain.

### **A. A QUICK LOOK AT DLT THEN AND NOW**

Nakamoto (2009) is considered the conventional originator of the original description of blockchain technology, although it is focused on the financial and Bitcoin applications. One should note, however, that the concepts surrounding blockchain predate this by a decade or so, and there is other research available on distributed ledgers previous to that timeframe. Beyond Bitcoin, DLT and blockchain have been researched for various financial and operational tracking purposes. Zheng et al. (2017) and Natarajan

et al. (2017) provide a general and fairly informal introduction into DLT and how it might integrate into mainstream day to day operations in the financial, private, and government sectors. Natarajan et al. (2017) also provides a sense of how “decentralized records of flow of commodities and materials across a supply chain by using trusted stakeholders to validate flows and movements” could benefit those stakeholders, leading credence to adopting DLT which would enhance trust in the supply chain. For an overview of blockchain research, consult Fosso et al., (2020), which highlights the benefits of the creation of value in operations and supply chain management (OSCM). Statistics such as the number of published papers by country, topic, keyword summary and relationships are recorded.

Although not explicitly addressing blockchain technology, Bonanni (2011) discusses supply chain discovery/awareness, concepts and concerns that motivate the current work. Bonanni argues for “Radical Transparency” in the context of sustainable (carbon cost) supply chains, carbon-footprint measured supply chains and product life cycle awareness and optimization. This runs into a similar problem set that DoD acquisition may encounter – companies’ unwillingness to reveal their supply chain details as trade secrets, or an inability to do so, being unaware of the source of their sources.

There has also been a line of research covering direct application of blockchain to supply chain management. Korpela et al. (2018) provides an analysis of how blockchain could be used to solve or ameliorate the issues of concern of the major stakeholders involved in a very large supply chain operation. The main contribution of the paper is proposed elimination of a third party to mediate/handle supply chain inter-business and then address these popular concerns as graphed in the following Table 1. Meanwhile, Banerjee (2018) provides an overview/summary of the use and benefits of blockchain in supply chain operations such as:

- Reduced counterfeiting and origin tracing
- Digital product details/lifecycle
- Custom-built provenance solutions: Software service providers can use the blockchain framework to build provenance solutions for its customers (permission blockchain)

Based on Banerjee's work, custom-built solutions appear to have gained traction within industry. For instance, Infosys® has developed a product provenance solution using Oracle® Blockchain Cloud Services that is based on Hyperledger™ Fabric. Infosys® has also developed a coffee bean tracking provenance solution for its customers. Such examples point towards a demand for custom built provenance solutions that can be developed with product or industry specific validations. It is important to note that the concept of provenance only functions when all the supply chain stakeholders are part of the blockchain network. The architecture of blockchain inherently traces products as they pass from one supply chain entity to another. These transactions are stored as blocks and chronologically linked according to the physical movement of "the goods." Supporting such tracking technologies motivates our solution (see Section C).

Kshetri (2018) provides a theoretical framework related to key objectives of Supply Chain Management (SCM). Kshetri's work covers several corporate case studies of how the Internet of Things (IoT) blockchain SCM can be used by companies with differing levels and areas of interest in supply chain verification/source confidence (see Table 1). Such case studies, including the Chipotle™ E-coli outbreak ingredient tracing case study, may shed light on potential parallel solution behaviors involving a faulty/compromised hardware component recall in the DoD. Under a similar formal goal, Queiroz et al. (2018) covers blockchain SCM adoption in the U.S. and India. The study advocates for drawing on emerging literature on blockchain, supply chain and network theory, as well as on technology acceptance models (TAMs). Queiroz et al. (2018) introduce a model based on a slightly altered version of the classical unified theory of acceptance and the use of technology (UTAUT).

**Table 1**

The cases selected and their classification in terms of incorporation of the IoT and deployment of blockchain to validate individuals' and assets' identities.

| Deg. of incorporation of IoT                                                                                                                                                                                                                                | High                                                                                                   | Low                              |

### **III. A METHOD FOR ADAPTING DISTRIBUTED LEDGER FOR SUPPLY CHAIN USE**

#### **A. UAV USE CASE: SYSTEMS DEPLOYED BY U.S. NAVY SHIPS**

Defining unique supply-chain characteristics of deployed Naval assets increasingly depend upon the deployment, maintenance and just-in-time improvement of unmanned systems.

Littoral Combat Ships (LCS) have two classes of relatively small surface warships designed for operations near shore by the U.S. Navy (“Littoral combat ship,” 2020). Modern designs allow for flexible mission execution, various mission payloads, and other tasking. Reduced crew complements mean individuals are assigned, yet with reduced inventories of spare parts and supplies.

The use of unmanned aerial vehicles (UAVs) help in this regard. These vehicles are employed for scouting and other rapid response detailing that minimize risk to the overall mission, ship and crew. The ecosystem for a typical UAV consists of four categories of components:

- Hardware: airframe, sensors, computers
- Software: communication, guidance and control
- Additive Manufacturing (AM): 3D printed wings, tails and other small parts for ad hoc repair
- Information: keys, training, repair instructions, feedback, safety

Within these four categories of components, each is different and necessary for aggregation into a complete device, and each has different stakeholders and supply chains feeding ships supplies. Thus, four parallel supply chains of interest exist, and each is interdependent; therefore, any merge solution should necessarily support all four aspects, as seen in Figure 1. Note that even with acquisition of a device as a single unit, the nature of updates, potential repairs, and parts reuse between devices imply that it must be possible, for tracking purposes over the device lifetime, to handle the merge of all four aspects.

Brutzman, Norbraten 29 JUN 2020

Figure 1. UAV Operational Assembly and Modification

## B. SYSTEM CONSTRAINTS AND REQUIREMENTS IDENTIFICATION

In this section the various system requirements are explored, in the context of the UAV use case.

### 1. Scenario: UAV Deployment, Repair, Operations

Suppose that a ship deploys with stock gear and consists of two distinct, yet similar versions of a UAV. The ship must maintain its current pace of operations until return to port, or resupply.

Under normal operations, the following issues may affect device history, in that they impact the integrity of the device or its trustworthiness, and therefore should be added in an authenticated manner to the device history:

- Software updates

- Training and safety updated to ship standard operating procedures (SOP) and tactics, training and procedures (TTP)

Now suppose that a collision occurs during testing between the two UAV causing damage to each vehicle. The following may also be important changes to the device history, requiring authenticated changes in device records:

- Hardware replacements on board, to include classified components
- 3D printing for upgraded tail assemblies
- Maintenance feedback to shore commands

Any merge solution must therefore support, per minimum such a variety of changes to the item history.

## **2. Merge Requirements Assessment – Verifiability**

In addition to the afore mentioned types of item record changes, there are also requirements in how a change is recorded. In particular, the record must be verifiable. In terms of verifiability, the following requirements are also essential and must be supported by a merge solution:

- Confirmation that a given component X is on the ship
- Confirmation of all devices in the inventory that have X as a component
- Confirmation if and when X has been replace/repaired/etc., within a particular device
- Confirmation of the change entity – the responsible party to change/split/remove/combine X as a component within devices
- Ability to add logs or metadata

The above requirements emerge from use case issues. For example, if a device component is found to be compromised and must be removed, the logged data associated with the device should indicate if it has been removed and by whom. Furthermore, is it important for administration purposes to identify all possible devices containing the compromised component for swift handling and damage mitigation. In these contexts, “components” may refer not only to hardware, but also malicious software or poorly executed additive manufacturing (e.g., 3D printed wings with vulnerable integrity).

### **3. Mergence Requirements Assessment – Flexibility**

Finally, flexibility requirements associated with mergence are listed. Since mergence solutions must support potential external (industry/non-DoD) supply chain tracking of unpredictable natures, the mergence solution must be fairly adaptable. Furthermore, external supply chain tracking may differ from internal (DoD) tracking, and the potential solution must support one or more blockchains used internally to the DoD. As many acquisition devices may be of a sensitive nature, the mergence solution must furthermore support various classification levels, such that unclassified devices may be administered in unclassified environments, while devices of higher classification levels can also be managed within the same mergence solution without sensitive information leakage. Finally, in addition to all of these, devices transfer hands between organizations ships, etc., requiring a flexibility to record management. This leads us to the following final four solution requirements:

- Flexibility independent of source/industry in the external supply chain
- Flexibility with internal blockchains(s) within DoD
- Flexibility with classification levels
- Flexibility for device transfer between organizations/ships/etc. internally

### **C. LEDGER MERGENCE EITHER IN BLOCKCHAIN OR AS A MODULAR APPROACH LEVERAGING EXISTING BLOCKCHAIN SOLUTIONS**

There is a natural separation between external-DoD and internal-DoD supply chain tracking. This intrinsically leads to a dual solution, with the acquisition boundary denoting a change in authenticity tracking. Even for internal supply chain tracking, satisfying all solution requirements appears, on the outset, to be impossible. Notably a solution that crosses classification boundaries must be carefully handled, especially for full item records and tracking information. This is handled by further separating out the internal DoD authentication chain into two parts.

## 1. External and Internal Chains

DoD equipment is typically procured via outside commercial manufacturing vendors. The supply chain starts outside of the DoD where parts and other equipment must be verified and validated before becoming available inside internal supply chains. Conceptually, manufacturers may require supply chain assurance as well, tracking purchased components for integration in building devices. This may take the form of various blockchains (see Figure 2 “Supply chain”). Minimally, manufacturers may be required to present verification on the types and sources of a device’s components. At acquisition, a new item record will be formed, such that the component history of the acquired device is verified and authenticated by the acquisition authority, who registers components under a digitally signed genesis block. Once a genesis block for the internal ledger is formed, tracking may proceed internally.

What is essential at the DoD boundary/component registration step is that actual verification of internal components to a device. Information on processing chips, software, extra must be recorded. This enables future tracking such that if, for instance, a component is later discovered to be compromised in the manufacturing chain, all devices containing the critical component can be identified. The genesis block thus serves as an initial registration for all components, such that it is only necessary to record changes to that initial list within the device history record.

Figure 2. DoD Acquisition: Verification of External Input Chains(s), Registering of Devices to Initiate Internal Chains

## 2. Mergence Operations

Internal tracking is broken into two further chains to support classification boundaries. The *device chain* handles immediate time history, and authenticates records

as visible to the admin. Moreover, the device chain is designed to support the current Depot Level Repairable (DLR) system. Within the merge solution, in addition to the device chain, one or more internal blockchains are also supported. These may be organization level blockchains, or classification level blockchains. Here, the term blockchain is employed for a distributed immutable ledger, without specification that restricts to any particular ledger format or consensus method. This in turn meets the flexibility requirements specified in Section B.

The following device chain operations are fixed, in accordance with the requirements:

- *Device registration*: adding new, original item to a ledger. This creates the genesis block for the device chain.
- *Device repair*: adding a new component onto an existing device. This differs from *device combine* in that the component being added has no registration history (i.e., no genesis block). This may occur if the repair takes place using additive manufacturing.
- *Device split*: separation of components within an existing device. This supports potential re-use or disposal, such as when a component breaks and is removed from the current item record (device history is still maintained). This creates two separate device chains: one for each split component.
- *Device combine*: integrate two components into a new combined device. This supports customization of devices after acquisition and parts replacement (e.g., a newly purchased component added to an existing device).

Device split can be employed if a device breaks, but components can be reused. For example, suppose that a UAV (UAV1) malfunctions but certain components can be used to repair another UAV (UAV2). The broken device would then have a device split operation in its item record, creating two new chains: one for component that will be reused and one for the remaining unusable assembly UAV1. A device combine operation then integrates the split component into UAV2. As such, the item history of UAV1 is

now linked to UAV2. If there were relevant repairs to the reused component or if it comes to light that the reused component was compromised during manufacture and must be pulled from use, it will be immediately clear from UAV2's record history that the part now resides within UAV2 instead of the UAV1 device carcass.

Each of the stated operations must be authenticated. For this be use the PKI infrastructure already inherent in the DLR system. The operator responsible for the device signs the various operations. The signature covers the current record for the device(s) being operated on as well as what type of operation is performed. The authenticated transcript is stored as part of the device chain. These operations are shown in Figure 3.

The distributed ledger and shared memory exist beyond the immediate device chain history, such that an item record cannot be changed *a posteriori*. For this, a blockchain is employed, which records the signatures from the device chain operations. Note that only signatures are required, and not the related device information, to be stored on the blockchain, although the latter may be. Storage of further information or metadata may be beneficial for device tracking but could also leak information (such as if the device or its location is sensitive). Instead, only the minimum information on the blockchain concerning the current signature state is required.

Figure 3. Sequencing Operations for Blockchains

### **3. Multilevel Security (MLS) Classification Agility Considerations**

For hybrid devices used in the fleet, activities may occur and be needed across multiple levels and domains of security, such as: UNCLASS, CONFIDENTIAL, SECRET, and TOP SECRET. A solution is to map to a Multilevel Security (MLS) classification system and demonstrate interoperability.

Note that while the device chain contains potentially classified information, the information sent to the blockchain is comprised of merely the signature on the data vs. the data itself; any further additions are optional. Even with a time code associated to the signature object representation there is no intrinsic value to the information outside of the context of the signed data, especially with a plentitude of blockchain transactions. Thus, the blockchain information can be shared across multi-level security systems since these codes are useless without ledger/database access.

In addition to the above observation, blockchains may be allowed to operate at different classification levels, such that more relevant device information may in fact be added to the blockchain than merely the signature. This in turn implies that any device may have a record with varying classification levels attached to different aspects of the associated information, and that the associated data may be placed on the relevant blockchain. Naturally, higher classification can correlate same and lower-level data records, but not write to them, per the properties of the MLS system. Figure 4 illustrates this framework in practice.

Figure 4. Multilevel Security (MLS) Classification Agility within a DoD Blockchain Network

To consider how this may work in practice, the reader can walk through the following conceptualized steps for handling the mergence solution of device chains and blockchains within MLS:

- 1) A new item genesis record for an UNCLASS device is created for the device chain. This correlates to a device origin record with signature information populated to the various blockchains.
- 2) The device is transferred from an UNCLASS environment to a SECRET environment. The device chain is now maintained at SECRET.
- 3) The device is repaired, using a combine operation on the device chain. Necessary information is populated to the appropriate and corresponding SECRET level blockchain, while other chains record signature information only.

If it is later discovered that the device contained a malfunctioning or compromised component (e.g., through manufacturer notification), then an operator can

see all associated components in the device genesis block, recognizing that the critical component is present. It can then be seen that the device is associated to a different classification (or organization blockchain) and the appropriate authority for that blockchain can be contacted, who can then trace the device's history to identify if the component is still present or has been replaced.

Strengthening Naval supply-chain accountability, integrity and trust that is distributed across exceptionally long, intermittent and diverse communication networks is an example of Data-Centric Security, which is an important topic being explored as part of the Network Optional Warfare (NOW) project (Network Optional Warfare, 2020).

#### **D. DOD EQUIPMENT REPAIR TRANSACTIONS USING THE HYPERLEDGER™ FABRIC FRAMEWORK FOR DISTRIBUTED BLOCKCHAIN LEDGER KEEPING**

It is important to show that such theoretical functionality is indeed achievable in practice. This project demonstrates an end-to-end exemplar scenario using the industry-grade software, the open-sourced Hyperledger™ Fabric (HLR) Framework (Hyperledger, 2020) hosted on GitHub (2020). This exemplar has been constructed to showcase what various repair level organizations might use to record supply chain transactions between them using DLT to merge separate blockchains into one.

##### **1. UAV Camera**

Present in the exemplar scenario are an organizational level (O-level) end user of an unmanned aerial vehicle (UAV) in its custody that houses a camera subcomponent, a depot level repairable (DLR) that requires repair at the depot level (D-level), and the D-level repair station. The client application transactions that take place and are recorded on the blockchain ledger are:

- 1) O-level issues the non-functional DLR camera to D-level for repair
- 2) D-level accepts and conducts the required repairs for the DLR camera
- 3) D-level reissues the repaired DLR camera back to O-level

The intent is to show chain of custody for the DLR camera subcomponent, camera metadata, i.e., serial number, and status of repair of the DLR in the supply chain and how each O-level and D-level ledger merge to comprise the DLR repair history.

The blockchain network, N, will comprise of the following consortium organizations, components and entities (see Figure 5):

- Organizations R1 (D-level), R2 (O-level) & R4 (blockchain network administrator).
- Client applications A1 (D-level transactor) & A2 (O-level transactor). Client applications conduct transactions on behalf of their respective organizations.
- Certificate authorities CA1, CA2 & CA4. Each organization can prefer their own vetted certificate authority.
- Peers P1 (D-level) & P2 (O-level). Peers maintain local copies of and record blockchain ledger transactions in accordance with agreed upon smart contracts (chaincode) within the consortium.
- Blockchain ledger L1. Each peer maintains and communicates with other network peers to ensure local blockchain ledger copies are kept uniform throughout the network.
- Smart contract (chaincode) S5. Peers are able to maintain blockchain ledger uniformity through consortium member agreed upon smart contracts.
- Network ordering service O4. The ordering service serves as the initial administrative gateway between consortium members upon network standup.
- Network configuration NC4. Consortium members R1, R2 and R4 all agree upon the blockchain network configuration policies administered by ordering service O4 via NC4.
- Channel configuration CC1. The channel configuration allows for network peers to accept and distribute blockchain ledger transactions between authorized organizations in accordance with NC4.
- Channel 1. The communications channel where organizational peers accept and record transactions between client applications A1 & A2 on channel 1.

Figure 5. DoD Equipment Repair Blockchain Network (N) Configuration Topology

## 2. Using the Fabric Test Network

Hyperledger (2020) provides a test network that developers can download and work their way through a demonstration of the capabilities of Hyperledger™ Fabric. The portal for that demonstration is here: [https://hyperledger-fabric.readthedocs.io/en/latest/test\\_network.html](https://hyperledger-fabric.readthedocs.io/en/latest/test_network.html). Depending on the operating system of the developer's choice, a specific environment is first set up on a local machine in order to leverage the Hyperledger™ Fabric framework. Once the prerequisites are complete, the test network is invoked via command line scripts and the demonstration can proceed. In our case the demonstration code was modified locally to mimic our UAV camera scenario.

## 3. DLR Transactions in Action

The following figures are from screenshots of a live network (N) demonstration.

Upon network startup/startup, the various organizational peers, admins, etc. are defined, registered, enrolled and assigned certificate authorities which then issue authenticating certificates for each respective network node. The agreed upon smart contract (chaincode) is deployed to each organizational peer node and tested. Finally, each organizational peer node is given local custody of the blockchain ledger which is then readied for acceptance of and recording of ledger transactions (see Figures 6-9).

```

Figure 9. Schema Checking and Transaction Testing of Deployed Chaincode Between Organizational Peers

The network (N) is now ready to facilitate transactions. Each client application (authorized organizational transaction entity) then submits their authentication data to network (N) before the network authorizes transactions to take place.

```

cd /Users/terry/javaapis/Hyperledger/dod-equipment-repair/unmanned-aerial-vehicle/consortium/dlevel/application-java; JAVA_HOME=/Library/Java/JavaVirtualMachines/jdk-14.0.2.jdk/Contents/Home
Running NetBeans Compile On Save execution. Phase execution is skipped and output directories of dependency projects (with Compile on Save turned on) will be used instead of their own

Figure 13. D-level UAV Camera Reissue Transaction

Figures 11-13 show the three transactions completed, as per the smart contract constructs initiated from each of the O-level and D-level authorized entities. These transactions were initiated from each client gateway interface application that has knowledge of the network (N) from their respective remote locations. The next two figures 14-15 show what the network logs as the transactions progress from the D-level perspective.

Figure 16. Successful Shutdown of Blockchain Network (N)

#### 4. Basic Network Timing Data

The table below annotates various local network timing data points using a 2015 Apple® MacBook Pro® laptop with a 3.1 GHz Dual-Core Intel i7 and 16 GB of RAM running the latest macOS® operating system.

| Network Action                        | Time Units   |
|---------------------------------------|--------------|
| Blockchain Network Startup/Standup    | 2 min 19 sec |
| Client Application Authentication     | 19.4 sec     |
| O-level DLR Issue Transaction         | 18.3 sec     |
| D-level Acceptance/Receipt ACK of DLR | 17.8 sec     |
| D-level Reissue of RFI DLR            | 18 sec       |

Table 2. Network Timing of Various DLR Transactions on Network (N)

The codebase for this presentation is located on the on the Naval Postgraduate School's GitLab server (Norbraten, 2020).
