## Background

- Traumatic hemorrhage is the leading cause of preventable death in civilian and military environments
- Blood components are frequently unavailable in the prehospital setting due to increased costs and lack of resources, training and viable portable refrigeration
- Hydroxocobalamin (HOC), a synthetic form of vitamin B12, works as an antidote for cyanide toxicity and increases blood pressure via nitric oxide scavenging

## Objectives

1. Evaluate whether the administration of HOC following hemorrhagic shock can improve hemodynamic parameters
2. Determine whether those effects are comparable to whole blood (WB) and lactated ringers (LR)

## Methods

- Thirty-six swine (*Sus scrofa*) weighing 65kg – 85kg used in 40% total blood volume hemorrhage
  - 18 controlled hemorrhage (CH)
  - 18 uncontrolled hemorrhage (UH)
- Randomized treatment: 500mL WB, LR or HOC
- Animals were monitored for six hours after treatment
- Hemodynamic parameters, blood gas analysis and chemistries were collected throughout the duration of the experiment
- Data reported as  $\pm$  SEM, statistical analysis performed by ANOVA ( $p < 0.05$ )

## Results

### Hemodynamic parameters

### Arterial Blood Gas analysis parameters

|                  | Controlled Hemorrhage (CH) |                 |                 | Uncontrolled Hemorrhage (UH) |                |                |
|------------------|----------------------------|-----------------|-----------------|------------------------------|----------------|----------------|
| Parameter        | WB                         | LR              | HOC             | WB                           | LR             | HOC            |
| Lactate          | 4.9 $\pm$ 0.4              | 4.3 $\pm$ 0.6   | 4.2 $\pm$ 0.2   | 2.1 $\pm$ 0.1                | 4.9 $\pm$ 0.4  | 3.9 $\pm$ 0.2  |
| K <sup>+</sup>   | 5.2 $\pm$ 0.2              | 4.9 $\pm$ 0.2   | 5.1 $\pm$ 0.1   | 4.4 $\pm$ 0.1                | 5.3 $\pm$ 0.3  | 4.7 $\pm$ 0.1  |
| O <sub>2</sub>   | 100 $\pm$ 1.4              | 103 $\pm$ 3.2   | 112 $\pm$ 1.4   | 108 $\pm$ 1.1                | 98 $\pm$ 2.2   | 102 $\pm$ 1.4  |
| CO <sub>2</sub>  | 34 $\pm$ 0.8               | 36 $\pm$ 0.6    | 35 $\pm$ 0.3    | 35 $\pm$ 0.4                 | 35 $\pm$ 0.4   | 34 $\pm$ 0.2   |
| Ca <sup>2+</sup> | 1.18 $\pm$ 0.02            | 1.23 $\pm$ 0.01 | 1.27 $\pm$ 0.01 | 1.2 $\pm$ 0.01               | 1.2 $\pm$ 0.01 | 1.2 $\pm$ 0.01 |

- Swine averaged a blood loss of 41% $\pm$ 0.02 for CH vs. 33% $\pm$ 0.07 for UH
- During both uncontrolled hemorrhage (UH) and controlled hemorrhage (CH), HOC groups maintained a higher systolic blood pressure (SBP), cardiac output (CO), SPO<sub>2</sub> and vascular resistance (SVR) that was comparable to WB and above LR levels.

## Conclusions

HOC administration resulted in improved hemodynamic parameters, and similar Ca<sup>2+</sup> levels compared to LR and were equivalent to WB in both controlled and uncontrolled hemorrhage. HOC may be a viable alternative when WB is not available.

## Limitations

- Animal model
- n=36
