NOTICES

When Government drawings, specifications, or other data are used for any purpose other than in connection with a definitely related Government procurement operation, the United States Government thereby incurs no responsibility nor any obligation whatsoever, and the fact that the Government may have formulated, furnished, or in any way supplied the said drawings, specifications, or other data, is not to be regarded by implication or otherwise as in any manner licensing the holder or any other person or corporation, or conveying any rights or permission to manufacture, use, or sell any patented invention that may in any way be related thereto.

Organizations or individuals receiving reports via Aerospace Research Laboratories automatic mailing lists should refer to the ARL number of the report received when corresponding about change of address or cancellation. Such changes should be directed to the specific laboratory originating the report. Do not return this copy, retain or destroy.

Reports are not stocked by the Aerospace Research Laboratories. Copies may be obtained from:

20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

A revised computer program for the design of axial compressors is presented. It comprises three principal sections, two alternative means of determining blade geometry and an aerodynamic computation for the flow through the compressor. One method of determining blade geometry uses various analytic meanlines for the blade sections, and leads to the aerodynamic analysis of the flow through specified blading. The other

DD FORM 1 JAN 73 1473 EDITION OF 1 NOV 65 IS OBSOLETE

UNCLASSIFIED

1. SECURITY CLASSIFICATION OF THIS PAGE (When Data Entered)

method consists of creating arbitrary blade sections to follow the flow directions previously determined in an aerodynamic design calculation. The aerodynamic design section incorporates a loss calculation routine that may be used to estimate the design point performance of the compressor. One, two, or all three sections may be used in any one run of the program. This second volume of two describing the program shows the FORTRAN program listing and an example of the use of the program.

PREFACE

The work described in this Final Report was performed by the University of Dayton Research Institute, 300 College Park Avenue, Dayton, Ohio 45469, under Air Force Contract F33615-74-C-4030 during the period October 1973 to October 1974. It was a portion of Project 7065, Task 04 of the Aerospace Research Laboratories, and Project 3066 of the Aero Propoulsion Laboratory. Technical Monitors for the Air Force were Dr. A. J. Wennerstrom, ARL/LF, and Mr. M. A. Stibich, AFAPL/TBC, both at Wright-Patterson Air Force Base, Ohio 45433. This report was initially identified as UDRI-TR-74-47 by the University of Dayton.

SECTION I

FORTRAN PROGRAM LISTING

The following pages show the FORTRAN program listings. Each program or subprogram is begun on a new page, except that the fluid properties package, Subroutine UDG1 through Function UDG9, has been listed as a single unit.

SECTION II

EXAMPLES OF USE OF PROGRAM

1. DISCUSSION OF EXAMPLE A

The example shown is the design of a single-stage compressor and is based upon a design described in Reference 1. The input data cards are shown in the next subsection, and selected output data are shown in the following subsection. An analytic meanline rotor blade and an arbitrary meanline stator are used, so that with the aerodynamic calculations all three program sections are used.

The original design was made using 15 streamsurfaces to describe the flow, but in the interests of economy, only 8 have been used here. The same computing station geometry is used here as was used in the original design, and alternate streamsurfaces, as derived previously, are input to the analytic meanline section for the rotor geometry determination. Streamsurfaces are specified from one station upstream of the leading edge to one station downstream of the trailing edge. Blade section specifications were also reproduced directly, and these specify a polynominal camberline blade with an uncambered leading edge. Output of NASTRAN data cards is specified by setting INAST = 4. Thus four-point averaging will be used, and no pressure load cards will be punched. Input to the interface routine includes a shape correction factor of 0.7, and a single deviation fraction curve, as was used originally. One degree of additional deviation at the trailing edge (over that determined by the basic deviation rule) is specified, and the point of maximum camber is given as 0.75 of the blade chord. The loss form indicator NLOSS is set to 4 for each station within the rotor blade, so that (in the aerodynamic analysis) loss coefficients will be determined as a function of the trailing edge values. Accordingly, NLOSS is set to 1 for the trailing edge, and a loss coefficient distribution is given. The results show the blade inlet, outlet, and camber angles as positive; they are set positive in this routine so that they may be used in conjunction with the deviation rule data. The additional deviation remains positive, but the total deviation is shown negative, as it is used in the aerodynamic section in conjunction with (generally) negative rotor blade angles.

The input printout from the aerodynamic section follows, and it is seen that blade geometry for stations 4 through 9 are to come internally from the analytic meanline section. These data are listed with the rest, and show, for stations 5 through 9, the deviation "rising" from about -1.5 degrees to the trailing edge values of about -13.5 degrees. No loss

coefficients are shown for stations 5 through 8; these will be generated internally from values at station 9, and the loss fraction curve shown as the final input data. A simple linear increase from leading edge to trailing edge is indicated. For the stator, whirl velocity is specified and NOUT2 is set to 1 from one station upstream of the bladerow to one station downstream. Thus data will be output for the arbitrary meanline blade section. For each of the stations within the stator, an isentropic efficiency variation is given, relative to conditions at the rotor inlet. At the trailing edge, a relative total pressure loss coefficient is given, because for both rotor and stator a loss re-estimation is specified. As NEVAL is negative for stations 9 and 15, the new losses will not be incorporated into the iteration, but will be computed after the solution is converged. One family of loss parameter/diffusion factor curves is given in the data, and is called out for both blades. For the rotor, NDEL is set to 2, and the specified Prandtl-Meyer expansion angle varies from zero at the hub to -5 degrees (that is, 5 degrees of compression) at the tip. As leading edge geometry is given, the incidence angles will be added to these values. NDEL is set to zero for the stator, so that no shock loss will be computed. Pressure load cards for the NASTRAN program are specified for both rotor and stator. Four-point averages are specified for the rotor, three-point for the stator.

The output from aerodynamic analysis shows details of the flow through the machine, and is very similar to that shown in Reference 1. The loss coefficient re-estimation shows a relatively high rotor loss coefficient, due principally to a less optimistic assumption regarding precompression of the inlet flow.

The stator blade design follows, producing a blade that corresponds to the air angle distribution determined through it in the aerodynamic section. A uniform 3 degrees of incidence and 1 degree of extra deviation are specified. INAST is set to -3, specifying the output of NASTRAN data cards for the stator, without pressure load cards (which are specified for the aerodynamic section). Three-point averages are to be used. Details of the resulting blade section for the innermost streamsurface are shown.

2. INPUT DATA CARD LISTING FOR EXAMPLE A

The input data cards are shown on the following pages, 50 cards per page. No completely blank cards have been used.

4. DISCUSSION OF EXAMPLE B

This example uses only the aerodynamic section of the program, and demonstrates the turbulent mixing calculation and the blade wake transfer calculation. The machine for which the computation is made is the so-called NACA Five-Stage Compressor that is described in References 2 and 3. A conventional multi-stage analysis calculation is set up, with a computing station at each blade edge (that is, there are two stations between each blade row). For each of the ten blade rows in the machine, fixed relative outlet flow angle and (two-dimensional) loss coefficient distributions are specified. The distributions are ones that describe well the performance of the blade rows at an operating point in the viscinity of the machine's design point, except that the loss coefficients do not reflect any variation in blade section performance with blade section location. In practical terms, this means that no additional rotor tip losses are incorporated. The wake transfer analysis was developed to account for migration of boundary layer material and is therefore applicable to the diffusion loss component of the relative total pressure loss coefficients. However, the subject compressor operates transonically in all stages at design speed, and so the rotor loss coefficients in the input data generally include a shock loss component in addition to the diffusion loss component. The input data item that controls the wake transfer rate, CONTR, is set to 1.0. The value is probably lower than it should be, and this compensates to some extent for the fact that (for the rotors) the whole loss coefficient is being manipulated instead of just the diffusion loss portion thereof. The input eddy viscosity, CONMX, is set to 2.0 ft^2/sec which is higher than the probable correct value.

A listing of the input data cards is shown in the next sub section, and the corresponding output from the program follows. The program has computed the results with difficulty, although just a few more iterations are apparently required for total convergence. With a final IVFAIL of 5 and final IFFAIL of 0, the result may be taken to be converged for most practical purposes. The following points should be noted when examining the results. When wake transfer calculations are made, the loss coefficients shown in the results differ from those in the input. When turbulent mixing calculations are made, the loss coefficients shown in the results differ from those in the input and efficiencies computed for streamlines may take on apparently impossible values because both of these parameters are computed from conditions on "streamlines".

It is of some interest to examine the effects of the wake transfer and mixing calculations upon the computed compressor performance, and shown below are some performance parameters for the four possible calculation modes involving (or not involving) wake transfer and mixing. The final station (outlet) total temperature difference between casing and hub streamlines is shown as indicative of the effects of the various calculations

upon the distributions of properties of the flow. All computations were made with identical data, except that the input data items NTRANS and NMIX were varied as shown.

NTRANS	NMIX	Total Pressure Ratio	Isentropic Efficiency	(T case - T hub) at outlet, deg.
0	0	5.188	.8313	40.9
0	1	5.264	.8341	3.9
1	0	4.524	.8073	259.4
1	1	4.512	.8086	194.8

It is apparent that the wake transfer calculation can drastically effect the machine overall performance and the distribution of properties of the flow. Also, the mixing calculation had considerably less effect on the overall performance, but did modify the distributions appreciably. It should be recalled that the calculations were somewhat simplified in that the relative outlet angles and base (two-dimensional) loss coefficients were fixed throughout.

Some final notes are given, as follows.

1) Correlation of empirical and computed results is needed to establish appropriate vales for the wake transfer rate constant, CONTR, and the eddy inviscosity, CONMX.

2) In order to correctly apply the wake transfer calculation to transonic blade rows the computer program should be modified so that shock and diffusion loss coefficient components may be separately manipulated.

3) If it is desired to use the wake transfer calculation when computing stations are located within blade rows, the program will need modification. Probably the only change would be to replace I-1 with I + NLI (I) (separately computed) wherever it occurs in the call statement starting on card AR. 225.

4) Both the wake transfer and mixing calculations substantially increase computation time. For a fixed number of iterations, each of these options taken separately increases computation time by a factor of approximately three, and taken together by a factor of approximately six. In the case of the wake transfer calculation option, taken above or with the mixing calculation option, this is further compounded by the fact that it increases the number of iterations required for solution by a factor of two or three.

6. OUTPUT DATA FOR EXAMPLE B

PROGRAM UD0300 - COMPRESSOR DESIGN - CONTROL SECTION

TITLE = NACA 5-STAGE COMPRESSOR FIXED CASCADE 2-D PERFORMANCE
NUMBER OF ANALYTIC MEANLINE BLADEROWS = 0
THERE WILL BE AN ENTRY TO THE AERODYNAMIC SECTION
NUMBER OF ARBITRARY MEANLINE BLADEROWS = 0

PROGRAM.VO0300.-.COMPRESSOR.DESIGN.-.AERODYNAMIC.SECTION

INPUT.DATA

TITLE = NACA 5-STAGE COMPRESSOR MIXING AND WAKE TRANSFERS CALCULATED

SPECIFIC HEAT AT CONSTANT PRESSURE = .24060
GAS CONSTANT = 53.3260
GRAVITATIONAL CONSTANT = 32.1740
JOULES EQUIVALENT = 778.160

NUMBER OF STATIONS = 23
NUMBER OF SIA ANLYSES = 11
MAX NUMBER OF PASSES = 20
MAX NUMBER OF ARBITRARY RADIUS = 10
BOUNDARY LAYER CALC INDICATOR = 1
NUMBER OF MOVING POINTS = 1
STREAMLINE DISTRIBUTION INDICATOR = 1
NUMBER OF LOSS/DEFACTOR CURVE SETS = 1
NUMBER OF LOSS/INCIDENCE CURVE SETS = 1
STREAMLINE INPUT INDICATOR = 1
STREAMLINE OUTPUT INDICATOR = 1
PRECISION PLOT INDICATOR = 0
MAX NUMBER OF LINES/PAGE = 30
WAKE TRANSFER CALC INDICATOR = 1
MAINSTREAM MIXING CALC INDICATOR = 1
NO OF STATIONS FROM ANALYTIC SECN = 11
LINE PRINTER PLOT INDICATOR = 0
MOMENTUM EQUATION FORM INDICATOR = 0

GRAVITATIONAL CONSTANT = 32.1740
JOULES EQUIVALENT = 778.160
BLADE DIMENSION SCALE FACTOR = 12.0000
BASIC TOLERANCE = .00100
KINEMATIC VISCOSITY = .00010
B.L. SHAPE FACTOR = .70000

PLOTTING SCALE FOR DIMENSIONS = 0.000
PLOTTING SCALE FOR PROPERTIES = 100.000
MINIMUM RADIUS ON PLOT = 10.000
MINIMUM PROPERTY ON PLOT = 0.000
MAXIMUM UNDERRELAXATION FACTOR = .5000
CONSTANT IN RELAXATION FACTOR = 6.0000

WAKE TRANSFER CONSTANT = 1.00000
TURBULENT MIXING CONSTANT = 2.00000

POINTS TO BE COMPUTED
