1.0 INTRODUCTION

The problem of controlling and disposing of mankind's wastes has, in the past several years, grown to such proportions as to demand attention. In particular, increased public concern over the quality of the environment has brought considerable pressure to bear in seeking solutions to these problems.

One of the most severe waste disposal problems facing us today is that of liquid waste. This is especially true in Eastern Massachusetts, where dense population, concentrated industries and often antiquated sewage treatment practices have combined to pollute many of our rivers and groundwater supplies and to materially threaten those which are not polluted. The sources of this pollution are basically three: domestic sewage, industrial wastewater and storm water runoff. Each offers its particular problems and is amenable to different solutions.

Before any solutions are sought, however, the scope of the problem at hand must be known. This requires data gathering efforts, such as the one contained in these pages, to provide the basic data on regional wastewater production necessary to successfully plan for its control.

1.1 Purpose

The purpose of this study is to collect existing information and generate new information on the magnitude and composition of certain industrial and manufacturing process wastewater discharges in the Eastern Massachusetts Metropolitan Area and to project the magnitude of this problem into the future. Additionally, the data collected is to be placed into a computer assisted retrieval and plotting system to allow it to be used as an effective planning tool.

1.2 Scope and Limitations

The scope of this project must be described in terms of two parameters: geographic focus and industries studied.

The geographic focus of this study is Eastern Massachusetts. The study area is bounded approximately by Route 495 and includes all of Suffolk County, most of Norfolk, Middlesex and Essex Counties and small portions of Plymouth County to the South and Worcester County to the West. As shown in Figure 1, the study area contains 109 communities. Of these 109 communities, thirty-two fall within the SUASCO study area. The remaining seventy-seven fall primarily within the drainage areas of the Neponset and Charles Rivers to the south of Boston and the Mystic, Danvers and Ipswich Rivers to the north. Table 1 lists the communities within the study area. Those which fall entirely or partly in the SUASCO study area are marked with an asterisk.

The industrial focus of this study is delineated in Table 2. These twenty-seven industrial groups represent most of the major water using industries in the Eastern Massachusetts Metropolitan Area.

Thus, the scope of the study is to inventory twenty-seven industries in 109 communities. This report includes studies of all the industries presented in Table 2 in the 109 communities which make up the Eastern Massachusetts Metropolitan Area.

To allow planning to meet future wastewater disposal needs, it was necessary to project the expected industrial waste loads well into the future. Current levels of industrial waste were projected to the years 1990, 2020 and 2050 and can serve as estimates for the intermediate and long-range planning of waste treatment facilities.

The limitations of the study are those of scale. The purpose of the study is to provide information on the magnitude and composition of industrial wastewater discharges for twenty-seven industrial groups at the regional level. The techniques used and the data collected are appropriate to this scale. Thus, the data contained herein is only appropriate for use at that scale and for the industries

covered. It is not intended to characterize exactly any one site, but rather to provide data on the aggregation of industrial sites in the region.

Finally, one of the purposes of this study was to develop a usable data acquistion system and computer plotting routine to allow the manipulation and mapping of the collected data. Such a system is required if the data is to become more than an artifact. The system developed for this study allows almost unlimited flexibility in selecting from the data bank and provides maps of the selected industrial locations at a scale of 1:150000 (1"=12,500') for the rapid identification and location of concentrations of industrial dischargers, and at a scale of 1:24000 (1"=2,000') for detailed plotting and correlation to standard scale USGS Quadrangle Maps. This is supported by USGS Quadrangle Maps which provide accurate locations for single sites.

1.3 Summary

Data was collected on the individual representatives of twenty-seven industrial groups found in the 109 communities in the Eastern Massachusetts Metropolitan Area. At each of the 743 representatives of these industrial categories, data was collected on the source and amount of industrial water use and the place and amount of industrial process water discharge. Data on the kind and amount of wastes contained in each wastewater stream were collected where known and estimated where unknown.

This information was then transferred to a computer-assisted data manipulation and plotting system designed for this purpose. This allowed the listing and plotting of all of the data and selected portions of the data.

The data manipulations performed indicated that the current level of industrial process water discharge in the study area is over 31,000,000 gallons per day for the twenty-seven industrial groups. Of this, 28,600,000 gallons per day (92% of the total) are being discharged by the 71 largest dischargers, while 56% of the locations discharged no process water.

Additional manipulations of the data indicated that the chemical industries (SIC Code 28) account for 26% of the process wastewater discharges of the industries surveyed; the food industry (SIC Code 20) accounts for 22%, the paper industries (SIC Code 26) for 16% and the textile industry (SIC Code 22) for 8%.

Finally, the data were used as the basis for the projection of future industrial waste loads in the area. These predictions indicate that improvements in water use technology will offset expected growth in industrial production to a great extent. In fact, process wastewater volume from the surveyed industries is expected to remain constant until 1990, followed by a rise to about 48,000,000 gallons per day by 2050. It is felt, however, that these rises may be conservative because of the expected implementation of more stringent Federal controls on industrial discharges and the consequent adoption of better treatment processes by the individual industries.

2.0 METHODOLOGY

To treat the industrial wastewater production in the study area properly, it was necessary to develop and use many sources of information. In an ideal case, each industrial location would know and divulge full information on its use and discharge of water. This, however, is seldom the case. In most instances, an individual industry will know its water use, but will have no idea of the quality or quantity of its process wastewater. This is particularly true of the small shops. Therefore, it was necessary to develop a method of estimating wastewater quality and quantity for those industries. Thus, the first step in the inventory process was to collect existing literature on the various industrial types covered in the survey.

2.1 Industrial Literature Surveys

Literature surveys were prepared for each industrial classification covered by the study. Data on the quality and quantity of process wastewater were compiled from the literature search and provided guidelines with which site-specific data from study area industries were compared and validated. In cases where no site-specific information is available, the literature provided data which served as estimates of industrial wastewater quality.

2.1.1 Data Sources

Several kinds of sources were used to compile the industrial literature surveys. Literature gathered from local public and university libraries, the EPA, and the Army Corps of Engineers provided information on industrial processes and wastewater production and case studies of individual manufacturing firms. Other information sources were agencies serving local industries and Massachusetts State government departments. A bibliography of the literature reviewed for industrial classifications is found in Appendix J.

2.1.2 Manipulation of Information

Wastewater figures found in individual case studies for a particular industry were compared, and where possible, averaged together to provide generalized figures for wastewater pollutant quantities. An attempt was made to locate as many case studies as possible on each kind of industry so that generalized values would be drawn from a representative cross section of the industry. Where a study was found to have already compiled and summarized the wastewater figures for a large number of individual manufacturers of an industry, this information was used in the estimation of effluent quality.

2.1.3 Discussion of the Industrial Literature Surveys

The bibliography presented in Appendix J was prepared from existing information found in the scientific literature. Thus, their completeness and accuracy is dependent upon the quality of that literature. It became apparent during the course of this study that, for the most part, the availability of wastewater literature on an industry was directly proportional to the severity of its pollution load. For example, Pulp and Papermaking, Textiles, and Leather are large users of water and often heavy polluters, and the wealth of literature on them reflects this. On the other hand, Glass manufacture uses almost no water and uses primarily silica, which is chemically inert, as a raw material. In this case, the literature contains almost no reference to wastewater quality.

Additionally, several of the industrial categories exhibit peculiarities of a particular industry within that category or peculiarities of the representatives of an industry in the study area. These are discussed individually below.

Chemical Industries, Plastics Industries: These groups require special treatment on a site-by-site basis. Each group includes a broad range of different processes, and no general summary of their wastewater quality is possible. Thus, the bibliographies presented for these groups reflect very broad groups of processes and cannot be used for accurate estimation of effluent quality.

Feedlots: For the purposes of this study the feedlot industry is defined as the close-penning and intensive feeding of livestock for the purposes of fattening the animals for market. Agricultural raising of stock where pasturage is important in the feeding of animals is excluded from this category. There are no feedlots, as such, in the study area. A search of public records and contacts with State officials failed to reveal any penned-feeding of beef or sheep. Poultry farms and swine herds were also investigated. All poultry farms were called, and it was discovered that they all confine their birds and collect the manure for sale as fertilizer. In this way, they realize an extra profit. The hog farms in the study area also failed to provide what could be called feedlot conditions. Discussions with Mr. Walter Lewis of the Massachusetts Division of Animal Health indicated that the hog farmers of the area held land in ratio to their numbers of animals and did not close-pen them, as would be the case in a feedlot.

Dairy Products Processing: The representatives of the dairy product industries knew less about their wastes than any other group. Therefore, effluent quality was estimated for nearly all representatives. This resulted in an unusually large estimated discharge of mercury, which was reported in the literature as being present in milk wastes. Thus, the mercury amounts listed for representatives of the dairy products industry should be viewed with some caution.

2.2 Location Surveys

To collect location and site-specific data on the industrial groups covered by the study, it was necessary to convert from the groups presented earlier in Table 2 to a set of industrial designations which would allow an accurate identification of the operations at a particular site. Such a set of industrial designations was found in the Standard Industrial Classification Manual-1972, published by the U. S. Office of Management and Budget. The correspondence between the study groups and the Standard Industrial Classification (SIC) Codes is given in Table 3. These codes represent the

major process in a plant, even though subprocesses might fall under other codes. An example of this is the electroplating associated with the production of electronic components. This listing allows the separation of industries into fine breakdowns of product and process. One note is in order about the SIC Codes. The manual assigns the digits of code sequentially, so that all textile mills have 22 as the first two digits of their code. Where groups of industries correspond to 2 - or 3 - digit SIC groups, only the major group corresponds to one or more 4-digit codes. This is the case with Electroplating and Petroleum Refining, for instance. There are also a few cases where more than one major SIC Code must be used to describe a group, such as Rendering, some representatives of which are found in Code 28, Chemicals, while others are found in Code 20, Foods.

Two additional items of preparatory work were necessary for location surveys. The first was the selection of a mapping scale and base maps. The locations surveyed were mapped on USGS Quadrangle Maps at a scale of 1:24000 (1 inch=2000 feet). The location system for the study area is presented in Figure 2, which shows the location of the USGS Quadrangle Maps necessary to cover the study area. A discussion of the use of the location coordinate system is presented in Section 2.2.2.

Finally, a data form was devised to allow the consistent presentation of data on each industrial location and to facilitate the transfer of this information into a data retrieval system. The form is shown in Figure 3 and provides the framework for the inventory discussion in Section 2.2.2, below.

2.2.1 Industry Site Lists and Verification

The list of industrial sites in each SIC Code group covered by the study was compiled from the 1973 edition of the Directory of New England Manufacturers and from current Standard and Poor's and Dun and Bradstreet's listings. This list was verified by consulting with the Massachusetts Department of Commerce and by individual telephoning. Mr. William Tsasfaras, of the Department of Commerce, indicated that their data files had been used in the preparation of the

Figure 2

THE LOCATION SYSTEM

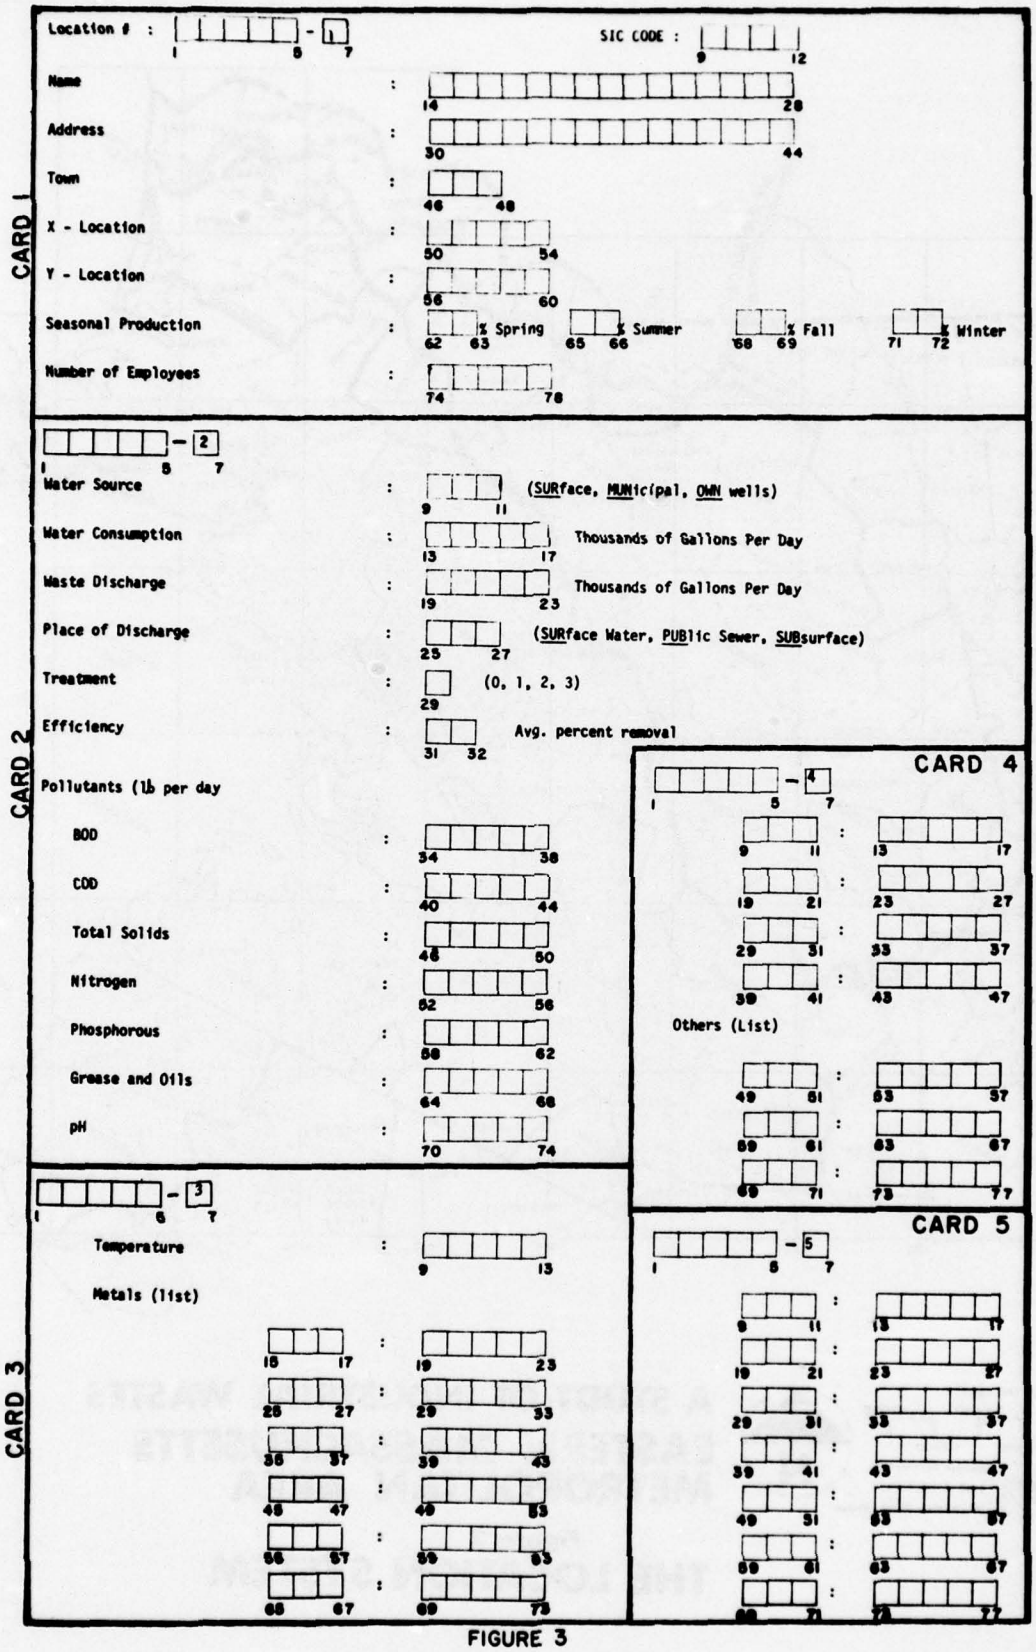

FIGURE 3
DATA COLLECTION FORM

New England Directory and that the 1973 version should be complete as of January 1, 1973. This was substantiated by spotcheck verification using the yellow pages of the telephone directory. Finally, about 60% of the locations listed in the study area were called individually. This allowed elimination of those firms which are offices or retail branches of manufacturing companies and those which have ceased operation since January 1, 1973. Thus, the list of industrial sites was positively verified to insure complete coverage and negatively verified to eliminate nonproducing locations. This listing, which identifies all industrial sites within the study area represented by the categories listed in Table 2 by name and address, is a portion of the data presented in Appendix A.

2.2.2 Information Sources and the Data Form

Many sources of information were used to supply more specific data for the industrial locations. These are discussed in the order that they appear on the data collection form.

Location #: A location number was assigned to each site inventoried. This number is simply a numerical identifier for a specific site. Location numbers were assigned so that a town is generally represented by a block of sequential numbers.

SIC Code: The four-digit SIC Code for each location was taken from the Directory of New England Manufacturers. The Directory is based on the 1967 version of the Code, but listings were converted to 1972 designations in those cases where there had been a change. The individual contacts confirmed the accuracy of the SIC Code listings in the Directory.

Name, Address and Town: The name, street address and town of each industrial site were taken from the Directory of New England Manufacturers and verified by telephone calls and visits to the Assessors' offices. They are listed on the data forms in abbreviated fashion to conserve space. The

name and address are abbreviated to 15 characters each, and the town is represented by a three-letter code, as indicated in Table 4.

Location: The locations of the individual industrial sites were found by consulting maps in the Assessors' offices of the towns in the study area. These locations were then transferred to USGS Quadrangle Maps, which form the basis of the location coordinate system presented earlier in Figure 2. The Quadrangle Maps are included with this report under separate cover.

The units used to enter the location coordinates on the data form correspond to a real world grid of 200 feet. The scale of the USGS Maps is 1"=2000 feet, so each grid square equals one tenth of an inch at this scale. Thus, one unit of a location coordinate refers to 200 feet in the real world. The USGS Quadrangle Maps which cover the study area were assigned corner coordinates based on this scale, as seen in Figure 2. To find the coordinates of a point on one of the Quadrangle Maps, it is necessary only to note the coordinates of the lower left corner of the quadrangle in Figure 2 and then measure the distance from the lower left corner to the point along the horizontal and vertical directions in tenths of inches and add these to the corner coordinates. The X location refers to the distance along the horizontal axis, and the Y location indicates distance along the vertical axis.

An example might be helpful. Suppose a location is mapped ten inches from the left-hand margin of the Natick Quadrangle Map and five inches from the bottom. Reference to Figure 2 indicates that the lower left corner coordinates of that quadrangle are X=510, Y=682.5. The coordinates of the point of interest are +100 units (10 inches) in the horizontal (X) direction and +50 units (5 inches) in the vertical (Y) direction as measured from the lower left of the quadrangle. Thus, the coordinates of the point are X=510 + 100 = 610 and Y=682.5 + 50 = 732.5. On the data sheet, these are rounded to the nearest whole unit and would be entered as X=610, Y=733.

Seasonal Production: The variation in seasonal production was taken from the individual phone contacts. Most industries showed uniform production over the year. The exceptions to this were the food industries (SIC Code 20). These industries, as expected, show seasonal variations of production reflecting availability of raw produce and livestock. As a group, these industries tend to show higher summer and fall production than winter and spring production. There were also a few locations in tanneries (SIC Code 3111) and chemicals (SIC Code 28) which showed variation, but their number was so few that generalities are impossible.

Number of Employees: The number of employees was taken from the Directory of New England Manufacturers and confirmed by the telephone contacts.

Water Use: Major water source, total consumption, process water discharge, major place of discharge, and treatment information was generally collected from phone contact with individual manufacturing plants. If water use figures were not available from this source, the town water departments were contacted to give figures for those industries on municipal systems. Information on water use was also available from industrial permit applications kept on file by the Environmental Protection Agency for those industries whose wastewater is discharged to a river or stream. Where none of these sources was able to provide this information, estimates of water use were made by using the industrial literature surveys, by comparison to similar sites in the area or by applying data contained in The Economics of Clean Water, published by the U.S. Environmental Protection Agency in 1972. The Economics of Clean Water contains breakdowns of industrial process water discharge for each area of the country by 4-digit SIC Code.

It should be noted that the discharge is process water only and does not include cooling water and sanitary water requirements. Thus, many locations that use large quantities of cooling water may show very large total consumption and very low or zero discharges.

The entries for treatment and efficiency represent estimates of the in-house treatment provided at a location. "1" refers to primary treatment such as screening, settling and neutralization; "2" refers to secondary treatment, normally by bacterial action, and "3" refers to tertiary treatment such as ion exchange. Estimations were marked by asterisks on the data sheets, which form a part of the backup documentation for this report.

Pollutants: For many of the industrial locations, figures for industrial wastewater pollutants were provided by the EPA permit files or by the companies themselves. Where this was not the case, estimates of pollutant loads were made from the industrial literature surveys or by comparison to other similar sites for which data were available. The first eight pollutants are commonly listed and were given assigned locations on the data form. Metals and other pollutants were less commonly listed, and, hence, were entered on the data sheets by using an identifier. The codes used to identify the metals and other pollutants are given in Table 5. For the metals, the total of all oxidation states was used, due to the paucity of information on the valence characteristics of the metals in manufacturing effluent. As before, estimated quantities are marked with an asterisk on the data sheet.

2.3 Data Retrieval and Plotting

To allow efficient use of the data files developed by the location surveys, a computer data retrieval system and a plotting routine have been developed and are in operation. This system consists of a data verification routine, a data loader, a data selection routine and a plotting routine. The system is designed to handle data from this study, but can be expanded to include contiguous areas which are being or will be studied.

2.3.1 Data Verification

The first stage in using the data retrieval system is to encode the data from location surveys onto computer cards. The card labels and card column numbers on the data form indicate the form of these cards. Five cards are necessary for each location, even if some of them contain only the identification number and sequence number (which is preprinted on the data sheets). This transfer of information from data sheet to computer card will seldom be without error. For this reason, the first portion of the data retrieval system is a data verifier which checks the coded data for a number of common errors.

Number and Sequence of Cards: Each location number must be represented by five cards in numerical order.

Shifted Data Entry: Blanks have been left in the data format between each data field. This allows a check for shifted data by checking those blanks. Another check is available because all numeric entries are right-justified. Any deviation from this is considered an error by the verifier.

Format: Those columns which contain only numeric data are checked for the presence of alphabetic characters.

Improper Codes: Metals and other pollutants are entered by the code designations shown in Table 5. Any other letters or symbols in those fields are rejected. This is also true for the codes given on the data sheet for water source and place of discharge.

When any of these errors are encountered in a check, a message is printed indicating the total number of errors in the deck and the location and type of each error. This allows the data deck to be corrected before final loading.

2.3.2 Data Loading

The data loader takes data which has been verified and corrected and loads it into a computer tape or disk file. This stores that data and allows it to be manipulated. The only processing done by the loader is that it distinguishes between zeroes and blanks. Thus, any field showing blanks is loaded as a-1 and any field showing a zero is given a value of zero. This allows a distinction to be made between fields for which information is not entered and fields which are known to be zero.

2.3.3 Data Selection

When the data has been loaded into a file, a number of selections may be made on the data and listed separately. This allows the selection of that portion of the data file which is of interest. A selection may be made on any one parameter, on several parameters or on a function of one or more parameters. The only fields which may not be selected on are Location Number, Name, Address and Location. This was done to insure that an individual location would not be selected. The assurance of this aided greatly in the collection of data during the telephone interviews.

Selection criteria which are available are "greater than", "less than" and "equal to". These may be grouped using logical statements to select ranges (BOD between 10 and 100 lb. per day) and other groupings of the data. The logical statements which are available are "and", "or" and a negation. The results of any selection made are printed out, followed by a summary of the records selected. This summary includes the number of records read, the number of records selected, the maximum and minimum location coordinates of the records selected and a breakdown of the numerical fields in the records, including the number of observations, the total and the average. Examples of several selections are given in Section 3, and a full description of the selection routine is given in the user's manual which accompanies this report.

2.3.4 Plotting

When a selection has been made, the selected records can be mapped by the computer. The plotting routine has been designed to use a line printer, so that the plots of the location of the selected points may be obtained simultaneously with the listings. Plots may be had at a scale of 1"=12,500' or 1"=2,000'. The plot routine attempts to place the data at its actual location. If, however, it cannot fit all the points required into an area, it will shift them as far as 2.5 inches in an attempt to plot them. True plotted points are shown as "XX" and shifted points as "**". If a point cannot be plotted within 2.5 inches of its location, it is not plotted. Such points are listed as "lost due to collision" as part of the plot routine output.

3.0 PRESENTATION AND DISCUSSION OF DATA

When the data for the industrial locations in the Eastern Massachusetts Metropolitan Area of the study area had been compiled, the completed data forms were keypunched and computerized. The data retrieval and plotting system was then used to sort the data into various forms for presentation and discussion.

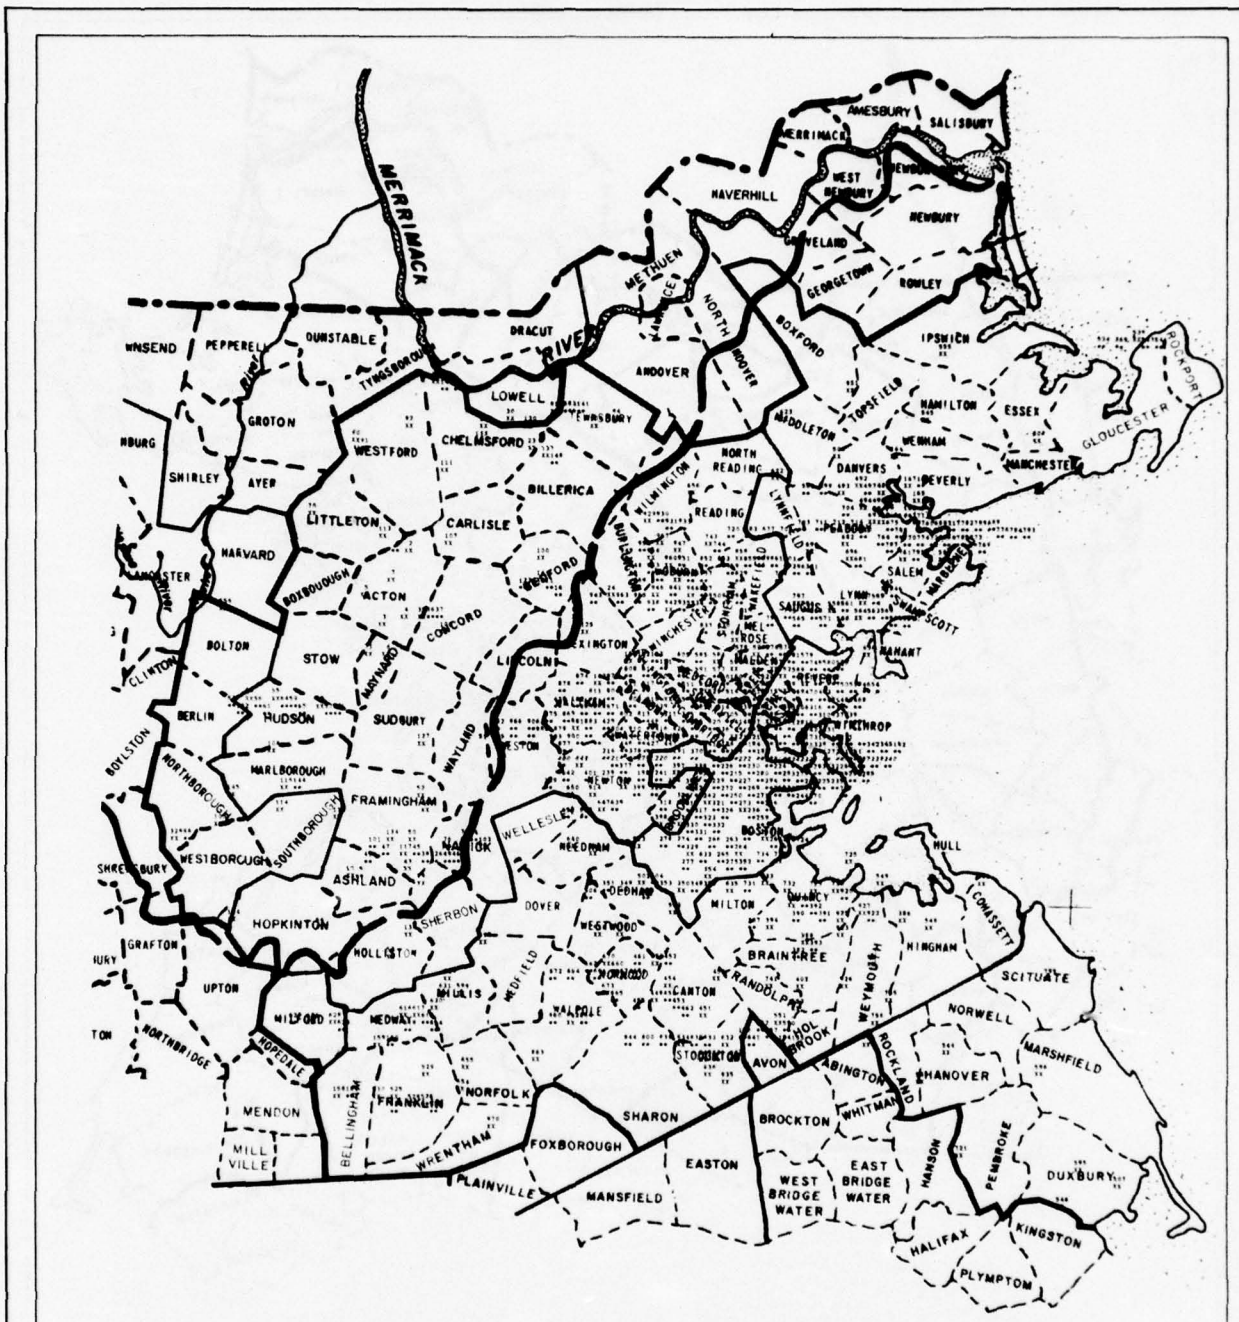
3.1 The Industries

Appendix A contains the list of the 748 industrial locations encountered in the study area which fell within the twenty-seven industrial groups surveyed. The locations of the individual sites are indicated on Figure 4. The tabulation and plotting indicate several significant points about industrial wastes in these communities.

First, industrial wastewater is a significant problem in the area. Process water discharges total in excess of 31,000,000 gallons per day for the industries surveyed. The total Biochemical Oxygen Demand (BOD) loading is 99,000 pounds per day, and the Chemical Oxygen Demand (COD) is 170,000 pounds per day. There are substantial quantities of nitrate, phosphorus and grease. Metals and other pollutants are well-represented.

Second, the industrial locations tend to concentrate in groups. This is particularly true of the areas around Boston. These dense groupings are of particular interest in planning waste disposal systems.

Finally, an examination of the listings in Appendix A will indicate that a few locations discharge a great deal of process water, while many locations discharge little or no process water. These conditions were investigated by selecting from the data file on the size of discharge.



A STUDY OF INDUSTRIAL WASTES
EASTERN MASSACHUSETTS METROPOLITAN AREA

Figure 5

INDUSTRIES DISCHARGING 50,000 OR MORE GALLONS PER DAY

Appendix B and Figure 5 show those industries, regardless of SIC category, discharging greater than 50,000 gallons per day. Although there are only 71 such locations, they discharge 28,600,000 gallons of wastewater per day and account for about 92% of the total daily process wastewater load of the surveyed industries. The sites are scattered throughout the area, but concentrations of them occur in Boston and the Peabody-Salem area.

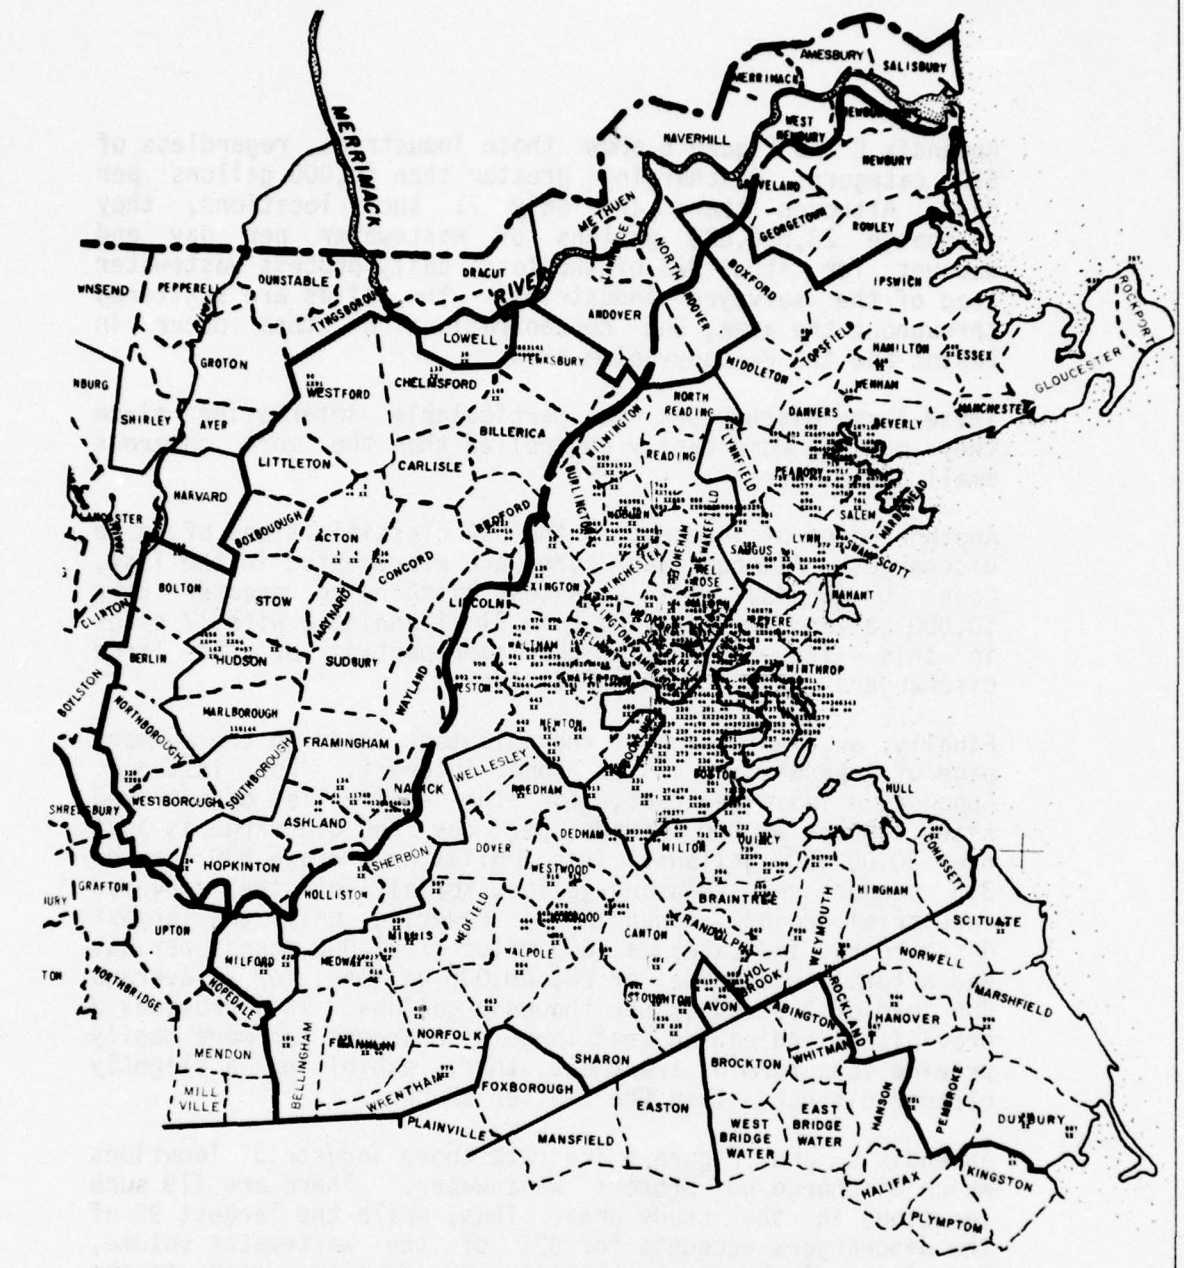
These large dischargers are particularly interesting since they may be more easily controlled than the more numerous small dischargers.

Another point of interest is the SIC classifications of these discharges. Although many codes are represented in the list, Code 20 (Foods), with 25 sites discharging greater than 50,000 gallons per day, and Code 31 (Tanning), with 17 sites in this list, account for the major portion of the large dischargers (42 sites out of 71 total).

Finally, an examination of the pollutant loads on the summary page of Appendix B is of some interest. For instance, Appendix A indicates that, for the entire list of surveyed sites, BOD is 99,000 pounds per day and discharge is just over 30,000,000 gallons. This implies an average BOD load of 3.3 pounds per thousand gallons for all of the surveyed industrial groups. Appendix B, covering only the largest dischargers, indicates a BOD value of 82,000 pounds per day and a total discharge of 28,600,000 gallons, for an average BOD load of 2.9 pounds per thousand gallons. This provides a provisional indication that large dischargers can more easily provide some form of treatment, thus, exhibiting a slightly cleaner discharge than the smaller shops.

Appendix C and Figure 6 indicate those industrial locations which discharge no process wastewater. There are 419 such locations in the study area. Thus, while the largest 9% of the dischargers accounts for 92% of the wastewater volume, 56% of the dischargers contribute no process water to the waste stream.

These zero dischargers are not confined to any well-defined group of SIC Codes, but generally are the smaller specialty shops in each group and are characterized by few employees.



A STUDY OF INDUSTRIAL WASTES
EASTERN MASSACHUSETTS METROPOLITAN AREA

Figure 6

INDUSTRIES DISCHARGING 0 GALLONS PER DAY

The exception to this is the hospitals (SIC Code 806) which, in general, have many employees, but produce only sanitary wastes.

3.2 Additional Listings

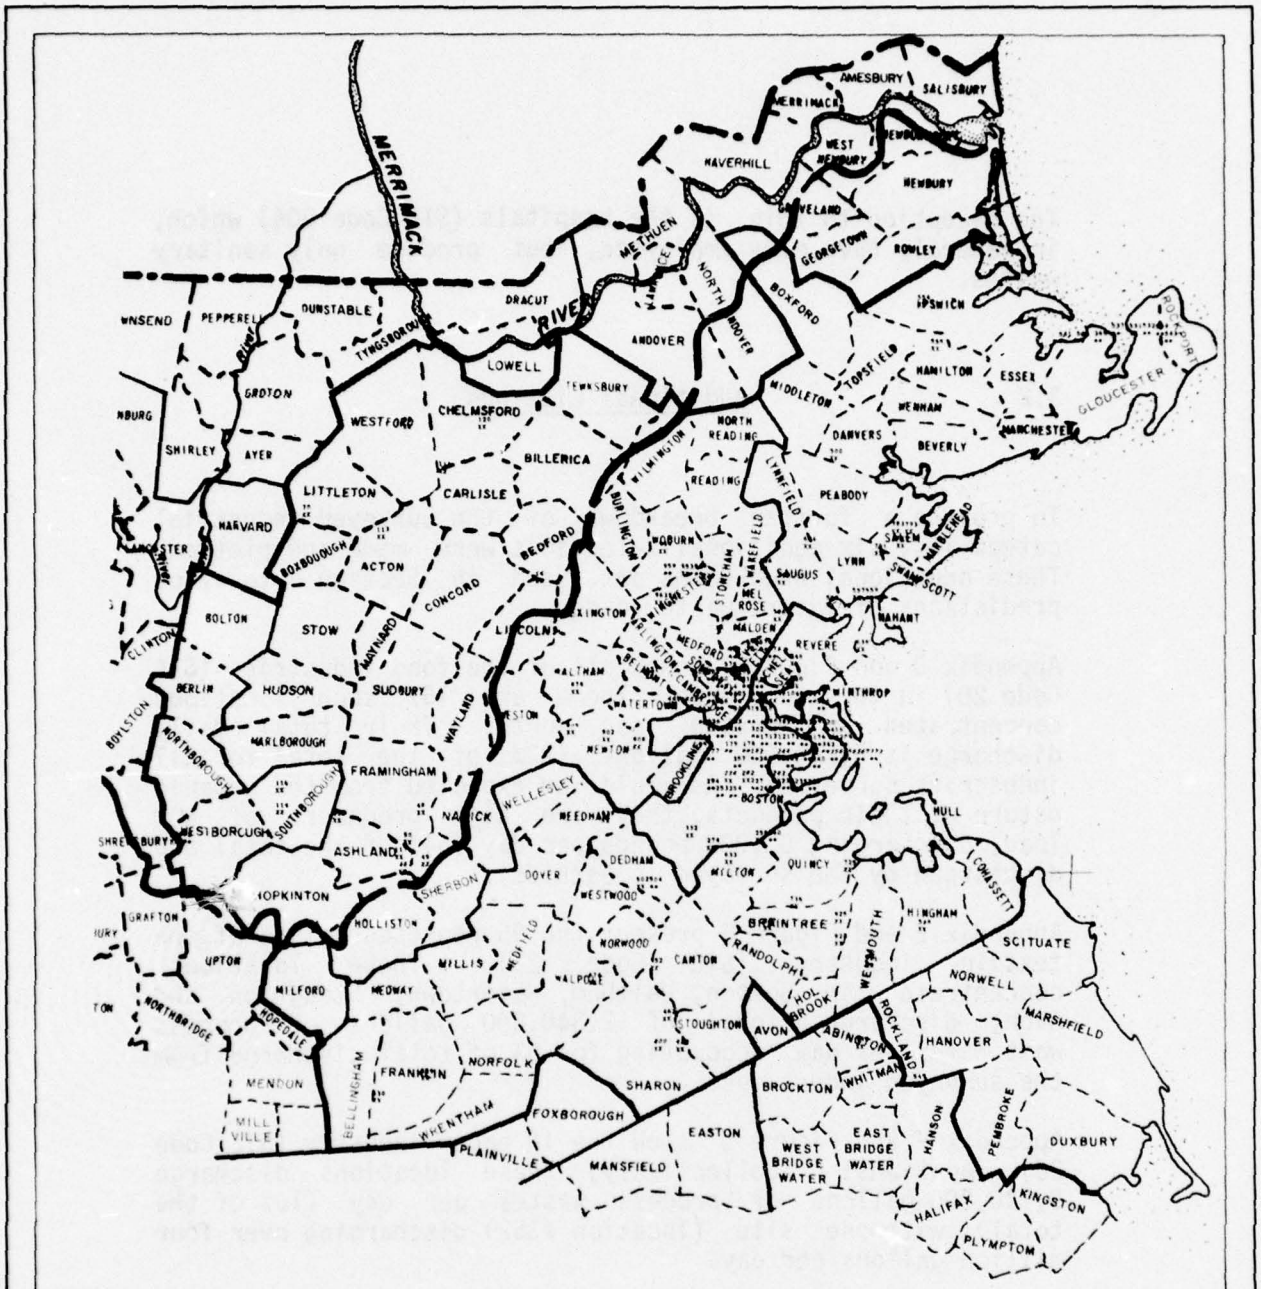
To provide a further breakdown of the surveyed industrial categories, six additional selections were made and plotted. These additional breakdowns are used in Section 4 to allow predictions of future waste loads.

Appendix D and Figure 7 show all of the food industries (SIC Code 20) in the study area. There are 157 such locations concentrated in Boston and north. Their total daily discharge is 6,750,000 gallons (22% of the total for all industries surveyed). As would be expected from the organic nature of their products, they are high producers of BOD load, discharging 53,000 pounds per day (54% of the total BOD discharged by the surveyed industries).

Appendix E and Figure 8 present the 95 representatives of the textile industry (SIC Code 22). These locations, concentrated in Boston, Waltham, Watertown, Stoughton and Avon, discharge a total of 2,340,000 gallons of process wastewater per day, accounting for 8% of total discharge from the surveyed industries.

Appendix F and Figure 9 show the 10 paper industry (SIC Code 26) locations. Collectively, these locations discharge 5,120,000 gallons of process wastes per day (16% of the total), with one site (location #352) discharging over four million gallons per day.

Appendix G and Figure 10 list and map the chemical producers (SIC Code 28) in the study area. These 102 plants discharge 8,000,000 gallons of process water per day. This represents 26% of the total industrial discharge and indicates that this group is the largest single source of industrial process wastewater in the group of industries covered by this study.



A STUDY OF INDUSTRIAL WASTES
EASTERN MASSACHUSETTS METROPOLITAN AREA

Figure 10

CHEMICAL INDUSTRIES

Finally, Appendix H and Figure 11 show the metals industry (SIC Code 33) in the area. This group, with 74 representatives, discharges 67,900 gallons of wastewater per day, with 60,000 gallons discharged at one location (Location #26). No pollutants were reported by this location when contacted, apparently because they fail to distinguish between cooling water and process water.

Together, these five groups discharge 22,300,000 gallons of industrial process wastewater per day. This is roughly 72% of the total discharge from the surveyed industries and confirms the results of other studies, (Merrimack: Designs for a Clean River), which indicate that these industries are normally the heaviest users and dischargers of water among the various industries. The one unusual fact which is apparent from this breakdown is the small contribution of the metals industry, which is often one of the heaviest producers of wastewater. The explanation for this lies in the form which the industry has taken in Eastern Massachusetts. Far removed from the country's major ore and coal sources, this area has very little smelting activity. Rather, the metal producers purchase raw stock elsewhere and are primarily involved in casting and sintering various objects from purchased stock.

4.0 FUTURE WASTE LOAD PROJECTIONS

To estimate the future industrial wastewater loads within the study area, it was necessary to make several assumptions. This was necessitated by the fact that quantitative projections have normally been undertaken for industrial water consumption rather than wastewater discharge.

It was assumed, therefore, that discharge is directly related to consumption and is, in fact, a constant percentage of consumption. This implies that, as industrial processes become more efficient in their use of water, both intake and discharge will decrease by similar amounts.

The basis for this assumption is that recycling can be expected to shift both process water consumption and discharge downward as follows. Suppose a plant uses water once through and has a five percent evaporative loss in its process. One hundred gallons of intake would entail ninety-five gallons of discharge. Now let us suppose that they recycle water for a second pass. One hundred gallons in would be reduced to ninety-five gallons on the first pass and to 90.25 gallons on the second pass. Thus, the assumption that consumption and discharge will decrease by similar amounts is slightly conservative in that evaporative losses will slightly reduce the ratio of discharge to consumption.

It was further assumed that the concentrations of the various pollutants in a wastewater stream will remain constant with time. This implies that a reduction or increase in total effluent volume will cause a like decrease or increase in the total amount of pollutants. This assumption is based on the observation that increased water economy is likely to increase the ease of recovery of waste products and to make some in-house treatment less difficult and expensive by reducing the total volume of flow.

Both of these assumptions represent a slight degree of conservatism and will tend to overestimate future waste loads, rather than underestimate them. It is likely that, with process improvements, more efficient use of water will slightly reduce the ratio of discharge to consumption.

Additionally, the controls on industrial wastes which are likely to be instituted as a result of the Federal Water Pollution Control Act Amendments of 1972 (Public Law 92-500) will most probably cause reductions in pollutant concentrations in industrial wastewaters. While the Act's goal of "Zero Discharge" by 1985 might not be realized, it does suggest that industrial wastes may be far better controlled in the future than currently.

Thus, the projections made herein for the industrial groups covered in this study are designed to serve as a reasonable upper bound for planning purposes. How nearly these upper bounds are reached depends on the level of enforcement of Public Law 92-500 and on future Federal and State legislation designed to control industrial wastes.

4.1 Projection Technique

Using the above assumptions, the technique chosen to predict future industrial wastewater discharges was to develop a projection factor by which existing wastewater volumes could be multiplied to estimate future volumes.

The methodology for the estimation of such a factor was developed by the NEWS Group of the U. S. Army Corps of Engineers and was presented by Robert H. Stewart and Ivan Metzger in a paper entitled "Industrial Water Forecasts" at the 1970 Conference of the American Water Works Association.

The projection factor, called "F", is defined as

$$F = \frac{E \times O}{R \times T}$$

where:

E = Employment factor
O = Output factor
R = Recirculation factor
T = Technology factor

These four factors are designed to account for the major variables governing changes in industrial water use.

The Employment Factor is defined as the ratio of future employment to current employment. Thus, as employment rises, production is assumed to rise which causes an increase in water use and discharge.

The Output Factor is the ratio of future product output per employee to current output per employee and causes the estimate of discharge to rise as employees produce more goods.

The Recirculation Factor is designed to take into account future economies of water use. It is defined as the future recirculation of water divided by the current recirculation of water. Thus, if an industry increased its recirculation, the estimated discharge will be reduced.

The Technology Factor is defined as the present water use per unit product divided by the future water use per unit product. Thus, if an industry produces a unit of product with less water, the value of "T" increases and the value of "F" decreases.

The combination of these four factors into one projection factor allows for an estimate of the net effects of growth or decline of an industry (measured by "E"), changes in employee efficiency (measured by "O") and changes in processes (measured by "R" and "T").

4.2 The Economic Factors (E x O)

A simple determination of the Employment and Output Factors can be made by noting a relationship between them.

$$E = \frac{\text{future employment}}{\text{current employment}}$$

$$O = \frac{\text{future output per employee}}{\text{current output per employee}}$$

This implies that:

$$E \times O = \frac{\text{future total output}}{\text{current total output}}$$

The most common measure of industrial output is constant dollar production. This allows a direct determination of E x O from economic projections of future constant dollar production. These projections are available from the 1972 Obers Projections-Regional Economic Activity, in the U.S. published by the U. S. Water Resources Council. The figures used are those presented for the Massachusetts Coastal Zone, which is the Obers study area most nearly approximating the Eastern Massachusetts Metropolitan Area.

Table 6 presents the E x O factors taken from the Obers Projections for the major industrial groups. It should be noted that the values for 2050 were linearly extrapolated from the values for 2000, 2010 and 2020 given by Obers. These factors indicate that production growth is expected in all groups, but that Paper, Chemicals and other Manufacturing will be the major areas of growth.

4.3 The Process Factors (R x T)

The Recirculation and Technology factors are, at best, only knowledgeable estimates of future conditions. These factors have been estimated for other studies and the state of the art is not such that the locational sensitivity of these factors can be accurately assessed. Therefore, the "R" and "T" values used for this projection were derived from those presented by Stewart and Metzger and from the values used in Alternative Regional Water Supply Plans for Northern New Jersey, New York City, Western Connecticut Metropolitan Area, November, 1971, prepared for the New England Water Supply Study (Corps of Engineers) by Metcalf and Eddy. In both of these studies, the "R" and "T" factors have been assumed to grow linearly with time. Thus, they were extrapolated on a straight line to yield values for 2050. The "R" and "T" factors are presented in Table 7.

TABLE 6. E x O FACTORS FOR WASTEWATER PREDICTIONS

	E x O			
Group	1973	1990	2020	2050
Food (SIC 20)	1.0	1.59	3.46	5.52
Textile (SIC 22)	1.0	1.17	1.70	2.29
Paper (SIC 26)	1.0	1.75	5.08	8.91
Chemical (SIC 28)	1.0	2.04	7.18	13.20
Primary Metals (SIC 33)	1.0	1.40	2.44	3.55
Others	1.0	1.73	4.96	8.67

TABLE 7. "R" AND "T" FACTORS FOR WASTEWATER PREDICTIONS

Group	1973		1990		2020		2050	
	R	T	R	T	R	T	R	T
Food (SIC 20)	1.0	1.0	1.3	1.1	1.9	1.3	2.5	1.5
Textile (SIC 22)	1.0	1.0	1.4	1.1	2.1	1.3	2.8	1.5
Paper (SIC 26)	1.0	1.0	1.4	1.1	2.1	1.4	2.8	1.7
Chemical (SIC 28)	1.0	1.0	1.9	1.3	3.5	1.7	5.1	2.1
Primary Metals (SIC 33)	1.0	1.0	1.4	1.1	2.1	1.3	2.8	1.5
Others	1.0	1.0	1.4	1.1	2.0	1.4	2.6	1.7

An examination of these factors indicates that both recirculation of water and technological economy of water will both increase in the future. This is especially noticeable in the chemical industries. These increasing economies will tend to offset the growth in discharge which would be predicted by the economic factors alone.

4.4 "F" -Factors and Projections

Combining the economic and process factors given in the preceding sections gives the weighting factors for predicting future waste loads. These factors are given in Table 8. These figures indicate that a combination of relatively slow growth and moderate technological improvements can be expected to reduce overall discharges for the textile industry and for the primary metals industry. In all others, production growth will outstrip technology improvements, and a net increase in discharge is expected.

The implications of this for the total process wastewater load in the study area may be investigated by using the industrial breakdowns presented in Section 3.2. Table 9 shows the computation of future waste loads from these breakdowns.

An examination of these predictions indicates that , for the industries surveyed, some overall growth in industrial wastewater discharge is to be expected in the study area. In fact, process wastewater loads for the surveyed industries are expected to remain essentially constant through 1990 and then to increase by 45% by 2020 and 55% by 2050.

Since the derivations of the growth factors made conservative assumptions regarding future legal action in the area of industrial waste control, some confidence may be had in these estimates. Thus, it appears that the industrial wastewater load from the surveyed industrial groups in the study area may remain fairly constant during the next two decades and then rise to 48 million gallons by 2050.

APPENDIX I

POINTS LOST FROM PLOTS

The plotting routine for the wastewater data makes an extensive effort to place all points on each output. However, if data density is such that a shift of greater than 2.5 inches is required, the point is not plotted. This usually occurs only at the 1:150000 scale and is limited to extremely dense areas. This appendix contains a listing of those points lost in the 1:150000 scale plots used in preparing Figures 4 through 11 of this report.

Figure 4. All Industries

Location numbers of points lost due to collision, ordered from top of map to bottom.
