REFORGER 77 SUPPORT

PART A

AN INDEPENDENT TEST OF THE
REFORGER 76 SUPPORT CLIMO PROGRAM

by

Murray J. Young

January 1977

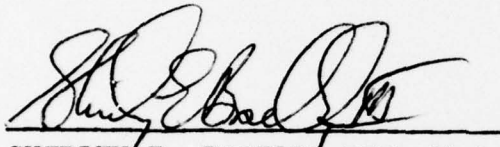

Approved for public release, distribution unlimited.

ORIGINAL CONTAINS COLOR PLATES: ALL DDC
REPRODUCTIONS WILL BE IN BLACK AND WHITE.

REVIEW AND APPROVAL STATEMENT

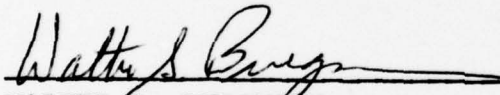

This report is approved for public release. There is no objection to unlimited distribution of this report to the public at large, or by DDC to the National Technical Information Service (NTIS).

This technical report has been reviewed and is approved for publication.

Preface

In response to a request from the Air Force Global Weather Central (AFGWC) the USAF Environmental Technical Applications Center (USAFETAC), developed a computerized climatology model (CLIMO) to "spread" climatology to grid points in Germany. This author described the development of the CLIMO model in USAFETAC Report 7966. This report revises the original Report 8065A in which a wrong statistical test was used to evaluate a model climatology and presents some of the results of the evaluation.

In the event that this report is incorporated into another report by the requester or any other agency, request that USAFETAC be furnished a copy of the new report in all cases where such dissemination is not prohibited.

This study was prepared to answer a specific question; how good is CLIMO? Therefore, this report is not expected to have any application beyond answering this question. Department of Defense (DoD) agencies and DoD contractors should refer any questions on this specific climatological study to USAFETAC for consultation.

AN INDEPENDENT TEST OF THE REFORGER 76
SUPPORT CLIMO PROGRAM

Introduction

The computerized climatology model (CLIMO) program described by Young [1] can be tested by reproducing the cumulative probability distributions of selected weather parameters at a selected station. For this test, the program was set to reproduce the cumulative percentage frequencies of the ceiling and the visibility in the format of Section D of the Air Weather Service Revised Uniform Summary of Surface Weather Observations (RUSSWO). Three nearby stations with different elevations were used for the independent test. This report describes the test and discusses the results.

Discussion

Ceiling, visibility, and wind data from 23 stations were used in the CLIMO dependent study. Of these 23 stations, only 20 stations were used for the ceiling and visibility. The additional three stations were used for the wind. These wind statistics failed to produce any realistic results. The additional three independent nearby stations were selected from the RUSSWO's to represent a range of heights and are indicated in Figure 1 by circles. The test stations are:

<u>WMO NO.</u>	<u>STATION</u>	<u>ELEVATION (above MSL)</u>
107295	Sandhofen, Germany	108 m (334 ft)
106870	Grafenwohr, Germany	415 m (1360 ft)
109710	Bad Tolz, Germany	716 m (2360 ft)

In the independent study, the hours of 0700 and 1600 LST were tested for the months of September, October, and November.

Test Procedures

Assuming that the observed frequencies and the model frequencies were the same, a test was made using the Kolmogorov-Smirnov One-Sample Test described by Siegel [2].

Table 1a shows the results of one test for a specific month, time of day, and test station. This table is described in detail because it shows the format for all other months, hours, and parameters tested.

The ceiling summaries in Table 1a contain 31 categories of heights ranging downward from 20,000 feet to zero feet. The largest difference between categories of the observed and modeled is used in the Kolmogorov-Smirnov One-Sample Test. For example, the maximum difference is at the 12,000-ft category (16.7% or 0.1670). This difference is greater than the critical value, 0.0553; thus, the difference is considered significant. Figure 2 is a plot of the observed data and model output. Three more of these detailed breakdowns of the test are included in Table 1b and Figure 3, Table 2a and Figure 4, and Table 2b and Figure 5. To reduce the amount of table preparation, only the significance test portions and a limited amount of data for the remaining months, hours, and stations are shown. Tables 3 and 4 show ceilings and visibilities, respectively. The differences in the values for the observed data and the model output for Bad Tolz were so great that a significance test was not needed.

Conclusions

Statistically, the observed and the modeled summaries were shown to be significantly different for all of the cases.

While the model seemed to work, it still needs further study. Possibly a different distribution equation (from DISFIT [1]) should be used. We need dependent sample data that includes, if available, stations at higher elevations. In any event, further development studies are needed if this concept of prediction or spreading is to be used.
