USER EVALUATION OF REPORT

REFERENCE: Technical Report N-49, *The Rational Threshold Value (RTV) Technique for the Evaluation of Regional Economic Impacts*

Please take a few minutes to answer the questions below, tear out this sheet, and return it to CERL. As a user of this report, your customer comments will provide CERL with information essential for improving future reports.

1. Does this report satisfy a need? (Comment on purpose, related project, or other area of interest for which report will be used.)

2. How, specifically, is the report being used? (Information source, design data or procedure, management procedure, source of ideas, etc.)

3. Has the information in this report led to any quantitative savings as far as man-hours/contract dollars saved, operating costs avoided, efficiencies achieved, etc.? If so, please elaborate.

4. What is your evaluation of this report in the following areas?

a. Presentation: _____

b. Completeness: _____

c. Easy to Understand: _____

d. Easy to Implement: _____

78 06 22 008

49

e. Adequate Reference Material: _____

f. Relates to Area of Interest: _____

g. Did the report meet your expectations? _____

h. Does the report raise unanswered questions? _____

i. General Comments (Indicate what you think should be changed to make this report and future reports of this type more responsive to your needs, more usable, improve readability, etc.) _____

5. If you would like to be contacted by the personnel who prepared this report to raise specific questions or discuss the topic, please fill in the following information.

Name: _____

Telephone Number: _____

Organization Address: _____

6. Please mail the completed form to:

Department of the Army

FOREWORD

This project was performed for the Directorate of Military Construction, Office of the Chief of Engineers (OCE), under Project 4A762720A896, "Environmental Quality for Construction and Operation of Military Facilities," Task 01, "Environmental Quality Management for Military Facilities," Work Unit 002, "Development of Environmental Technical Information System." Mr. V. Gottschalk, DAEN-MCE-D, was the OCE Technical Monitor.

This research was made possible through the efforts of DOD personnel, consultants from Battelle Columbus Laboratories and the University of Illinois, and scientists and engineers of the U.S. Army Construction Engineering Research Laboratory (CERL).

Administrative support and counsel were provided by Dr. R. K. Jain, Chief of the CERL Environmental Division. COL J. E. Hays is Commander and Director of CERL, and Dr. L. R. Shaffer is Technical Director.

THE RATIONAL THRESHOLD VALUE (RTV)
TECHNIQUE FOR THE EVALUATION OF
REGIONAL ECONOMIC IMPACTS

1 INTRODUCTION

Background

The passage of the National Environmental Policy Act (NEPA),¹ generated a renewed interest in the modeling of environmental phenomena. Many experts believed that models would solve the complex problems of environmental analyses. However, these models have frequently fallen short of their proponents' optimistic expectations. Often, this failure can be related to the final interpretation of the model output. One of the requirements of environmental impact analysis is determining the significance of impacts. Model output alone cannot address this requirement; some criterion or "yardstick" is first necessary.

CERL researchers involved in the development of the Economic Impact Forecast System (EIFS)* identified this problem in the economics area. Estimated changes in business volume, income, employment, etc., were provided by the EIFS model, but no analysis tool for evaluating model output was provided. This weakness especially created problems in the economics area, where changes in business volume are often presented in millions of dollars. To the user, these figures seem quite significant; however, to the economist, their relationship to the local economy in aggregate would be used to evaluate model output. The problem was perplexing and the model development, following a traditional scientific path, had failed to address this aspect of user need. Therefore, it was necessary to develop a systematic approach for determining a rational threshold value (RTV) for economic and related social impacts.

Objective

The objective of this study was to develop an RTV technique or a criterion for determining "significance" of impact for economic and related social impacts resulting from Army military activities.

¹ National Environmental Policy Act of 1969, 83 Stat. 852, 42 USC 4321 et seq. (January 1970).

* A computerized system which calculates the economic impacts on a specific region of a new military project or action.

Approach

The requirements for adequate socioeconomic analysis were reviewed, based on historical precedents and on the knowledge of civilian and DOD scientists familiar with NEPA, economic impact analysis, and subsequent court interpretations. Groups of socioeconomic elements were then condensed into a smaller number of "indicator" variables, based on scientific prediction capabilities and the availability of sufficient data. A method for conducting temporal analysis of the indicator variables was developed, and a study of the effects of this technique on hypothetical DOD actions was undertaken. This report summarizes the results of this development and analysis.

Mode of Technology Transfer

The RTV technique has been incorporated into EIFS and DA Pam 200-2, *Economic Impact Forecast System--Description and User Instructions*, will be revised accordingly.

2 IDENTIFICATION OF THE NECESSARY ELEMENTS

Consultation with practicing regional economists, environmental analysts, environmental lawyers, and DOD personnel produced the following list of socioeconomic elements:

1. Change in business volume
2. Change in personal income
3. Change in employment
4. Impact on local government revenues and expenditures
5. Changes in income and employment distribution
6. Impact on local housing
7. Impact on regional economic stability
8. Impact on local school systems
9. Impact on local government bond obligations
10. Change in population
11. Change in welfare and dependence
12. Change in social control
13. Aesthetic consideration.

This list of elements indicates those considerations which have been controversial with respect to DOD problems^{2, 3} in the socioeconomic area. Many are broadly defined and nebulous, while others are easily defined and relatively easy to address. Subsequent sections of this report define these individual elements, clarify their importance, explain their military relevance, and otherwise indicate their meanings.

² "Breckinridge et al., vs Schlesinger," U.S. District Court, Eastern District of Kentucky, No. 75-100 (October 31, 1975).

³ "McDowell vs Schlesinger," U.S. District Court, Western District of Missouri, Western Division, No. 75-CV-234-W-4 (June 19, 1975).

Change in Business Volume

Business volume is an indication of a region's local aggregate economic activity. As used in EIFS,⁴ it is the total dollar flow of the four major sectors of a local economy: the wholesale, retail, manufacturing, and services sectors. As indicated previously, this number, in terms of dollars, can be quite large. The 1972 business volume figures for some representative DA installation regions are as follows:

<u>Installation</u>	<u>Counties in the Region</u>	<u>1972 Values</u>
Fort Bragg, NC	10	\$2,783,328,000
Fort Benning, GA	11	1,644,505,000
Fort Bliss, NM	4	1,490,959,000
Fort Campbell, KY	10	590,504,000
Fort Sam Houston, TX	8	3,075,644,000
Fort Monroe, VA	11	2,958,373,000
Fort Riley, KS	8	528,286,000

One could surmise quite accurately that a large change in military activity would be required to affect the figures shown significantly. Changes in total business volume, although often large, should not be viewed and evaluated in the absence of data which can effectively establish some perspective. The identified impact can be quite large, since impacts are traced through the various sectors and the "multiplier" effect is measured. However, this "multiplier" phenomenon is considered in the definition of total business volume; hence, resultant changes, put in perspective, can have remarkably small impacts on business volume in the aggregate.

⁴ R. D. Webster, et al., *The Economic Impact Forecast System: Description and User Instructions*, Technical Report N-2/ADA027139 (Construction Engineering Research Laboratory [CERL], June 1976).

Change in Total Personal Income

Income includes wages and salary income for work performed as an employee during a specified time. Changes in income may result from changes in the quantity of work performed or products sold, or from changes in the price of labor. DOD activities affect personal income through the direct addition or removal of income and through the resulting secondary effects on DOD-dependent labor services. This effect can be brought about by changes in the number of salaries or wage earners as well as by the alteration of activity levels. For example, the reduction in personal income at a facility could be effected through either a reduction in the number of employees or a reduction in the number of hours worked per employee.

Change in Employment

As in the case of income, the effects of DOD action on employment can take two forms: (1) number of employees, or (2) work effort per employee. Therefore, employment can be measured in two ways: (1) number of employees, and (2) total employment in man-years. These two measures are different, and conversion between the two systems is not simple. The difference in the two concepts is significant, particularly with respect to local controversy. In the latter case, an aggregation occurs, allowing the consideration of both full-time and part-time employees. Considering these various levels of definitions, it can easily be seen that a reduction in 500 man-years of employment will not culminate in 500 unemployed persons. The effects of DOD actions on employment are similar to those of income. The direct impact produces the total effect and can be viewed as a "multiplier" or "ripple" phenomenon.

Impact on Local Government Revenues and Expenditures

Revenues for the operation of local governmental functions will normally fall into one or more of the following categories: property taxes, sales taxes, income taxes, and state or Federal aid. The importance of each revenue category is dependent on the county or municipal government selected. Real estate or property taxes are the most commonly discussed method of providing revenues for local governments. Normally, real property--land, housing, or businesses--is assessed, or an appraisal of its value is performed. This appraisal is usually less than the actual market value, the ratio being set by law in many cases. The property tax rate is then applied to the assessed value, and the appropriate taxes collected.

Federal facilities are exempt from local real property taxation. This exemption can certainly be viewed as a reduction in the total tax base of the community. However, since no revenues are directly received, the opening or closing of a facility has no impact on local real property revenues.

Sales tax revenues are dependent on retail sales receipts. Although the sales tax is often viewed as a state tax, the county or municipal governments are rebated a certain portion of the sales tax revenues for local governmental operation. Often, food items and similar necessities are exempted from sales tax collection. The operation has a significant effect on sales tax revenues through the direct purchases of taxable goods by employees and any portion of economic activity in the retail sales sector which can be taxed.

Income tax revenues are directly related to personal income. Local income taxes are sometimes added to Federal and state income taxes to provide additional local revenues. DOD activities affect the income tax category of revenues through the impact on total regional personal income.

State and Federal aid provide additional revenues for local governments. Although much of this category is actually a rebate of taxes originally collected locally, in many cases, the impact can be substantial. Perhaps the most important DOD-related form of aid is the aid given to schools to support the education of dependents of military employees. Frequently, the support of education under this program can be substantial. The removal of these funds can often have a severe detrimental impact on the affected region. For this reason, programs to insure the gradual reduction of support over time are available for implementation.

Local governmental expenditures cover such services as schools, utilities, and services. Schools are usually designed to accommodate a specified number of students. Fluctuations in this level of activity can be a severe problem. Utilities such as sewer, water, streets, and lighting are often designed for a certain population level or activity pattern. DOD-related changes can alter the designed load, and therefore affect how efficiently these services are used. This lack of efficiency can be a serious problem in instances where a large capital investment has been made and the people necessary to pay for the investment through use of its services are gone.

Changes in Income and Employment Distribution

Both income and employment can be measured in aggregate terms. Although this method is much easier to implement when assessing impacts, potential shortfalls can occur. In the aggregate form, no measure of the distribution is available. Most of the employment or income distribution may be contained in only a few sectors of a local region. This implies a tremendous dependence on these few sectors. An obvious example is the agriculturally-based economy. As revenues in this sector fluctuate, service industries based on this sector also fluctuate. If an economy were DOD-service oriented, those services would fluctuate with installation activity fluctuations. Income distribution measured according to percentage distribution can indicate, to some extent, the region's stability.

Impact on Local Housing

A region's housing market is a good indicator of the area's economic well-being. While increases in housing property value can be attributed to both inflation and increased demand, the demand factor is most susceptible to DOD-related activities. Both an increase in an installation's construction activity and a greater number of personnel living off base can increase the demand for housing. In the former case, the demand is often of short duration, lasting only as the workers reside in the area; in the latter case, the demand is long term only if the additional personnel continue to reside in the community. Reductions in activity almost always affect the demand negatively. These impacts may occur only in certain subregions of the community, or they may be distributed throughout the community, depending on the distribution of affected DOD personnel.

Impact on Regional Economic Stability

When a local economy is based primarily on a small number of economic sectors, an unhealthy dependence on these sectors is established. As the primary movers of the local economy, their business cycles can dictate the condition of the regional economy. Diversity is the key to eliminating these effects. If a DOD action eliminates one principal sector (in many cases, the military sector itself), the elimination reduces the diversity and adversely affects the region's stability.

Impact on Local School Systems

Schools are a form of governmental service. The purely economic ramifications of school impacts can be handled as an impact on the local government's expenditure and revenue balance; however, the social ramifications can require a very different approach. DOD dependents may differ to some degree from their peers in a local school system. These differences may be attributable to their possible increased mobility, different value systems, and different home environments (i.e., living on base as opposed to the civilian off-base community). These social ramifications required additional study.

Impact on Local Government Bond Obligations

Often, local communities will accept the "status quo" as a permanent situation. As a result, financial obligations in support of schools, utilities, and other municipal projects are often easily obtained. When this "status quo" is interrupted, as in the case of DOD reductions, a heavy burden can be placed on the community which can create a tremendous amount of controversy.

Change in Population

Population changes can have both social and economic ramifications. Changes in the social strata because of the removal of people who comprise a large portion of a leadership element or because of changes in local institutions or organizations are examples of social change brought about by population change. Population changes often accompany or trigger the impacts on local government (for example, impacts on schools), and changes in property values.

Change in Welfare and Dependency

The welfare and dependency agencies assist individuals or families who are temporarily unable to provide for themselves, such as the unemployed. Agencies that provide such services are supported by local and state taxation, grants from other governmental levels, and private charitable organizations. Changes in DOD-related employment and income directly affect the operation of these processes.

Change in Social Control

Social control includes such services as law enforcement, court activities, and related actions. If the number of military and associated personnel increases, there will be a greater demand for social control services.

Aesthetic Considerations

The economic and social well-being of a region is often indicated through somewhat nebulous aesthetic qualities. A region suffering reductions in economic vitality is often characterized by vacant buildings, high unemployment, and other factors which tend to promote a bad concept of the community to prospective businesses or residents. While hard to define, the general atmosphere and aesthetic appearance of a community are indicative of such a situation.

These elements represent those agreed upon by personnel familiar with NEPA and recent controversial court actions related to DOD mission changes and realignments. Consideration of these elements would insure the proper environmental analysis of socioeconomic impacts connected with DOD actions. Although closely related and mutually dependent, these factors are all individually important when assessing the magnitude of proposed DOD-related changes.

3 IDENTIFICATION OF THE RTV TECHNIQUE

Basis for Development of Indicators

To assess the "significance" and derivation of rational threshold values, the list of elements provided in Chapter 2 must be reduced to insure that the RTV technique is an efficient tool. Assessment can be based on the following considerations.

Predictive Capability of Existing Forecasting Techniques

Regional economics is, at first glance, a very quantitative science. The overall accuracy of state-of-the-art forecasting techniques is still subject to controversy, even among prominent practitioners. Elements used to evaluate predicted impacts should be chosen so as not to imply an accuracy that is not available. Once an indicator variable is selected, some assurance of the ability to estimate that variable is essential. If no measurement can be assured, standards of evaluation are not useful.

Availability of Data to Adequately Address the Identified Problem

Given that sufficient analysis procedures exist, the availability of adequate data to drive the predictive system should also be assured. The analysis or estimation of regional economic change can be divided into three stages: data acquisition, impact estimation, and impact evaluation. The RTV value itself can be used in the latter stages, and many techniques can be chosen to address the middle stage; however, the data acquisition stage is often the limiting factor. The best predictive technique cannot be used if its data requirements are unreasonable.

Relative Cost of Effective Implementation

The three phases of economic analysis must be combined into one systematic tool. The resource requirements of the total tool must be low enough to insure that it can be used in daily operations. The cost of its implementation is directly related to the data requirements, the sophistication of the subsystems, and the number of indicator variables.

Selection of Preliminary Indicators

Following the establishment of these considerations as prime factors in developing the RTV system, elements were consolidated as shown in Figure 1.

The development of the preliminary scheme shown was predicated principally on the considerations of predictive capability, data availability, and relative cost.

Changes in business volume, employment, personal income, and population are the indicators for these elements; however, population is also an indicator for other significant impacts or elements, as shown in Figure 1. The heavy dependence on population of these variables is based principally on the role of a population shift in significantly changing them. Any impacts on the four variables indicated (local government revenues and expenditures, local housing, local school systems, and local bond obligations) would be accompanied and probably driven by a population change. Other problems which might materialize without the population change (for example, if employment were reduced) are still addressed by remaining variables: welfare and dependency, social control, employment and income distribution, etc.

Analysis of Selected Indicators

After the elements or indicators were selected, a means of analyzing them was required. Since some change in a DOD-related activity would be the basis for using the RTV technique, a reasonable approach seemed to be analyzing historical changes. An analysis, both in a temporal and spatial sense would, to some extent, indicate a region's fluctuating trends. Since temporal data is normally the series used for this type of analysis, fluctuation of the variables over time was selected as the analysis element.

Figure 2 generally indicates the type of analysis which can be made. The curved line indicates the normal type of growth which can be seen on the majority of plots for any community. As shown, a straight line can be drawn between the final and starting points of the growth curve. This has an averaging effect and tends to indicate very clearly the type of fluctuation exhibited by the community under study. Figure 3 is an additional visualization of the fluctuation. Deviations from the average are plotted. For example, if a growth of 3 percent were shown in a time interval, and the average rate were 5 percent, a negative 2 percent would be plotted. If a growth rate in excess of the average were shown, a positive deviation would be indicated. The concept is simply based on the creation of a "yardstick" against which a specified change may be compared, thus establishing some perspective.

<u>Indicators</u>	<u>Elements</u>

Impact on Regional Economic Stability	

Figure 1. Resultant preliminary indicators.

Figure 2. Analysis of variable X.

Figure 3. Yearly percentage deviation in variable X.

Inflationary trends must be considered in cases where dollar values are used. Otherwise, a bias in favor of growth would be developed and the resultant trend would not represent the true fluctuation. To adjust for inflation of the dollar values, the Consumer Price Index (CPI) was used for the appropriate years, and all dollar values were adjusted to 1967 equivalents. (1967 is normally used as a base year; since the threshold values will eventually become percentages, the results are the same, regardless of the base year used.)

After the indicators and an approach were selected, existing data sources were reviewed. The source selected was the Bureau of Economic Analysis (BEA) data series which covers income, employment, and population. Figures 4 and 5 indicate the type of data available from this source.

BEA data is available for the income, employment, and population variables. No good source with an adequate time series for business volume was found, so some indication of the fluctuation in business volume was necessary. The breakdown of personal income shown in Figure 4 seemed the most promising. The "nonfarm" category of total personal income was selected as a measure of business volume fluctuation. This is based on the fact that a reduction in business volume would tend to affect total personal income directly. Although over adjustments could be made in a business to account for business slumps, such as inventory reduction, the income picture would most likely be affected. At worst, the historical fluctuation exhibited would be less than that found in a "true" business volume measure. Therefore, the resultant analysis would probably be conservative.

Case Studies for Selected Regions

Pursuing this avenue of investigation, data were obtained which indicate historical flexibility in relation to specific economic factors. For example purposes, selected data elements are presented and analyzed on the following arbitrary regional areas (some areas reflect those recently addressed or impacted by DOD action):

- Middlesex County, NJ
- Lubbock County, TX
- Talledega County, AL
- Washington, DC, SMSA
- Lexington-Bluegrass Army Depot
- Bourbon County, KY
- Clark County, KY
- Fayette County, KY
- Madison County, KY
- Montgomery County, KY
- Scott County, KY
- Fort Monmouth, NJ
- Monmouth County, NJ
- Middlesex County, NJ
- Ocean County, NJ

The tentative results of these studies are shown in Tables 1 through 16 and Figures 6 through 21. Not all factors are plotted, but trends are indicated. Before reviewing the figures, the following additional explanations should be noted:

1. The average yearly rate of change is shown as a percentage based on the last year of record.
2. The maximum fluctuations are also shown as percentages, which are calculated by dividing the deviation by the element's value for the first year of the time interval.

The calculations used to produce the curves are self-explanatory. Dollar values were adjusted, using Wholesale and Consumer Price Indices to correct for inflationary trends. The resulting figures are 1967 dollars. Since percentages are obtained for thresholds, using the base year should not affect using the thresholds to evaluate project impact.

The case studies, although few in number, imply two principal conclusions:

1. The "natural" or historical fluctuations in the plotted economic elements indicate that regions differ both in cycle and in magnitude of fluctuation. Hence, any attempt to use a "national" percentage figure for a specific community could be misleading and would be subject to court challenges; however, using the data available for a specific region, it would be easy to defend threshold values which are region-specific.

2. There are some problems with data availability for a time sufficient to adequately address the problem. This is particularly true for investigating employment trends; however, a "band" of acceptable impact levels can be derived, based on available information. This would be conservative, in that the range would be smaller than if the curves were allowed to reach the optimum level on either the positive or the negative scale. Extending the curves in either direction would result in a wider range, and hence higher absolute thresholds.

Yearly Deviation from Average Rate (x 10³)

Figure 21. Deviation in average yearly growth rate in population, Fort Wolters, TX.

Using this technique to gauge economic elasticity or resilience, threshold values can be derived which represent the maximum percentages of fluctuation which have occurred historically. This would represent fluctuations which a particular community has endured and would provide a basis for comparing an action's impact to that fluctuation. Therefore, the arbitrary assignment of the same absolute thresholds to varying regions is avoided. No predetermined courses of action can be taken until each region's economy has been evaluated. A systematic approach to this evaluation enables a more defensible conclusion.

Definition of Acceptable Limits of Fluctuation

As shown in Figures 6 through 21, communities or regions exhibit a large degree of fluctuation in the indicator variables selected. In establishing a band of fluctuation around the "average growth rate" variable, and using that band to screen probable impacts, it seems that some degree of conservatism is needed. The band could be made smaller by selecting some arbitrary percentage of the maximum fluctuation--for example, 50 percent. This methodology, although arbitrary, is very similar to the traditional engineering concept that potential threat to human life is often the basis for choosing a factor of safety for bridges, dams, etc. A similar weighting system can be devised for the RTV concept, based on the potential impact of a project on individuals.

In relation to one another, the severity of potential impact increases in the following order: Total business volume, total personal income, total employment, and total population. Business volume impacts can be absorbed by manipulation of other factors, such as inventory, new equipment, etc. Impacts on individual workers or proprietors are neither assured nor immediate. Changes in employment and income, however, are immediate problems, with individuals either being impacted through less work per pay period, or no work at all. This impact usually is accompanied by a corresponding fluctuation in personal income, which also directly impacts individuals. Population, as an indicator of potentially controversial impacts in other areas, is extremely important and should be strenuously weighted to reflect this importance.

Keeping these relative weightings in mind, the scheme shown in Table 17 was developed.

Table 17

Allowable RTV in Percentages of Maximum Historical
Deviation in Average Yearly Growth Rate

	Increase*	Decrease*
Change in Total Business Volume	100%	75%
Change in Personal Income	100%	67%
Change in Total Employment	100%	67%
Change in Population	100%	50%

*These percentages represent deviations from average yearly growth rate. The average yearly growth rate is obtained from analysis of data for the past 10 years. In cases where data are not available for the past 10 years, a minimum of 5 years is needed.

These percentage allowances are arbitrary but sensible. The maximum positive historical fluctuation is allowed without reduction because of the positive connotations of economic growth. Although cases of damaging economic growth have been cited, and the "zero-growth" concept is being accepted by many local planning groups, the effects of reductions and closures are much more controversial. Figure 22 shows the effect of these weightings on the general concept.

Figure 22. The weighted RTV concept.

Cumulative RTV Weighting

The singular evaluation of RTV parameters, although beneficial to the decision-making process, requires one additional evaluation factor. NEPA's emphasis on the consideration of cumulative impacts seems to support a similar consideration of the RTV factors. Although the absolute thresholds of the four principal factors (business volume, income, employment, and population) may not be surpassed, the effect of cumulative proximity to the thresholds may indicate a problem.

To account for this phenomenon, a weighting scheme is recommended to insure that in all factors cumulatively, the threshold is not being approached. As shown for a hypothetical case in Table 18, the "border-line" case can be reevaluated by using this technique. Taking each factor separately, significance is not implied in the table; however, encroachment on the threshold is obvious. The technique builds an additional safeguard into the RTV analysis. If the cumulative ratio of impact to threshold exceeds 3, significance is implied. For example,

this case would represent a cumulative significance of

$$\frac{-1.15}{-1.2} + \frac{-.46}{-.53} + \frac{-.48}{-.50} + \frac{-1.0}{-1.2} = .96 + .87 + .96 + .83 = 3.62$$

Since 3.62 > 3.0, the project would be considered important enough to warrant further study.

Table 18

A Hypothetical Regional Analysis of Significance

Factor	%Change Historical		Allowance Criteria		2 Change Thresholds		Predicted*		Significance?	
	(+)	(-)	(+)	(-)	(+)	(-)	(+)	(-)	Yes	No
Business Volume	3.2	-1.6	100%	75%	3.2	-1.20	--	-1.15		
Personal Income	2.6	-.8	100%	67%	2.6	-.53	--	-.46		
Total Employment	4.2	-.75	100%	67%	4.2	-.50	--	-.48		
Population	5.0	-2.4	100%	50%	5.0	-1.2	--	-1.0		

*These percentages represent deviations from average yearly growth rate. The average yearly growth rate is obtained by analyzing data for the past 10 years. In cases where data are not available for the past 10 years, a minimum of data for 5 years is needed.

4 CASE STUDY EVALUATION OF PERCENTAGE REDUCTION AND THE RTV TECHNIQUE

CERL is developing an economic impact prediction methodology^{5,6,7} (EIFS) for use by DOD elements in complying with NEPA. Although this technique is still under development, it represents a method of quickly obtaining a great deal of background economic information; the estimated resultant magnitudes of change provided by this technique are reasonable; however, it is well recognized that the technique tends to slightly overstate impacts. (An overstatement merely acts as a safety factor by insuring that identified "worst case" impacts are considered early in the Environmental Impact Analysis/Statement.) As development continues, the accuracy of predictions should improve. For this study, several regions were evaluated using the current CERL methodology.

EIFS was queried for eight DOD installations and percentage reductions in respective military and civilian personnel. Table 19 lists the selected installations and percentage reductions investigated.

Table 19
Information Used to Calculate Input Data
to the EIFS Model

Installation	Existing Manpower* (Military/Civilian)
1. Fort Huachuca	5791/5413
2. Fort Ord	16,278/2455
3. Fort Gordon	16,166/4247
4. Fort Campbell	22,304/4207
5. Fort Polk	11,671/2727
6. Fort Devens	5245/1500
7. Fort Monmouth	1045/6327
8. Fort Lewis	23,000/3000

*Data obtained through phone inquiry.

- ⁵ R. D. Webster, et al., *Development of the Environmental Technical Information System*, Interim Report E-52/ADA009668 (CERL, April 1975).
- ⁶ R. D. Webster, et al., *The Economic Impact Forecast System Description and User Instructions*, Technical Report N-2/ADA027139 (CERL, June 1976).
- ⁷ R. D. Webster, et al., *Development of the Economic Impact Forecast System (EIFS) - The Multiplier Aspects*, Draft Technical Report (CERL).

Multi-county regions were defined around the selected installations as follows:

- Fort Huachuca, AZ
 - Pima County, AZ
 - Santa Cruz County, AZ
 - Cochise County, AZ
- Fort Ord, CA
 - Monterey County, CA
- Fort Gordon, GA
 - Richmond County, GA
 - Columbia County, GA
 - Jefferson County, GA
 - Aiken County, SC
- Fort Campbell, KY
 - Montgomery County, TN
 - Stewart County, TN
 - Christian County, KY
 - Trigg County, KY
- Fort Polk, LA
 - Verna County, LA
 - Beauregard County, LA
 - Calcasieu County, LA
 - Rapides County, AL
- Fort Devens, MA
 - Middlesex County, MA
 - Worcester County, MA
 - Suffolk County, MA
 - Hillsborough County, NH
- Fort Monmouth, NJ
 - Monmouth County, NJ
 - Ocean County, NJ
- Fort Lewis, WA
 - Pierce County, WA
 - Thurston County, WA

Although the actual technique for regional definition is under study by CERL and other organizations, the regional definitions identified by the DA Comptroller^a were used for this study.

Percentage reductions were calculated from Table 19 and used as inputs to EIFS. No change in local expenditures for goods and services was included in the analysis. Therefore, the resultant model inquiries represent only personnel changes. Table 20 summarizes the results of the model inquiries and indicates the range at which the thresholds were

⁸ *Economic Multipliers for Army Base Realignment Studies*, DCA-R-33 (Directorate of Cost Analysis, Office of the Comptroller of the Army, July 1976).

theoretically violated. Since the EIFS model prediction of the population variable is not yet implemented, only three variables are shown.

The results of the model inquiry and evaluation indicate that for the regions selected, very few of the results would have been interpreted as significant until employment was sizably reduced at the installations. The wide variability in results indicates the degree of difference between various DOD-dependent communities. The fluctuation patterns of the economy, volume of activity, and size of the original change all have some bearing on the importance of the impact. As shown for Fort Devens, MA, the impact of full closure would not be singled out as a significant impact using this technique. In the case of Fort Monmouth, NJ, however, the thresholds are violated at a very low level of reduction. In the case of Fort Devens, the high values are caused by the large degree of fluctuation and a very large local economy. In the case of Fort Monmouth, the economy is smaller, while the historical levels of fluctuation remain the same.

Although a small number of installations were analyzed, the range shown in Table 20 indicates that in many cases, this technique will allow relatively large shifts in DOD personnel before the RTV criteria are violated; however, this conclusion is valid only for those economies which are either quite large or have high natural fluctuations of economic activity, and cannot be applied to all actions in general. It is fairly clear, however, that a system of this type would not be overly restrictive on DOD actions.

Table 20
Summary Results of Model Inquiries

<u>Element</u>	Base No.	Percentage Reduction Producing Significant Impact*						
		1	2	3	4	5	6	7
Business Volume	22	38	59	22	47	293	25	44
Total Personal Income	22	29	39	22	30	197	6	26
Total Employment	12	12	31	20	27	156	8	23

*For example, the upper limit for manpower reductions at Base 3 was 59 percent using business volume as an indicator, 39 percent using total personal income, and 31 percent using total employment. It should be noted that these figures are based on salary and manpower reductions only. No reductions in local procurements were considered.

5 CONCLUSIONS

The rational threshold value technique can be used to determine the significance of economic and related social impacts which might result from Army military activities. The socio-economic elements necessary for developing RTV techniques are changes in business volume, personal income, and employment; impact on local government revenues and expenditures; changes in income and employment distribution; impacts on local housing, regional economic stability, local school systems, and local government bond obligations; changes in population, welfare and dependence, and social control; and aesthetic considerations.

To insure the efficiency of the RTV, the significance and derivation of RTVs were assessed on the basis of three considerations: predictive capability of existing forecasting techniques; availability of data to adequately address the identified problem; and relative cost of effective implementation. Using the elements selected by these assessment methods, several hypothetical case studies were investigated to ascertain the practicality and usefulness of the technique. Results of these studies indicate that the RTV technique can be used as a screening device to establish the significance of economic and related social impacts resulting from Army military activities.
