18. SUPPLEMENTARY NOTES The view, opinions, and/or findings contained in this report are those of the author(s) and should not be construed as an official Department of the Army position, policy, or decision, unless so designated by other documentation.		
19. KEY WORDS (Continue on reverse side if necessary and identify by block number) Laminated and fiber-reinforced composites Variational methods Vibration frequencies Lower and upper bounds for Harmonic waves eigenvalues		
20. ABSTRACT (Continue on reverse side if necessary and identify by block number) In this project attention has been focused on: (1) The accurate calculation of the dispersive properties of laminated and two- and three-dimensional fiber-reinforced elastic composites; (2) The accurate determination of natural frequencies of composite plates and beams, or plates and beams with variable dimensions or with inclusions; (3) Calculation of upper and lower bounds for the eigenfrequencies in (1) and (2); and (4) The assessment of the effect of fiber geometry on the dynamic properties of the fiber-reinforced composite.

A. Statement of Problem Studied and Summary of Basic Results

In addition to their strength and special thermomechanical attributes, elastic composites, if properly designed, can be highly dispersive when subjected to stress pulses. Therefore, in using composites, one of the most significant objectives often is to implement a design which provides for a maximum attenuation by dispersion of stress waves without a sacrifice in the needed strength and other properties. Also, one needs to know the detailed stress distribution in a given composite when subjected to elastic waves. Furthermore, plates and shells with inclusions, with variable thicknesses, and/or with various reinforcements, are common ingredients of modern structural components in technology. The dynamic behavior and the thermal conductivity properties of these elements are of obvious importance to a designer.

Many characteristics of composites relating to the phenomenon of elastic wave propagation can be brought into focus by considering harmonic waves. For example, if the dispersion curve of a given composite deviates sharply from the straight line, the composite would be highly dispersive. Moreover, since pulses can be decomposed into their Fourier components, the dominant effect may be discussed in terms of the corresponding harmonics. Since these harmonics constitute the eigenfunctions, they can be suitably combined to define the response to various short-duration pulses. Thus it appears that the study of harmonic waves in composites can provide a basis for a better understanding and design of elastic composite materials. In a similar sense, many aspects of the dynamics of composite plates and shells can be understood in terms of their natural modes of vibration. In this project attention has been focused on: (1) The accurate calculation of the dispersive properties of laminated and two- and three-dimensional fiber-reinforced elastic composites; (2) The accurate determination of natural frequencies of composite plates and beams, or plates and beams with variable dimensions or with inclusions; (3) Calculation of upper and lower bounds for the eigenfrequencies in (1) and (2); and (4) The assessment of the effect of fiber geometry on the dynamic properties of the fiber-reinforced composite. This latter consideration can play an important role in the design of structural elements, such as helicopter blades, where it may become necessary, for example, to alter the vibrational frequencies of an element without having to modify its over-all geometry.

The calculations are based on a new quotient which has been formulated by the author recently. This quotient is based on a general variational method in which the displacement and stress fields are given independent variation. It has been shown under the present project that the new quotient yields extremely accurate results, even with the crudest approximating functions, hence making the new quotient superior to the Rayleigh quotient. With the aid of the new quotient, lower and upper bounds for the eigenfrequencies have also been obtained. These bounds are very close to each other.

C. List of Participants

Principal Investigator:

Professor S. Nemat-Nasser

Visiting Scholars:

Professor C. O. Horgan (Visiting Professor at Northwestern University)

Professor S. Minagawa

Postdoctoral Research Associate:

Dr. F. C. L. Fu

Graduate Student:

Mr. K.-W. Lang, Research Assistant - Ph.D. degree awarded August 1978

Short-Time Participation:

Professor T. Mura, consultation

Dr. K. S. Parihar, computer programing

Mr. C.-C. Mo (graduate student), computer programing
