SUPPLEMENT TO WSEG RESEARCH MEMORANDUM NO. 10

REVISION OF FALLOUT PARAMETERS
FOR LOW-YIELD DETONATIONS

Since the original publication of WSEG Research Memorandum No. 10 we have become aware of additional information on the transport of radioactive debris from low-yield detonations. These data indicate that one cannot assume the same distribution of activity versus particle size for both high- and low-yield detonations. We are, therefore, issuing this supplement which is intended to correct the data for the kiloton-yield range. *K*

Analysis of this additional low-yield deposition data indicates that the debris is carried only about half as far as would be expected if the distribution of activity versus particle size were the same as for the megaton-yield detonations. Since there is no information available indicating how the low-yield results should join with the high-yield results, a simple modification of the T function has been arbitrarily selected which accomplishes this change and feeds smoothly into the previous results at about one megaton. The revised expression for T to replace equation (37) in Research Memorandum No. 10 is:

$$T = \left[12 \left(\frac{h_0}{50} \right) - 2.5 \left(\frac{h_0}{50} \right)^2 \right] \left[1 - \frac{1}{2} e^{-\left(\frac{h_0}{25} \right)^2} \right]$$

(This, of course, also changes the expression for T on page 51 of Research Memorandum No. 10.) Figure 1 shows the new plot of

T versus h which then replaces Figure 12 of Research Memorandum No. 10.)

A new set of tables is included which incorporate these changes and give the new results. The new tables can be read exactly as the previous tables. One change should be noted. The new tables are plotted for values of the shear: .2, .4, .8 knots per thousand feet instead of: .1, .2, .4 as was done in the original memorandum. This change was made because a re-examination of the meteorological data indicates that these values are more typical of the effective fallout winds in temperate zones for the lower altitude radioactive clouds.

Since the original publication, two other questions have been raised which merit some comment:

The first question concerns the total radiation assumed per megaton. Additional calculations have now been carried out by C. F. Miller at USNRDL on the fractionation of fission products other than rare gases. His results seem to indicate that the DASA value used for k (the number of roentgen square miles per megaton fission) may be too high. However, additional research will be required to clarify this point.

The second point concerns the extent of upwind fallout, which was inadequately qualified in the original memorandum. It is pointed out that it takes a finite time before extensive fallout begins to arrive on the ground and, therefore, in the case of very strong winds the cloud might be carried completely

9-8-60-1

FIGURE 1
SUPPLEMENT TO
WSEG RM NO. 10

downwind before debris covering a large area arrived on the ground. The model used here does not allow for such a delay and, therefore, always produces an upwind extent which, while less than most older models under conditions of large wind is, nevertheless, quite significant in some applications. The available experimental data on upwind deposition have been examined again with this problem in mind. Unfortunately little or no experimental data is available on upwind fallout from ground bursts under conditions of large effective winds. The existing ground burst deposition patterns show little or no downwind drift of the measured upwind extent despite considerable direct evidence for a time delay in the deposition. Consequently, it is not possible to resolve the question by direct examination of this experimental data. Any attempt at a resolution must depend on a combination of analysis of existing data and theoretical extrapolation. Because the fallout processes at early time are poorly understood there are inherently large uncertainties in such an extrapolation.

A specific investigation of the upwind fallout data for megaton yields, using both water and land surface burst data, has been made by Gilbert J. Ferber of the U.S. Weather Bureau. ^{1/} Ferber proposes an empirical rule for the estimation of upwind fallout which is based on about a 20-minute delay between the detonation and the first arrival of significant fallout. He

1/ Upwind Fallout from Nuclear Detonations in the Megaton Range
by Gilbert J. Ferber, April 1960.

also tabulates experimental data on upwind and crosswind extent of fallout for comparison with his predictions. Examination of his tabulated data shows that the data are generally consistent with the Ferber predictions and that at least two water surface bursts are not consistent with the tabulations in this memorandum where no time delay is included. It may, therefore, be appropriate to incorporate such a delay in the model.

Such a simple delay can be rigorously incorporated into the predictions of this memorandum simply by translating all contours downwind by a distance equal to that traveled by the effective wind in the delay time. When a 20-minute delay is included, the results of this memorandum become quite consistent with the data tabulated by Ferber.

Unfortunately, the data on actual time of arrival of radioactive debris indicate that the time of arrival will vary from considerably less than 20 minutes close to ground zero to considerably more at larger distances. The use of the constant delay, therefore, under conditions of large wind may leave the region in the immediate vicinity of ground zero erroneously free of significant fallout. The existing experimental data on time

2/ The "upwind" extent shown for "zero" wind in the tables is not related to the problem considered here. That extent is quite arbitrary and actually results from using a value for the x component of the shear which is close to .2 knots/1000 feet. Other values for s_x would give very different results. The case is shown only to indicate qualitatively the behavior of the formula for very low wind speeds.

of arrival and displacement of arrival position with wind velocity at early times is not adequate to provide a reliable prediction of the extent of fallout near ground zero under conditions of medium to large effective fallout wind. Thus, in any application where specific fallout contours near the ground zero are important, neither this model nor any model presently available can be used without qualification. It seems quite likely that correct answers for megaton yields would fall between those obtained with about 20-30 minute displacement and those obtained with none. If it is necessary to make an estimate it may be appropriate to displace the crosswind extent given for ground zero about 20 minutes downwind and connect this crosswind estimate with smoothly tapered contours to a diminished estimate of upwind extent. The upwind extent for low wind velocities should decrease almost linearly with increasing wind velocity, but more slowly for large wind velocities which affect the close in region of early fallout. This general result is obtained by Ferber by using a two-mile minimum for the upwind extent. To give this effect in a reasonable way for a variety of yields one can reduce all the upwind distances given in the tabulation by a factor of the form $\frac{1}{1 + \gamma W}$, where γ is roughly equal to $\frac{1}{800} h_0 / \gamma_0$. This decreases the upwind extent by about a factor of two at 20 knots for a 5-megaton burst and by a factor of four for a 60-knot wind. While the contours near ground zero estimated in this way appear to be reasonably consistent with the available data for both water and ground burst megaton detonations, they should be treated as rough estimates only and should not be used without appropriate qualifications.

Much the same type of uncertainty near ground zero is also applicable to low-yield detonations, however, it is clear that the delay time for fallout arrival from very low yields is very much less than 20 minutes. If the effective delay as assumed above were proportional to the stabilization height of the radioactive cloud, it would imply a delay for other yields (in hours) of about $(1/3 h_0/50)$. There is some indication that the upwind extent obtained in this way is somewhat too small for very small yield detonations, where no toroid is formed. For such yields it may be better to use the tabulated contours without alteration.
