ABSTRACT

A computer data reduction system has been reprogrammed to sample individual scan recordings of the line-spread function of laser light propagating through the turbulent marine boudary layer.

The distribution of spatial frequencies of the Modulation Transfer Functions from random single scan samples from experimental data sets has been investigated. A preliminary analysis indicates that the zero spatial frequency component of the MTF is log-normal distributed.

I. INTRODUCTION

Atmospheric turbulence adversely affects the propagation of a laser beam or the performance of an imaging system. The Modulation Transfer Function (MTF) is a measure of the degradation of resolution and thus the relative ability of the atmosphere to transmit spatial frequency information. Knowledge of the MTF of the atmosphere is necessary for prediction of the beam cross-sectional profile on target and spot wander for a high energy laser and its beam projection system.

Members of the faculty of the Naval Postgraduate School (NPS), Department of Physics and Chemistry, have investigated the effects of atmospheric turbulence on the propagation of optical radiation in the marine boundary layer.

The work started in 1973 and has continued through 1978. The research has been concentrated on developing a model for the MTF depending on wavelength, range and a properly path-position weighted value of the turbulence structure constant for optical index Cn. The work for the period 1 July 1974 - 30 September 1977 is described in Ref. 1. Field experiments were performed by transmitting laser light of different wavelengths along various seapaths. The received intensity was detected by a slit-scanning telescope system and recorded on tape. The Cn value was determined by computer calculations.

The objective of this report is to describe the development of a computer program which samples individual scan

recordings of the line-spread function and determines a preliminary statistical distribution of the spatial frequency content of the Modulation Transfer Function.

II. ANALYSIS OF DATA

A. FUNCTIONAL DESCRIPTION

1. Data

Experimental data are the intensities of the line-spread functions as recorded on a 4-channel magnetic tape. One track is used for verbal identification of date, time and pertinent experimental information. Two tracks are used for recording scans and the last track is used for recording the trigger signal.

Verbal information has been cross-checked against experiment log book and MTF data output. Data have been recorded for one and two wavelengths simultaneously. Only data for .6328 microns have been analyzed in this report. The line-spread function was sampled by the scanning detector at a rate of 50Hz and recorded at a tape speed of 37.5 inches per second.

2. Data Reduction

The data reduction is done on a Nicolet Instrument Company, NIC-80 data processor. This is a data digitizer followed by a 12K 20-bit digital computer and a Tektronix CRT display unit. The NIC-80 computer is controlled by a Hewlett-Packard HP-9825 desk top type programmable calculator.

The NIC-80 computer reads the line-spread function for one scan, performs a Fourier Transform (FT) analysis of the signal and transfers the FT spatial frequency components 0 - 19 to the HP-9825. The MTF of the atmosphere is calculated

by dividing the FT of the line-spread function by the FT of the optics. The FT of the optics is stored by the NIC-80 and transfered to HP-9825. The experimental analog signal is digitized at 1024 points. The DC component is removed by manual setting of signal bias based upon observation of scan on CRT display. Any remaining DC component is compensated by subtracting the average intensity value of 32 points at each end of the digitized signal.

When not performing FT and transfer operations, the NIC-80 remains in signal display mode with successive scans being displayed on CRT.

The computation and transfer time for one scan has been observed to be 5 seconds, and will be the time between sampling of scans. During data reduction, the tape recorder was operated at 3.75 IPS, corresponding to 5 scans per second. This implies that about every 25th scan of the recorded data was sampled for analysis. The number of scans sampled was limited by the length of experimental data recorded, normally in the order of one minute, or 3000 scans. This allowed a sample size of 100 - 125 for data analysis. An attempt to run the recorder at .375 IPS speed was not successful due to problems with the trigger signal.

3. Statistical Analysis

The HP-9825 calculates the MTF at 20 different spatial frequencies from 0 to 38000 per radian in steps of 2000 per radian. These spatial frequency points are labeled 0 to 19 and are tested for normal and log-normal distribution. Goodness

of fit is determined by the Chi Square test. A data summary containing mean, standard deviation and Chi Square values for normal and log-normal tests is outputted on the printer. Mean and $\pm$ 1 standard deviation for frequency points 0 - 19 is plotted, with the zero spatial frequency normalized to a value of unity and all other data adjusted correspondingly. A histogram showing relative distribution of MTF values for one specific spatial frequency is plotted as requested in program input.

Examples of the above are given in Figures 1, 2 and 3 respectively. The relationship of the MTF distribution to the Cn value has been investigated. The Cn values ranged in the order of 8×10^{-8} to 1×10^{-7}. Typical line-spread functions for two different Cn values are shown in Figure 4. Note that Cn squared values are given.

The value of Cn used has been taken from existing MTF data outputs. If no output was available, an MTF analysis was performed. A detailed discussion of MTF and Cn is given in Ref. 1. The scan presentation is a function of time and detector position. The dwell time setting was obtained by analyzing calibration data recorded on tape. Dwell time is the sampling time per data point. Data have been obtained by recording the detector output with a diffraction grating of known dimensions placed in front of the telescope. This provides a known reference of angular spread. The dwell time is adjusted so that the angular spread of the first order diffraction as observed on the display is equal to the reference value.

B. PROGRAM THEORETICAL CONSIDERATIONS

The data were tested for normal and ln normal distribution.

1. Normal Curve

The normal or Gaussian curve is expressed as

$$Y = \text{constant} \exp\left(-\tfrac{1}{2}\left(\frac{x-\bar{x}}{s}\right)^2\right)$$

where

- x is the value of MTF for normal test distribution or value of ln MTF for log-normal distribution.
- $\bar{x}$ is the unbiased estimate of the Mean of the MTF values or Mean of ln MTF values.
- s is the unbiased estimate of the standard deviation of the distribution.
- Y is the probability density of the distribution.

Constant = $i/s\sqrt{2\pi}$, where i is the width of a histogram bin to make area under curve equal to i.

The Mean $\bar{x}$ is the arithmetic Mean given by:

$$\bar{x} = \sum_{i=1}^{N} x_i/N$$

where N is the number of observations (samples).

The standard deviation s is the positive root of the Variance s squared given by

$$s^2 = \sum_{i=1}^{N} (x_i-\bar{x})^2/(N-1)$$

For computational purposes the following algebraically equivalent formula has been used:

$$s^2 = \left(\sum_{i=1}^{N} (x_i)^2-\left(\sum_{i=1}^{N} x_i\right)^2/N\right)/(N-1)$$

The probability density curve has been computed and plotted over a range of Mean $\pm$ 3 standard deviations.

2. Goodness of Fit

Test of goodness of fit to tested distribution has been done by histogram and Chi Square calculation.

The width of the histogram bins is a program variable expressed as a ratio of the standard deviation. 1/3 has been used corresponding to a total of 18 bins. The number of samples with values within a bin is expressed as a fraction of 1, so that the area of the histogram is equal to the width of the bin interval.

The Chi Square goodness of fit value has been calculated from

$$x = \sum_{i=1}^{n} \frac{[Nf(n)-F(n)]^2}{Nf(n)}$$

where

N = number of observations

n = number of histogram bins

F(n) = number of observations within a bin

The term Nf(n) is the theoretical number of observations which should fall within a bin. The probability area has been calculated as the sum of a rectangle and a triangle approximating the area under the normal curve. The sampling distribution of the Chi Square statistics is tabulated as a function of degrees of freedom and percentile. The number of degrees of freedom is calculated from

df = k-n-1

where

k = number of bins in histogram

n = number of parameters estimated

For a 18 bin histogram with mean and standard deviation estimated, the degrees of freedom is 15, with a 95 percentile value tabulated as 25. A calculated Chi Square value less than 25 will, at the 5% significance level, imply that the data fits the given distribution.

C. COMPUTER PROGRAMS

1. NIC-80 Data Reduction Program

This program has been developed utilizing subroutines from the existing MTF analysis program. Pages 3 and 4 of the MTF program have not been changed. Main program is on page 1 and a data transfer subroutine has been inserted on page 2. Program flowchart is given in Figure 5A. Program listing is on page 122.

2. Data Analysis Program

Due to limited HP-9825 memory capacity, this program has been split into two parts stored on separate program files. During operation, programs are loaded and executed under program control. Program "A" is on file 8 and contains NIC-80 control and all analysis functions except data summary, which is on program "B" located on file 9. Programs are documented on flowcharts (Figures 6 and 7). Program listings are on pages 117-121. Execution of analysis program requires HP tape inserted with track 1 available for data storage.

Each data file must be minimum 160 bytes long and the number of files must be equal to or larger than the number of scans sampled.

Execution time for a 100 scan analysis run is of the order of 90 minutes. Most of this time is required for tape movements and operations.

III. RESULTS

A total of 24 data analysis runs have been performed. Five of these have been on the same data sets in order to investigate consistency of distribution within the same data set.

An arbitrary grading system for goodness of fit over a range of spatial frequencies has been established as follows:

- All components in range within 95 percentile = 1.
- One component in range outside 95 percentile = 2.
- Two or more components in range outside 95 percentile = 3.

Data summary and MTF mean and standard deviation plots are given on pages 39-86, arranged in order of decreasing order of Cn. A distribution analysis summary is tabulated on pages 31-33. A set of histograms for all spatial frequencies for one data set is given on pages 87-112.

A. CONSISTENCY OF DISTRIBUTION

Data set number 12 has been run 5 times to verify consistency of distribution as only every 25th scan was sampled.

Utilizing the grading system for spatial frequency ranges 0, 1-6, 7-12 and 13-19, the following results as given in Table II and III, were found:

TABLE I

TABLE II

Grading Consistency of Data from Same Data Set

Frequency Range	Number of Runs with Grading					
	Normal			Log Normal		
Grade	1	2	3	1	2	3
0	1	4	0	4	1	0
1 - 6	1	0	4	5	0	0
7 - 12	0	0	5	3	1	1
13 - 19	0	0	5	3	2	0

The number of samples which met the 95 percentile criterion for each spatial frequency in the 0 - 6 frequency range is listed in Table III.

TABLE III

Consistency of Individual Frequency Components from Samples of Same Data Set

Frequency	Number of Samples within 95%	
	Normal	Log Normal
0	1	4
1	1	5
2	2	5
3	3	5
4	3	5
5	2	5
6	3	5

The results indicate that the distribution can be expected to give same Chi Square values for different sample series from same data set.

B. FACTORS AFFECTING DISTRIBUTIONS

1. Scintillation

If the intensity of a laser beam which has propagated through a turbulent medium is observed at a point, the intensity appears to fluctuate or scintillate in a random way.

It has been shown that the values of the logarithm of the amplitude follow a Gaussian distribution (Ref. 1, page 15). Spatial frequency component zero represents the area under the curve (signal). This area is proportional to the received intensity. It is thus expected that the distribution of the zero spatial frequency component should fit the log normal distribution.

2. Signal to Noise Ratio

The amplitude of the spatial frequencies decreases with increasing frequency number. For spatial frequency 15 and above, the amplitude is of the order of 10% of the zero spatial frequency component. At higher frequencies noise will contribute more relative to the amplitude. Noise is considered normal distributed, and it is expected that the distribution at higher frequencies is normal.

C. RESULTS AND DISCUSSION

1. Log-Normal Distribution of 0 Spatial Frequency

In 13 of 20 runs the spatial frequency zero fits the Ln normal Chi Square 95 percentile criterion. For runs which

do not meet the distribution criterion, the ratio of mean to standard deviation is in the order of 2. This may indicate saturation, and thus not follow log normal distribution (Ref. 1, page 16).

The results do indicate that the zero spatial frequency is log normal distributed.

2. Normal Distribution of Higher Frequencies

For data analysis the modulus, e.g., absolute value of the data has been used, and sign of the data has not been included. This will introduce a skewness of distribution. It is believed that this is the reason for lack of normal distribution for data at higher frequencies.

3. Distribution versus Cn Value

Data have been arbitrarily grouped into ranges with respect to Cn values as follows:

Cn High: $Cn > 6.10^{-8}$

Cn Medium: Cn between 2.10^{-8} and 6.10^{-8}

Cn Low: $Cn < 2.10^{-8}$

The ratio of distributions graded 1 for the various Cn ranges is listed in Table IV.

The results do not indicate that the distribution does change with Cn values. For all analysis results, it should be noted that the sample size is small, and the results should be interpreted as indications only.

TABLE IV

Ratio of Distribution Graded
1 for Different Cn Ranges

Cn	Spatial Frequency	Normal	Log Normal
H	0	5/6	5/6
I	1 - 6	2/6	3/6
G	7 - 12	3/6	2/6
H	13 - 19	0/6	0/6
M	0	3/7	4/7
E	1 - 6	1/7	5/7
D	7 - 12	0/7	3/7
I	13 - 19	0/7	2/7
U			
M			
	0	4/7	4/7
L	1 - 6	3/7	5/7
O	7 - 12	0/7	1/7
W	13 - 19	1/7	2/7

D. RECOMMENDATIONS FOR FURTHER WORK

To reduce analysis computing time, the HP-9825 should be equipped with additional memory capacity. To eliminate use of tape for data storage, memory should be increased to 25K.

The data analysis for each run should be stored and analyzed for mean and standard deviation. Several runs on the same data set should be performed to verify distribution.

Number of scans sampled in each run should be increased by either solving signal trigger problem at low tape speed or by reprogramming NIC-80 computer to perform and store partial analysis results.

APPENDIX A

Operating Instructions for Data Analysis

A. Initialization

1. NIC-80, Analysis program not loaded

(a) Turn on computer with key, depress "STOP"

(b) Turn on Data Bus unit

(c) Set toggle switches 0 - 11 to up position

(d) Depress "LOAD PC"

(e) Depress "CONTINUE"

(f) Press "EXECUTE"

2. HP-9825

(a) Turn on HP-9825

(b) Insert Data Analysis cassette and load track 0, file 1 for NIC-80 loading program

(c) Push "RUN"; c, d, i, r, n, o, 1, s, t is displayed.

(d) Push "n" and "CONTINUE"; load file # is displayed. The NIC-80 data analysis program is located on files 2, 3, 4 and 5. Enter one of these numbers and push "CONTINUE".

(e) Display - c, d, i, r, n, o, 1, s, t. Push "1" and continue. The section of the program will be transferred to NIC-80. At the end of each transfer, check sums are printed and should be identical.

(f) Repeat steps (d) and (e) until entire program is transferred. If NIC-80 contained MTF analysis program previously, only files 2 and 3 are necessary to transfer.

(g) On NIC-80, push "STOP", depress "START" and push "EXECUTE" on completion of program loading.

3. Tape Recorder

(a) Turn switch to 3.75 IPS

(b) Switch on DC bias boxes. These should be turned off during non-operating periods to avoid draining batteries.

(c) Set frequency control knob on appropriate channels to FM and 1kc bandpass for signal and trigger. Voice channel requires 37.5 IPS and 100 Kc for operation.

(d) Turn on oscilloscope.

4. Pulse Generator

(a) Turn on power

(b) Set to external trigger pulse.

(c) Set width to 10 microseconds. On tape recorder, depress "DRIVE" and adjust oscilloscope for optimum display.

B. EXECUTION

1. HP-9825

(a) Load track 0, file 8 and push "RUN"

(b) Data entry;

Wavelength, e.g., .6328

Optics, e.g., .4572

Dwelltime, e.g., 95

Number of scans, e.g., 125

Push "CONTINUE" after each entry. On last "CONTINUE" NIC-80 will enter Display/Standby mode. HP-9825 will display "CONTINUE WHEN READY".

2. NIC-80

(a) Verify green control light is on

(b) Adjust CRT for optimum display of scans

(c) Adjust DC level by knobs on bias boxes. Use low resolution on vertical display scale, and adjust signal to center around horizontal scale.

(d) Adjust horizontal position of signal by pulse generator delay knob so as to center around vertical axis.

3. To start data collection, push "CONTINUE" on HP-9825. When all scans are completed, NIC-80 will return to Display/ Standby mode and may be taken off-line.

4. Data Analysis (HP-9825 only)

(a) On completion of data collection, "HISTOGRAM AND CONTINUE" is displayed. Check that plotter and printer are ready before pushing "CONTINUE".

(b) Data entry;

Date, e.g., 021577 (month, day, year)

Time, e.g., 1423

Cn arg, e.g., 8.07

Power, e.g., -8

Push "CONTINUE" after each entry.

(c) Unnormalized values for MTF spatial frequencies 0 and 1 are printed for verification of absolute and relative values.

(d) Data entry; "No. of class intervals" is displayed. Enter number of histogram bins per unit standard deviation.

Normally 3. Push "CONTINUE".

(e) Display "FREQ PLOT, YES-1". Push "1" and "CONTINUE" if plot of MTF mean $\pm$ 1 standard deivation for spatial frequency 0 - 19 is required.

(f) Display "LN DATA? YES-1". Enter 1 and push "CONTINUE" if data analysis of normal distribution is completed.

Display "LN ANALYSIS". Push "CONTINUE" if data is to be converted to Ln data.

(g) Display "DATA SUM? YES-1". Enter 1 and push "CONTINUE" if data summary is required.

Display "SUMMARY, CONT.". Push "CONTINUE" to start execution of data summary program.

(h) Display "SPAT FREQ". Enter spatial frequency number (0 - 19) for which histogram will be plotted.

Display "REPLACE PAPER AND CONTINUE". Push "CONTINUE" when plotter is ready.
